Brooder house was properly scrubbed and cleaned at least a week before the trail began. After the house, equipments were properly cleaned. The house was allowed to dry out thoroughly. The house and equipments were fumigated using 1% formalin. Three inches depth of litter were made on the floor. Few days before the chicks arrived, equipments were arranged in brooder house and the electric bulbs were started to adjust temperature and light. The temperature under the brooder house was slightly above 35°C. The corners of brooding space were made rounded off with cardboard and metal chick guards to prevent chicks from piling up in the corner. All these preparations were completed for Kadaknath chicks before they were procured to brooder house. A chick guard of about 15 cm height was used at a distance of 30 to 40 cm away from the brooder and was moved away for the every day. It was completely removed after two weeks.

Litter materials

For the present experiment three litter materials namely sand, rice hulls and paddy straw + rice hulls (50:50) were used for rearing the Kadaknath chicks. Rice hulls were procured from the nearby rice mill, paddy straw taken from village shivnathpur and sand was taken from kumarganj market. These litters were clean, dry and free from fungal growth. The thickness of litter was 3.0 cm. After spreading this litter on the floor with proper thickness was covered with newspaper up to 4 days of brooding.

Parameters recorded

Behaviour

The behaviours in the Kadaknath recorded in this study were chosen from preliminary observations and defined as a list of 12 states which have given here.

1. Eating
2. Drinking

Abstracts

The present study was conducted to investigate the effect of different litter materials on growth performance of Kadaknath chicks. 300 Kadaknath chicks were raised on three litter treatments viz. Sand, rice hulls and rice hulls plus chopped paddy straw (1:1) eac of two replicates in each treatment. The result showed that chicks reared on paddy straw + rice hulls litter had significantly hig weight, lower feed intake and better FCR(P<0.05). The body weight of chicks raised under sand and rice hull litter did n significantly, however the average daily feed intake of chicks under rice hulls was significantly higher than that of under sand lit performance index of the earlier study period was significantly higher in paddy straw+ rice hulls followed by sand and ri respectively.

***Key words**: Kadaknath, feed, body weight, sand, rice hulls, litter materials*

Introduction

Desi fowls are cheaply reared as scavenging flocks by feeding household left over and their meat and egg taste are preferred over those of exotic chickens (Dessie and Ogle, 2001).Wood shaving has been standard choice for poultry litter for many years. Rice hulls appear to be a favourable alternative to wood shavings (Grimes *et al.*, 2007).Various types of litter materials like sand (shields *et al.*, 2005), gypsum (Grimes *et al.*, 2007), rice and wheat straw (Sreehari Sharma 2010), ground corn cob and soyabean straw(De Avila *et al.*, 2008) have been utilised as bedding materials for rearing of poultry birds. Sand has shown good potential as an alternate litter for more reuse quality and very less caking.

Pine shavings and saw dust are the most desirable and most widely used litter materials for broiler production in the United States. About 60% of farmers used saw dust as litter materials, 16.7% used wood shaving, 20% used both wood shaving and saw dust while 3.3% of farmers do not use bedding materials. The types of litter used by farmer depend on locality and availability (Kalu E. 2015) . Paddy husk is most commonly used litter material in northern India.Sigroha et al., (2017) used saw dust, wheat straw, rice husk, river bed sand and sandy soil as litter materials and found higher weight of birds at 42 days of age in wheat straw followed by sandy soil, saw dust, river bed sand and rice husk. As far as seen in literature there is no concert conclusion for litter type and thickness for various regions and climates. In view of above a study was undertaken with following objectives-

To investigate the effect of litter material on the growth perf of kadaknath fowls

To study the feed conversion efficiency of kadaknath fow various bedding materials

Materials and Methods:

The present investigation was carried out to study the e different litter materials on growth performance, feed gain Kadaknath fowl. The study was carried out at the poultry Teaching Livestock and Poultry farm of the College of V science and Animal Husbandry, N.D.U.A.T. Kumarganj, U.P., situated at a distance of 42 km away from Faizabad cit km away from Jagdishpur Industrial area at an altitude o above sea level and latitude of 26° 47' North and longitude o East and it falls in Eastern plain Zone of Middle Gange region of India.

Experimental period and climatic conditions

The experiment was conducted in the months of Nove February which comprised winter season of this region. Du period, the climatic parameters have been shown in table average minimum temperature recorded during study pe 12.54°C, while the average maximum temperature was There were a few showers of rain, ranging from 62 to 123 average was 92.5 cm during this period. The topography o almost even and most of the farm area remains dry round Parasitic infestation was moderate.

Climatological parameters recorded during experiment period

S.No	Climatological Parameters	Average Value	Average Max	Average Min
1.	Environmental temperature(°C)	18.7	24.86	12.54
2.	Relative humidity (%)	70.35	77.68	57.86

Experimental animals

To carry out present investigation, 300 straight run day old Kadaknath Chicks, from college hatchery were got issued. These 300 kadaknath chicks were divided into two batches; each batch consisted of 150 Kadaknath Chicks. Each batch was subdivided in three equal groups of 50 chicks viz. Group1 (sand), Group2(rice hulls), Group3(paddy straw + rice hulls) randomly distributed among three pens. Each pen was equipped with fresh litter, feeder and waterer. All the birds were raised on pukka floor with sand, rice hulls and paddy straw + rice hulls (50:50) as litter materials. Chicks were reared under standard uniform managemental practices up to the age of 42 days and observations for different parameters were recorded simultaneously. Thereafter, a replication was made with the next batch of chicks.

Brooding and rearing of chick

Brooder house

The cold room brooding method was applied for brooding an of Kadaknath Chicks in the brooder house. Brooding was pukka floor using deep litter system. Each group of Kadakna placed in separate pens which were visually isolated from e along with provision of adequate ventilation and artificial li brooder house.

Preparation of brooder house to receive Kadaknath chic

Brooder house was properly scrubbed and cleaned at leas before the trail began. After the house, equipments were cleaned. The house was allowed to dry out thoroughly. The h equipments were fumigated using 1% formalin. Three inches litter were made on the floor. Few days before the chicks equipments were arranged in brooder house and the elect were started to adjust temperature and light. The temperatu the brooder house was slightly above 35°C. The corners of space were made rounded off with cardboard and metal chi to prevent chicks from piling up in the corner. All these pre

Abstract

The study was conducted to investigate effect of vitamin E and zinc on cortisol hormone during peripartum period in Karan Fries cows. Sixteen pregnant Karan Fries (KF) cows were selected from the herd of National Dairy Research Institute (NDRI) Karnal, on the basis of their body weight, BCS and parity. Eight cows were kept in control group and other eight cows in treatment group which were supplemented with 1000 IU vitamin E and 60 ppm zinc per day per cow. Blood samples were collected on the days -60, -45, -30, -15, -7, 0, +7, +15, +30, +45, +60 with respect to expected date of calving. Plasma was analyzed for Cortisol hormone. Body weight and Body condition score (BCS) of all the experimental animals were recorded on the day of blood collection. Plasma cortisol was significantly ($P<0.001$) lower in treatment group as compared to control group (2.98 vs. 3.10 ng/ml). There was a steady increase in the body weight of control and treatment cows towards parturition and was found a significant ($P<0.001$) difference between the control and treatment groups. The body condition score of control and treatment groups decreased by 33.05% and 17.76% respectively after calving. This showed that the control group cows lost significantly ($P<0.001$) more body condition as compared to treatment group cows. The results of this study indicated that supplementation of vitamin E and zinc have beneficial effects in changing cortisol level in this way that improves body condition and decreases the effect of parturition stress in the animals.

Keywords: Cortisol, Body Condition Score, Energy Metabolites, Peripartum period, Vitamin E, Zinc

Introduction

Cortisol is a steroid hormone that helps the body respond to stress. It is also called the stress hormone. It is released in response to stress and low blood glucose concentration. It is the principal glucocorticoid during the reproduction and lactation of cows [1]. Adrenal secretion of cortisol is modulated by a complex negative feedback mechanism involving the central nervous system, hypothalamus, pituitary and adrenals [2]. The synergistic action of endogenous cortisol along with other hormones has been found to be critical for parturition and initiation of lactation in domestic animals [3]. At term the corticosteroid concentration rises in the plasma of peripartum cows [4, 5, 6]. Plasma total cortisol level increased from 2.13 ng/ml to 2.62 ng/ml till one day prepartum and increased to 6.08 ng/ml at parturition in crossbred cows. The level decline from 3.42 ng/ml on 1 day postpartum to 2.49 ng/ml at 3 day postpartum [6]. In Murrah buffaloes level of cortisol was found 1.46 ng/ml at 30 day prepartum which increased to 3.78 ng/ml at parturition and decline to 1.89 ng/ml at 3 day postpartum[2].

Cortisol concentrations have been used as a physiological marker of stress. During heat acclimation there is reduction of plasma cortisol that helps in reduction of heat production of animals[7]. An initial increase in cortisol occurs due to acute heat stress followed by a decline after prolonged exposure in cows. The animals adjust physiologically to elevated heat loads by decreasing adrenal corticoid output [7]. Cortisol concentrations have been found lower in high producing cows at day 30 than at day 90 or in nonlactating cows due to reduced pulse amplitude. Low cortisol concentrations likely participate in the enhanced production observed in high producing cows [8]. Heat exposure at temperature above 40°C has been found to raise the cortisol level to almost double the pre-exposure levels [9]. Similar results were also found by others in hot-dry, hot-humid and winter seasons in crossbred cows (4.17, 4.35 and 2.09 ng/ml respectively) [10].

Materials and Methods

Experimental design

The study was conducted at the Cattle Yard of National Dairy Research Institute, Karnal, Haryana (India). Karnal is situated on an altitude of 250 meter above mean sea level, latitude and longitude position being 29°42" N and 79°54" E respectively. The maximum ambient temperature in summer goes up to 45°C and minimum temperature in winter comes down to 0°C with a diurnal variation in the order of 15-20°C. For the present study 16 Karan Fries (KF) peripartum cows were selected from the herd of National Dairy Research Institute, Karnal, 8 cows kept in Control group and other 8 cows in Treatment group. The cows in the control group were supplemented with no vitamins, and in the treatment group, they were given 1,000 IU of vitamin E and 60 ppm zinc per cow per day from 60 days prepartum to 60 days postpartum. Animals were maintained in open area with asbestos roof in the sides of the open area, where the animals were offered feed. The open area had brick floor. The animals were free to move inside the controlled open area. All the animals were fed as per the standard feeding practices followed at the NDRI farm.

Blood sampling

Blood samples (10 ml/cow) were collected in the morning (6:00 AM) before feeding in sterile heparinised vacutainer tubes (BD VacutainerTM, UK) from jugular vein puncture, posing minimum disturbance to animal, on the days -60, -45, -30, -15, -7, 0, +7, +15, +30, +45 and +60 with respect to expected date of calving. Day '0' represented the day of calving. Blood samples were brought to the laboratory in the icebox soon after collection and centrifuged at 1,200×g at 4°C for 20 min to separate the plasma. Plasma samples were stored at -20°C until analysis of Cortisol.

Sample analysis

Blood sample was analyzed for cortisol. Plasma Cortisol was determined by "Cortisol EIA kit" from Cayman Chemical Company, Ann Arbour, USA. Body weight and Body condition score (BCS) of all the experimental animals was recorded on the day of blood collection using a scale of 1 to 5.

Statistical analysis

Statistical analysis of data was carried out to find the mean ± SE. Two-way ANOVA was done to find significant difference between groups and days of experiment and their interaction by using SYSTAT 3.1 (2004) software.

Results and Discussion

Cortisol

The mean±SE of plasma cortisol concentration of control cows was 2.87±0.09 ng/ml 60 days before calving and on the day of calving it increased to 3.24±0.07 ng/ml. Further, in treatment group the plasma cortisol concentration was 2.78±0.03 ng/ml 60 days before calving and on the day of calving it increased to 3.10±0.03 ng/ml. In present study, the overall mean±SEM of plasma cortisol concentration was found significantly ($P<0.001$, Table 2) lower in treatment group as compared to control group. Plasma levels of cortisol varied between 2.3-3.5 ng/ml during pre and postpartum in Holstein cows [11]. After 7 days of calving it's level started decreasing up to 60 day of lactation.

ABSTRACT

Forty two (42) apparently healthy, non-pregnant, non-lactating Chhotanagpuri ewe, having body weight ranging between 14.11±0.09 to 15.38±0.06 Kg were selected and selected ewes were isolated from rams 2 months prior to melatonin administration. The selected animals were allocated randomly into seven groups viz. Group-I [Normal control], Group-II [Long day (LD) control], Group-III [LD + Melatonin administration orally (3mg/day)], Group-IV [(LD + Melatonin administration subcutaneously (1mg/day)], Group-V [Short Day (SD) control], Group-VI [SD + Melatonin administration orally (3mg/day)] and Group-VII [SD + Melatonin administration subcutaneously (1mg/day)] comprising six animals in each group. Rams were then introduced into each group after completion of exogenous administration of melatonin. Blood sample without anticoagulant in vials was collected from each animal day before the start of experiment and there after every month up to fifth month. After administration of melatonin, serum glucose was decreased in group- III, IV, VI and VII in comparison to group-I, although this decrease was not statistically significant. An increasing trend of serum glucose was observed in all groups from third to fourth month. Total protein at first month was significantly ($P<0.05$) higher in group VI in comparison to 0 day. After administration of melatonin, total serum protein concentration was significantly ($P<0.05$) decreased in group VI in comparison to first month and continued up to third month. At fifth month, total serum protein was significantly ($P<0.05$) lower in group III, IV and VI in comparison to 0 day and first month.

Introduction

Sheep husbandry is backbone of rural economy in India. The Chhotanagpuri sheep is the only recognized breed of sheep found in Jharkhand with a few numbers in Bihar and West Bengal. This breed is maintained solely for mutton production. They produce coarse wool of poor quality. This is being utilized for carpet manufacturing. Sheep

Management of traumatic proptosis in a pug: A case study

Sandeep Yadav, Vibha Yadav, RP Diwakar and Pramod Kumar

Abstract
A three years old male pug dog, weigh 10 kg was presented to Jai Pet Care Clinic Raebareli, Uttar Pradesh for treatment with unilateral traumatic proptosis. All clinical parameters were normal. Physical examination revealed partial prolapse of right eye globe with severe periorbital edema, haemorrhage, absence of menace and presence of miosis. Therapeutic management done by administration of triflupromazine @4mg/kg I/M for sedation, dexamethasone and gentamicine 0.2ml each in combination injected through intra palpebral route, which was repeated on 5th day. Animal was also given intramuscular injection of gentamicin @5mg/kg, dexamethasone @0.125mg/kg, vitamine B complex 2.0 ml and chlorpheniramine maleate @0.5mg/kg only once for 5 consecutive days. Eye drop of moxifloxacine and dexamethasone 4 times a day for instillation, chloramphenicol ointment 4 times a day for local application and enrofloxacin @5mg/kg orally once for 7 days were used. Animal recovered successfully after 7 days of regular treatment. Vision was assessed by simple vision testing using junction box, after 15 days of recovery and found normal.

Keywords: Pug, proptosis, therapeutic management

Introduction
Proptosis is forward displacement of globe which occur secondary to any blunt trauma to head [7]. Proptosis typically occurs in dogs following trauma to the face or head. Certain breeds of dog are more prone to eye proptosis than others because of their differences in facial conformation. The most common cause of proptosis in small breed dogs is a fight with a larger dog. During trauma, the globe is luxated from the orbit, and eyelid spasms prevent its retraction. Secondary orbital hemorrhage and swelling displace the globe further from the orbit following corneo-conjunctival drying and malacia [3]. Prognosis depends on pupil size and reflexes, duration of exposure, other globe or orbital damage, breed and other systemic trauma. Approximately 40–60% of dogs, but very few cats, recover vision. Traumatic proptosis can occur in any breed and in both dogs and cats. Only 20-40% of dogs that have the reattachment of the eyeball regain their vision.

Case history and observations
A three year old male pug of 10 kg weight was presented at Jai Pet Care Clinic Raebareli, Utter Pradesh with unilateral traumatic proptosis having recent history of blunt head trauma by hitting head against the wall. Clinical examination revealed partial prolapse of right eye globe (fig.-1) through the pulpebral fissure with severe periorbital edema (fig.-2), haemorrhage without fracture of skull. There was absence of menace and presence of miosis. Corneal examination revealed concurrent finding of pigmentary vascular keratitis. All clinical parameters of the pug were normal.

Blood sample without anticoagulant in vials was collected from each animal day before the start of experiment and there after every month up to fifth month. Lymphocyte % in third and fourth month of experiment was significantly ($P<0.05$) lower in all groups (group-I to VII) in comparison to 0 day, first and second month. At fifth month, lymphocyte % was significantly ($P<0.05$) higher in group III, IV, VI and VII in composition to third and fourth month of experiment.

Keywords: Ewe, Photoperiod, Melatonin, Lymphocyte percent count

Introduction

Short days enhance immune function in individuals with robust reproductive responses to photoperiod. Total splenic lymphocyte number, and macrophage counts were significantly higher in hamsters exposed to short days, as compared to animals exposed to long photoperiods (Brainard *et al.*, 1988). Photoperiodic influences on lymphocyte number and total white blood cell count have been reported for deer mice (Blom *et al.*, 1994); short day (LD 8:16) mice possessed more white blood cells than animals maintained in long day lengths (LD 16:8). Importantly, all laboratory studies of photoperiodic effects on immune function have reported enhanced immune function in short day lengths (Nelson and Demas, 1996). Although many field studies support this hypothesis, with data suggesting enhanced immune function and decreased disease prevalence during the winter as compared to the summer, a substantial number of studies have reported the opposite pattern of results (Nelson and Demas, 1996); i.e., reduced immune function is coincident with the short days of winter. These conflicting results can be resolved by considering additional environmental factors, not usually manipulated in laboratory studies. For example, winter-associated stressors {e.g., restricted food and low ambient temperatures} appear to counteract short day enhancement of immune function in the lab.

Exogenous administration of melatonin increased the lymphocyte percentage in Broiler chicks (Abozahra *et al.*, 1998), Rats (Anwar *et al.*, 1998), and Squirrels (Rai *et al.*, 2009). Rai and Haldar (2003) reported daily subcutaneous injection of melatonin at 17:30 to 18:00 hr significantly increased the lymphocyte count of blood in adult male squirrels, while pinealectomy decrease percent lymphocyte count in peripheral blood and bone marrow. The precise mechanism responsible for this melatonin induced increase in lymphocyte percentage is not clear. However, several mechanisms may be involved in this respect. Haldar *et al.* (2006) accessed the effect of melatonin on immune parameters in a seasonally breeding animal, the Indian palm squirrel F. pennant and bird P. asiatica during reproductive phases in vivo as well as in vitro. Melatonin treated squirrels and birds showed an increase in percent lymphocyte count (% LC) and percent stimulation pinealectomy in squirrels. Melatonin administration recovered all the decreased immune parameters to the control level (Rai and Haldar, 2003). MEL supplementation also enhanced all immune parameters in both in vivo and in vitro, suggesting that the immune system was sensitive during the reproductively active phase to MEL when peripheral melatonin level was low and the role of melatonin could be important for the maintenance of the immune status of seasonal breeders.

As reported by Etim *et al.* (2014[a]) immune status is a function of leucocytes, lymphocytes and Neutrophils. Lymphocytes are known to play key roles in immune defense system of both man and animals (Etim et al., 2014[b]). The objective of this experiment was to determine Lymphocyte percent count in Chhotanagpuri sheep after exogenous administration of melatonin following different photoperiods.

Materials and Methods

The present study was conducted in Department of veterinary physiology, College of veterinary science and A.H., Birsa Agricultural University, Kanke, Ranchi-6, Jharkhand located at 23.36°N latitude and 85.33°E longitude with an altitude of 651 m above mean sea level. Design of experiment was approved by the Institutional Animal Ethics Committee vide letter no.-139/528/RVC/IAEC. Forty two (42) apparently healthy, non-pregnant, non-lactating Chhotanagpuri ewes, having body weight ranging between 14.11±0.09 to 15.38±0.06 Kg reared under uniform managemental husbandry practices were selected. Selected ewes were isolated from rams prior to melatonin administration. The selected animals were allocated randomly into seven groups (viz. group-I to group-VII) comprising six animals in each group. Group-I [Normal control]:- The animals in this group were exposed to normal variation in day length. Group-II [Long day (LD) control]:- In this group in addition to natural sun light, artificial light was provided to animal for maintaining 16-18 hours of light every day for the period of one month and considered as long day control. Group-III [LD + Melatonin administration orally (3mg/day)]:- In this group in addition to natural sun light, artificial light was provided for maintaining 16-18 hours of light every day for the period of one month and after that 3 mg melatonin was administered orally for one month to each animal. Group-IV [(LD + Melatonin administration subcutaneously (1mg/day)]:- In this group in addition to natural sun light, artificial light was provided for maintaining 16-18 hours of light every day for the period of one month and after that 1 mg melatonin was administered subcutaneously for one month to each animal. Group-V [Short Day (SD) control]:- Animals in this group were provided only 8 hours natural day light and were then kept in a light-proof shed for 16 hours exposure in dark every day for the period of one month. This group served as short day control. Group-VI [SD + Melatonin administration orally (3mg/day)]:- Animals in this group were provided only 8 hours natural day light and were then kept in a light-proof shed for 16 hours exposure in dark every day for the period of one month and after that 3 mg melatonin was administered orally for one month to each animal. Group-VII [SD + Melatonin administration subcutaneously (1mg/day)]:- Animals in this group were provided only 8 hours natural day light and then were kept in a light-proof shed for 16 hours exposure in dark every day for the period

HEAT STRESS INDICES, STANDARDS AND LIMITS WITH REFERENCE FOR CATTLE AND BUFFALOES

Abstract

An IPCC special report on the impacts of global warming of 1.5 °C above pre-industrial levels would be a world first and, accordingly, no previous experience in the determination of acceptable heat stress limits, criteria or indices is wholly applicable. However, some tropical countries are already at beyond high temperature and much of the knowledge gained in managing and rearing of animal at such heat stress will be helpful in making adequate planning for acceptable environmental control at the greater thermal tress being contemplated. Accordingly, it is necessary to take cognisance of the dairy industry's experience in most tropical countries and of standards and regulations already established in South America and elsewhere in order to ensure acceptable conditions and control standards that compare favourably and defensibly with those in other dairy industries. Different countries uses of heat stress limits, criteria and indices were investigated as it was necessary to determine to what extent any other indices, limits or criteria would be applicable to tropical conditions. In addition, it was necessary to establish whether there was a single heat stress index that could be used in thermal stress for tropical climatic conditions. It was found that an appropriate combination of heat stress indices would be required in planning for and ultimately controlling thermal conditions in tropical climatic conditions. The solar radiations and humidity being contemplated and the concomitant potential heat hazard present too great a risk for reliance on environmental component of heat stress, such as wet-bulb temperature at present in common use locally. The study recommends that a heat stress index, preferably WBGT be used to design an modern dairy farm's ventilation system and that wet-bulb temperature be used to monitor and control the system once it is implemented.

Introduction

Environmental conditions that is conducive to safe and productive for cattle and buffaloes. Although many aspects of a dairy farming environmental conditions would be much the same as those already prevailing in poultry, sheep, goat and other animal farming sector the variations in high metabolic energy requirement to which animal are exposed would increase by virtue of increased depth. The paper therefore offers some guidelines for the use of heat stress indices and limits as would be applicable for dairy farming.

Thermal conditions and the heat stress imposed on animal will be the most significant environmental consequences of dairy farming, indicating a need to quantify the effects of heat on animal health and their production performance. This represents a difference in purpose from the traditional concern with heat stress. The principal motivation in efforts to evaluate and control heat stress in the dairy farm has been to minimize its detrimental effects on animal. This has resulted in the development heat stress indices based same on physiological tolerance and production performance criteria. Given the critical impact that productivity will have on the success or failure of dairy farming criteria should form part of the fundamental basis for determining the thermal standards. In the past, a number of heat stress indices have been devised in attempts to combine various environment variables into a single number indicative of the heat stress imposed on cattle and buffaloes. Although such a number can provide some measure of environmental heat stress, there are many and varied criteria for evaluating the acceptability of thermal conditions for dairy farming.

Heat stress indices

The incidence of heat stress as measured by the frequency of days with THI greater than 80 has increased significantly over the 40-year period on record. This is due to both changes in the temperature variables used and also the incidence of drought as drought years appear to be also associated with high stress frequency.

In hot climates, high ambient temperatures, humidity, wind speed, and high direct and indirect solar radiation are the main environmental stress factors that impose strain on animals (Finch, 1985, Silanikove, 2000). Heat stress indices range from simple measurements of ambient air temperature to indices that try to provide a weighted estimation of all environmental factors involved. Keeping the fact that heat stress is caused by multiple environmental or thermal factors, it is often misleading to use ambient temperature alone as the indicator of heat stress. Different heat stress indices have been proposed that indicate level of thermal stress. Thom suggested a Temperature-Humidity Index (THI) based on dry bulb and wet bulb thermometers.

The Temperature Humidity Index (THI) has been widely used as a heat stress index in beef and dairy (cattle & buffaloes) industries (Stokka *et al.*, 1996: West, 1999; Mader *et al.*, 2002). Following a list of temperature humidity indices:

$$THI\ 1 = (0.15 \times T_{db} + 0.85 \times Twb) \times 1.8 + 32$$

(Bianca, 1962),

$$THI\ 2 = (0.35 \times T_{db} + 0.65 \times Twb) \times 1.8 + 32$$

(Bianca, 1962),

$$THI\ 3 = [0.4 \times (T_{db} + Twb) \times 1.8 + 32 + 15$$

(Thom, 1959),

$$THI\ 4 = (0.55 \times T_{db} + 0.2 \times Tpo) \times 1.8 + 32 + 17.5$$

(National Research Council, 1971),

$$THI\ 5 = (1.8 \times T_{db} + 32) - (0.55 - 0.0055 \times RH) \times (1.8 \times T_{db} - 26) = 0.81 \times T_{db} + 0.143 \times RH) + 0.0099 \times RH \times T_{db} + 46.3$$

(National Research Council, 1971),

$$THI\ 6 = (T_{db} + Twb) \times 0.72 + 40.6$$

(National Research Council, 1971),

$$THI\ 7 = (T_{db} + 0.36 \times Tpo) + 41.2$$

(Yousef, 1985a),

A review: heat stress in cow and buffaloes in India

Pramod Kumar, Rishikant, Rabindra Kumar, KN Singh and Mukesh Kumar

Abstract
India is a tropical climatic country in which heat stress is an important disadvantageous factor that reduces the production performance of cattle and buffalo and conduces to significant decrease in milk yields in dairy cows and buffalo and some metabolically disorders. The objective of this review is to known the heat stress metabolism, its causing factors and its preventative methods for increase the production performance through manage mental and nutritional procedures.

Keywords: Tropical, Heat, Temperature, Conduction, Convection, Radiation, Evaporation, Panting, Sweating, Moisture

Introduction

Climatic conditions of India are such that the hot and humid season is relatively long, there is intense radiant energy for an extended period, and there is generally the presence of high relative humidity. Thus, heat stress is chronic in nature especially for animal, there is often little relief from the heat during the evening hours, and intense bursts of combined heat and humidity further depress performance of animal. Lactating dairy cattle and buffaloes create a large quantity of metabolic heat and accumulate additional heat from radiant energy (West, 2003) [20]. Heat production and accumulation, coupled with compromised cooling capability because of environmental conditions, causes heat strain in the cattle and buffaloes to increase to the point that body temperature rises, intake declines and ultimately the cow's productivity declines.

Heat stress is caused by a combination of climatic factors like air temperature, humidity, solar radiation, wind velocity etc. A common time for experience adverse effects of high temperatures is during transport (Fiore *et al*, 2009) [6]. Transport is a multi affected stressor that can create or exacerbate existing heat loads. Handling of animal, increases body temperature. Animal are adversely affected any time the ambient temperature is more than their thermoneutral zone, which ranges about 25°C. Because that heat stress conduces to some disadvantageous affect on livestock, many researchers work about heat stress in animal.

Thermoneutral zone

The Thermoneutral Zone (TNZ) is defined as. "the range of ambient temperature within which metabolic rate is at a minimum, and within which temperature regulation is achieved by non evaporative physical processes alone" (Bligh & Johnson, 1973) [3]. The lower critical ambient temperature range point and the upper critical ambient temperature point indicate the limits of the TNZ. The ambient temperature below, which the rate of heat production of a resting homeotherm increases to maintain thermal balance, is the lower critical temperature (LCT). The upper critical temperature (UCT) may be defined as the ambient temperature when the: (a) metabolic rate increases; (b) evaporative heat loss increases; or (c) tissue thermal insulation is minimal (Silanikove, 2000) [14]. Below and above these temperature limits heat production is increased. The width of the thermoneutral zone will vary depending on age, species and breed, level of nutrition, previous state of temperature acclimation or acclimatization, level of productivity, housing conditions, insulation, and behavior etc (Yousef, 1985b) [22]. In order to more clearly define the TNZ (Silanikove, 2000) [14] suggested that the subdivision of the TNZ into a zone of thermal well-being is most suitable to describe the relation between an animal and its environment. Figure 1, illustrate this concept.

SELECTING A SUITABLE HEAT STRESS INDEX TO PROTECT CATTLE AND BUFFALOES IN HOT AND HUMID CLIMATE

Abstract

An assessment of any climate conditions requires extensive measurements to be health and production performance of animal in the climatic zone. This can be labour-intensive, time-consuming and consequently impractical for daily production and comfort assessments of the animals. Therefore, a simple indicator like a heat stress index is needed to enable a quick, valid and acceptable evaluation of animal climatic conditions on a regular basis. This can be explained by the unending quest to develop a "universal index," which has led to the proliferation of many proposed heat stress indices. In this research study is to discuss the selecting a suitable heat stress index for thermal planning and management purposes in hot and humid climatic zone for dairy industries. A method is proposed a defined strategy for selecting and recommending heat stress indices to be used in a particular climatic zone and worldwide based on a heat stress index. The performance of different heat stress indices used in dairy industries and other cattle farm varies based on the climatic conditions and the level of activities. Therefore, carefully selecting or establishing a suitable heat stress index is of paramount importance to ensure the comfort, health and increasing productivity of the cattle and buffaloes. These methods assess and select the most appropriate index for hot and humid climatic conditions to protect the cattle and buffaloes from thermal stress. Although complex, the method presents results that are easy to interpret and understand than any other methods.

Keywords: climatic zone, heat stress index, thermal stress, dairy industries.

Introduction

Heat stress is chronic in nature, there is often little relief from the heat during the evening hours, and intense bursts of combined heat and humidity further depress performance. Lactating dairy cattle and buffaloes create a large quantity of metabolic heat and accumulate additional heat from radiant energy [1]. The ability of many indices using these elements have been developed in past; but their utility remained limited. Majority of studies on thermal stress in livestock have used temperature-humidity index (THI). THI represent the combined effect of air temperature and humidity with level of heat stress. Milk yield and DMI exhibited significant declines when maximum THI reached 77. Later research determined that the critical values for minimum, mean, and maximum THI were 64, 72 and 76 respectively [2]. In addition, a climate change scenario was constructed by raising both the minimum and maximum temperatures by 2.76°C, which is a mid-range temperature change for approximate doubling of atmospheric greenhouse gas concentrations. The incidence of stress days as measured by THI greater than 80 has increased significantly over the 40-year period (60%) and the climate change scenarios suggested further, substantial increases (138%) in the frequency of such heat stress days. In addition, in the climate change scenario there was a very marked increase in days where animals could no longer thermo regulate by sweating alone [3]. Different animal species have different sensitivities to air temperature, humidity, solar radiation and wind velocity etc. Cattle and buffaloes have differences in their heat tolerant capacity. Cattle can tolerate high temperatures at low air humidity than buffaloes. This is due to the fact that, cattle can dissipate heat more efficiently by surface evaporation whereas buffaloes use surface evaporation for body cooling to a limited extent.

This research study posed the question of which index can be recommended for a hot and humid climate? In this paper, a method is used to compare a thermal comfort model with some of the most widely used heat indices in dairy industries and another cattle farm. The method is applied to predict the "comfort zone" and to recommend an index based on its production performance as close as possible to the "comfort zone." The comparative analysis uses comfort data including air temperature, airflow velocity, humidity and estimated physiological parameters such as respiration rate and rectal temperature.

Cattle and buffaloes have capacity to maintain their body temperature with in a precise limit even after exposure of environmental extremes [4]. Animals gain heat from three sources: chemical, mechanical and thermal. Chemical and mechanical heat transfer relates to metabolic processes and represents the body's main heat sources. The influence of the thermal environment on an animal is primarily exerted through energy exchanges involving convection, conduction, radiation and evaporation [5]. There are mechanisms by which the body can regulate its core temperature both at rest and during activity, and in both hot and cold or humid environments, along with health risks that are associated with physical activity in the aforesaid environments [6]. Assessment of "Thermoneutral Zone" must start with the maximum production with wellbeing of animal. It is extremely difficult to classify the many factors that affect thermal comfort. The interaction between the physical demands imposed upon an animal his physiological status, and his psychological attitudes. Because thermal comfort is rather subjective and restrictive, it is better to define a Thermoneutral Zone within which most animals will be comfortable. This necessitates the need to define a "zone" in which most of the animals will consider comfortable, the so-called comfort zone. This comfort zone will be ascribed using the climatic and physiological parameters of the environment and some existing thermal comfort models.

The Thermoneutral Zone (TNZ) is defined as "the range of ambient temperature within which metabolic rate is at a minimum, and within which temperature regulation is achieved by non-evaporative physical processes alone [7]. The lower critical ambient temperature range point and the upper critical ambient temperature point indicate the limits of the TNZ. The ambient temperature below, which the rate of heat production of a resting homeotherm increases to maintain thermal balance, is the lower critical temperature (LCT). The upper critical temperature (UCT) may be defined as the ambient temperature when the: (a) metabolic rate increases; (b) evaporative heat loss increases; or (c) tissue thermal insulation is minimal [8]. Below and above these temperature limits heat production is increased. The width of the thermoneutral zone will vary depending on age, species and breed, level of nutrition, previous state of temperature acclimation

The idea of the thermal index goes back to 18th century [9]. Without considering the dry-bulb temperature, perhaps the first published heat stress index was the wet-bulb temperature proposed by Haldane [10]. Since then a large number of heat stress indices have been proposed.

ABSTRACT

The study was conducted to investigate the effect of α-tocopherol acetate and zinc on milk composition in Karan Fries cows. Twenty pregnant Karan Fries cows were selected two months before expected date of calving. The experimental animals were randomly divided in to two groups namely control group (ten cows) and treatment group (ten cows). Treatment group cows were supplemented with α-tocopherol acetate @ 1000 IU/day/cow and zinc @ 60 ppm/day/cow. Milk fat % was lower in treatment group than control group but the overall fat in treatment group was found significantly higher than control group (4.47±0.20 vs. 3.95±0.27, P<0.01). The overall mean milk protein % was found 3.08±0.04 vs. 3.05±0.11, milk lactose % 4.47±0.08 vs. 4.48±0.10 and SNF % 8.17±0.15 vs. 8.15±0.17 in control group and treatment group, respectively which showed that there was no significant difference between the groups. The overall mean (±SEM) of somatic cell count of milk was found significantly lower (P<0.001) in treatment group than control group. The results of this study indicated that supplementations of antioxidants like α-tocopherol acetate and zinc have beneficial effects in improving quality of milk.

Introduction

For good quality dairy products there is need to know the quality aspects of milk produced. Since the diet is the fastest way to modify the milk production and quality in animals, even if the relations between the feeding and milk composition are quite complex. Trace elements, along with vitamins and minerals, are essential nutrients for cellular metabolism. They are critical components of almost every aspect of how a body grows, develops, functions and reproduces. Vitamin E is crucially involved in immune system function, such that supplementation with supranutritional levels of the vitamin E, results in improved immune responses and milk production (Chawla and Kaur, 2005; Baldi, 2005; Baldi *et al.*, 2008; Chandra and Aggarwal, 2009). There was significant decrease of somatic cell count (SCC) in milk at 15 days of lactation (0.29×10^6 vs. 0.86×10^6) in cows supplemented with 1000 IU vitamin E / day during dry period (Kaur *et al.*, 2002). The somatic cell count is internationally recognized as a parameter for assessing the milk quality and udder health. The present

ABSTRACT

Cattle and buffaloes experience different level of stress during summer and hot humid conditions. However, the assessment of the heat stress and the translation of the heat stress in terms of physiological and psychological strain is complex. For over a century attempts have been made to construct an index, which will describe heat stress satisfactorily. The many indices that have been suggested can be categorized into two groups: "*physiological indices*" and "*environmental*", or "*direct indices*". The first groups are sophisticated indices, which are based on physiological variables; they are difficult to calculate and are not feasible for daily use. The latter group comprises of simple indices, which are based on the measurement of basic environmental variables. In this group many indices are in use for over four decades: the "temperature humidity index" (THI) and the "*TGWB Index*". The following research on heat stress indices and their comparison and evaluation to animal production and their performance. With the present knowledge it is suggested to adopt the TGWB Index under tropical conditions is recommended because globe temperature takes into accounts Tdb and solar radiant heat exchange and can help in finding stress level.

Introduction

In India during summer cattle and buffaloes are exposed to severe environmental heat stress, which may deteriorate productivity and performance of animals may even threaten to their survival. Thus, it is expected that the physiological heat strain experienced by an animal will be related to the total heat stress to which they are exposed, serving the need to maintain body-core temperature within a relatively narrow range of temperatures. Many attempts have been made to estimate the stress inflicted by a wide range of climate, or to estimate the corresponding physiological strain and to combine them into a single index—a heat stress index. The difficulties in creating a universal heat stress index are outlined in the present research and a simple way to

INTEGRATION BETWEEN THE THERMAL STRESS INDEX (TGWB) AND THE LIVESTOCK STRAIN INDEX (LSI) AS A GUIDELINE FOR DAIRY FARMING IN TROPICAL CLIMATE

Abstract

A new thermal stress index (TGWB Index), based on Air temperature (Tdb), globe temperature (Tg) and wet bulb (Twb) temperature suggests as a potential substitute for the temperature humidity index (THI) for cattle in tropical climate. This new stress index, found to have a high correlation to THI, is constructed from fast reading meteorological response sensors (Tdb, Twb, and Tg) that take only a few seconds to reach equilibrium. Furthermore, the TGWB Index is the first stress index using direct measurements of solar radiation and is calculated as follows:
TGWB Index = 0.78 (Tg + Twb) + 35.8
The recently suggested Livestock Strain Index (LSI) is capable of indicating physiological strain and analyzing milk production of cattle. The LSI is constructed from rectal temperature (Tre) and respiratory frequency rate (Rf) as follows:
$LSI = 5\ (Tre_{obs.} - Tre_{min.}).\ (Tre_{max.} - Tre_{min})^{-1} + 5\ (Rf_{obs.} - Rf_{min.}).\ (Rf_{max.} - Rf_{min})^{-1}$
Where Tre_{obs} and Rf_{obs} are the observed measurements Tre_{max} and Tre_{min}, and Rf_{max} and Rf_{min} are maximum and minimum simultaneous measurements taken at any time. The LSI is scaled from 0-10, whereby each variable LSI_{Tre} or LSI_{Rf} which represent the cardiovascular and the thermoregulation systems respectively. The purpose of this study was to develop guidelines based on TGWB Index and LSI for dairy cattle for combat to heat stress. In order to integrate LSI and TGWB Index, we decided to use both the LSI_{Rf} and LSI_{Tre} component, which represents the respiratory frequency rate and the strain reflected by the cardiovascular system. Furthermore, LSI_{Rf} and LSI_{Tre} are easier to measure, are easier to implement and simplifies the integration with TGWB Index. Concomitantly, it also categorizes the strain between 0-5, the higher the value, the higher the strain.

Key words: Tropical climate, Thermal stress, Indices, Solar Radiation, LSI, TGWB Index

Introduction

The incidence of heat stress as measured by the frequency of days with THI greater than 80 has increased significantly over the 40-year period on record. This is due to both changes in the temperature variables used and also the incidence of drought as drought years appear to be also associated with high stress frequency.

In hot climates, high ambient temperatures, humidity, wind speed, and high direct and indirect solar radiation are the main environmental stress factors that impose strain on animals (Finch, 1985, Silanikove, 2000). Heat stress indices range from simple measurements of ambient air temperature to indices that try to provide a weighted estimation of all environmental factors involved. Keeping the fact that heat stress is caused by multiple environmental or thermal factors, it is often misleading to use ambient temperature alone as the indicator of heat stress. Different heat stress indices have been proposed that indicate level of thermal stress. Thom suggested a Temperature-Humidity Index (THI) based on dry bulb and wet bulb thermometers. The Temperature Humidity Index (THI) has been widely used as a heat stress index in beef and dairy (cattle & buffaloes) industries (Stokka *et al.*, 1996: West, 1999; Mader *et al.*, 2002). Following a list of temperature humidity indices:

$THI\ 1 = (0.15 \times T_{db} + 0.85 \times Twb) \times 1.8 + 32$ (Bianca, 1962),

$THI\ 2 = (0.35 \times T_{db} + 0.65 \times Twb) \times 1.8 + 32$ (Bianca, 1962),

$THI\ 3 = [0.4 \times (T_{db} + Twb) \times 1.8 + 32 + 15$ (Thom, 1959),

$THI\ 4 = (0.55 \times T_{db} + 0.2 \times Tpo) \times 1.8 + 32 + 17.5$ (National Research Council, 1971),

$THI\ 5 = (1.8 \times T_{db} + 32) - (0.55 - 0.0055 \times RH) \times (1.8 \times T_{db} - 26) = 0.81 \times T_{db} + 0.143 \times RH) + 0.0099 \times RH \times T_{db} + 46.3$ (National Research Council, 1971),

$THI\ 6 = (T_{db} + Twb) \times 0.72 + 40.6$ (National Research Council, 1971),

$THI\ 7 = (T_{db} + 0.36 \times Tpo) + 41.2$ (Yousef, 1985a),

The above indices have been used to calculate stress for each combination of environmental variables corresponding to the measurements made in the animals, in order to assure that each animal response was associated to a given environmental condition. The index THI1 is used to monitor discomfort of temperature and humidity in humans. The THI2 and THI7 have been empirically determined for cattle exposed to heat stress conditions in climatic chambers. How these indices from controlled environments relate to field conditions? With diurnal fluctuation of environmental variables remain unanswered (Bohmanova *et al.*, 2007). The index THI3 is used to monitor the degree of discomfort in humans. The THI5 represents cattle heat stress index, designed to indicate level of heat stress of outdoors cattle (West, 2003); and THI6 has been developed by the United State Weather Bureau to describe discomfort in humans.

THI values of 70 or less are considered comfortable, 75 to 78 stressful, and values greater than 78 because extreme distress and animals are unable to maintain normal body temperature (Silanikove, 2000). The THI fails to reflect the contributions of other environmental factors, such as airflow and thermal radiation.

As noted before, the index has gained immense popularity over the years. The temperature humidity index (THI) is in use in temperate climatic condition for cattle. The Temperature Humidity Index (THI) has been widely used as a heat stress index in beef and dairy industries (Stokka *et al.*, 1996: West, 1999; Mader *et al.*, 2002). It is important to note the correlation of temperature humidity index (THI) to physiological responses was only partially tested and was based mainly on the correlation between the number of heat stress cases of dairy animal and the heat load as calculated by the THI. I have inroduced my new thermal stress index (TGWB) based on Air temperature (Tdb), globe temperature (Tg) and wet bulb (Twb) temperature as follows:

TGWB Index = 0.78 (Tg + Twb) + 35.8

This newly developed index was validated by using large databases and was found to be highly correlated to the temperature humidity index (THI). TGWB Index differs from other indices that have been suggested in the past for two main reasons. First, new thermal stress index (TGWB) based on Air temperature (Tdb), globe temperature (Tg) and wet bulb (Twb) temperature, aside from using temperature

EFFECT OF A-TOCOPHEROL ACETATE AND ZINC SUPPLEMENTATION ON LEPTIN HORMONE DURING DRY PERIOD AND EARLY LACTATION IN CROSS BRED COWS

Abstract

The study was conducted to investigate the effect of α-tocopherol acetate and zinc supplementation on Leptin Hormone during dry period and early lactation in cross bred cows. Twenty pregnant Karan Fries cows were selected on the basis of their body weight, BCS and parity, ten cows were kept in control group and other ten cows in treatment group which were supplemented with 1000 IU α-tocopherol acetate and 60 ppm zinc per day per cow. Blood samples were collected on the days -60, -45, -30, -15, -7, 0, +7, +15, +30, +45, +60 with respect to expected date of calving. Plasma was analyzed for Leptin hormone. Body condition score of all the experimental animals was recorded on the day of blood collection. At parturition, BCS decreased significantly ($P<0.01$) in control group than treatment group. The plasma concentration of leptin was decreased at parturition and the level was significantly ($P<0.001$) higher in treatment group as compared to control group (3.66 vs. 2.55 ng/ml). Plasma NEFA was significantly ($P<0.001$) lower in treatment group as compared to control group. The results of this study indicated that supplementation of α-tocopherol acetate and zinc have beneficial effects in changing Leptin hormone level in this way that improves body condition and metabolic status of the animals.

Keywords: *Leptin, Body Condition Score, Energy Metabolites, α-tocopherol acetate, Zinc*

Introduction

Leptin is a 16 kDa protein hormone and it is synthesized by white adipose tissue. Leptin is involved in regulation of feed intake, energy balance, immunity and reproduction (Houseknecht *et al*., 2000; Ahima and Flier, 2003). After parturition, dairy cows suffer from an intense energy deficit caused by the onset of copious milk secretion and an inadequate increase in voluntary food intake which contributes to a decline in plasma leptin. This decline mirrors that of plasma insulin but is reciprocal to the profile of plasma growth hormone (GH), suggesting that both hormones may regulate plasma leptin in periparturient dairy cows (Block *et al*., 2001). Energy deficit of early lactation reduces leptin synthesis in white adipose tissue (WAT), and suggest roles for insulin, GH and metabolic fuels in mediating this effect of energy balance (Block *et al*., 2001). A concomitant suppression of immune functions and metabolic disorders during early lactation are related to decreased fertility (Butler and Smith, 1989). This may partly be due to decrease in blood concentrations of vitamins A & E and Zn (Meglia *et al*., 2001, Chandra, 2009). To meet the nutritional demands of milk synthesis during early lactation, dairy cows need to mobilize body reserves causing negative energy balance until nutrient intake covers the demands.

Material and methods

Experimental design

The study was conducted at the Cattle Yard of National Dairy Research Institute, Karnal, Haryana (India). For the present study 20 Karan Fries (KF) peripartum cows were selected from the herd of National Dairy Research Institute, Karnal, 10 cows kept in Control group and other 10 cows in Treatment group. The cows in the control group were supplemented with no vitamins, and in the treatment group, they were given 1,000 IU of α-tocopherol acetate and 60 ppm zinc per cow per day from 60 days prepartum to 60 days postpartum over and above the normal feeding schedule at dairy farm of NDRI.

Blood sampling

Blood samples (10 ml/cow) were collected in the morning (6:00 AM) before feeding in sterile heparinised vacutainer tubes (BD VacutainerTM, UK) from jugular vein puncture, posing minimum disturbance to animal, on the days -60, -45, -30, -15, -7, 0, +7, +15, +30, +45 and +60 with respect to expected date of calving. Day '0' represented the day of calving. Blood samples were brought to the laboratory in the icebox soon after collection and centrifuged at 3000 rpm at 4°C for 20 min to separate the plasma. Plasma samples were stored at -20°C until analysis of Leptin hormone. Body condition score (BCS) of all the experimental animals was recorded on the day of blood collection using a scale of 1 to 5.

Sample analysis

Blood sample was analyzed for plasma leptin and NEFA. Plasma Leptin was determined by "Bovine Leptin ELISA Quantitation kit" from Cusabio Biotech Co., Ltd. The copper soap solvent extraction method modified by Shipe et al. (1980) was adopted for the estimation of plasma NEFA.

Statistical analysis

Statistical analysis of data was carried out to find the mean ± SE. Two way ANOVA was done to find significant difference between groups and days of experiment and their interaction by using SYSTAT 3.1 (2004) software. The correlations among the various parameters were also calculated (Snedecor and Cochran, 1994).

Results and Discussion

Leptin

The mean±SE of plasma leptin concentration of control cows was 6.06±0.10 ng/ml 60 days before calving and on the day of calving it decreased to 2.55±0.31ng/ml. Further, in treatment group the plasma leptin concentration was 6.19±0.11ng/ml 60 days before calving and on the day of calving it decreased to 3.66±0.11ng/ml. In present study decrease in the plasma leptin concentration of control and treatment group cows was 57.92% and 40.87% respectively from 60 days before calving to the day of calving. This decrease was more significant ($P<0.01$) from 30 days before calving to the day of calving in control group than treatment group. After parturition it's level remained low up to 30 days then started increasing up to 60 days of lactation.

In present study there was found a positive correlation between leptin with BCS and insulin and a negative correlation was found between leptin with NEFA in control and treatment group of cows around parturition. The plasma concentration of leptin was positively correlated with plasma concentrations of insulin and negatively correlated with plasma concentrations of growth hormone, cortisol and non-esterified fatty acids (Block *et al*., 2001; Chelikani *et al*., 2008). Sauerwein *et al*. (2004) investigated that in ruminants the decline in plasma leptin levels towards parturition is probably caused by the decline in adiposity and insulin concentrations. In ruminants and other animals, leptin is synthesized in proportion to the overall degree of adiposity and acts on the central nervous system to reduce voluntary feed intake (Ehrhardt *et al*., 2000). Leptin, mainly produced in adipose tissue, inhibits feed intake and down-regulates adipose tissue deposition. Block *et al*. (2001) showed that leptin is negatively correlated with the amount of nonesterified fatty acids, which reflects the amount of fat mobilization. From early to mid pregnancy circulating leptin levels increased and remained elevated until late pregnancy in cattle (Liefers *et al*., 2003; Villalobos *et al*., 2007).

ABSTRACT

In the Changing global scenario, exploding world population, limited natural recourses and environmental degradation are posing a greatest challenge to the sustainable production and reproduction of livestock for human population. Climate change has profound effect on livestock. The anticipated rise in temperature due to climate change is likely to aggravate the heat stress in livestock, adversely affecting their productive and reproductive performance. Heat is the major constraint in tropical and sub tropical climatic conditions which negatively affects production and reproduction of livestock species. Cattle and buffaloes experience different level of stress during summer and hot humid conditions. Climatic conditions in the India are such that the warm (or hot) season is relatively long, there is intense radiant energy for an extended period, and there is generally the presence of high relative humidity. Thus, heat stress is chronic in nature, there is often little relief from the heat during the evening hours, and intense bursts of combined heat and humidity further depresses the performance. Heat production and accumulation, coupled with compromised cooling capability because of environmental conditions, causes heat strain in the cattle and buffaloes to increase to the point that body temperature rises, intake declines and ultimately the cow's productivity declines. Temperature-Humidity Index (THI) available with different temperature and humidity weightage are suitable for different specific areas.

Key words : *Global Scenario, Climate change, Livestock, challenges, Heat stress index, THI.*

One of the greatest challenges to production from lactating dairy cattle and buffaloes facing dairy farmers in the India is heat stress. Climatic conditions in the India are such that the warm (or hot) season is relatively long, there is intense radiant energy for an extended period, and there is generally the presence of high relative humidity. Thus, heat stress is chronic in nature, there is often little relief from the heat during the evening hours, and intense bursts of combined heat and humidity further depress performance. Lactating dairy cattle and buffaloes create a large quantity of metabolic heat and accumulate additional heat from radiant energy (West, 2003). Heat production and accumulation, coupled with compromised cooling capability because of environmental conditions, causes heat strain in the cattle and buffaloes to increase to the point that body temperature rises, intake declines and ultimately the cow's productivity declines.

Rectal Temperature : A change in rectal temperature has been considered an index of heat stored in large animals and other mammals. For well-hydrated beef cattle living in temperate climates, the range of normal rectal temperature is 36.7 to 39.1°C (Cunningham, 2002).

Normal rectal temperature in Indian cattle has been reported to be 38.3 ± 0.3°C by Mullick (1961) and Bhattacharya et al., (1965). For zebu cattle and crossbred bullocks, normal rectal temperature was reported to be 38.3 and 38.4°C, respectively (Upadhyay, 1982). Heat inputs cannot be equal to heat outputs at all times; therefore, the maintenance of body temperature within this range is achieved through a system of temperature regulation. To regulate body temperature the animal have a variety of temperature sensors located within the body. There are specific temperatures sensitive neuronal structures located in the skin and in the mucous surfaces of the buccal cavity, in regions of the spinal cord, and in the hypothalamus of the midbrain (Bligh, 1985). These sensors relay information to the pre-optic area of the hypothalamus, which is thought to be the main centre for temperature regulation. The pre-optic area of the hypothalamus then initiates mechanisms to either increase or decrease heat loss or production (Cunningham, 2002). In the regulation of body temperature, the hypothalamus behaves as if it has a normal "set-point". When rectal temperature rises above or falls below the set point, heat losing, or heat gaining mechanisms are initiated (Cunningham. 2002).

Respiration Rate : The other method of evaporative heat loss available in cattle is via respiration. Respiration rate (RR) has long served as a gross indicator of heat during hot weather, increasing when animals need to maintain homoeothermy by dissipating excess heat stress as other avenues become inadequate (Hahn. 1999). The normal

EFFECT OF EXOGENOUS MELATONIN AND DIFFERENT PHOTOPERIODS ON TOTAL LEUCOCYTE COUNT IN CHHOTANAGPURI EWE

P. K. Choudhary[1*], A. K. Ishwar[2], P. K. Maurya[1], P. Kumar[1] D. Niyogi[3] and M. Kumar[4]

[1]Department of Veterinary Physiology and Biochemistry, [3]Department of Veterinary Pathology, [4]Department of Veterinary Anatomy and Histology, C.V.Sc. and A.H., N.D.University of Agriculture and Technology, Kumarganj, Faizabad, U.P., [2]Department of Veterinary Physiology, R.V.C., B.A.U., Ranchi.

Abstract

Forty two (42) apparently healthy, non-pregnant, non-lactating Chhotanagpuri ewe, having body weight ranging between 14.11±0.09 to 15.38±0.06 Kg were selected and selected ewes were isolated from rams 2 months prior to melatonin administration. The selected animals were allocated randomly into seven groups viz. Group-I [Normal control], Group-II [Long day (LD) control], Group-III [LD + Melatonin administration orally (3mg/day)], Group-IV [(LD + Melatonin administration subcutaneously (1mg/day)], Group-V [Short Day (SD) control], Group-VI [SD + Melatonin administration orally (3mg/day)] and Group-VII [SD + Melatonin administration subcutaneously (1mg/day)] comprising six animals in each group. Rams were then introduced into each group after completion of exogenous administration of melatonin. Blood sample without anticoagulant in vials was collected from each animal day before the start of experiment and there after every month up to fifth month. TLC at first month was significantly ($P<0.05$) higher in all short day groups (V, VI and VII) and significantly ($p<0.05$) lower in long day groups (II, III and IV) in comparison to 0 day. After administration of melatonin, TLC was significantly ($p<0.05$) higher in group III, IV, VI and VII in comparison to first month. At third and fourth month TLC was significantly ($P<0.05$) low in group VI and VII in comparison to second month.

Introduction

Melatonin signaling is necessary for photoperiodic adjustment in immune responses; it is difficult to parse the differential direct effects of melatonin on immune cells from indirect modulatory actions on other neuro-endocrine axes including the systems that control gonadal and adrenal steroids. However, the hypothesis that melatonin acts on immune function via down- stream hormonal effects has not been born out, as gonadectomy and steroid replacement has minimal effect on photoperiodic plasticity in immune system (Prendergast *et al*., 2005). Further, although androgens tend to be immunosuppressive estrogens often have the opposite effect (Klein, 2008). Therefore, the short-day induced gonadal regression would likely induce opposite effects in males and females if sex steroids were directly responsible for photoperiodic adjustments in immune responses. In general, both males and females respond similarly to changes in day length (Bilbo and Nelson, 2003). Gonadal steroids probably serve to modulate the larger melatonin-mediated effects of day length rather than directly driving photoperiodic changes (Prendergast *et al*., 2008).

Exogenous administration of melatonin increased the total leucocytic count and lymphocyte percentage in Broiler chicks (Abozahra *et al*., 1998), Rats (Anwar *et al*., 1998), and Squirrels (Rai *et al*., 2009). Rai and Haldar (2003) reported daily subcutaneous injection of melatonin at 17:30 to 18:00 hr significantly increased the lymphocyte count of blood in adult male squirrels, while pinealectomy decrease total leucocyte count and percent lymphocyte count in peripheral blood and bone marrow. The precise mechanism responsible for this melatonin induced increase in total leucocytic count and lymphocyte percentage is not clear. However, several mechanisms may be involved in this respect.

The major functions of the white blood cells and its differentials are to fight infections, defend the body by phagocytosis against invasion by foreign organisms and to produce or at least transport and distribute antibodies in immune response (Etim, 2015). Thus, animals with low white blood cells are exposed to high risk of disease infection. While those with high counts are capable of generating antibodies in the process of phagocytosis and have high degree of resistance to disease and enhancing adaptability to local environment and disease prevalent conditions (Isaac *et al*., 2013). As reported by Etim *et al*. (2014[a]) immune status is a function of leucocytes, lymphocytes and Neutrophils. Lymphocytes are known to play key roles in immune defense system of both man and animals (Etim et al., 2014[b]). The objective of this experiment was to determine total leucocyte count in Chhotanagpuri sheep after exogenous administration of melatonin following different photoperiods.

Materials and Methods

The present study was conducted in Department of veterinary physiology, College of veterinary science and A.H., Birsa Agricultural University, Kanke, Ranchi-6, Jharkhand located at 23.36^{0}N latitude and 85.33^{0}E longitude with an altitude of 651 m above mean sea level. Design of experiment was approved by the Institutional Animal Ethics Committee vide letter no.-139/528/RVC/IAEC. Forty-two (42) apparently healthy, non-pregnant, non-lactating Chhotanagpuri ewes, having body weight ranging between 14.11±0.09 to 15.38±0.06 Kg reared under uniform managemental husbandry practices were selected. Selected ewes were isolated from rams prior to melatonin administration. The selected animals were allocated randomly into seven groups (viz. group-I to group-VII) comprising six animals in each group. Group-I [Normal control]: - The animals in this group were exposed to normal variation in day length. Group-II [Long day (LD) control]: - In this group in addition to natural sun light, artificial light was provided to animal for maintaining 16-18 hours of light every day for the period of one month and considered as long day control. Group-III [LD + Melatonin administration orally (3mg/day)]: - In this group in addition to natural sun light, artificial light was provided for maintaining 16-18 hours of light every day for the period of one month and after that 3 mg melatonin was administered orally for one month to each animal. Group-IV [(LD + Melatonin administration subcutaneously (1mg/day)]:- In this group in addition to natural sun light, artificial light was provided for maintaining 16-18 hours of light every day for the period of one month and after that 1 mg melatonin was administered subcutaneously for one month to each animal. Group-V [Short Day (SD) control]: - Animals in this group were provided only 8 hours natural day light and were then kept in a light-proof shed for 16 hours exposure in dark every day for the period of one month. This group served as short day control. Group-VI [SD + Melatonin administration orally (3mg/day)]: - Animals in this group were provided only 8 hours natural day light and were then kept in a light-proof shed for 16 hours exposure in dark every day for the period of one month and after that 3 mg melatonin was administered orally for one month to each animal. Group-VII [SD + Melatonin administration subcutaneously (1mg/day)]: - Animals in this group were provided only 8 hours natural day light and then were kept in a light-proof shed for 16 hours exposure in dark every day for the period of one month and after that 1 mg melatonin was administered subcutaneously for one month to each animal. Rams were introduced into each group after completion of exogenous administration of melatonin. Blood samples were collected from each animal day before the start of experiment and there after every month up to fifth month. Blood (0.5ml) was collected from each animal in clean EDTA coated tubes and Total Leucocytes Count (x 10^{3}/µl blood) was counted as per

Effect of refind sunflower oil on weight loss and internal quality characteristics of white leghorn hen eggs at room and refrigeration temperatures

SS Chauhan, Basant Singh, RK Sharma, DV Singh and J Palod

Abstract
The 164 Infertile Eggs of White Leghorn were procured from Central Avian Research Institute, Izatnagar, Bareilly, (U.P.). The birds were maintained on similar feed and environmental conditions. The 164 eggs were divided in four groups, each comprising of 41 eggs. These groups were categorized into two groups and were kept at room temperature and remaining two was kept in refrigerator. The weight and internal quality of egg as Albumen Index, Yolk Index, Haugh Unit were recorded. The experiment was designed in simple randomized block with Four treatments and two temperatures. The result showed that the weight loss of egg and yolk index, were differ significantly in comparison to control while Haugh Unit at room temperature and Albumen Index did not differ significantly at room and refrigeration temperature. Refind Sunflower Oil prolonged the shelf-life of eggs to 28 and 75 days under room and refrigeration temperature while in control it was 14 days and 60 days under room and refrigeration condition.

Keywords: Yolk index, albumen index, Haugh unit

Introduction
Poultry production has emerged as an important and fastest growing sector of our livestock economy. Poultry farming has become very encouraging enterprise in modern India for small farmers, landless labours, educated un-employed youths as well as for big entrepreneurs. The gap between availability and the requirement shows a huge scope for further growth and development of poultry industry in India Egg is a rich source of high quality animal protein and is often used as standard for measuring the quality of the other food proteins. It is an important source of unsaturated fatty acid, minerals especially iron and phosphorus and almost all the vitamins. It is well balanced amino acid profile and easy digestibility makes it a valuable protective food in human diet. Egg is the wholesome food of animal origin, which cannot be adulterated by any human means till, is reaches to ultimate consumer in original form. It is the only source of high quality proteinous food and is very useful to fight malnutrition in India. Egg being very useful in human diet requires proper preservation to ensure its accept abilities for a longer period. Eggs are highly perishable commodity and need fast movement from the point of production to the point of consumption, particularly during summer months. It starts deteriorating from the moment it is laid. Research indicated that one out of every four egg produced in India did not reach to the consumer in good conditions. Oil coating is one of the most important methods for preserving eggs. The oil seals the pores of the shell which prevents the evaporation of moisture, entry of microorganism, odours and escape of gases. This checks the weight loss of egg and maintains the good internal quality for longer period because some of the physiochemical changes in the egg contents are being retarded. Keeping aforesaid points in view, the present investigation on Refined Sunflower Oil was undertaken with following objectives: To evaluate the changes in the internal quality and weight loss in oil coated and uncoated eggs held at room and refrigeration temperatures.

Materials and Methods
A total of 164 freshly laid, infertile eggs of a single strain of White Leghorn of same age and reared in cages under identical condition of feeding and management were procured from Central Avian Research Institute, Izatnagar, Bareilly, (U.P.). The eggs of almost similar and weight were selected for study. The candling was done at the time of procurement and before the start of experiment for selecting the sound egg. These 164 eggs were divided in four

Effect of refind sunflower oil on weight loss and internal quality characteristics of white leghorn hen eggs at room and refrigeration temperatures

SS Chauhan, Basant Singh, RK Sharma, DV Singh and J Palod

Abstract
The 164 Infertile Eggs of White Leghorn were procured from Central Avian Research Institute, Izatnagar, Bareilly, (U.P.). The birds were maintained on similar feed and environmental conditions. The 164 eggs were divided in four groups, each comprising of 41 eggs. These groups were categorized into two groups and were kept at room temperature and remaining two was kept in refrigerator. The weight and internal quality of egg as Albumen Index, Yolk Index, Haugh Unit were recorded. The experiment was designed in simple randomized block with Four treatments and two temperatures. The result showed that the weight loss of egg and yolk index, were differ significantly in comparison to control while Haugh Unit at room temperature and Albumen Index did not differ significantly at room and refrigeration temperature. Refind Sunflower Oil prolonged the shelf-life of eggs to 28 and 75 days under room and refrigeration temperature while in control it was 14 days and 60 days under room and refrigeration condition.

Keywords: Yolk index, albumen index, Haugh unit

Introduction
Poultry production has emerged as an important and fastest growing sector of our livestock economy. Poultry farming has become very encouraging enterprise in modern India for small farmers, landless labours, educated un-employed youths as well as for big entrepreneurs. The gap between availability and the requirement shows a huge scope for further growth and development of poultry industry in India Egg is a rich source of high quality animal protein and is often used as standard for measuring the quality of the other food proteins. It is an important source of unsaturated fatty acid, minerals especially iron and phosphorus and almost all the vitamins. It is well balanced amino acid profile and easy digestibility makes it a valuable protective food in human diet. Egg is the wholesome food of animal origin, which cannot be adulterated by any human means till, is reaches to ultimate consumer in original form. It is the only source of high quality proteinous food and is very useful to fight malnutrition in India. Egg being very useful in human diet requires proper preservation to ensure its accept abilities for a longer period. Eggs are highly perishable commodity and need fast movement from the point of production to the point of consumption, particularly during summer months. It starts deteriorating from the moment it is laid. Research indicated that one out of every four egg produced in India did not reach to the consumer in good conditions. Oil coating is one of the most important methods for preserving eggs. The oil seals the pores of the shell which prevents the evaporation of moisture, entry of microorganism, odours and escape of gases. This checks the weight loss of egg and maintains the good internal quality for longer period because some of the physiochemical changes in the egg contents are being retarded. Keeping aforesaid points in view, the present investigation on Refined Sunflower Oil was undertaken with following objectives: To evaluate the changes in the internal quality and weight loss in oil coated and uncoated eggs held at room and refrigeration temperatures.

Modulation of Performance Index, Glucose and Cholesterol Level in Broiler Chickens Fed Diets Containing Different Supplements

S.S. Chauhan[1, 2], R.K. Sharma[3], A. Kumar[1], S.K. Shukla[3], J. Palod[1], M.K. Singh[1, *], 10.18805/IJAR.B-4122

ABSTRACT

Background: The present study evaluated the effect of dietary inclusion of various feed supplements and their combination on the performance index, glucose and serum cholesterol for 6 weeks.

Methods: Day-old broiler chicks (n=252) were randomly assigned to seven treatment groups, each with 3 replicates. The first treatment was designated as control (T_0) in which no supplement was added to the feed, while in treatments T_1: organic mineral mixture (Organomin forte), T_2: organic mineral mixture (Vannamin), T_3: probiotics (Microguard), T_4: enzyme (Biozyme -XPR) and probiotics, T_5: emulsifier (Lipigon) were provided through feed. In the T_6 group, 3 percent less energy was given through feed.

Result: Significant improvement ($p<0.05$) was observed in performance index and HDL cholesterol and significant ($P<0.05$) decline in the glucose, total cholesterol, LDL cholesterol and triglyceride in broilers under supplementary groups as compared to control groups. The results of the present study indicated that it is possible to produce lean meat to an extent by manipulating diets which lead to better performance index of broilers during the overall period, which led to the release of more nutrients which helped in absorption, assimilation and utilization.

Key words: Broiler, Cholesterol, Lean meat, Performance index, Supplements.

INTRODUCTION

Poultry production in India has taken a quantum leap in the last six decades, emerging from an entirely unorganized and unscientific farming practice to a commercial production system with state-of-the-art technological interventions (Singh *et al*., 2017).

Corn and soybean meal are two major ingredients in commercial poultry diets in many parts of the world which contain a lower concentration of antinutritive high molecular weight-soluble nonstarch polysaccharides (NSP) that can impede normal digestion and absorption processes of nutrients including carbohydrates and proteins in the digestive tract by Govil *et al.* (2017). About 400-450 kcal of energy per kg of diet is not digested when birds are fed a typical corn-soy ration by Cowieson (2010).

The use of organic mineral mixtures improves performance, activates immune stimulation, optimizes minerals absorption and utilization and improves oxidative status in broiler chicks (Ravindran 2013).

Probiotic (Microguard) on administration passes through stomach reaches intestine where it colonizes occupying the intestinal villi and prevents pathogens from attaching to the intestine and at the same time favors the growth of favorable and essential microflora in the gut. They also produce substances like bacteriocins and local acting antibiotics that are antagonistic to pathogens. It also secretes enzymes like protease, amylase and lipase along with other nutrients and supplements which can be used by the lactic acid-producing and other useful bacteria to multiply rapidly and to sustain them for a longer time in the intestine. Further prevents clostridial and salmonella infections and reinforces the integrity of the gut wall and stimulates intestinal immunity-enhancing production of secretory antibodies.

ABSTRACT

The aim of the study was to investigate the effects of various feed supplements on minerals status and kidney health of broiler chickens. Two hundred fifty two, day-old Cobb-400 broiler chicks were randomly distributed into seven groups with 3 replicates of 12 chicks each. The first treatment was designated as control (T_0) in which no supplement was added to the feed, while in treatments T_1: organic mineral mixture (Organomin forte), T_2: organic mineral mixture (Vannamin), T_3: probiotics (Microguard), T_4: enzyme (Biozyme -XPR) and probiotics, T_5: emulsifier (Lipigon) were provided through feed. In T_6 group, 3 per cent less energy was given through feed. The serum calcium levels were significantly (P<0.05) increased in supplemented groups as compared to T_0 (control) group in both the periods while phosphorus values were significantly (P<0.05) increased in supplemented groups during starter period. Urea, Uric acid, BUN and creatinine values were significantly (P<0.05) decreased in supplemented groups as compared to T_6 group in both the periods. B/C ratios were significantly (P<0.05) decreased in all supplemented groups except T_3 and T_4 in both the periods. Therefore, it could be concluded that dietary supplementation maintained the mineral homeostasis and did not have adverse effect on kidney function.

Key words: Broiler chicks, Kidney function, Mineral profile, Supplements.

INTRODUCTION

The Indian broiler farmers rely on the commercial feeds produced by feed mill industries. In general, commercial broiler feeds have been formulated to meet the nutritional requirements of the birds. In some cases, the bad feed handling on the farm such as prolonged storage or inadequate storage conditions may, however, impair the nutritional qual-ities of the feeds. Such condition may cause specific micronutrient deficiencies, especially minerals, leading to growth retardation in broilers (Aviagen, 2014). To optimize the growth potential of modern broilers in the commercial farms, the commercial broiler feeds are generally supplemented with organic mineral mixtures, probiotics, enzymes and emulsifiers.

Increased level of creatinine in serum can be indicative of kidney damage (Yalcin *et al.*, 2012). Certain probiotic microorganisms have the ability to use urea, creatinine and other toxic chemicals as its nutrients for growth (Salim *et al.*, 2011). Therefore, relatively low level creatinine may be an indication of the renal protective effects of the probiotic microorganism.

Hence, it would be interesting to investigate the effect of such dietary treatment on the performances and physiolog-ical responses of broiler chickens. Taken together, the present study aimed to investigate the effect of supplementation of various dietary supplements and their combination on their mineral homeostasis and kidney functions.

MATERIALS AND METHODS

Experimental birds and dietary treatments

The present study was undertaken at the Instructional Poultry Farm (IPF) of Govind Ballabh Pant University of Agriculture and Technology, Pantnagar, U.S. Nagar. A total of 252, day old commercial broiler chicks (Cobb) were procured for conducting the experiment. All the chicks were individually weighed and randomly allotted to seven different groups each with three replicates of 12 chicks. Average body weight of chicks was similar for all the treatment groups. The study was conducted for a period of 6 weeks under standard management conditions. Feed and water were provided ad *libitum*. The detail of experimental diets is given in Table 1.

Serum analysis

Blood samples (2 ml) were taken from the wing vein of 6 fasting broilers per treatment groups on 21st and 42th day of experiment. Serum was obtained by centrifugation of blood at 3000 rpm for 10 min, and then it was frozen at -20°C for future analysis. Serum sodium (Na) and potassium (K) were

In some cases, the bad feed handling on the farm such as prolonged storage or inadequate storage conditions may, however, impair the nutritional qual-ities of the feeds. Such conditon may cause specific micronutrient deficiencies, especially minerals, leading to growth retardation in broilers (Aviagen, 2014). To optimize the growth potential of modern broilers in the commercial farms, the commercial broiler feeds are generally supplemented with organic mineral mixtures, probiotics, enzymes and emulsifiers.

Increased level of creatinine in serum can be indicative of kidney damage (Yalcin *et al*., 2012). Certain probiotic microorganisms have the ability to use urea, creatinine and other toxic chemicals as its nutrients for growth (Salim *et al*., 2011). Therefore, relatively low level creatinine may be an indication of the renal protective effects of the probiotic microorganism.

Hence, it would be interesting to investigate the effect of such dietary treatment on the performances and physiolog-ical responses of broiler chickens. Taken together, the present study aimed to investigate the effect of supplementation of various dietary supplements and their combination on their mineral homeostasis and kidney functions.

MATERIALS AND METHODS

Experimental birds and dietary treatments

The present study was undertaken at the Instructional Poultry Farm (IPF) of Govind Ballabh Pant University of Agriculture and Technology, Pantnagar, U.S. Nagar. A total of 252, day old commercial broiler chicks (Cobb) were procured for conducting the experiment. All the chicks were individually weighed and randomly allotted to seven different groups each with three replicates of 12 chicks. Average body weight of chicks was similar for all the treatment groups. The study was conducted for a period of 6 weeks under standard management conditions. Feed and water were provided ad *libitum*. The detail of experimental diets is given in Table 1.

Serum analysis

Blood samples (2 ml) were taken from the wing vein of 6 fasting broilers per treatment groups on 21st and 42th day of experiment. Serum was obtained by centrifugation of blood at 3000 rpm for 10 min, and then it was frozen at -20°C for future analysis. Serum sodium (Na) and potassium (K) were

Effect of organic mineral mixtures, probiotics, enzymes, emulsifier and liver supplements on serum protein and serum biochemical profile of broilers

SS Chauhan, RK Sharma, DV Singh, SK Shukla and Jyoti Palod

Abstract
A feeding trial was conducted to evaluate the effects of organic mineral mixture, probiotics, enzymes, emulsifier and liver supplements on serum protein profile and serum biochemical profile. For this purpose, a total of 396 day-old commercial broiler chicks (Cobb) were used and randomly allocated into 11 groups with three replicates of 12 chicks each. The results revealed that at 42nd day, all the supplemented groups were significantly ($P<0.05$) higher in total protein than T_0 group. All the supplemented groups were significantly ($P<0.05$) higher in albumin than T_0 group. All the supplemented groups were significantly ($P<0.05$) higher in globulin than T_0 group. All the supplemented groups were significantly ($P<0.05$) higher in albumin/ globulin ratio than T_0 group. Glucose values in T_4 T_9 and T_{10} groups were significantly ($P<0.05$) lower than T_0 (control) group. Total cholesterol values in T_2, T_3, T_4 T_5, T_9 and T_{10} groups showed significant ($P<0.05$) decrease compared to the T_0 (control). HDL-cholesterol values in T_3, T_4, T_5, T_9 and T_{10} showed significant ($P<0.05$) increase compared to the T_0 (control). All the supplemented groups showed significant ($P<0.05$) decrease in LDL- cholesterol values compared to the T_0 (control) except T_6, T_7 and T_8. All the supplemented groups showed significant ($P<0.05$) decrease in triglycerides values compared to the T_0 (control) except T_6 and T_7. All the supplemented groups showed significant ($P<0.05$) decrease in AST values compared to the T_0 (control) except T_2, T_6, T_7 and T_8. All the supplemented groups showed significant ($P<0.05$) decrease in ALT values compared to the T_0 (control) except T_4 and T_5.

Keywords: Organic mineral mixtures, serum protein, serum biochemical

Introduction
Poultry is one of the fastest growing segments of the agricultural sector in India. Globally, India ranked 3rd after China and USA with a production of 88.1 billion eggs (2016 – 2017) and 6th after USA, China, Brazil, Mexico and Indonesia with a production of 3.46 million tons of chicken meat (2016- 2017). The poultry sector in totality accounts for 0.60 per cent of the national GDP (2017–2018). The annual egg and broiler production of India is 70 billion eggs and 3.8 million tons respectively, with per capita consumption of 68 eggs and 2.5 kg chicken meat against the ICMR recommendations of 180 eggs and 11 kg poultry meat (CARI VISION 2050) [1]. Poultry meat has significant role in Indian diet valued at US $ 6.6 billion. Favoured by socio- economic conditions like rising purchasing power and changing food habits of the people this sector is driven by ever increasing domestic demand. Poultry meat is an excellent source of high quality protein, vitamins, and minerals and is not subjected to cultural and religious restrictions. Rising input cost in poultry production has necessitated the need to look for feed supplements which can enhance the nutrient utilization efficiency of feeds thereby improving performance of poultry and resultant increase in profitability. In this context use of organic minerals, probiotics, enzymes, emulsifiers and liver supplements seems promising. Use of organic minerals in poultry diets has been shown to have multiple beneficial effects including higher absorption and increased antibody levels as they may provide alternative pathways for absorption, by decreasing mineral excretion. Similarly, use of probiotics and feed enzymes have been reported to regulate gut integrity, reduce digestive disorders, improve nutrient absorption/ feed efficiency, increases production, check the mortality and lowering of feed cost. Poultry produces emulsifiers in the form of bile, however, at times it is insufficient in view of added fats and oils. Also, as the digestive tract in young birds is not completely developed, fat absorption from the feed matrix is hampered. Hence, addition of emulsifier into the diet can overcome this problem by reducing the size of the fat globules forming small micelles and increasing the total surface available for enzymatic digestion.

Abstract

The present study evaluated the effect of dietary inclusion of various feed supplements and their combination on the haematological and biochemical parameters. Day-old broiler chicks (n=252) were randomly assigned to seven treatment groups, each with 3 replicates. The first treatment was designated as control (T0) in which no supplement was added to the feed, while in treatments T1; organic mineral mixture (Organomin forte), T2; organic mineral mixture (Vannamin), T3; probiotics (Microguard), T4; enzyme (Brozyme -XPR) and probiotics, T5; emulsifier (Lipigon) were provided through the feed. In the T6 group, 3 percent less energy was given through feed from 1st to 6th weeks of age respectively. TEC, MCHC, and DLC values were significantly increased in the broilers of feed supplemented groups in comparison to control. TLC, PCV and Hb and was significantly increased in the broilers of feed supplemented groups in comparison to control except the T6 group. MCV and MCH values were significantly ($P<0.05$) decreased in the broilers of supplemented groups in comparison to control. Biochemical estimations showed a significant increase in TSP, albumin, and globulin and AST and ALT significant decrease in supplemented groups.

Introduction
Poultry is one of the fastest growing segments of the agricultural sector in India with compound growth rates of 6% and 10% per annum in egg and broiler production. Globally, India ranked 3rd in after China and USA with a production of 88.1 billion eggs (2016-2017) and 6th after USA, China, Brazil, Mexico and Indonesia with a production of 3.46 million tons of chicken meat (BAHS, 2017). The per capita consumption of eggs and meat is about 69 eggs and 3.4 kg meat per person per annum in India. In the country, eggs and broilers has been shown to rise at a rate of 8 –10 per cent per annum. The poultry sector in totality accounts for 0.60 per cent of the national GDP (2017–2018). As per FAOSTAT (2016), world's per capita consumption of poultry meat has increased from 2.88 kg to 14.13 kg over the last five decades. Poultry meat is an excellent source of high quality protein, vitamins, and minerals and is not subjected cultural and religious restrictions. Broiler meat is rich in nutrients primarily as a source of protein (21.4g/ 100g) with fewer calories (119 kcal/ 100g). Organically complexed minerals may provide alternative pathways for absorption, by decreasing mineral excretion. Organic trace minerals (OTM) supplementation to broiler diet is not directly associated with improved broiler performance, a single or blend of OTM in diets has been shown to have multiple beneficial effects. Probiotics are live microbial feed supplements which beneficially affect the host poultry birds by improving its intestinal microbial balance (Isolauri *et al.*, 2004) [4]. *Lactobacillus spp, Saccharomyces cerevisiae* and *Bacillus coagulans* have been used as a source of probiotics for improving growth performance. Poultry naturally produces enzymes which help in digestion of feed nutrients. The benefits of using enzymes in poultry diets include not only enhanced bird performance. Poultry produce emulsifiers in the form of bile however it is at times insufficient in view of added fats and oils. Hence, addition of emulsifier from external sources becomes obligatory in poultry feed. Broilers fed the diet containing soybean oil and emulsifier presented higher body weight gain. Liver stimulants possess hepato – protective and hepatogenic properties, tone up liver resulting into increase utilization of nutrients and hence better performance. Keeping the above facts in view, an experiment was conducted to determine the effect of supplementation of organic mineral mixtures, probiotics, enzymes, emulsifier and liver stimulants on the Feed Conversion Ratio and Performance Index of broilers.

Materials and Methods
A total of 396 day old commercial broiler chicks (Cobb) were procured for conducting the experiment. All the chicks were individually weighed and randomly allotted to eleven different groups each with three replicates of 12 chicks.

ABSTRACT

A feeding trial was conducted to study the effects of organic mineral mixture, probiotics, enzymes, emulsifier and liver supplements on the carcass traits of broilers. For this purpose, a total of 396 day-old commercial broiler chicks (Cobb) were used and randomly allocated into 11 groups with three replicates of 12 chicks each. The results revealed that maximum dressed yield with and without giblets at six weeks was noted in group T_{10} i.e. broilers supplemented with enzymes with probiotics, liver supplement 1 and emulsifier followed by T_4, T_6, T_3, T_5, T_2, T_1 and T_9. Similarly, all the supplemented groups showed significant ($P<0.05$) increase in the cut up parts compared to the control except T_8, T_7 and T_8. Supplemented groups also showed significant ($P<0.05$) decrease in the processing losses except in T_7 for blood loss & feather loss and in T_6 & T_7 for head loss. Thus, it may be concluded that supplementation has been found beneficial in yielding more edible meat with lesser dressing losses.

All the supplemented groups showed significant ($P<0.05$) increase in juiciervalues compared to the T_1 (control) except T_7. All the supplemented groups showed significant ($P<0.05$) increase in overall acceptabilityvalues compared to the T_1 (control) except T_7.

Introduction

Poultry is one of the fastest growing segments of the agricultural sector in India. India is the third largest egg producer after China and USA and the fourth largest poultry producer after China, Brazil and USA. The annual egg and broiler production of India is 70 billion eggs and 3.8 million tons respectively, with per capita consumption of 68 eggs and 2.5 kg chicken meat against the ICMR recommendations of 180 eggs and 11 kg poultry meat (CARI VISION 2050). Poultry meat has significant role in Indian diet valued at US $ 6.6 billion. Favoured by socio- economic conditions like rising purchasing power and changing food habits of the people this sector is driven by ever increasing domestic demand. Poultry meat is an excellent source of high quality protein, vitamins, and minerals and is not subjected to cultural and religious restrictions. Rising input cost in poultry production has necessitated the need to look for feed supplements which can enhance the nutrient utilization efficiency of feeds thereby improving performance of poultry and resultant increase in profitability. In this context use of organic minerals, probiotics, enzymes, emulsifiers and liver supplements seems promising. Use of organic minerals in poultry diets has been shown to have multiple beneficial effects including higher absorption and increased antibody levels as they may provide alternative pathways for absorption, by decreasing mineral excretion. Similarly, use of probiotics and feed enzymes have been reported to regulate gut integrity, reduce digestive disorders, improve nutrient absorption, feed efficiency, increase production, check the mortality and lowering of feed cost. Poultry produces emulsifiers in the form of bile, however, at times it is insufficient in view of added fats and oils. Also, as the digestive tract in young birds is not completely developed, fat absorption from the feed matrix is hampered. Hence, addition of emulsifier into the diet can overcome this problem by reducing the size of the fat globules forming small micelles and increasing the total surface available for enzymatic digestion.The addition of synthetic emulsifier to broiler diets is a recent practice as compared to other dietary supplements. Polyherbal liver stimulants possess hepato – protective, hepatogenic, immunomodulatory and antioxidant properties, which tone up liver resulting in increased utilization of feed and better performance.Keeping the above facts in view, an experiment was conducted to determine the effect of supplementation of organic mineral mixtures, probiotics, enzymes, emulsifier and liver stimulants on the serum biochemical and sensory characteristics parameters of broilers.

Materials and Methods

A total number of 396 day old commercial broiler chicks (Cobb) were procured for undertaking the experiment. All the chicks were individually weighed and randomly allotted to eleven different groups each with three replicates of 12 chicks. The groups were designated as T_1: basal diet, T_2: chicks fed basal diet along with organic mineral mixture 1 (Organomin forte) @ 0.5 g per kg feed, T_3: basal diet along with organic mineral mixture 2 (Vitamomin) @ 0.5 g per kg feed,T_4: basal diet along with probiotics (Microgrand) @ 0.1g per kg feed,T_5: basal diet along with enzymes + probiotics (Biozyme - XPR) @ 0.5 g per kg feed, T_6: basal diet along with emulsifier (Lipigest) @ 0.5 g per kg feed, T_7: basal diet with 3% less energy, T_8: basal diet with 3% less energy along with liver supplement 1(Superliv protect) @ 0.5 g/kg feed, T_9: basal diet with 3%2 less energy along with liver supplement 2 (X- liv Pro) @ 0.5 g/kg feed, T_{10}: basal diet along with enzyme with probiotics (Biozyme - XPR), liver supplement 1(Superliv protect) and emulsifier (Lipigest) @ 0.5 g/kg feed.Average body weight of chicks was similar for all the treatment groups. The broiler chicks were housed in deep litter system under standard management practices. Blood samples were collected from six experimental birds of each group i.e. two broiler chicks from each replicate on 21st and 42nd day of experimental feeding. Glucose was done spectrophotometrically by enzymatic GOD-POD method with the help of Span Diagnostic Kit at 505 nm wavelength (Sacks, 1998). Total cholesterol was estimated spectrophotometrically using Span Diagnostic Kit with enzymatic CHOD-PAP method at 505 nm wavelength (Tietz, 1998). Triglycerides was estimated at 505 nm spectrophotometrically using Span Diagnostic Kit by GPO – PAP, end point assay (Stein and Mayer, 1995).HDL cholesterol concentration was estimated spectrophotometrically at 560 nm by phosphotungstate method (Tietz, 1998). LDL cholesterol was estimated by Beckman coulter model no-Au480 fully automatic biochemistry analyser. ALT was estimated using Ecoline diagnostic kit based on reference method of International Federation of Clinical Chemistry (IFCC) at 340 nm wavelengths (Bergmeyeret al.,1986). AST was measured by Kinetic method using Labkit diagnostic kit at 330 nm wavelength (Tietz, 1998). The sensory quality of meat samples was evaluated by meat descriptive analysis method (Keeton and Findlings, 1984). The experimental data obtained were analyzed statistically using completely randomized design (CRD) as per the

Body weight gain and feed intake of broiler chickens fed different feed supplements

SS Chauhan, RK Sharma, DV Singh, SK Shukla and Jyoti Palod

Abstract
A feeding trial was conducted to evaluate the effects of Organic Mineral Mixtures, Probiotics, Enzymes, Emulsifier and Liver Supplements on Body Wt. Gain and Feed Intake parameters of broilers. For this purpose, a total of 396 day-old commercial broiler chicks (Cobb) were used and randomly allocated into 11 groups with three replicates of 12 chicks each. The results revealed that at 21st and 42nd days Body Wt. Gain values in all the treatment groups were significantly ($P<0.05$) higher than T_0 (control) group except T_7 and T_8. At 21st and 42nd days Feed intake values in all the treatment groups were significantly ($P<0.05$) lower than T_0 (control) group except T_6 while whereas it increased significantly in T_7 and T_8 groups.

Keywords: Organic mineral mixture, probiotic, emulsifier

Introduction
Poultry is one of the fastest growing segments of the agricultural sector in India with compound growth rates of 6% and 10% per annum in egg and broiler production. Globally, India ranked 3rd in after China and USA with a production of 88.1 billion eggs (2016 – 2017) and 6th after USA, China, Brazil, Mexico and Indonesia with a production of 3.46 million tons of chicken meat (BAHS, 2017). The per capita consumption of eggs and meat is about 69 eggs and 3.4 kg meat per person per annum in India. In the country, eggs and broilers has been shown to rise at a rate of 8 –10 per cent per annum. The poultry sector in totality accounts for 0.60 per cent of the national GDP (2017–2018). As per FAOSTAT (2016), world's per capita consumption of poultry meat has increased from 2.88 kg to 14.13 kg over the last five decades. Poultry meat is an excellent source of high quality protein, vitamins, and minerals and is not subjected cultural and religious restrictions. Broiler meat is rich in nutrients primarily as a source of protein (21.4g/ 100g) with fewer calories (119 kcal/ 100g). Organically complexed minerals may provide alternative pathways for absorption, by decreasing mineral excretion. Organic trace minerals (OTM) supplementation to broiler diet is not directly associated with improved broiler performance, a single or blend of OTM in diets has been shown to have multiple beneficial effects. Probiotics are live microbial feed supplements which beneficially affect the host poultry birds by improving its intestinal microbial balance (Isolauri *et al*., 2004) [3]. *Lactobacillus spp. Saccharomyces cerevisiae* and *Bacillus coagulans* have been used as a source of probiotics for improving growth performance. Poultry naturally produces enzymes which help in digestion of feed nutrients. The benefits of using enzymes in poultry diets include not only enhanced bird performance. Poultry produce emulsifiers in the form of bile however it is at times insufficient in view of added fats and oils. Hence, addition of emulsifier from external sources becomes obligatory in poultry feed. Broilers fed the diet containing soybean oil and emulsifier presented higher body weight gain. Liver stimulants possess hepato – protective and hepatogenic properties, tone up liver resulting into increase utilization of nutrients and hence better performance. Keeping the above facts in view, an experiment was conducted to determine the effect of supplementation of organic mineral mixtures, probiotics, enzymes, emulsifier and liver stimulants on the body weight gain and feed intake parameters of broilers.

Materials and Methods
A total of 396 day old commercial broiler chicks (Cobb) were procured for conducting the experiment. All the chicks were individually weighed and randomly allotted to eleven different groups each with three replicates of 12 chicks.

ABSTRACT

Chauhan, S.S., Sharma, R.K., Singh, S.K., Shukla, S.K., Palod, J. and Singh, M.K. 2020. Assessment of certain feed supplements on antibody titer, faecal pathogens and NPK contents of litter in broilers. Indian Journal of Poultry Science, 55(1): 59-62.

The present study evaluated the effect of dietary inclusion of various feed supplements and their combination on the antibody titer, faecal pathogens and NPK contents of broilers for 6 weeks. Day-old broiler chicks (n=252) were randomly assigned to seven treatment groups consisted of 3 replicates per treatment. The first treatment was designated as control (T_0) in which no supplement was added to the feed, while in treatments T_1: organic mineral mixture, T_2: organic mineral mixture, T_3: probiotics, T_4: enzyme and probiotics, T_5: emulsifier were provided through the feed. In the T_6 group, 3 percent less energy was given through feed. Immunoglobin G were significantly ($P<0.05$) increased and cortisol values decreased in supplemented groups as compared to the T_0 (control) group. The pathogens *viz., E. coli* and *Salmonella enteritidis* were found absent in the faeces of birds of all the experimental groups. The nitrogen, phosphorus and potassium values were significantly ($P<0.05$) increased in feed supplemented groups than the T_0 (control) group. The increase in IgG levels in supplemented groups indicated the better immune status of the birds whereas decreased levels of cortisol in the treated groups showed lower levels of stress.

Keywords: Broiler, Faecal pathogens, Immuno-modulatory effect, NPK contents, Litter

INTRODUCTION

In the last five decades, there has been considerable progress in the poultry industry due to improved genetics, nutrition, housing, and disease control. The ban on the use of antibiotics and restricted use of medication has aggravated the problems of poultry farmers along with the increased susceptibility of birds to various diseases and stressors. Effective control of diseases and improvement in the performance of birds is possible only by enhancing the bird's immune system. Along with environmental factors, external stressors and the genetic makeup of the birds, various nutrients also play an important role in attaining the competitive performance (Singh *et al.*, 2017). Feed manufacturers and nutritionists know very well about the feasibility to assemble well-balanced diets including all essential as well as minor nutrients.

The use of organic mineral mixtures improves performance, activates immune stimulation, optimizes minerals absorption and utilization and improves oxidative status in broiler chicks (Ravindran, 2013).

Probiotic (Micro-guard) on administration passes through stomach reaches intestine where it colonizes occupying the intestinal villi and prevents pathogens from attaching to the intestine and at the same time favours the growth of essential microflora in the gut. They also produce substances like bacteriocins and local acting antibiotics that are antagonistic to pathogens. It also secretes enzymes like protease, amylase, and lipase along with other nutrients and supplements which can be used by the lactic acid-producing and other useful bacteria to multiply rapidly and to sustain them for a longer time in the intestine. Further prevents *E. coli*, clostridium, coccidia and salmonella infections and reinforces the integrity of the gut wall and stimulates intestinal immunity-enhancing production of secretory antibodies (Chaudhary *et al.*, 2017).

The use of exogenous feed specific enzymes (Brozyme) breaks down non-starch polysaccharides (NSPs) in feed ensuring more nutrient bioavailability and reduces the viscosity of the gut caused by NSPs–improves intestinal absorption of nutrients. Prevent gut pathogens to ensure gut health (Narasimha *et al.*, 2016).

The non-ionic emulsifier (Lipigon) promotes performance and reducing the nutrition density of faeces. It aids fat-soluble vitamin absorption, increases energy: protein ratio retains moisture of feed and maintains its nutritive value and keeps liver free from fat deposits.

Keeping in view the above facts, it is necessary to increase the availability of dietary nutrients by different

Abstract

A total of one hundred and sixty four fresh, infertile eggs of White Leghorn Hen Eggs were procured from a single flock of same age from Central Avian Research Institute, Izatnagar, Bareilly (UP). These 164 eggs were divided into 4 groups, each comprising of 41 eggs. These groups were categorized into two groups and were kept at room temperature and remaining two groups were kept in refrigerator. Room temperature noticed from 22°C to 38°C and relative humidity from 40 to 75 per cent. The temperature of refrigerator was noted as 8 ±1°C and relative humidity from 75 to 85 per cent. The Shelf Life, Percentage weight Loss, Albumin Index, Yolk Index and Haugh Unit were noted. The treatment T_2 and T_4 enhanced the Shelf- Life of eggs for a maximum period of 35 days at room and 90 days at refrigeration temperature. The untreated eggs T_1 and T_3 (control) maintained the organoleptically acceptable life for a period of 14 days and 60 days at room and refrigeration temperature, respectively. Significantly lower percentage of weight loss of eggs was found in Refined Groundnut Oil treated eggs. Significantly lower decline in Albumen Index was found in Refined Groundnut Oil treated eggs. Significantly lower decline in Yolk Index was found in Refined Groundnut Oil treated eggs. Significantly lower decline in Haugh Unit was found in Refined Groundnut Oil treated eggs.

Key Words – Shelf Life, Albumin Index, Yolk Index and Haugh Unit

Introduction

Poultry is one of the fastest growing segments of the agricultural sector in India. Globally, India ranked 3rd after China and USA with a production of 88.1 billion eggs (2016 – 2017) and 6th after USA, China, Brazil, Mexico and Indonesia with a production of 3.46 million tons of chicken meat (BAHS, 2017). The poultry sector in totality accounts for 0.60 per cent of the national GDP (2017–2018). The annual egg and broiler production of India is 70 billion eggs and 3.8 million tons respectively, with per capita consumption of 68 eggs and 2.5 kg chicken meat against the ICMR recommendations of 180 eggs and 11 kg poultry meat (CARI VISION 2050). Favoured by socio-economic conditions like rising purchasing power and changing food habits of the people this sector is driven by ever increasing domestic demand. Egg is a rich source of high quality of animal protein and is often used as standard for measuring the quality of the other food proteins. It is an important source of unsaturated fatty acids, minerals especially iron and phosphorus and almost all the Vitamins with the exception of Vitamin C. It is well balanced amino acid profile and easy digestibility makes it a valuable protective food in human diet. It is the only source of high quality proteinous food and is very useful to fight malnutrition in India. Oil coating is one of the most important methods for preserving eggs which can be safely applied by semi- skilled persons who are engaged in this profession by the daily or by the daily consumers. The oil seals the pores of the shell which prevents the evaporation of moisture, entry of microorganism, odours and escape of gases. This checks the weight loss of the egg and maintains the good internal quality for longer period because some of the physiochemical changes in the egg contents are being retarded.

Materials and Methods

A total of 164 White Leghorn Hen Eggs were divided into four groups each comprising 41 eggs. The following four treatments were done and were designated as T_1: Untreated eggs used as control kept at room temperature. T_2: Dipping in the Refined Groundnut Oil kept at room temperature. T_3: Untreated eggs used as control and kept at refrigeration temperature. T_4: Dipping in Refined Groundnut Oil and kept at refrigeration temperature. Weekly weight loss determinations were done for control and oiled eggs held at room temperature.Whereas the same were studied at fortnightly intervals for the eggs which were stored in refrigerator. Albumen and Yolk Indices were determined by the method of Heiman and Carver (1936) and Funk (1948) respectively. The Haugh Unit was measured according to Haugh (1937). The data were analysed statistically as per methods given by Panse and Sukhatme (1957).

Results and Discussion

The Results of the present study have been presented under following heads:

Effect of Refined Groundnut Oil treatment on the shelf- life of eggs

The treatment T_2 and T_4 increased the shelf life 35 days at room temperature and 90 days at refrigeration temperature. The minimum storage life was found in control (un- oiled) eggs where it was 14 days and 60 days under room and refrigeration conditions, respectively.

Table -1: Effect of Refined Groundnut Oil treatment on the shelf-life of eggs at room and refrigeration temperatures

Treatments	Shelf- life of eggs in days at different temperatures.	
	Room Temperature (30±8°C; 40 – 75%RH)	Refrigeration Temperature (8±1°C; 75 – 80% RH)
T_1 (Control)	14	60
T_2	35	90

The superiority of Refined Groundnut Oil in extending the shelf-life of eggs at both the atmospheric conditions might be due to their better shell pore sealing property and therefore, there had been a less loss of moisture and CO_2 from the eggs coated by Refined Groundnut Oil coating media.

Effect of Refined Groundnut Oil treatment on the Percentage loss in weight of oil coated and un-coated eggs at weekly interval kept at room temperature

There was a very slow rate of decrease in weight of oil coated eggs in comparison to control. At room temperature the maximum percentage loss in egg weight was observed in T_1 (control) group (7.7%) after 14 days of storage which was significantly higher than that of oil treated eggs. The minimum loss in egg weight during storage was found in T_2 (0.37%).

Table- 2: Percentage loss in weight of oil coated and un-coated eggs at weekly interval kept at room temperature

Treatments	Days of storage		Overall mean
	D1 (7 days)	D2 (14 days)	
T_1 (Control)	4.290	7.708	5.999
T_2	0.016	0.376	0.196

CD 5% = 1.99

Effect of Refined Groundnut Oil treatment on the Percentage loss in weight of oil coated and un-coated eggs at fortnightly interval kept at refrigeration temperature

At refrigeration temperature significantly, highest loss in egg weight was recorded in untreated eggs (T_3) to the extent of 9.11%. The

ABSTRACT

A feeding trial was conducted to study the effects of organic mineral mixture, probiotics, enzymes, emulsifier and liver supplements on the carcass traits of broilers. For this purpose, a total of 396 day-old commercial broiler chicks (Cobb) were used and randomly allocated into 11 groups with three replicates of 12 chicks each. The results revealed that maximum dressed yield with and without giblets at six weeks was noted in group T_{10} i.e. broilers supplemented with enzymes with probiotics, liver supplement 1 and emulsifier followed by T_4, T_6, T_3, T_5, T_2 , T_1 and T_9. Similarly, all the supplemented groups showed significant ($P<0.05$) increase in the cut up parts compared to the control except T_8, T_7 and T_9. Supplemented groups also showed significant ($P<0.05$) decrease in the processing losses except in T_7 for blood loss & feather loss and in T_6 & T_7 for head loss. Thus, it may be concluded that supplementation has been found beneficial in yielding more edible meat with lesser dressing losses.

Key words: *Broilers, Enzymes, Probiotics, Organic mineral mixture, Emulsifier*

INTRODUCTION

Poultry is one of the fastest growing segments of the agricultural sector in India. India is the third largest egg producer after China and USA and the fourth largest poultry producer after China, Brazil and USA. The annual egg and broiler production of India is 70 billion eggs and 3.8 million tons respectively, with per capita consumption of 68 eggs and 2.5 kg chicken meat against the ICMR recommendations of 180 eggs and 11 kg poultry meat[1]. Poultry meat has significant role in Indian diet valued at US $ 6.6 billion. Favoured by socio- economic conditions like rising purchasing power and changing food habits of the people this sector is driven by ever increasing domestic demand. Poultry meat is an excellent source of high quality protein, vitamins, and minerals and is not subjected to cultural and religious restrictions. Rising input cost in poultry production has necessitated the need to look for feed supplements which can enhance the nutrient utilization efficiency of feeds thereby improving performance of poultry and resultant increase in profitability.

Probiotics are live microbial feed supplements which beneficially affect the host poultry birds by improving its intestinal microbial balance (Isolauri *et al*., 2004) [5]. *Lactobacillus spp, Saccharomyces cerevisiae* and *Bacillus coagulans* have been used as a source of probiotics for improving growth performance. Poultry naturally produces enzymes which help in digestion of feed nutrients. The benefits of using enzymes in poultry diets include not only enhanced bird performance. Poultry produce emulsifiers in the form of bile however it is at times insufficient in view of added fats and oils. Hence, addition of emulsifier from external sources becomes obligatory in poultry feed. Broilers fed the diet containing soybean oil and emulsifier presented higher body weight gain. Liver stimulants possess hepato – protective and hepatogenic properties, tone up liver resulting into increase utilization of nutrients and hence better performance. Keeping the above facts in view, an experiment was conducted to determine the effect of supplementation of organic mineral mixtures, probiotics, enzymes, emulsifier and liver stimulants on the body weight gain and feed intake parameters of broilers.

Materials and Methods
A total of 396 day old commercial broiler chicks (Cobb) were procured for conducting the experiment. All the chicks were individually weighed and randomly allotted to eleven different groups each with three replicates of 12 chicks.

Comparative evaluation of the wound healing potential of *Tinospora cordifolia* and its combination with local Insulin therapy in diabetic rabbits

Ajit Kumar Singh, B Om Preethi, HN Singh, AK Gangwar, D Niyogi and Kh Sangeeta Devi

Abstract
Wound healing is impaired in diabetes mellitus. Therefore, the present study was carried out for the evaluation of healing potential of *Tinospora cordifolia* and its combination with local Insulin therapy in diabetic wounds. Diabetes was induced in the animals of group I and II. The wounds were created on the thoraco-lumbar area in each animal under general anesthesia. The animals of group I were treated with oral suspension prepared from methanolic extract of *T. cordifolia* stem and the animals of group II were treated with combination of oral *T. cordifolia* and local insulin therapy. The soframycin ointment was applied over wounds in both the groups. The rate of wound healing was assessed on the basis of colour digital imaging, wound morphometery, histopathological and Scanning Electron Microscopic (SEM) studies. On the basis of observations, the rate of wound healing recorded in group II animals was significantly higher and better than group I.

Keywords: healing potential, *Tinospora cordifolia*, Insulin therapy

Introduction

Diabetes mellitus is a metabolic disorder characterized by hyperglycemia and alteration in carbohydrate, fat and protein metabolism associated with absolute or relative deficiency of insulin secretion and/or insulin action (Kameswara *et al.*, 2003) [14]. It is one of the major contributors to delayed wound healing. Wound healing is the restoration of tissue architecture and function following an injury (Kumar *et al.*, 2007) [17]. Normal wound healing is a complex phenomenon covering four overlapping phases i.e. inflammation, proliferation, remodeling and maturation (Sumitra *et al.*, 2005) [5]. In diabetes mellitus, all these four phases are hampered and the wound remains in a chronic inflammatory state and fails to heal in a timely and orderly manner. Hyperglycemia and infection are the major causes for the delayed wound healing (Sandhya *et al.*, 2011) [30]. Bacteria thrive on the increased glucose available in the bloodstream, and that at the same time the high glucose concentration inhibits neutrophil action, leading to a proliferation of bacteria and infection. Infection and inflammation lead to imbalance of protease and reactive oxygen species, essential growth factors are degraded, the ability of angiogenesis is impaired and cell recruitment to the wound sites is inhibited (Blakytny and Jude 2006) [4]. All these factors hampering the process of healing make the management of diabetic wounds difficult.

It has been proposed that absolute or relative lack of insulin contributes to delayed wound healing in diabetes (McIntosh and Pederson 1999) [24]. Clinical and animal experiments have indicated that local treatment with insulin may improve wound healing in diabetes (Madibally *et al.*, 2003) [22]. The role of topical insulin in the promotion of wound healing in several animal models has been reported by previous workers (Liu *et al.*, 2005; Zhang *et al.*, 2007) [20, 40]. In addition, insulin injected diffusely into the wound can accelerate wound re-epithelialization (Zhang *et al.*, 2007) [40]. In modern medicine, no satisfactory effective therapy is still available to cure the diabetic wounds and associated complications. Though insulin and other modern therapies are being used for the management of diabetic wounds, but they also have drawbacks like resistance (Piedrola *et al.*, 2001) [25]. Moreover, the modern therapeutic treatments are very expensive. Thus, all these factors compel for the search of safe and affordable alternatives with minimal adverse effects, which can be taken for long durations. Recently, there has been increasing interest in the use of medicinal plants. *Tinospora cordifolia* is one of them. It is a deciduous climbing shrub of the family *Menispermaceae*. It is distributed throughout the Indian subcontinent and China (Singh *et al.*, 2003) [33].

ABSTRACT

Diabetes mellitus is one of the major contributors to delayed wound healing. So far there is no significantly effective therapy for diabetic wound healing. The present study aimed to evaluate the healing efficacy of Tinospora cordifolia and local insulin therapy in diabetic wounds. Eighteen animals were made diabetic using alloxan monohydrate. These animals were divided into two groups A and B each having nine animals. The wounds were created on the thoraco-lumbar area in each animal under general anesthesia. The animals of group A were treated with oral suspension prepared from methanolic extract of T. cordifolia stem and the animals of group B were treated with local insulin therapy. The soframycin ointment was applied over wounds in both the groups. The wound healing efficacy of T. cordifolia and local insulin therapy was assessed on the basis of wound condition, colour digital imaging, wound morphometery, histopathological and Scanning Electron Microscopic (SEM) studies. The rate of wound healing recorded in group B was significantly higher and better than group A. On the basis of observations of this study, it was concluded that T. cordifolia and local insulin therapy both enhanced the rate of healing in diabetic wounds but local insulin therapy shown the better healing efficacy.

INTRODUCTION

Normal wound healing is a well orchestrated process that results in restoration of tissue integrity. This process is hampered in Diabetes mellitus leading to delayed wound healing. Persistence of inflammation and neutrophil infiltration are characteristics associated with impaired wound healing in diabetes [1,2]. Hyperglycemia is responsible for the development of infections in diabetic wounds. Bacteria thrive on the increased glucose available in the bloodstream and at the same time the high glucose concentration inhibits neutrophil action, leading to a proliferation of bacteria and infection. Infection and inflammation lead to imbalance of protease and reactive oxygen species, essential growth factors are degraded, the ability of angiogenesis is impaired and cell recruitment to the wound sites is also inhibited [3] consequently wound remains in a chronic inflammatory state. Management of such wounds poses a great challenge. Recently, there has been increasing interest in the use of medicinal plants because of their antidiabetic and wound healing properties. *Tinospora cordifolia* is one of them (Fig. 1a and 1b). It is a deciduous climbing shrub of the family *Menispermaceae.* It is distributed throughout the Indian subcontinent and China [4]. The plant has been reported as anti-diabetic and anti-hyperglycemic [5], anti-inflammatory [6], antioxidant [7], anti-stress [8] and wound healing properties [9]. In Diabetes mellitus there is absolute or relative lack of insulin which contributes to wound healing complications [10]. The role of local insulin in the promotion of wound healing has been reported by several workers [11,12,13]. It stimulates the growth and development of different cell types, and affects proliferation, migration and secretion by keratinocytes, endothelial cells, and fibroblasts [14]. It also stimulates protein turnover [15]

DECELLULARIZATION OF SKIN AND FISH SWIM BLADDER

Kh. Sangeeta Devi, A. K. Gangwar*, Mahesh Kumar Verma, Ravi Prakash Goyal, Ranjeet Kumar and Yogendra Singh
Department of Veterinary Surgery & Radiology, College of Veterinary Science And Animal Husbandry, Narendra Deva University Of Agriculture And Technology, Kumarganj, Faizabad-224 229 (U.P.)

Abstract
Biologic scaffolds are typically procured by processes that involve decellularization of tissues or organs. Preservation of the complex composition and three-dimensional architecture of the extracellular matrix is highly desirable but it is established fact that most methods of decellularization result in disruption of the architecture and leads to potential loss of surface structure and composition. An overview of decellularization of skin and fish swim bladder, their effect upon resulting ECM structure and composition are presented herein.
Key words: Decellularization, Skin, Fish swim bladder

Introduction

Biomaterials have become critical components in the development of effective new medical therapies for wound care. Natural collagenous materials are being investigated for surgical repair because of inherent low antigenicity and their ability to integrate with surrounding tissue (Gangwar *et al.*, 2015). Xenogeneic and allogeneic cellular antigens are recognized as foreign by the host and result in an adverse inflammatory response or overt immune-mediated rejection of the tissue (Erdag *et al.*, 2004). The effective removal of antigenic epitopes associated with cell membranes and intracellular components of tissues and organs is necessary to minimize or avoid an adverse immunologic response by allogeneic and xenogenic recipients of the biological scaffold materials (Schmidt and Baier, 2000).

The use of natural biomaterials has typically pre-treatment aimed at (1) preserving the tissue by enhancing the resistance of material to enzymatic or chemical degradation, (2) reducing the immunogenicity of the material, and (3) sterilizing the tissue (Schmidt and Baier, 2000). Biological materials composed of extracellular matrix are typically processed by methods that include decellularization and/or chemical cross-linking to remove or mask antigenic epitopes, DNA, and damage associated molecular pattern (DAMP) molecules (Gilbert *et al.*, 2006, Bianchi *et al.*, 2007). Biomaterials composed of decellularised ECM have been shown to promote the healing process via modulation of the host immune response, resistance to bacterial infections, allowing reinnervation and reestablishing homeostasis in the healing region (Badylak and Gilbert, 2008, Badylak *et al.*, 2009). Biological tissues from both allogenic and xenogenic sources have been used for surgical repair of tissue defects (Kumar *et al.*, 2012).

The fish swim bladder or air bladder or gas bladder is a white glistering, two chambered organs developing as a diverticulum from the wall of the pharynx in the gut of fish. It is a rich source of Type I collagen (Rose *et al.*, 1998). Most fish collagens have been found to consist of two α-chain variants, which are normally designated as α_1 and α_2. It consists of one-third glycine, contains no tryptophan or cysteine and is very low in tyrosine and histidine. Alpha-2 has a higher affinity for SDS and consequently exhibits a higher mobility than α1 (Kubo and Takagi, 1984). Rose *et al.* (1998) extracted collagen from swim bladder of fish. Kumar *et al.* (2015) Decellularised the fish swim bladder using sodium deoxycholate resulted in a complete loss of cellular structures. The tunica externa and interna were completely acellular. The collagen fibres were loosely arranged than the native tissue.

The cell extraction from biological tissues may remove their cellular antigens (Courtman *et al.*, 1994). As a means for reducing the antigenic response to xenograft materials, extraction removes lipid membranes and membrane-associated antigens as well as soluble proteins (Courtman *et al.*, 2001). However, even with complete extraction of cellular proteins, it would still be anticipated a cross-species response directed toward the structural proteins if acellular tissues were used as a xenograft (Liang *et al.*, 2004). This cross-species response due to the structural proteins may be further reduced by crosslinking (Olde Damink *et al.*, 1996). The high enzymatic turnover rate of extracellular matrix (ECM) *in vivo* makes stabilization of collagen-based biomaterials necessary. This can be achieved by chemical cross-linking methods, which provide biomaterials with desired mechanical properties for implantation and defect repair (Jorge-Herrero *et al.*, 1999). Several chemical agents have been used to achieve this goal. Glutaraldehyde (GA) is the most widely used reagent for cross-linking collagen. However, GA is associated with cytotoxicity *in vitro* and *in vivo*, caused by the presence of unreacted functional groups or by the release of those groups during enzymatic degradation of the cross-linked biomaterials (Huang-Lee *et al.*, 1990). Use of EDC to crosslink collagen seems to yield biomaterials with good biocompatibility, higher cellular differentiation potential (Ponticiello *et al.*, 2000) and with increased resistance against enzymatic degradation (Olde Damink *et al.*, 1996).

Decellularization of biomaterials

The goal of a decellularization is to efficiently remove all cellular and nuclear material while minimizing any adverse effect on the composition, biological activity, and mechanical integrity of the remaining extra cellular matrix (Gilbert *et al.*, 2006). Decellularization can be brought about by specific physical, chemical, and enzymatic methods which leave a material composed essentially of extra cellular matrix components. These acellular tissues retained their natural mechanical properties and promote remodeling of the prosthesis by neovascularization and recellularization by the host (Schmidt and Baier, 2000).

A decellularization protocol generally begins with lysis of the cell membrane using physical treatments or ionic solutions, followed by separation of cellular components from the ECM using enzymatic treatments, solubilisation of cytoplasmic and nuclear cellular components using detergents, and finally removal of cellular debris from the tissue. These steps can be coupled with mechanical agitation to increase their effectiveness (Gilbert *et al.*, 2006).

Ionic detergents are effective for solubilizing both cytoplasmic and nuclear cellular membranes but tend to denature proteins by disrupting protein–protein interactions (Seddon *et al.*, 2004). Sodium deoxycholate is very effective for removing cellular remnants but tends to cause greater disruption to the native tissue architecture when compared to sodium dodecyl sulphate (Gilbert *et al.*, 2006). Osmotic shock with a hypotonic or hypertonic solution such as deionized water or low ionic strength solution is used to lyse the cells within tissues and organs (Woods *et al.*, 2005).

Decellularization of the skin has been done by various chemical and enzymatic techniques to remove the cellular components, yet residual cellular components and lipids could not be removed. That might have promoted the undesired effects such as calcification and host immune response resulting inflammatory reaction in the recipient. It was also mentioned that, even after the removal of cells and debris from the biomaterials the extracellular matrix of the acellular tissue itself might elicit some amount of immune response (Coito and Kupiec-Weglinsky, 1996).

Following decellularization, all residual chemicals must be removed to avoid an adverse host tissue response to the chemical (Gilbert *et al.*, 2006). Acellular scaffolds have been used successfully in animals (Gangwar *et al.*, 2006). Removal of cells from the tissue leaves the complex mixture of structural and functional proteins that constitute the ECM. Decellularization of tissues can be done by physical

OCULAR SETARIASIS IN A HORSE
A CASE STUDY

Yogendra Singh[1], Ravi Prakash Goyal[1], Ranjeet Kumar[1], Kh. Sangeeta Devi[2], Anil Kumar Gangwar*[3]

Department of Veterinary Surgery and Radiology, College of Veterinary Science and Animal Husbandry, Narendra Deva University of Agriculture and Technology, Kumarganj-224 229, Ayodhya (UP)

Abstract

A 4 years horse was presented at the Veterinary Clinical Complex, Ayodhya, Uttar Pradesh, India, with impaired vision and cloudiness in the left eye. On close examination, a thread like larva was seen in the anterior chamber of the eye and was later diagnosed as setariasis. Finally, the setaria was removed by surgery aspirating it with a 16 gauge hypodermic needle. To avoid recurrence, Ivermectin was administered @ 200 µg/kg. setaria larva was collected and recovery was uneventful. Opacity cleared in about 3 weeks.

KEY WORDS: Eye worm, Paracentesis

Introduction

Ocular Setariosis in horses reported from many parts of India including Jammu and Kashmir [1]. It is an intra ocular helminth parasite and classified under nematodes. Setariasis is caused by the migration of immature stages of setaria labiato-papillosa (S. digitata) and setaria equi. In sub-clinical stage lacrimation and conjunctivitis is seen followed by cloudiness of cornea resulting in corneal opacity. Similar lesions are seen in Thalizia infection also but the parasite is lies either under the conjunctiva or in the vitreous cavity of the eyeball [2]. The infection occurs in equines when infected mosquitoes feed around eyes and deposit the infective larvae there, which enter and migrate in the anterior chamber of the eye [3]. Damage to the eye is caused by the serrated cuticle of the worm and movement of larvae leads to corneal opacity [4]. Ocular setariasis is usually treated surgically either by paracentesis or by aspiration [5]. Surgical treatment has been advocated & found successful [6], though medical treatment has been reported [7]

ANAMNESIS

Owner reported that animal is having cloudy appearance in its left eye since three weeks, which is increasing day by day. The animal was attended by a veterinarian previously. During clinical examination, cloudiness was observed in the left eye and on close examination a thread-like larva was seen in the eye. Thereafter, the case was referred for surgical correction at VCC unit.

CLINICAL SIGNS

Important clinical signs noted at the time of presentation included a snake-like, whitish parasite moving swiftly in the aqueous humour of the left eye, photophobia, corneal opacity, blepharospasm, mild lacrimation and head tilt, moderate depression, stiff gait and moderate fever (40°C). Haematological data shows a decrease in erythrocyte (RBC) count, haemoglobin and haematocrit (PVC), together with leucocytosis and an accelerated erythrocyte sedimentation rate (ESR).

TREATEMENT

The animal was properly restrained in lateral recumbency under sedation by xylazine (1.1 mg/kg). Regional anesthesia was achieved by 2% lignocaine hydrochloride. A 10 ml disposable syringe with an 18-gauge needle was inserted into the anterior chamber of the affected eye at 12 o'clock position of the cornea about 5 mm away from the limbus. The parasite was then successfully removed from the eye by sucking along with aqueous humor. After the removal of the parasite, ointment Neosporin-H was applied over the eye 3-4 times a day for 1 week. No additional surgical procedure was done to relieve the blindness of the affected eye. The worm removed was 5.2 cm long (Fig.1) and was identified as Setaria spp. under light microscopic. Ivermectin was administered at 200 µg/kg to avoid recurrence. The animal recovered without complications and corneal opacity was cleared after 4 weeks after treatment.

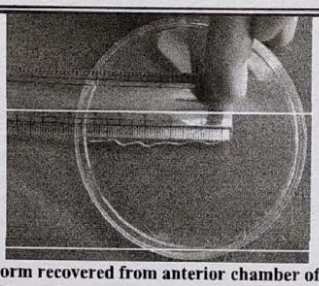

Fig.1: Eye worm recovered from anterior chamber of horse's eye

Results and Discussion

Setaria equina is found inside the anterior chamber of the horse's eye. This filaroidea nematode, which is normally found inside the peritoneal cavity of horses, may cause serious intraocular damage [8]. *Setaria equina* has an indirect life cycle. Microfilaria is transmitted by blood sucking insects. Larva of parasite arrives in the anterior segment of the eye and grows into immature adult. Clinical signs attributed to ocular fiariasis are caused by the resultant iridocyclitis which may be manifested by aqueous flare, hypopyon, photophobia, epiphora, miosis and corneal oedema as reported by Gangwar and coworkers [5]. Often the parasite cannot be visualised because of the opacity of the cornea and aqueous humour. Diagnosis and treatment Iridocyclitis of uncertain etiology in a horse merits a careful examination, with a focal light source and magnification, for the presence of intraocular parasites. If opaque media prevents a thorough intraocular examination symptomatic treatment for the uveitis may be instituted and the examination repeated. The treatment of choice for intraocular filariasis has been surgical removal of the parasite followed by treatment for uveitis. Although ivermectin has recently been reported to be 80 per cent effective against adult S equina at a dose of 0.2 mg/kg bwt and 88 per cent effective at a dose of 0.5 mg/kg bwt [9].

Conclusion

Setaria worm present into the anterior chamber of eye was successfully retrieve by using paracentesis technique without serious complications. After removal of worm, vision was found clear, corneal opacity was gradually reduced and eye was completely clear after 4 weeks.

THREE DIMENSIONAL (3D) BIOPRINTING

Ravi Prakash Goyal[1], Yogendra Singh[1], Ranjeet Kumar[1], Kh. Sangeeta Devi[2], Anil Kumar Gangwar[3]

Department of Veterinary Surgery and Radiology, College of Veterinary Science and Animal Husbandry, Narendra Deva University of Agriculture and Technology, Kumarganj-224 229, Ayodhya (UP)

Abstract

Bioprinting is a part of tissue engineering which is used for the development of three-dimensional (3D) tissue constructs by automated computer-aided deposition of living cells, extracellular matrix (ECM) components, and biochemical factors at a specified position with adequate numbers and right combinations [1, 2]. Bioprinting first came into existence in 2003. It is a 3D fabrication technology involving biological tissues, organs and cells for different medical and biotechnology applications. Due to the limited organ donors worldwide, scientists have started utilizing bioprinting technology for various areas of regenerative medicine to possibly cope up with organ-shortage gap. Three dimensional bioprinting is the utilization of 3D printing like techniques to combine cells, growth factors, and biomaterials to fabricate biomedical parts that maximally imitate natural tissue characteristics [3]. Three dimensional bioprinting is the process of creating cell patterns in a confined space using 3D-printing technologies, where cell function and viability are preserved within the printed construct. 3D printing enables design and manufacture of construct that are architecturally close to native tissue [4]. Day to day innovations leads to produce the desired tissue or organ through bioprinting of cells or extracellular matrix by depositing 3D gel layer by layer to. Also, 3D bioprinting has begun to incorporate the printing of scaffolds, [5]. These scaffolds can be used to regenerate joints and ligaments [6].

Introduction

Bioprinting is a part of tissue engineering which is used for the development of three-dimensional (3D) tissue constructs by automated computer-aided deposition of living cells, extracellular matrix (ECM) components, and biochemical factors at a specified position with adequate numbers and right combinations [1, 2]. Bioprinting first came into existence in 2003. It is a 3D fabrication technology involving biological tissues, organs and cells for different medical and biotechnology applications. Due to the limited organ donors worldwide, scientists have started utilizing bioprinting technology for various areas of regenerative medicine to possibly cope up with organ-shortage gap. Three dimensional bioprinting is the utilization of 3D printing like techniques to combine cells, growth factors, and biomaterials to fabricate biomedical parts that maximally imitate natural tissue characteristics [3]. Three dimensional bioprinting is the process of creating cell patterns in a confined space using 3D-printing technologies, where cell function and viability are preserved within the printed construct. 3D printing enables design and manufacture of construct that are architecturally close to native tissue [4]. Day to day innovations leads to produce the desired tissue or organ through bioprinting of cells or extracellular matrix by depositing 3D gel layer by layer to. Also, 3D bioprinting has begun to incorporate the printing of scaffolds, [5]. These scaffolds can be used to regenerate joints and ligaments [6].

THE BASICS OF BIO-PRINTING

Three-dimensional bio-printing generally follows three major steps viz. pre-bioprinting, bioprinting and post-bioprinting [7]. **Pre-bioprinting** is the process of creating a hypothetic model that the bioprinter will later create and choosing the desired materials that will be used. **Bioprinting** shares three basic concepts with an ordinary desktop printer–hardware, ink (bio-ink), and paper (biomaterials). Three major types of printers have been applied to the field of tissue engineering: inkjet, laser-assisted, and extrusion. The **post printing** process is important for the acquisition of a reliable 3D biological construct with appropriate mechanical integrity/strength and biological functionality as per need of the body.

TYPES OF BIO PRINTERS

Ink jet bioprinters:

This type of bio printing also known as 'Drop-on-demand printing' which is one of the inkjet printing technologies, enables the printing of complex and detailed sections of living tissues or organs on the culture substrates utilizing cells and/or biomaterials as bio-ink [8]. The inkjet printer makes use of nozzle that generates isolated droplets of cells laden material by means of piezoelectric or thermal actuation system. Acoustic waves or thermal forces, respectively, liquid drops are ejected onto a substrate. This method has the potential to accelerate the study of tissue bio fabrication [9]. Also, the skill of printing biomaterials is drawn upon drug delivery systems, which have also become an essential technique in tissue bio fabrication. This work presents the research trends in inkjet printing as a bio applicable technology, particularly in the fields of tissue engineering and drug delivery systems. The inkjet printing system ejects the ink droplets in large quantities, rapidly and uniformly. Thus, this property of the inkjet printing system is applied for fabricating various kinds of monodisperse microparticles [10].

Inkjet Bioprinting Technology for Pharmaceutical Applications:

Drug-loaded polymer microparticles with random shapes were manufactured by the inkjet printing system and printed four types of microparticles (circle, grid, honeycomb, and ring) using a mixture of PLGA, paclitaxel (PTX), and N, N-dimethylacetamide as bio-inks [11]. Creation of miconazole-coated microneedles for use in treating fungal infections is in use [9]. They fabricated the microneedle structures by dynamic mask micro stereo lithography and used the inkjet printing system to load miconazole into microneedles.

Limitation of Ink Jet Bio Printing:

There is a need to work with biological materials in liquid forms, which in most of the cases demand a fast polymerization procedure post printing. Nozzle clogs, when using solution with high cell densities and cell viability is one of the limitations of this technology [9]. Many drugs would be lost with pharmaceutical applications method.

Micro-Extrusion Printing:

It is a modification of inkjet printer. Extrusion-based printing is a pressure-driven technology. The extrusion material from micrometric aperture takes place. By continuous force, this technique allows to print incessant cylindrical line. The systems robotically extrude biological material by pneumatic or mechanical administration system onto a substrate. Almost all kind of hydrogels with changing viscosities can be printed with this approach. Compared to inkjet printers, micro-extrusion printing allows the deposition of the large number of cells generating construct with general tissue size [9]. It has limited application for certain soft tissue applications of small pore sizes [12]. Hard tissues with size larger than 10 mm also printed [13]. Cell viability reduced due to shear stress when cells are in viscous fluids during the extrusion.

The main advantage of extrusion bioprinting is the ability to print with very high cell densities [14]. The pressure used for the extrusion of the material has the potential to alter the cell morphology and function. This fabrication technique uses highly viscous hydrogel and does not necessarily require any chemical additives for the curing of printed structure [15]. Rheological behaviour of the hydrogel ink is very important for extrusion-based bioprinting. Hydrogels are mostly non-Newtonian fluids, meaning that their viscosity changes with shear rate.

EXTIRPATION OF EAR FIBROMA IN BUFFALO

A. K. Gangwar, Sangeeta Devi Khangembam and Mahesh Kumar Verma
Department of Veterinary Surgery and Radiology
College of Veterinary Science and Animal husbandry, Narenra Dev University of Agriculture and Technology, Kumarganj, Faizabad-224 229 (U.P.)

Abstract

Fibroma is a benign tumour of mesenchymal origin and its occurrence as cutaneous fibroma is rare in cattle when compared to other cutaneous tumours like paillomas. A case of hard fibroma over the lateral aspect of ear pinna in a buffalo was managed successfully by radical surgery. Local analgesia was achieved by using xylazine @ 0.05 mg/kg BW I/M and local infiltration of 2% lignocaine hydrochloride, respectively. After aseptic preparation of the site, two semicircular incisions were given around the base of the mass and growth was extirpated. Haematoxylin and Eosin (H&E) stained tissue section of tumour mass showed dense tissue of mature fibroblasts in collagenous stroma that oriented in different interlacing or parallel planes (Fig. 5). Fibrocytes were hyperchromatic having elongated fusiform nuclei with few mitotic figures at places. Based on the findings of the histopathology the mass was confirmed as fibroma.

Key words: Fibroma, Ear pinna, Buffalo, histopathology

Introduction

Neoplasm is an abnormal mass of tissue which is common in old age animals but can occur at any age of life with significant morbidity and mortality (Tyagi and Singh, 1993). Fibroma is a benign tumour of mesenchymal origin and its occurrence as cutaneous fibroma is rare in cattle when compared to other cutaneous tumours like paillomas. The fibromas can be found in different places of body especially on head, neck and shoulder (Gurram *et al.*, 2017). The cutaneous tumours may not always hinder the routine function of animal, but may depreciate the aesthetic appearance. The present paper reports a case of hard fibroma over the lateral aspect of ear pinna in a buffalo.

Materials and methods:

Case history and Clinical signs:

An 8 year old non-descript she buffalo was presented to the Surgery and Radiology unit of TVCC with a hanging hard mass on the lateral surface of left ear pinna (Fig.1). Detailed enquiry revealed the growth that was observed by the owner 6 months before which is gradually increasing in size. On clinical examination, it was measured about 5 inches in diameter at the time of presentation to the clinic. The tumor appeared as hard solitary ball like, painless movable swelling with skin covering. Appetite of the animal was normal and all physiological parameters were within normal limit.

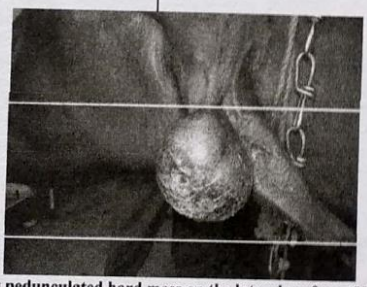

Fig.1: Buffalo showing pedunculated hard mass on the lateral surface of left ear pinna

Surgical treatment:

After 24 hours of fasting, sedation and local analgesia was achieved by using xylazine @ 0.05 mg/kg BW I/M and local infiltration of 2% lignocaine hydrochloride, respectively. After aseptic preparation of the site, two semicircular incisions were given around the base of the mass involving fresh skin and tissues. The mass was separated by blunt dissection sparing the major blood vessels of the ear pinna. Finally the growth was extirpated and subcutaneous sutures were applied with catgut no.1 using subcuticular suture pattern. Skin was closed by simple interrupted suture pattern using silk no. 2 (Fig.2). Postoperative care includes intramuscular injection of Intamox® (3 gram) and Melonex® (10 ml) for 5 and 3 days respectively. Antiseptic dressing was done with Betadine. Sutures were removed on 12th post-operative day. For histopathological examination, the tissue sample was preserved in 10% formal buffered saline.

Abstract

The present study was conducted on the bovine having different surgical ailments of hoof/digit. The bovines having foot disease(s) were divided in to two groups having six animals/limbs in each group. For intravenous regional anesthesia (IVRA), tourniquet was placed circumferentially at the middle of the metatarsus/ metacarpus. The anesthetic lignocaine @ 4 mg/kg b.wt. (group I) and, lignocaine @ 4 mg/kg b.wt. + ketamine @ 3.0 mg/kg b.wt. (group II) was injected in the radial vein. The anesthetic potency was monitored by observing the HR, PR, RR, Systolic pressure, Diastolic pressure, SPO2 and RT. In group I the heart rate increased significantly ($P < 0.05$) between 15 and 40 minutes and it significantly ($P < 0.05$) decreased in group II at 10 minutes interval. In group I pulse rate increased significantly ($P < 0.05$) at 20 minutes. Thereafter, the value decreased significantly ($P < 0.05$) at 60 minutes (68.00±1.15). However, no significant ($P > 0.05$) change in pulse rate was noted in group II animals at any time interval. There was no significant change in respiration rate in both groups. Respiration rate was significantly decreased after removal of tourniquet in group I animals. Peripheral oxygen saturation in group I significantly ($P < 0.05$) decreased at 15 minutes and increased significantly ($P < 0.05$) up to 60 minutes (89.66±0.80). In group II the value decreased significantly ($P < 0.05$) up to 60 minutes. Systolic pressure significantly increased at 15 and 20 minutes in group I animals. However in group II, systolic pressure increased at 60 minute interval. After removal of tourniquet, systolic pressure and diastolic pressure was significantly increased in group II. Sensory block onset time and motor block onset time was less in group II as compared to group I animals. Sensory block recovery time and motor block recovery time was longer in group II as compared to group I animals. It was concluded that lower IVRA technique was found suitable for hoof examination and surgery. Intravenous regional anesthesia was achieved more efficiently in group II as compared to group I animals. Postoperative analgesia was more in group II animals.

Key words: Claw surgery; IVRA; Ketamine

Introduction:

Anesthesia is defined as an irreversible loss of sensation in any part or whole body induced by anaesthetics or combination of preanesthetic and anesthetic that depresses the activity of nervous tissue. Local and regional anesthesia depresses the peripheral nervous tissue and general anesthesia depresses the central nervous system. Local and regional anesthesia is an integral part of large animal surgery because it is economic and easy to perform. Regional anesthesia is required to perform minor as well as major surgical interventions for correction of different surgical ailments. Intravenous regional anesthesia (IVRA) is induced in a part of the limb with intravenous injection of a local anesthetic into an extremity isolated from the rest of the systemic circulation with a tourniquet. It is an alternative method of general anesthesia for the patients at high risk (Mohr, 2006) and produces a rapid onset of anesthesia and skeletal muscle relaxation (Hassanein, 2016). The effect of anaesthesia disappears rapidly after tourniquet deflation. Intravenous regional anesthesia is safe for the patient having cardiovascular, respiratory or any other systemic disease. It is an ideal technique for operative procedures with anticipated duration of 60-90 minutes and success rates between 97-98% (Charath *et al.*, 2015). The ideal IVRA should have rapid onset, require less dose of local anesthetic (LA), reduce tourniquet pain, and prolonged postoperative analgesia. This may be achieved by addition of some adjuncts to LA (Bansal *et al.*, 2011).

Ketamine, a phenyl-piperidine derivative, is an intravenous anesthetic agent. At subanesthetic doses, it exerts a noncompetitive blockade of *N*-methyl-aspartate (NMDA) receptors. NMDA receptors play role in synaptic plasticity and are specifically involved in central nervous system facilitation of pain processing. NMDA receptor antagonists have been implicated in perioperative pain management (Elmetwaly *et al.*, 2010). Ketamine also has local anesthetic qualities, which have been studied as a sole agent for IVRA (Lauretti *et al.*, 1999). In addition to spinal cord NMDA receptors, have also been identified on peripheral unmyelinated sensory axons. This can explain why ketamine as an NMDA receptor antagonist was able to attenuate the tourniquet pain. Ketamine 0.5 and 0.3% produced adequate IVRA. Present study is under taken to evaluate the efficacy of intravenous regional anesthesia using lignocaine hydrochloride and its combination with ketamine in bovine.

Materials and methods

The present study was conducted on the bovine having different surgical ailments of hoof/digit. The bovines having claw disease(s) were divided in to two groups having six animals/limbs in each group. The animals were prepared as per routine surgical procedure. The affected animals were off fed for overnight and limb was shaved below the level of knee/ hock. No premedication was given to any of the animal. Animals were casted and restrained in lateral recumbency with affected limb upper most. The site was prepared aseptically and the area was painted with antiseptic solution. Intravenous regional anesthesia was induced as per the standard technique (Yavari *et al.*, 2017). Briefly, tourniquet was placed circumferentially in the middle of the metatarsus/ metacarpus (Fig. 1). Butterfly canula was placed in the radial vein and the area is exsanguinated.

Lignocaine hydrochloride alone @ 4mg/kg b.wt. was injected in group I animals. However, in group II animals, combination of Lignocaine hydrochloride (@ 4mg/kg b.wt.) and ketamine hydrochloride (@ 3mg/kg b.wt.) was injected in the radial vein (Fig. 1). After removing the needle, injection site was compressed with povidone iodine soaked cotton swab for about 1 minute to avoid unintended drainage of the local anaesthetic from the punctured vein or formation of a haematoma. The anesthetic potency was monitored by observing the following parameters:

ABSTRACT

The bovine having surgical ailments of claw, were divided in to two groups having six animals/limbs in each group. Tourniquet for standard and modified intravenous regional anesthesia (IVRA), was placed circumferentially at the middle of the metacarpus and just below dewclaw in group I and II, respectively. Lignocaine was injected @ 4 mg/kg and 2 mg/kg b.wt. in group I and group II animals, respectively. In group I, pulse rate increased significantly ($P < 0.05$) at 20 and 30 minutes. Heart rate increased significantly ($P < 0.05$) at 20 minute and 30 minute interval in group I and II animals, respectively. In animal of both groups, oxygen saturation significantly ($P < 0.05$) decreased during study time period. Systolic pressure significantly increased at 15, 20 and 20 minutes in group I animals. It was concluded that modified IVRA technique was safer as compared to standard IVRA.

Key words: Bovine, Claw diseases, IVRA, Lignocaine.

INTRODUCTION

Claw diseases are common in dairy cattle and can be treated in their early stages by therapeutic claw trimming (Thomas *et al.*, 2016). Intravenous regional analgesia is safe, reliable and cost-effective technique for providing anesthesia as well as bloodless short surgical procedures of extremities (Lumb and Jones, 1984). Bier's block can easily be used in field condition with minimum facility available. The disadvantages include local anesthetic (LA) toxicity, poor muscle relaxation, tourniquet pain and minimal postoperative analgesia (Muhammad and Muhammad, 2012). The ideal IVRA solution should have rapid onset, require less dose of local anesthetic (LA), reduce tourniquet pain and prolong post-deflation analgesia. This may be achieved by addition of adjuncts to LA (Kognole *et al.*, 2004). In presently available technique of IVRA, the tourniquet is placed at the mid metacarpal/ metatarsal region and large amount of local anesthetic is needed which sometimes may lead to local anesthetic toxicity during release of tourniquet (Skarda, 1987). Signs of toxicity can include drowsiness, minor convulsions and seizures, trembling and profuse salivation with hypotension (Weaver *et al.*, 2005).

To overcome this problem, dose of the local anesthetic can be reduced by applying tourniquet just below the dew claws. No study till date has been undertaken on lower IVRA in bovines. Due to the paucity of literature on this aspect, the current study is designed to compare the efficacy of different doses of lignocaine hydrochloride for standard IVRA with modified IVRA.

MATERIALS AND METHODS

The present study was conducted on the cattle having different surgical ailments of hoof/digit. The cattle having claw disease(s) were divided in to two groups having six animals/limbs in each group. The animals were prepared as per routine surgical procedure. The affected animals were off fed for overnight and limb was shaved below the level of knee/ hock. No premedication was given to any of the animal. Animals were casted and restrained in right lateral recumbency with affected limb upper most. The site was prepared aseptically and the area was painted with antiseptic solution. Intravenous regional anesthesia was induced as per the standard technique in group I animals (Yavari *et al.*, 2017). Briefly, tourniquet was placed circumferentially in the middle of the metacarpus (Fig 1). Butterfly canula was placed in the radial vein and the area was exsanguinated. However in group II animals, tourniquet was applied just below the dew claws and butterfly canula was placed in the axial digital vein (Fig 2). Lignocaine hydrochloride was injected @ 4mg/kg b.wt. and 2mg/kg b.wt. in group I and II animals, respectively. After removing the needle, injection site was compressed with povidone iodine soaked cotton swab for about 1 minute to avoid unintended drainage of the local

CONGENITAL UDDER AND TEAT ABNORMALITIES IN BUFFALOES

Anil Kumar Gangwar*, Kh. Sangeeta Devi, Ghanshyam Patel and Mahesh Kumar Verma

ABSTRACT

Three buffaloes with congenital athelia with amastia and polythelia with polymastia (presence of five and six functional quarters and teats) were placed on record.

Keywords: *Bubalus bubalis*, buffaloes, Athelia, amastia, polythelia, polymastia

INTRODUCTION

The udder of the buffalo is composed of four quarters each of which is a separate unit and is considered as an independent compartment. Supernumerary teats, fused teats, teat fistula, teat spider and imperforate teat are certain congenital conditions of teat (Tyagi and Singh, 1999). Genetic and environmental factors are responsible for these congenital defects. The presence of congenital athelia with amastia and polythelia with polymastia is rare in buffaloes. Congenital athelia with amastia has not been reported so for in this literature as for as our knowledge is concerned.

MATERIALS AND METHODS

Three buffaloes of age ranging between 4 to 6 years were presented to the Teaching Veterinary Clinical Complex for treatment of other disorders. These anomalies were recorded during close clinical examination. In one case, the anomaly was recorded during surgical correction of upward fixation of patella. During medial patellar desmotomy, it was seen that the udder of the animal have only two teats with one quarter in each half (Figure 1). After detailed enquiry it was recorded that her dam also had two teats.

The other two buffaloes were having five and six functional quarters and teats. The buffalo having five teats had three functional quarters in right half and two functional quarters in left half (Figure 2). However, the buffalo having six teats had three functional quarters in each half (Figure 3).

RESULTS AND DISCUSSION

Athelia and amastia is a very rare occurrence. Congenital mal-development of udder and teats could be an inherited trait as the anamnesis revealed that the dam of the presented animal

Comparative evaluation of lignocaine hydrochloride alone and its combination with pentazocine lactate for intravenous regional anaesthesia in cattle

Shaurya Kumar, Anil Kumar Gangwar, Sangeeta Devi Khangembam, Rabindra Kumar, Vipin Kumar Yadav, Ravi P Goyal, Yogendra Singh, Ranjeet Kumar, Parvez Ahmed and Rajesh Kumar Verma

Abstract
The cattle having different surgical ailments of hoof/digit were divided in to two groups including 6 cattle in each group. Lignocaine hydrochloride (@ 4 mg/kg b.wt) and combination of lignocaine HCl + pentazocine lactate (4 mg/kg b.wt. + 1.0 mg/kg b.wt.) was injected in the radial vein in group I and II animals, respectively for inducing IVRA. In group I the HR and PR increased significantly ($P < 0.05$) at 20 minutes. The RR increased at 10 minutes in group I and between 30 and 60 minutes in group II. Oxygen saturation significantly ($P < 0.05$) decreased between 5, 10, 15, 20 and 30 minutes interval. Systolic pressure significantly increased between 15 and 30 minutes in group I animals. SBOT was less and SBRT was significantly ($P < 0.05$) more in group II as compared to group I. MBOT was similar in both group I and II animals. Efficacy of lignocaine in combination with pentazocine for producing IVRA was more as compared to lignocaine alone.

Keywords: Claw diseases, Lignocaine, IVRA, Bovine

Introduction

Distal limb and hoof/claw deformities such as fracture, interdigital fibroma, overgrown hoof, white line disease and sole ulcers are common disorders in cattle (Solano *et al.*, 2016) [18]. Claw trimming is the only method of treatment of early stages claw horn lesions (Thomas *et al.*, 2016) [20]. Cows with necrotic claw lesions represent a major welfare concern like chronic lameness for weeks and treatment of cases without necessary local anaesthesia. The more severe cases in which the inflammation and purulent infection reaches the pododerm, and inner structures of the horn shoe, leads to purulent arthritis of the coffin joint, osteomyelitis or necrosis of tendons and ligaments, amputation of claw or resection of the coffin joint under local anaesthesia (LA) is the only treatment of choice. Adequate pain relieving agents like lignocaine hydrochloride (2%) and non-steroidal anti-inflammatory drugs (NSAIDs) should be administered to control postoperative pain as claw surgeries are painful for diseased cattle (Janssen *et al.*, 2016) [10].

Intravenous regional analgesia is a safe and most commonly used technique with success rates between 97-98% (Charath *et al.*, 2014) [4]. Also this technique can be performed with minimum instruments and there is minimal bleeding at the surgical site (Reuben *et al.*, 2002) [16]. This technique provides analgesia of the limb or digits for short surgical procedures. Intravenous regional anesthesia is particularly advantageous to use in critically ill patients that are not fit for general anaesthesia. Being a regional technique it avoids all the complications of general anesthesia. It works through the retrograde diffusion of the local anaesthetic along and then out of the veins running adjacent to nerves within neurovascular bundles. Standard IVRA involves administration of 0.5% lidocaine solution. The disadvantages include local anesthetic (LA) toxicity, inadequate muscle relaxation, pain at the tourniquet site and minimal postoperative analgesia (Muhammad and Muhammad, 2012) [13]. Lignocaine remains the standard local anesthetic agent and most often used for IVRA. Advancement in the field of IVRA aimed at reducing the tourniquet pain increasing tourniquet tolerance improving the chances of intra operative and post-operative analgesia and decreasing the drug related adverse

Abstract Biological detergents like sodium deoxycholate, sodium dodecyl sulphate and Triton X-100 impairs the collagenous and non-collagenous proteins. glycosaminoglycans and growth factors. Further, certain chemical and enzymes are responsible for residual cytotoxicity in the decellularized extracellular matrix. The main focus of this study was to explore the decellularization property of soap nut pericarp extract (SPE) for development of decellularized tubular esophageal scaffold. For this 2.5, 5.0 and 10% concentrations of SPE were used for decellularization of caprine esophageal tissues. Histological analysis of hematoxylin and eosin and Masson's trichrome stained tissue samples confirmed decellularization with preservation of extracellular matrix microarchitecture. Scanning electron microscopic images of luminal surface of decellularized esophageal matrix showed randomly oriented collagen fibres with large interconnected pores and cells were absent. However, the external surface was more textured with fibrous structures and collagen fibres were well preserved. DAPI stained decellularized tissues revealed complete removal of nuclear components, verified by DNA content measurement and SDS-PAGE. The FTIR spectra of decellularized esophagus shows absorption peaks of amide A, B, I, II and III. Elastic modulus of the decellularized esophagus scaffolds increased ($P > 0.05$) as compared to native tissues. Histological and scanning electron microscopic evaluation of in vitro seeded scaffolds showed

DAPI staining

ABSTRACT

The aim of this study is to develop a novel decellularization method using aqueous extract of soap nut pericarp (SPE) and its evaluation using hematoxylin–eosin staining, scanning electron microscopy, diamidino-2-phenylindol (DAPI) staining, mechanical testing, sodium dodecyl sulfate polyacrylamide gel electrophoresis and DNA quantification. The presently available decellularization agent raises some concerns due to the potential for presence of residual cytotoxic agents in the extracellular matrix. Histological analysis of hematoxylin and eosin and masson's trichrome stained processed aortic samples shows complete decellularization with preservation of extracellular matrix microarchitecture at 120 h. Further, staining of tissue samples with DAPI demonstrates complete removal of DNA fragments. Quantitative evaluation of DNA in the decellularized aorta tissues demonstrated a significant ($P < 0.01$) decrease in DNA content as compared to native tissues. Collagen quantification assay indicate no significant ($P > 0.05$) difference in its content between native and decellularized caprine aorta. Tensile strength of the decellularized scaffolds decreased non-significantly ($P > 0.05$) when compared to native tissues. There was no significant ($P > 0.05$) difference in young's modulus of elasticity, stiffness and stretch ratio between native aortic tissues and decellularized aortic scaffolds. Histological and scanning electron microscopic examination of in vitro cultured scaffold demonstrated the cell viability and proliferation of primary chicken embryo fibroblasts. SPE treatment is thus capable of producing cytocompatible decellularized caprine aorta scaffold with preservation of extracellular matrix architecture for vascular tissue engineering and could be applied widely as one of the decellularization agent.

1. Introduction

The clinical cases of cardiovascular diseases are increasing day by day and need for the development of substitute vessels is quite obvious. Biological scaffolds constructed from decellularised xenogenic extracellular matrix (ECM) have emerged as promising biomaterials for replacing defective and/or diseased vasculature (Badylak et al., 2009). Tissue decellularization is the process of removal of cellular components to produce acellular extracellular matrix (ECM). Decellularization techniques are classified by chemicals used, such as acid or alkaline treatment, biological detergent treatment, or enzymaic digestion and the physical methods. Chemical and/or enzymatic treatment is concerned with the use of chemical reagents like sodium deoxycholate (Gangwar et al., 2013), Triton X-100 and DNase (Gangwar et al., 2006). These detergents may damage collagenous and non-collagenous proteins, GAGs and growth factors. The use of chemical and enzymatic agents raises some concerns due to the potential for the presence of residual cytotoxic agents in the decellularized ECM (Choi et al., 2012).

The fruit of *Sapindus mukorossi*, a member of the family Sapindaceae, contains 10.1 % saponins in the fruit pericarp. These saponins are

Development of novel intravenous regional anaesthetic technique for desensitization of hoof in cattle

VIPIN KUMAR YADAV[1], ANIL KUMAR GANGWAR[1]✉, SANGEETA DEVI KHANGEMBAM[1], RAVI PRAKASH GOYAL[1] and RABINDRA KUMAR[1]

Acharya Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya, Uttar Pradesh 224 229 India

Received: 24 September 2020; Accepted: 20 July 2021

ABSTRACT

The cattle having hoof diseases were selected in the study and divided into 2 groups having 6 animals in each group. For induction of intravenous regional anesthesia, tourniquet was placed circumferentially at the metacarpus and just below dewclaw in group 1 and 2, respectively. Mixture of lignocaine and ketamine (L+K) (4 mg/kg and 3 mg/kg b. wt.) was injected in the radial vein in group 1 animals. However, in group 2 animals the dose of L+K was halved (2 mg/kg and 1.5 mg/kg b. wt.) and injected in the dorsal common digital vein III. The anesthetic potency was monitored by observing the HR, PR, RR, systolic pressure, diastolic pressure and SPO_2. In group 1 the heart rate decreased significantly at 10 min interval. Peripheral oxygen saturation significantly decreased up to 60 min and 40 minutes in group 1 and 2 animals, respectively. Systolic pressure significantly increased at 60 minute interval in group 1 animals. After removal of tourniquet, systolic pressure and diastolic pressure was significantly increased in group 2. Sensory and motor block onset time was less in group 2 as compared to group 1. Sensory and motor block recovery time was long in group 2 as compared to group 1 animals. It was concluded that novel IVRA technique was more safe as compared to standard IVRA for the hoof anesthesia in cattle because low doses of local anesthetic are required in this technique with early sensory and motor block, and prolonged effect.

Keywords: Bovine, Hoof diseases, IVRA, Ketamine, Lignocaine

Local and regional anesthesia techniques are the integral part of large animal surgery for economy and practical point of view. Hoof diseases are very common in dairy cattle, especially in poorly managed livestock farm (Thomas *et al.* 2016). Intravenous regional analgesia is relatively safe and economic technique for inducing anesthesia as well as bloodless short duration surgical procedures of extremities (Lumb and Jones 1984). This technique can be utilized for the management of cattle hoof diseases in field condition with minimum available facilities (Kumar *et al.* 2020). The disadvantages of IVRA encompass local anesthetic toxicity, poor muscle relaxation, tourniquet pain and minimal postoperative analgesia (Muhammad and Muhammad 2012). The ideal IVRA solution should have rapid onset, require less dose of local anesthetic, reduce tourniquet pain, and prolong post-deflation analgesia. This can be attained by adding certain adjuncts to local anesthetics (Kognole *et al.* 2004). In standard IVRA technique, the tourniquet is applied at the metatarsal or metacarpal region and large amount of local anesthetic is required, which sometimes may lead to local anesthetic toxicity during release of tourniquet (Skarda 1987, Weaver *et al.* 2005).

Ketamine is a general anesthetic but it also has local anesthetic qualities, which have been studied as a sole agent for IVRA (Lauretti *et al.* 1999). Ketamine antagonizes the spinal cord N-methyl D-aspartate (NMDA) glutamate receptors. These receptors affect analgesia through peripheral mechanisms, including inhibition of peripheral C fibre neurons (MacIver and Tanelian 1993). In addition to spinal cord, NMDA receptors have also been found on peripheral unmyelinated sensory axons. Ketamine is a potent analgesic agent that possesses both central and peripheral sites of action (Pedersen *et al.* 1998).

We utilized peripheral application of ketamine as an adjunct to lignocaine for IVRA. Further, to investigate the problem of local anaesthetic toxicity, dose of the local anesthetic was reduced using modified IVRA technique. No study till date has been undertaken on lower IVRA in bovines. Due to the paucity of literature on this aspect, the current study is designed to compare the efficacy of standard IVRA with modified IVRA using ketamine as an adjunct to lignocaine hydrochloride.

MATERIALS AND METHODS

The cattle having surgical conditions of hoof of forelimbs were included in the present study. The animals were

MODIFIED INTRAVENOUS REGIONAL ANAESTHESIA FOR MANAGEMENT OF CLAW DISEASES IN BUFFALO

Yogendra Singh[1], Anil Kumar Gangwar[1,*], Sangeeta Devi Khangembam[1], Vipin Kumar Yadav[1], Ravi Prakash Goyal[1], Parvez Ahmad[1], Ranjeet Kumar[1], Rabindra Kumar[2] and Rajesh Kumar Verma[3]

ABSTRACT

In the present study, the buffalo having surgical affections of claw were divided randomly in to two groups having six animals in each group. Tourniquet was placed circumferentially at the middle of the metacarpus in Group I (standard IVRA) and just below dewclaw in Group II (modified IVRA) animals. In Group I animals, lignocaine hydrochloride and dexmedetomidine mixture was injected 4 mg/kg and 5 µg/kg b.wt in the radial vein. However, in Group II above drugs were injected in half doses in the axial digital vein. Heart rate and respiration rate decreased significantly in both group of animals. In Group I pulse rate decreased significantly ($P<0.05$). After removal of tourniquet no significant changes in HR, PR and RR was observed in both groups of animals. Peripheral oxygen saturation (%) decreased significantly in both groups of animals even after removal of tourniquet. Systolic and diastolic pressure significantly ($P<0.05$) decreased in both group of animals. Mean arterial pressure decreased significantly ($P<0.05$) in both groups at 5 and 10 minutes interval. In Group II animals, the value increased significantly at 20 and 40 minutes interval. Sensory and motor block onset time was lower in Group II as compared to Group I animals. SBRT was more in Group II animals and MBRT was more or less similar in both groups. None of the animal of both group showed sign of toxicity except stumbling in 4 animals of group I just after release of tourniquet.

The corona virus disease 19 (COVID-19) is a highly transmissible and pathogenic viral infection caused by severe acute respiratory syndrome corona virus 2 (SARS-CoV-2), which emerged in Wuhan, China and spread around the globe. SARS-CoV-2 is a large positive-sense single-stranded ribonucleic acid (RNA) virus that comprises of four structural proteins, i.e., nucleocapsid protein (NP) which holds the viral RNA while, spike protein (SP), envelope protein (EP), and membrane protein (MP), make the viral envelope. A characteristic of corona viruses (CoVs), the crown-like appearance is due to presence of the spikes having a diameter of 50-200 nm and length up to 20 nm on the surfaces (Chan *et al.*, 2020). WHO declared COVID-19 as a public health emergency of international concern (PHEIC) on January 30, 2020 and a pandemic on March 11, 2020. It exhibits a range of clinical manifestations, from mild flu-like symptoms viz. running nose, sneezing, coughing, fever, sore throat, and loss of smell to life-threatening conditions dyspnoea due to lung congestion (CDC, 2020). The transmission directly occurs by coughing, sneezing and without covering the mouth from infected person when droplets containing virus come into the air is inspirated by healthy person. The droplets containing virus when dropped on surfaces like clothes, furniture's, floor and fomites indirectly come in contact by touching them a healthy person get infection and further can pass the virus between individuals. The intermediate source of origin and transfer to humans is not known, however, the rapid human to human transfer has been confirmed widely (Zhou P *et al.*, 2020; Perlman S, 2020; Benvenuto D *et al.*, 2020).

To check the spread of COVID-19 it is of immense importance to identify asymptomatic cases that cause the spread of the virus on close contacts. At present commercially available COVID-19 tests fall into two major categories. The first category includes molecular assays for detection of SARS-CoV-2 viral RNA based techniques like polymerase chain reaction (PCR) or nucleic acid hybridization. The second category includes serological and immunological assays that used to detect antibodies produced by individuals as a result of exposure to the virus or detection of antigenic proteins in infected persons. The early development of diagnostic technology is always essential in any epidemic preparedness strategic plan (Peeling *et al.*, 2019).

Structure of SARS-CoV-2

The structure of SARS-CoV-2 comprises of spikes, which are formed by the spike glycoprotein (S) (Fig. 1). S is a major glycoprotein (Mol. Wt. ~180 kDa) that consists of two subunits, i.e., S1 and S2 (Li *et al.*, 2020). S1 contains a receptor binding domain (RBD), which is responsible for recognizing and binding with the host cell receptor, i.e., angiotensin converting enzyme 2 receptor (ACE2) found in the lower respiratory tract (Xie *et al.*, 2020). On the other hand, S2 contains other basic elements needed for the membrane fusion. S is the common target for neutralizing antibodies and vaccines, while the amino-terminal S1 subunit of S is the most variable immunogenic antigen. Additionally, SARS-CoV-2 has nucleoprotein (N) (Mol. Wt. ~40 kDa), the most abundant viral phospho protein produced and shed during infection. The template mRNA of N is the most abundant subgenomic RNA. Nucleoprotein exhibits high immunogenicity and can be detected in either serum or urine samples during the first two weeks of infection with peak viral shedding around ten days after infection (Paules *et al.*, 2020). Being a large protein, it can be detected via a sandwich immunoassay.

Furthermore, SARS-CoV-2 contains membrane protein (M), which is the most abundant protein on the complete virion particle. The envelope small membrane protein (E) is the smallest major structural protein of SARS-CoV-2, which is involved in viral assembly, release of virions, and pathogenesis.

Symptoms

Signs and symptoms of COVID-19 may appear 2 to 14 days after exposure which include fever, cough and shortness of breath or difficulty in breathing. Other symptoms can include tiredness, aches, runny nose, sore throat, headache, diarrhoea, vomiting and some people have experienced the loss of

INTRODUCTION :

Staphylococcus aureus is a opportunistic pathogen of significant importance because of its ability to cause a wide range of diseases and capacity to adopt to diverse environmental forms (Lowy, 1998; Waldvogel, 2000). The organism colonises skin, skin glands and mucous membrane, causing infections both in human and animals such as rashes, inflammations of bones and the meninges as well as septicaemia (Aklilu et al., 2010). One reason for the continuing important role of *S. aureus* in disease is its propensity to become resistant to antimicrobials. *Staphylococcus aureus* has the characteristic ability to rapidly develop resistance to virtually any antibiotic coming into clinical use (Pantosti *et al*., 2007). Penicillin and its derivatives, including methicillin have been used for the treatments of infections caused by *S. aureus* (Rayner and Munckhof, 2005). However, certain strains of *S. aureus* developed resistance known as Methicillin resistant *Staphylococcus aureus* (MRSA).

Mechanism of resistance:

Methicillin resistance is due to the acquisition of *mecA* gene, that encodes new protein designated PBP2a, belonging to the family of enzymes necessary in building the bacterial cell wall. The protein (PBP2a) has a very low affinity for β-lactams antibiotics and confers resistance to Methicillin and the other beta-lactams (Pantosti *et al*., 2007). A new methicillin resistance mechanism gene, *mec*C was described in *S. aureus* (Porrero et al., 2014). García-Álvarez et al. (2011), Paterson et al. (2012), Walther et al. (2012) and Paterson et al. (2014) reported MRSA isolates carrying *mec*C gene from humans and animals.

Types Of MRSA:

There are two types of MRSA : Hospital acuired and community acquired.Hospital- and community-acquired MRSA, which occur in different populations, tend to cause different types of infections. Hospital-acquired MRSA can cause a wide variety of infections, from surgical site infections to invasive disease. These strains are major causes of nosocomial infections associated with indwelling medical devices and surgical site.

Human community-acquired-MRSA infections are mainly associated with superficial skin or soft tissue disease. Some community-acquired MRSA strains have caused other types of illnesses, including severe sepsis, necrotizing fasciitis and necrotizing pneumonia. Community-acquired strains can also occur in hospitalized populations

Historical perspectives of MRSA

The history of Methicilin resistant *Staphylococcus aureus* (MRSA) started with the development of antibiotics.Penicillin was discovered in 1928 by Alexander Fleming and quickly put into production. The 1940s saw penicillin being commonly used to treat a number of different infections. It also spawned the development of other antibiotics, like streptomycin, erythromycin, tetracycline and amoxicillin. Over time and use, the Staphylococcus bacteria naturally developed resistance to this drug, primarily due to the adaptive nature of the bacteria and the rampant overuse of the antibiotics in their early stages. Penicillin was used in the 1940s to

duction:

timicrobial resistance (AMR) now a days is becoming a global problem and ing to rise in mortality and cost of treatment (Singla et al., 2014). AMR is defined as ce to antimicrobial drugs to which the microorganism was found sensitive. robial resistant bacteria in animal husbandry are directly related with these drugs is expanding throughout the world and have become a major problem in both veterinary n medicine (Baron et al., 2014). Antibiotics are widely used in animals as well as to fight with bacterial infections. However, their inappropriate use (use of broad s antibiotics at insufficient doses and unprofessional choice of antibiotics without to an antibiogram) or even their inexpedient use lead to the emergence of multidrug MDR) bacteria which limit the treatment options. India is the largest consumer of bial drugs in the world with 13 billion standard units in 2010 (CDDEP, 2015). The list ritical antimicrobial resistant microorganism (ARMs) has been published by the alth Organization (WHO) against which new antibiotics need to be developed WHO, 2017).

tam antibiotics are among the largest antimicrobial class used for treatment of fections world-wide. It is the most commonly prescribed antibiotics against serious both human and animals in India. These antibiotics include penicillin derivatives, ins and monobactams like aztreonam and carbapenem derivatives. Extended-lactamases (ESBLs) are an enzyme that hydrolyses most of the β-lactam and thus confers resistance against penicillins, 3rd and 4th generation

REVIEW ON LISTERIOSIS A ZOONOSIS AND ITS PUBLIC HEALTH IMPORTANCE

Introduction

Listeriosis is known by various names viz. circling disease, silage sickness, leukocytosis, cheese sickness, tiger river disease by Veterinarians, medical doctors and people involved in food science. Gustav Hülphers discovered this bacterial strains for the first time and named bacillus hepatis which later become popular as Listeria monocytogenes (Hülphers, 1911; McLauchlin, 2004; Hülphers, 2004). After one and half decade Murray et al. (1926) also identified bacteria identical to Listeria monocytogenes, which caused monocytosis in rabbit and guinea pig. That's why Murray is credited as first person to find out Listeria. This disease lacks its true definition of zoonosis because of involvement of an inanimate reservoir (food) as the major cause of listeriosis. Till sixties of twentieth century Listeria monocytogenes was regarded as the single species of genus Listeria but later other species have been identified. Listeriosis is of utmost importance regarding public health because of its high mortality (20 to 30%) and due to high epidemic potential. This has high ability to survive in a wide range of temperatures and to make biofilms on various environmental surfaces, which serve as natural habitats or reservoirs in food hygiene (Duggan and Phillips, 1998). Transmission may happen directly especially among veterinarians, performing gynecological interventions with aborted animals.

It was a belief that Listeriosis is caused by direct transmission from animals to humans but it has been established that animals may be diseased or asymptomatic carriers of Listeria monocytogenes shedding the organism in their faeces. Now it is a general consideration that ingestion is the main mode of infection and food being the main vehicle of infection. A food related listeriosis outbreak was found in the Maritime Provinces of Canada (1981) which was not considered until the outbreak of California from January to August 1985 (James et al., 1985; Linnan et al., 1988) that food was recognized as an important vehicle of Listeria transmission. According to Mead et al. (1999) important vehicle of Listeria transmission is food in 99% of listeriosis cases. In medical physicians and other medical staff at risk are described as nosocomial infection. To understand the ecology including the zoonotic aspects is important in the prevention of transmission of Listeria monocytogenes.

Cultural characteristics

Listeria is aerobic and facultatively anaerobic. It has two forms S and R. On normal incubation after 24 hours, incubation colonies on nutrient agar are round, 0.5-1,5 mm in diameter, translucent, smooth, with glistening surface (S forms) while prolonged incubation makes colonies rough (R forms). Colonies show hemolytic activity on blood agar, which distinguishes Listeria monocytogenes from some other species of genus Listeria. Typical inverted "pine tree" like growth appears below 3 to 5 mm of the surface on semisolid medium. On sheep blood agar (5% v/v) Listeria monocytogenes exhibit positive CAMP reaction with Staphylococcus aureus but not with Rhodococcus equi.

Toxicity occurring in Pomeranian, puppy

A B S T R A C T

A 45 day old *Pomeranian male puppy weight 1.254 kg* was coming to pratap clinic of veterinary and veterinary medicine Manipuri Uttar Pradesh, for treatment. Earlier puppy was treated for tick infestation as per the owner told by given about 10mg of ivermectin tablet orally. Owner observed some clinical sign after 8 to 10 medication. Clinical examination revealed hypothermia (99.2˚F), tremors, ataxia, partial blindness, dilated pupil, weakness, incardination, no responsiveness, unable in defecation and behavioural changes. Therapeutic management was done by the administration of avil 0.5-1ml, neurokind 1-2ml,RL 20ml, NS 50ml, manitol 1-2ml/kg BW IV stat, vetacept 0.5ml/day repeated 6 hourly and dexamethasone @ 0.25-0.5mg/kg BW IM BID, rectal enema for passing feaces to withdrawal ivermectin on first day and with infusion of 20 ml dextrose (5%) IV. The dog recovered uneventfully after treatment.

Introduction

Ivermectin is a macrolide antibiotic produced from a fungus first isolated from a soil sample in Japan, *Streptomyces avermitilis*. The ivermectins are a class of chemicals that have a novel mode of action against nematode and arthropod parasites (Roder, 1998). Ivermectin is an antiparasitic drug belonging to the avermectin family of compounds. Ivermectin is a mixture of 80% or more of an analog of avermectin B1a and 20% or less of an analog of avermectin B1b. These compounds are 2 of 4 ivermectins produced by the actinomycete *Streptomyces avermitilis*. Although similar in structure to the macrocyclic lactones, ivermectins have no antibacterial or antifungal activity. They do have a broad spectrum of activity against nematode and arthropod parasites of both plants and animals (Campbell, 1983). All major gastrointestinal and lung nematodes and certain ectoparasites of cattle, sheep, horses and swine, intestinal nematodes, ear mites and sarcoptic mange of dogs, infective-stage heartworm and microfilariae of dogs, and certain intestinal nematodes of chickens are effectively eliminated by ivermectin (Roberson, 1988). Ivermectin is an agonist for the neurotransmitter gamma-

Management of traumatic proptosis in a pug: A case study

Sandeep Yadav, Vibha Yadav, RP Diwakar and Pramod Kumar

Abstract
A three years old male pug dog, weigh 10 kg was presented to Jai Pet Care Clinic Raebareli, Uttar Pradesh for treatment with unilateral traumatic proptosis. All clinical parameters were normal. Physical examination revealed partial prolapse of right eye globe with severe periorbital edema, haemorrhage, absence of menace and presence of miosis. Therapeutic management done by administration of triflupromazine @4mg/kg I/M for sedation, dexamethasone and gentamicine 0.2ml each in combination injected through intra palpebral route, which was repeated on 5th day. Animal was also given intramuscular injection of gentamicin @5mg/kg, dexamethasone @0.125mg/kg, vitamine B complex 2.0 ml and chlorpheniramine maleate @0.5mg/kg only once for 5 consecutive days. Eye drop of moxifloxacine and dexamethasone 4 times a day for instillation, chloramphenicol ointment 4 times a day for local application and enrofloxacin @5mg/kg orally once for 7 days were used. Animal recovered successfully after 7 days of regular treatment. Vision was assessed by simple vision testing using junction box, after 15 days of recovery and found normal.

Keywords: Pug, proptosis, therapeutic management

Introduction

Proptosis is forward displacement of globe which occur secondary to any blunt trauma to head [7]. Proptosis typically occurs in dogs following trauma to the face or head. Certain breeds of dog are more prone to eye proptosis than others because of their differences in facial conformation. The most common cause of proptosis in small breed dogs is a fight with a larger dog. During trauma, the globe is luxated from the orbit, and eyelid spasms prevent its retraction. Secondary orbital hemorrhage and swelling displace the globe further from the orbit following corneo-conjunctival drying and malacia [3]. Prognosis depends on pupil size and reflexes, duration of exposure, other globe or orbital damage, breed and other systemic trauma. Approximately 40–60% of dogs, but very few cats, recover vision. Traumatic proptosis can occur in any breed and in both dogs and cats. Only 20-40% of dogs that have the reattachment of the eyeball regain their vision.

Case history and observations

A three year old male pug of 10 kg weight was presented at Jai Pet Care Clinic Raebareli, Utter Pradesh with unilateral traumatic proptosis having recent history of blunt head trauma by hitting head against the wall. Clinical examination revealed partial prolapse of right eye globe (fig -1) through the pulpebral fissure with severe periorbital edema (fig.-2), haemorrhage without fracture of skull. There was absence of menace and presence of miosis. Corneal examination revealed concurrent finding of pigmentary vascular keratitis. All clinical parameters of the pug were normal.

An overview on antimicrobial resistance in Extended-spectrum β-lactamase producing E. coli and Klebsiella species of bovine origin and its zoonotic importance in present scenario

Vibha Yadav[1*], R. K. Joshi,[2] and Namita Joshi[3]
1.Asstt. Prof., 2.Prof.&Head, Deptt of Vety. Microbiology; 3.Prof.&Head, Deptt of VPH & Epidemiology; College of Veterinary Science & Animal Husbandry
Acharya Narendra Deva University of Agriculture and Technology, Kumarganj, 224229 Ayodhya (U.P.)

Abstract

Emergence of antimicrobial resistance in animal husbandry is of utmost concern as it has resulted in therapeutic failure. It is a complex phenomenon due to triangular interplay of the host, pathogens and antimicrobial agents. Nowadays resistance to antibiotics of ? -lactum groups expanding rapidly worldwide and threatening the public health care due to limited treatment options. However, their inappropriate use or even their unnecessary use leads to the development of multidrug resistant bacteria. Members of Enterobacteriaceae, are most commonly implicated food borne pathogens as they are generally commensal in GIT of human and animal. Among them Escherichia coli and Klebsiella pneumoneae strains have been found resistant to most of the common antimicrobials which may be alarming for human health. Resistance may be intrinsic, may be acquired through spontaneous mutations or may occur due to horizontal gene transfer. Due to horizontal gene transfer, even non-pathogenic microbial species may become pathogenic and serve as an ecological reservoir of resistant genes.

Introduction:

Today, antimicrobial resistance (AMR) has become a global issue, contributing to rise in mortality and cost of treatment. Antimicrobial resistance (AMR) is the resistance of a microorganism against an antimicrobial agent to which it was originally sensitive [1] (WHO, 2013). Dispersion of antibiotics is done at large scale, in India even sometimes without any proper prescription. Animal Husbandry is not untouched and antibiotics are used to a great extent, which needs enforcement of strict government rules and regulations for their use in field conditions [2]

Extended-spectrum ?-lactamases (ESBLs) are enzymes that hydrolyse most of the ?-lactam antibiotics and thus mediate resistance to penicillins, 3rd and 4th generation cephalosporins (Saravanan et al., 2018). Beta-lactamase inhibitors, inhibit these ESBLs such as clavulanic acid, sulbactam and tazobactam [3]. The genes encoding for these enzymes are commonly found both on the chromosomes and plasmids among Enterobacteriaceae family [4].

Among Enterobacteriacae, E. coli and Klebsiella species are main environmental pathogens associated with various illnesses such as acute bovine mastitis [5], pathogenic E. coli with diarrhoea and extra intestinal infections in humans and animals [6], K. pneumoniae with respiratory and urinary tract as well as bloodstream infections [7]. Resistance to extended-spectrum ?-lactams occurs mainly in members of Enterobacteriaceae family through plasmids encoded ESBL genes [8].

Antimicrobial resistance and modes of transmission:

Antimicrobial resistance (AMR) is not limited to only specific area but has also been considered as worldwide global health issue for both human and veterinary field. It is a complex phenomenon due to triangular interaction of the host, pathogens and antimicrobial agents. There is an estimate that up to 2050, approximately 10 million per year deaths will occur due to infections with resistant bacteria [9]. Development of antibiotic resistance in animal pathogens is due to use of antibiotics in agriculture and animal husbandry practices which has emerged as major threat for animal health and their welfare aspect [10]. Most of the time antibiotics are used in livestock at sub-therapeutic levels for growth promotion, prophylaxis and treatment. The development of AMR has been attributed with prolong and indiscriminate use of antimicrobials in food animal production and in the treatment of bacterial infections [11]. In U. K. a

Abstract

With its initial outbreak in China, the virus was referred as "coronavirus". WHO has named it "severe acute respiratory syndrome coronavirus 2" (SARS-CoV-2). It has been described as the successor to SARS-CoV-1 which is a positive-sense single-stranded RNA virus. The virus spreads mainly between people who are in close contact (less than two metres or six feet) through small droplets produced during coughing, sneezing, or talking. Infected people exhale the contaminated droplets which are then inhaled into the lungs, or settle on other non- infected people's faces his/her mucosae (mouth and nose) or conjunctiva (eyes) get exposed to potentially infective respiratory droplets to cause new infection. Organism may enter to human cells by binding to the receptor angiotensin converting enzyme 2 (ACE2). Research works are in progress to find potential targets to control the pandemic. To control and treat the virus various targets are under study and these targets range from modulating host cell receptor for the virus entry to generate an effective adaptive immune response.

Introduction

In present scenario, the term Corona has become an appalling word, which is not limited to the single country or continent but has been pandemic. The World Health Organization (WHO) recommended initially in January 2020 as "2019 novel coronavirus" as per its guideline of 2015 [1-3]. Before it during the initial outbreak in Wuhan, China, the virus was commonly referred to as "coronavirus", "Wuhan coronavirus" or "Wuhan virus" [4,5]. On 11 February 2020, "severe acute respiratory syndrome coronavirus 2" (SARS-CoV-2) was adopted by the International Committee on Taxonomy of Viruses. The WHO sometimes refers to SARS-CoV-2 as "the COVID-19 virus" in public health communications to avoid confusion with the disease SARS and the name HCoV-19 was included in some research articles [6,7].

The National Institutes of Health has described it as the successor to SARS-CoV-1 (NIH, 2020) which is a positive-sense single-stranded RNA virus. It is contagious in nature to humans, and the World Health Organization (WHO) has designated the ongoing pandemic of COVID-19 a Public Health Emergency of International Concern [8].Taxonomically, SARS-CoV-2 is a strain of severe acute respiratory syndrome-related coronavirus (SARSr-CoV) [9]. It is found to have zoonotic origins and has close to genetic similarity of bat coronaviruses (approx 99%), it emerged from a bat-borne virus [10-12].There is no prove yet to link an intermediate animal reservoir, such as a pangolin, to its introduction to humans [13]. There is little genetic diversity in the virus, that indicates the spread of SARS-CoV-2 to humans which has occurred in late 2019.

Common symptoms are fever, cough, fatigue, shortness of breath, loss of smell and taste. Most of the cases result in mild symptoms, some leads to acute respiratory distress syndrome (ARDS) likely precipitated by a cytokine storm, multi-organ failure, septic shock, and blood clots (CDC, 2020). The incubation period is typically around five days but it may range from two - fourteen days [14]. If no members of the community are immune and no preventive measures have been taken then it has been estimated that each infection results in 1.4 to 3.9 new ones. The virus primarily spreads between people through close contact and via respiratory droplets produced from coughs and sneezes [15]. It mainly enters human cells by binding to the receptor angiotensin converting enzyme 2 (ACE2) [16].

Transmission of Infectious Diseases

Infectious diseases result due to invasion of host by a pathogenic agent. The continuous survival of infectious agents depends on their successful transmission to a susceptible host. Infection and replication of infectious agents is necessary to maintain the cycle of infection. Knowledge of life cycle of an infectious agent is essential for selecting the most applicable or approximate contact technology. There are horizontal and vertical two major modes of transmission of infectious diseases.

Abstract

History of infectious diseases as old as the human civilization, and need of protection against these infections has been always remain one of the prime concerns. Among all infectious agents, viruses are the most notorious, vibrant, active and important. In last ten years we have seen the emergence and identification of several new viral infections of global significance but have also been witnessed development of highly innovative new antiviral drug therapies. Earlier most commonly used antiviral agents are Acyclovir, Idoxuridine, Brivudine, Foscarnet, Zidovudin, Adamantane, Ribavirin and Interferons. In special reference to HIV, modern therapeutic pattern is Highly Active Retroviral Therapy in which combination of three or more antiviral agents are used. Several new and promising antiviral drugs have been approved viz. TLR agonists, Salivary micro-RNAs, Telbividin, Etravirine, Dolutegravir, Peramivir, Daclastavir and Ribavirin which allow better options to control various viral infections.

Introduction

"Prevention is better than cure" a slogan arises with the history of infectious diseases. It is as old as the human civilization and need of protection against these infections has been always remain one of the prime concerns. Infectious diseases are a leading cause of death, and alone accounted for one-fourth to one-third of total deaths worldwide. Among all the infectious agents, viruses are the most notorious, vibrant, active and important. Viruses are obligate parasites having DNA or RNA as their genetic material with markedly different mutation rates that can be quantified. Some viruses show remarkable genetic stability and others show variable rate of mutation. In the last three decades, several new viruses have been reported from all over the world and have caused major outbreaks (WHO report,2005). The first virus that was described was tobacco mosaic virus in 1892 by Dmitri Ivanovsky. Since then, about 5,000 viruses have been discovered and also there are many ways for the treatment of viral infection (Fraenkel and Wagner,1977). Viruses have many differences that characterize them from other microorganisms, as they contain only one type of nucleic acid (DNA or RNA), but never both of them simultaneously and also, they do not contain ribosomes or other cellular organelles. This is the reason why all viruses needed a host cell in order to multiply and outside of host cell they are inactive (Kornberg A, 1988). Meanwhile, we are struggling against viruses and lack foolproof antiviral therapies against them. For effective antivirales therapy, have to understand the genetic, molecular, structural as well as functional diversity of viruses, the intricacy of viral multiplication, immune escape, association of host cell machinery for replication and host immune response. Owing to such development, researchers were able to find out appropriate targets against viruses, and as a result many antiviral drugs have been developed.

In last ten years we have seen the emergence and identification of several new viral infections of global significance, (Satcher D,1988; Marston *et al*.,2014) but they have also witnessed the development of highly innovative new antiviral drug therapies, which have, for example, dramatically improved the prognosis of those infected with HIV (Hogg *et al*.,2008) and now are radically changing the care of those infected by hepatitis C (Sheridan C ,2014). However, concerns have been expressed about the increasing costs of developing new drugs and bringing them into clinical use (House of Commons, 2005, Mestre-Ferrandiz J *et al*.,2012, Scannell JW *et al*.,2012, Pammolli F *et al*.,2011, Hay M *et al*.,2014). Each virus affects only some cells (*e.g.* the HIV virus affects CD4+ T cells and macrophages). The multiplication cycle of viruses consists of four main parts. First is the entrance of the virus into the host-cell. Immediately after, the expression of viruse's genes, the multiplication of the nucleic acid and the synthesis of proteins follows. New virions are formed and released from the host-cell by cell lysis (Mycek MJ *et al*.,1999) or exocytosis.

Since 1960's many antiviral drugs have been discovered and gave us the opportunity to deal with many viral infections that we could not before. Most of them are efficiently used nowadays, while new substances are tested in order to produce newer, safer and more efficient drugs (Edwards RA and Rohwer F, 2005).

Traditional antivirals used in different infections

Herpetic infections

Herpetic infections are most common among human population and sometimes can lead to serious diseases, such as cancer. The cycle of herpes virus is characterized by activation and remission periods (Sheridan C, 2014). In the active period, virus-containing blisters are found and this situation can persist for several days, or sometimes, up to three weeks. During that period of time the virus becomes contagious and other people can be easily contaminated by direct skin contact or body fluids. On the other hand, in the remission period the virus stays in the sensory nerves of the central nervous system (CNS) without showing symptoms of infection (asymptomatic period). Following drugs are used in treatment of herpetic infection.

Acyclic Nucleosides:

Acyclovir: used as a selective inhibitor of herpes simplex virus (HSV) replication was an important breakthrough in the development of antiviral drugs. Its selectivity is based on a specific recognition by the HSV-encoded thymidine kinase. Gradually, the derivatives of acyclovir with improved properties have been developed (Scannell JW *et al*.,2012). **Ganciclovir** is effective also against Cytomegalovirus (CMV) infections (Pammolli F *et al*.,2011). **Valaciclovir** and **Valganciclovir** are prodrugs that are *in vivo* converted to the parent drug. **Penciclovir** is the active metabolite of the oral product (Hay M *et al*.,2014). Acyclovir is converted to acyclovir triphosphate by enzyme thymidine kinase and then it is incorporated into the viral DNA (Mycek MJ *et al*.,1999).

Nucleoside analogues:

Idoxuridine: is a nucleoside analogue used only topically for treatment of herpes simplex keratitis.

Trifluridine is used topically in the eye for treatment of herpetic infections (Hay M *et al*.,2014; Edwards RA and Rohwer F, 2005).

Varicella-Zoster virus infection

Primary infection caused by varicella-zoster virus (VZV) is manifested by varicella (chickenpox), while reactivation of latent virus causes herpes Zoster (shingles). In immunocompetent children,varicella is usually not a serious disease,but can cause severe morbidity and mortality in adults and in immunocompromised individuals.

Brivudine is an analogue of thymidine. Mechanism of action includes incorporation into the viral DNA and inhibition of viral replication by blocking the action of DNA polymerases (De Clercq E, 2004).

Vidarabine is a nucleoside analogue used systematically against varicella-zoster and herpes simplex infections. Mechanism of action

ABSTRACT

Livestock plays an important role in welfare of rural population of India and its economy. It contributes 9% of GDP and employs 8% labor force of the country. However respiratory and reproductive disorders in dairy animals due to various etiological agents have led to significant economic losses to dairy animals. The losses are due to abortions, metritis, retention of placenta, repeat breeding, death of animals, loss of production and trade restrictions etc. IBR caused by BoHV1, is a disease of domestic and wild cattle. BoHV1 is a member of the genus Varicellovirus in the subfamily Alphaherpesvirinae, family Herpesviridae and order Herpesvirales. Based on restriction endonuclease fingerprinting, BoHV1 is classified into three subtypes, namely, BoHV1.1, BoHV1.2a and BoHV1.2b. Most BoHV1.1 strains have been isolated from respiratory tract diseases or abortion cases and BoHV-1.2 strains from lesions of genital organs. Subtypes 1.1 and 1.2a have been associated with severe diseases including infection of the foetus and abortion and BoHV1.2b strains are generally involved in mild rhinitis or vaginitis. BoHV1 infection occurs in all continents and is responsible for the significant losses resulting from disease and trade restriction.

Introduction

Livestock plays an important role in welfare of rural population of India and its economy. It contributes 9% of GDP and employs 8% labor force of the country. However respiratory and reproductive disorders in dairy animals due to various etiological agents have led to significant economic losses to dairy animals. The losses are due to abortions, metritis, retention of placenta, repeat breeding, death of animals, loss of production and trade restrictions etc. IBR caused by BoHV1, is a disease of domestic and wild cattle. The first report of disease caused by BoHV1 was made as a venereal disease in a bull and contact cows (Ryehner, 1841) which was subsequently referred to as Blaschenausschlag in German literature. The viral aetiology of the disease was proved by Reisinger and Reimann (1928). The first published report on respiratory IBR came from Schroeder and Moys (1954) where they described an apparently new upper respiratory disease of dairy cattle that occurred in California in 1953. ABSTRACT

India is an agriculture based country and livestock sector in an integral component of it where, livestock production is largely in the hands of women. Livestock sector plays a significant role in the socio-economic development of India. Its growthis pro-poor and inclusive. Livestock helps in generating a continuous flow of income andemployment. The sector empowers women as they perform a large number of activities relatedto livestock production. According to the working group report on animal husbandry and dairying12th five year plan (2012-17), animal husbandry helps in improving gender equity. More thanthree-fourth of the labour requirement in livestock production is met by women. Most of the animal farmingactivities such as fodder collection, feeding, watering, and health care, management, milking and household-level processing, value addition and marketing are performed by women. The outstanding demand for livestock products gives considerable opportunitiesfor the rural women to escape poverty by diversifying livestock production. In this backdrop thestudy aims to highlight the role of Indian livestock sector in empowering rural women. It furtherestimates the contribution of animal husbandry vis-à-vis other agricultural activities in providingcasual, regular and self-employment to rural women.

Key words : *India, Livestock sector, Rural women.*

India is an agriculture based country and livestock sector is an integral component of it and livestock isgenerally considered a key asset for rural livelihoods. In India, livestock production is largely in the hands of women. In 2010-2011, livestock generated outputs worthRs. 2075 billion (at 2004-05 prices) which comprised 4% of Gross Domestic Product (GDP)and 26% of the agricultural GDP (PlanningCommission, 2012). Women play a major role in the livestock production activities in India. The female share in the agricultural labour force is case of India is about 30% (Sofa and Doss, 2011). About 70% of the agricultural workers, 80% of food producers, and 10% of those who process basic foodstuffs are women and they also undertake 60 to 90% of the rural marketing; thus making up more than two-thirdof the workforce in agricultural production (http://www.wikigender.org). Most of the animal farming activities suchas fodder collection, feeding, watering, and health care, management, milking and household-level processing, valueaddition and marketing are performed by women.The rapidly increasing demandfor livestock products creates opportunities for empowerment of women (Taneja, 2013). Therefore, there is a need tocorrect gender bias in livestock sector, veterinary education, research and service delivery systems as to enhance theeffectiveness of women-oriented livestock development programs (Anonymous, 2012-17).A women iseconomically empowered when she has both thecapacity to succeed and proceed economicallyand the power to make and act on economicdecisions (Golla *et al.*, 2011). Women play a veryimportant role in agriculture and on average theyconstitute 43% of agricultural labour force indeveloping countries (FAO, 2011). Out of 600 million rural poor of theworld who keep livestock two third are women(FAO, 2012b). Livestock are the largest non-landassets in rural asset portfolios. Livestock are thesignificant productive asset with high expectedreturns (Njuki, 2013). Livestock are the assetwhich can be easily owed by women and whichhave the potential to make contribution towardsthe reduction in the gender asset gap with inhousehold (Kristjanson *et al.*, 2010) and livestockoften is the single asset for rural women which isowned and controlled by them and which servesas an important source of income and cash forthem during the time of need (World Bank, 2009). In rural livestock based countries two thirdportion of low income livestock keepers areconstituted by rural women especially theactivities related to small livestock production(poultry, sheep, goats), milking and processingof milk are carried out primarily by women (Thornton, 2001; and FAO, 2011a).The importance of livestock for women'sincomes in developing countries has also beenwidely accentuated (Quisumbing *et al.*, 1995; andValdivia *et al.*, 1996). Dairy cooperatives havebeen chief means of bringing women in poorareas successfully into the cash economy in EastAfrica (Broken and Seyoum, 1992), India(Schneider, 1995) and Bolivia (Valdivia *et al.*,1996). Livestock sector gives a unique opportunityfor women to get empowered, however due tolack of awareness of the role that rural women play in livestock sector. In thisbackdrop the paper aims to highlight the opportunities to women in livestock sector as well as theircontribution in animal husbandryvis-

Climate change affecting animal health and production : A review

Vibha Yadav[1], Shivendra Pratap[2] and RajPal Diwakar[3]
1&3 Asstt.Prof. 2 MVScScholar, Deptt of VetyMicrobiology,NDUAT,Kumarganj,Faizabad U.P.

ABSTRACT

The threat perception of climate change is well known and its provoking impact is being noted at many levels. Various scientific reports of the Intergovernmental Panel on Climate Change (IPCC) indicate that climate change will impact the globe severely, and these impacts will vary depending on the region and on ecosystems. Animal production systems, climate change and animal health are inter-related via complex mechanisms. Direct exposure to climate change comprises changing weather patterns (increasing temperatures, more precipitation, rising sea-level and more frequent extreme events). Indirect exposure comprises changes in water, air and food quality, vector ecology and changes in ecosystems, agriculture, industry and settlements. Animal production influences climate change by emitting greenhouse gases such as methane and nitrous oxide. According to the IPCC, agricultural activities, including animal production, account for 10-12% of global emissions. This means that animal production offers major opportunities for reducing emissions, as well as for increasing the sequestration of greenhouse gases. But climate change in turn affects production (affecting nutrition, access to water and animal health). Animal health could be affected both by extreme events (for example high or low temperatures) and by the emergence and re-emergence of infectious diseases, some of them transmitted by vectors that are highly dependent on climatic conditions. In the case of the veterinary services of the countries, it will be necessary to build their capacity to handle the greater risks associated with climate change.
Key words: *climate change, livestock, animal production, animal health*

Received 12.07.2017 Revised 09.08.2017 Accepted 24.08.2017

INTRODUCTION

The scientific evidences point to climate change having an increasing impact on life on the planet. Average temperatures will rise, rainfall patterns will change, and extreme weather events such as storms, flooding, drought and heat waves will become more frequent and more intense. These processes are not something that will occur in the future however they are already happening. We are encountered to these phenomena on daily basis. Intergovernmental Panel on Climate Change (IPCC) for 2007 comprises an update on the state of knowledge of the associations between weather/climatic factors and public health outcomes for human populations concerned (Patz *et al.*, 2005). Within this framework, animal health as well as animal production will be particularly affected by climate change because it is so dependent on climate. The Intergovernmental Panel on Climate Change (IPCC) is sending out a clear message that human activities are contributing massively to global warming and to climate change. Economies, especially those of the most economically-developed countries, use large quantities of fossil fuels (oil, coal, natural gas), which generate very large quantities of greenhouse gases, in particular carbon dioxide, that contribute to climate change. In addition to carbon dioxide, human activities add methane and nitrous oxide to the atmosphere. These gases are generated in city landfills, livestock farms, rice fields and through the use of nitrogenous fertilizers. Some greenhouse gases are manufactured artificially, such as the fluorinated gases used in refrigeration and air-conditioning systems. Although methane and nitrous oxide have a potentially very powerful greenhouse gas effect, they have not been released into the atmosphere is such large quantities as CO_2, and their half life in the atmosphere is shorter. This means that CO_2 originating from human activities is the gas with the biggest impact on climate change. Animal production is a major component of food security. Through it we obtain products such as milk, eggs and meat, which are an intrinsic part of any global food security policy. Moreover, worldwide demand for these products is high and threatens to increase substantially in line with rises in population and average per-capita incomes. Raising livestock provides other non-food essential products, such as milk and

ABSTRACT

Extended-spectrum β-lactamase producing organisms are expanding rapidly throughout the world and have become a problem for both veterinary and human medicine. Among family Enterobacteriacae, *Escherichia coli* and *Klebsiella* are of major public health concern. In the present study, a total of 240 buffalo milk and faecal samples were collected from two districts of eastern plain zone of Uttar Pradesh (India). Total 59.58% isolates were identified including 53.33% *E. coli* and 6.25% *Klebsiella* spp. by PCR, out of which 41.25% isolates were confirmed as ESBL producers comprising 36.66% *E. coli* and 4.58% *Klebsiella* species by phenotypic confirmatory tests. All ESBL positive isolates were found 100% sensitive to aminoglycosides and polypeptide class of antibiotics and 100% resistant to 3rd generation cephalosporins and ampicillin. Out of total ESBL producers, 78.0% isolates were found multidrug resistant. The present study revealed predominance of ESBL as well as MDR in *Klebsiella* spp. as compared to *E. coli* and highlights a great threat for horizontal gene transfer.

Keywords: Antibiogram, Buffalo, *E. coli*, ESBLs, *Klebsiella*

How to cite: Yadav, V., Joshi, R.K., Joshi, N., Kumar, A. and Singh, S. (2021). Status of multidrug resistance among ESBL producing *E. coli* and *Klebsiella* spp. isolates of buffalo origin in eastern plain zone of Uttar Pradesh. *Haryana Vet.* **60(2)**: 208-212.

Today, antimicrobial resistance (AMR) has been a global problem contributing to rise in cost of treatment and mortality (Singla *et al.*, 2014). The problem of AMR is expanding rapidly throughout the world and has become a problem for both veterinary and human medicine (Reist *et al.*, 2013). Extended-spectrum β-lactamases (ESBLs) are enzymes that can hydrolyse most of the β-lactam antibiotics and thus mediate resistance to penicillins, 3rd and 4th generation cephalosporins (Saravanan *et al.*, 2018). ESBLs are most commonly detected among Enterobacteriaceae like *E. coli* and *Klebsiella* spp. Extensive use of antibiotics leads to the development of multidrug resistance (MDR) organisms. MDRs in Enterobacteriaceae is increasing day by day that lead to limited antimicrobial treatment options which are posing a treatment challenge, and a major cause of morbidity and mortality worldwide (WHO, 2016).

Due to paucity of data on ESBL and MDR index in Eastern Plain Zone of Uttar Pradesh, the present study focussed on the MDR pattern among ESBL producing *E. coli* and *Klebsiella* spp. isolates from milk and faecal samples of healthy and diseased buffaloes of eastern plain zone of Uttar Pradesh (India). It will help the researchers, field veterinarians and farmers in selection of antibiotics for therapeutic purpose.

MATERIALS AND METHODS

Sample collection : Total 240 samples (120 milk samples and 120 faecal samples) were collected between August 2019 to June 2020 from 5 tehsils of Ayodhya and 3 tehsils of Sultanpur district of Eastern Plain Zone of Uttar Pradesh, India. Samples were collected randomly from apparently healthy and clinically infected animals and sampling consisted of 10 normal and 5 mastitic milk samples from each of the tehsil. Likewise, 10 normal and 5 diarrhoeic faecal samples from above mentioned regions were collected. Collected samples were immediately transported to Veterinary Microbiology Laboratory under cold condition for further processing.

Isolation and Identification : Samples were enriched with 2 ml nutrient broth and incubated for 24 hrs at 37 °C. A loopful of inoculum was directly streaked on MacConkey agar (MLA) plates and incubated at 37 °C for 24 hr. Colonies showing rose pink colour were picked up and transferred to nutrient agar slant and incubated at 37 °C for 24 hrs. Thereafter, cultures were streaked on Eosine Methylene Blue (EMB) agar plates and colonies showing specific characteristics were identified by the method of Cruickshank *et al.* (1975). Further identification of the isolates was done using Gram's staining and standard biochemical tests, viz., IMViC pattern, catalase, nitrate reduction, urease, triple sugar iron agar and sugar fermentation as per method of Edward and Ewing (1972).

Extraction of genomic DNA : DNA templates were prepared by using snap-chill method as described by

Detection and Molecular Characterization of Extended-spectrum β-lactamase Producing *E. coli* and *Klebsiella* spp. Isolates of Cattle Origin in Eastern Plain Zone of Uttar Pradesh

V. Yadav[1], R.K. Joshi[1], N. Joshi[2], Amit Kumar[3], S.V. Singh[4], D. Niyogi[5]

10.18805/IJAR.B-4762

ABSTRACT

Background: Antibiotics are widely used in animals and human for treatment without referring an antibiogram that resulted into the proliferation of ESBL producing strains. Nowadays resistance to β-lactam groups of antibiotic is expanding rapidly worldwide and threatening the public healthcare due to limited treatment options. Therefore this study aimed to detect ESBL resistance genes in *E. coli* and *Klebsiella* spp. isolated from various sources of cattle in this area of study.

Methods: Total 240 samples were collected during August, 2019 to June, 2020, from two districts of Eastern plain zone of Uttar Pradesh. *E. coli* and *Klebsiella* spp. isolates were confirmed using *uidA* and 16S *rRNA* gene respectively. *in vitro* antibiotic sensitivity test was performed using disc diffusion method. ESBL producing isolates was confirmed by DDST, ESBL E-strip and PCR analysis by targeting (bla-$_{CTX\text{-}M\text{-}1}$, bla-$_{CTX\text{-}M\text{-}9}$, bla-$_{TEM}$ and bla-$_{SHV}$) genes.

Result: PCR analysis of these isolates confirmed 135(56.25%) as *E. coli* and 16(6.67%) as *Klebsiella* spp. Antibiotics found to be most resistant were ampicillin (89.40%) followed by cefotaxime (72.18%), cefpodoxime (71.52%), ceftriaxone (66.9%), aztreonam (61.0%) and ceftazidime (54.30%). Total 101(66.88%) isolates were confirmed as ESBL producers using DDST and 92(60.92%) by ESBL E-strip test. ESBL genes were detected in 87(57.61%) isolates by PCR analysis and among them, bla-$_{CTX\text{-}M\text{-}1}$ was found most dominant gene.

Key words: Antibiogram, Cattle, *E. coli*, ESBL, *Klebsiella*.

INTRODUCTION

The emergence of antimicrobial resistance (AMR), especially among *Enterobacteriaceae* has been increasingly problematic and posses serious threat for both human and animal health (WHO, 2013). It is directly related with the use of these drugs in animal husbandry at insufficient doses and unprofessional choice which limit the treatment options. Resistant bacteria include both pathogenic and commensal organisms, with the later serving as a potential reservoir for mobile resistance elements (Khachatryan *et al*., 2004). Resistance among ESBL organism is mediated by enzyme Extended-spectrum β-lactamases (ESBLs) that hydrolyses most of the β-lactam antibiotics and mediates resistance against penicillins, 3rd and 4th generation cephalosporins (Saravanan *et al*., 2018). Among *Enterobacteriaceae, E. coli* and *Klebsiella* spp. are major ESBL producers and have been identified as global threat due to their increasing prevalence in livestock in last few years (Reuland *et al*., 2013). ESBL has been also reported in various niches as commensal in human, animals and environment. Such ecological niches may serve as reservoir and vehicle for transmission and dissemination in production animals due to their direct contact with food chain (Madec *et al*., 2017). Since no in depth study has been done on distribution of ESBL among cattle in this area of study and also their possible role in development of resistance to other species or pathogens. The present study will provide database to

Detection of Carbapenemase Genes (bla_{-NDM}, bla_{-KPC}, $bla_{-OXA-48}$) in *Escherichia coli* and *Klebsiella* species, Isolated from Milk Samples of Bovine in Eastern Plain Zone of Uttar Pradesh

Vibha Yadav[1], Rajesh Kumar Joshi[1], Namita Joshi[2], Amit Kumar[3], Satyavrat Singh[4]

10.18805/IJAR.B-4543

ABSTRACT

Background: Among enterobacteria *E. coli* and *Klebsiella* spp. are of great concern in health care settings, as these bacteria sometimes may contaminate the milk due to unhygienic practices and poor udder condition which have been associated with various illnesses. Therefore, this study aimed to detect the carbapenem resistant *E. coli* and *Klebsiella* spp. of bovine milk origin with regard to the risk of human transfer via the food chain in community.

Methods: Total 240 samples were collected from Ayodhya and Sultanpur districts of Eastern Plain Zone of Uttar Pradesh (India). Confirmation of *E. coli* and *Klebsiella* spp. isolates was done by using species specific uidA and 16S rRNA gene, respectively. Then, carbapenemase positive *E. coli* and *Klebsiella* spp. were confirmend by DDST, MBL E-strip test and PCR analysis by targeting (bla_{-NDM}, $bla_{-OXA-48}$ and bla_{-KPC}). Antibiogram of all carbapenemase positive isolates was performed against 20 antibiotics of 12 different classes.

Result: In the present study, total 74(30.83%) isolates were identified including 55(22.92%) *E. coli* and 19(7.92%) *Klebsiella* spp. by PCR, out of which 12(16.21%) isolates were confirmed as carbapenemase producers comprising 7(12.72%) *E. coli* and 5(26.31%) *Klebsiella* spp by DDST and E-strip. All carbapenemase positive *E. coli* were found 100% sensitive to polymyxin-B and chloramphenicol, while all *Klebsiella* spp. were 100% sensitive to amikacin and polymyxin-B. Resistance against imipenem, meropenem, cefotaxime, cefpodoxime, ceftazidime, ceftriazone, aztreonam and ampicillin ranged between 80.0%-100%. All carbapenemase positive isolates were found multidrug resistant. Carbapenemase genes bla_{-NDM} and bla_{-KPC} were detected in *E. coli* while $bla_{-OXA-48}$ and bla_{-KPC} were detected in *Klebsiella* spp.

Key words: Carbapenemase, *E. coli*, *Klebsiella* spp., MBL-E test, Multidrug-resistance.

INTRODUCTION

Carbapenems are one of the most important groups of antimicrobials which are used as a last resort of antibiotics to combat the infection of multidrug resistant (MDR) pathogens. Unfortunately, the use of carbapenems has increased worldwide in past few years (Wang *et al.*, 2015), hence MDR and carbapenemase producing *Enterobacteriaceae* (CPE) have been increasing globally at a alarming rate. Resistance to carbapenem is generally mediated by various mechanisms such as loss of outer membrane porins, production of carbapenemase enzymes and over-expressed efflux pump. Majority of bacterial isolates that harbour these enzymes belong to *Enterobacteriacae*, because Gram negative bacteria producing ESBL enzyme led to higher carbepenem usage in human being which has resulted in the wider occurrence and spread of CPE (Muller *et al.*, 2018) in environment. The spread of these bacteria into many species may occur though sewage and waste water. Among *Enterobacteriacae*, *E. coli* and *Klebsiella* spp. are main environmental pathogens, associated with various illnesses and acute bovine mastitis (Koovapra, 2015). Resistant genes of these antibiotics are frequently located on mobile genetic elements which can be horizontally transferred (Ansari *et al.*, 2018) between the bacteria. CPE among livestock are of great

Isolation, Identification, Molecular Characterization and Antimicrobial Resistance Profiling of ESBL Positive *E. coli* Isolates of Cattle in Eastern Zone of Uttar Pradesh

Vibha Yadav[1*], Rajesh K. Joshi[2], Namita Joshi[3], Amit Kumar[4], Mrinal Srivastva[5], Satyavrat Singh[6], Pankaj K. Chaudhary[7]

Abstract

In this present study total of 240 milk and fecal samples were collected from two districts of the plain Eastern zone of Uttar Pradesh (India). Among 240 samples, a total of 135 (56.25%) isolates were confirmed as *E. coli* using a species-specific uidA gene oligonucleotide primer. Eighty-six (63.70%) ESBL producing *E. coli* isolates were recovered out of 135 isolates using confirmatory phenotypic methods. The antimicrobial resistance pattern revealed that all isolates showed (60-100%) resistance against cefotaxime, cefpodoxime, ceftriaxone, ampicillin, ceftazidime, aztreonam, etc. and 100% sensitivity against gentamicin, amikacin, chloramphenicol, and polymyxin-B. The multi-drug resistance (MDR) pattern of ESBL organisms was assessed by using the multiple antibiotic resistance (MAR) index. Out of 86 ESBL positive isolates, 70 (81.39%) *E. coli* was showed multi-drug resistance in the study. MAR index of these isolates was in the range from 0.25 to 0.75. The most frequently observed MAR index was 0.30 against 28 isolates. Antibiotic resistance patterns against non-β-lactam antibiotics were also observed, and 51 isolates showed resistance against both β-lactam and non-β-lactam antibiotics, while 19 isolates showed resistance against only β-lactam antibiotics of different groups.

Keywords: Antibiogram, Cattle, *E. coli*, ESBLs, MAR index, uidA gene.

Ind J Vet Sci and Biotech (2021): 10.21887/ijvsbt.17.2.4

Introduction

Antimicrobial resistance (AMR) has been a global problem contributing to rise in mortality and cost of treatment. Antibiotics are widely used in animals and humans to fight bacterial infections. However, their indiscriminate use leads to the emergence of multidrug-resistant bacteria, limiting the treatment option (Saidani *et al.*, 2017). *E. coli* is the average inhabitant of the intestinal microbiota of animals and mammals and plays an essential role in host metabolism, immunology, and nutrition.

Production of Extended-spectrum β-lactamases (ESBLs) is the most common resistance mechanism to third-generation cephalosporins among Enterobacteriaceae, including E. coli *Klebsiella* species. β-lactams are the most commonly prescribed antibiotics against bacterial infections. The emergence of ESBL producing strains has limited the use of broad-spectrum cephalosporins in the management of serious infections caused by these pathogens, which results in therapeutic failures and a high mortality rate (Roy *et al.*, 2013).

Currently, there is a paucity of information on ESBL producing *E. coli* from animals in this region and their possible contributions to the development of resistance to other species or pathogens. Hence, surveillance-based study, antimicrobial resistance profiling, searching for an alternative antibiotic is the need of the hour to address the global issue of antimicrobial resistance. Hence, in this study, isolation, biochemical analysis, molecular characterization by uidA gene, detection of ESBL positive isolates by phenotypic methods, and antibiotic resistance profiling of ESBL positive

(RESEARCH PAPER IN VETERINARY MICROBIOLOGY)

Abstract

The samples of cervical mucus of 21 crossbred and 20 Desi cows in and around the NDUAT Campus, Narendra nagar, Faizabad (Utter-Pradesh). The isolation of bacteria and in-vitro sensitivity pattern of various drugs against these isolates were carried out. The bacterial isolates comprised of Staphylococcus spp. Streptococcus spp. Pseudomonas spp. Anthracoids spp. E.coli, Corynaebacterium-spp. And some of the untyped Gram positive and Gram negative bacilli and coccobacilli among 14 crossbred and Desi cows with positive infection. Gentamicin was found effective in 92.9 per cent cases. The other drugs followed after Gentamicin in crossbred cows were ampicillin, Kenamycin and tetracycline in 28.6, 21.4 and 14.3 per cent cases respectively, whereas in desi cows other drug found effective were tetracycline, Kenamycin, Chloramphenicol, Streptomycin and ampicillin in 42.9, 42.9, 35.7,14.3 and 7.1 per cent cases respectively.

Introduction

Mainly buffalo is a triple purpose animal producing milk, meat and draught power. The country has made a grand specter on the World stage being top milk producer and leading meat exporter. The analysis shows that in 2015-16 nearly 36% of the milk production is contributed by Indigenous and 13% by non-descript buffaloes. The total buffalo meat production in 2015-16 was 1611 tones, which is 26% of total meat production in India. The buffalo population in Uttar Pradesh is 30625 thousand and in India it is 108702 thousand according to 19th Livestock Census. This particular livestock species has immense potential for poverty alleviation and rural entrepreneurship. However, just like any other successful agribusiness enterprises, buffalo farming too needs a highly dedicated scientific advisory system for decision making support.

The repeat breeding is the major problem responsible for poor productivity in cattle and buffaloes. It not only decreases the life time milk production but also increases the cost of milk production. A large number of micro-flora has been isolated from repeat breeder cattle and buffaloes in India. It is necessary to identify the micro-flora from cervical mucus of repeat breeders and to test in-vitro sensitivity pattern of these micro-flora prior to use of any antimicrobial agent in such animals.

Materials and Methods

A total of 41 (forty one) repeat breeder cattles in and around the NDUAT Campus, Narendra nagar, Faizabad (Utter-Pradesh). These cattles did not show any apparent illness in their reproductive organs but were not conceiving even after artificial insemination as well as natural service. The samples of cervical mucus was collected from these cattles aseptically and were inoculated on various media like blood agar (BA), Mac Conkey's lactose agar (MLA), Nutrient broth (NB) and Nutrient agar (NA) for primary isolation. The inoculated plates were incubated at 37^{0}C for 24 to 48 hours aerobically. The bacterial growth were obtained and tested against many antimicrobial agents for their in-vitro sensitivity and resistant pattern as per Cruickshank et al., (1975).

Results and Discussion

Out of 41 samples analysed for bacterial isolation 14 samples in crossbred (66.7%) and desi (70%) repeat breeder cattles were found positive for bacterial infection. Among animals positive for bacterial infection, 35.7 and 64.3% cases showed single and mixed infection, respectively in crossbred cows whereas 64.3 and 35.7% desi cows showed single and mixed infection respectively. The microorganisms isolated from cervical mucous of crossbred cows included untyped Gram negative bacilli (35.7%) untyped Gram negative coccobacilli (28.6%), *Staphylococus spp.* And *Pseudomonas spp.* (21.4% each), *E.coli*, untyped Gram positive bacilli, untyped Gram positives coccobacilli (14.3% each) and *Streptococcus spp., Anthrocoides spp.* And *Corynaebacterium spp.* (7.1% each). Untyped Gram negative bacilli and coccobacilli mainly affected the repeat breeder crossbred cows. On the other hand, the microorganisms isolated from cervical mucus of crossbred repeat breeder cows included *Pseudomonas spp.* And *E.coli* (42.9 %) *Anthrocoides spp.* (28.6%) *Staphyloccus spp.* And untyped Gram negative bacilli (14.3% each) and untyped Gram positive and Gram-negative coccobacilli (7.1% each). It reveals that *Pseudomonas* and *E.coli* were main source of infection among cross bred repeat breeder cows. Similar isolates were found by many scientists from cervical mucus of repeat breeder cows (Desmukh and Markandiya, 1995 and Singh et al., 1998).

The in-vitro drug sensitivity results indicated that Gentamicin was found effective in 92.9% cases of both crossbred and desi repeat breeder cows. Singh et al., (1998) reported percent sensitivity of Gentamicin whereas, Gupta et al., (1997) and Dessmukh and Markandiya, (1995) found sensitivity of Gentamicin against the isolates of Cervical mucus of repeat breeder cows as 94.1% and 91.3%, respectively, which is close agreement with the present findings. The other drugs which were found sensitive against the isolates of cervical mucus included Ampicillin (28.6%), Kanamycin (21.4%) and Tetracycline (14.3%) in crossbred cows and Kanamycin and Tetracycline (42.9% each), Chloramphenicol (35.7%), Streptomycin (14.3%) and Ampicillin (7.1%) in crossbred cows. It was observed that Streptomycin and Chloramphenicol were not found effective in any crossbred cow but their sensitivity in 14.3% and 35.7% cases respectively was recorded in crossbred cattle.

The results obtained by sensitivity test indicated that Gentamicin may be considered as drug of choice in for repeat breeder cows. The same results are recommended by Singh et al., (1998), Dessmukh and Markandiya, (1995) and Ramaswamy et al., (1991). However, it may further be stated that antibiotic sensitivity testing should periodically be carried out in order to rationalize the treatment against specific microorganism in specific locality.

Conclusion

The authors are thankful to the Dean, College of Veterinary Science & Animal Husbandry, Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P) and also thank to Head of the Department of Veterinary Microbiology to providing necessary facility to carry out this research work.

ABSTRACT

In recent years *Escherichia coli* has emerged as a more problematic organism causing considerable losses worldwide due to increased susceptibility of birds. Resistance of E. coli to antibiotics is well known, which is a major obstacle in the control of infection. This problem is more vibrant in developing countries like ours due to uncontrolled use of antibiotics. Antimicrobial drug sensitivity of the isolates was tested for different antibiotics using the modified disc diffusion method. The antibiogram of seventy *Escherichia coli* isolates was studied against 12 antibiotics viz. ofloxacin, pefloxacin, ampicillin, amikacin, gentamicin, piperacillin, chloramphenicol, co-trimoxazole, tetracycline, cefotaxime, ceftizoxime and ciprofloxcin. Out of seventy *Escherichia coli* isolates tested, highest 69 (98.57 percent) isolates exhibited resistance against cefotaxime followed by 60 (85.71 percent) isolates showing resistance against piperacillin, 58 (82.86 percent) isolates showed resistance against tetracycline, 37 (52.86 percent) isolates were resistance to co-trimoxazole, 16 (22.86 percent) isolates were resistant to ceftizoxime, 14 (20 percent) isolates were resistant to pefloxacin, 11 (15.71 percent) isolates against ampicillin, 10 (14.26 percent) isolates showed resistance against ofloxacin and 7 (10 percent) isolates were resistant to ciprofloxcin and chloramphenicol both. Only one isolate (earch 1.43 percent) was found resistant against gentamicin and amikacin. Multiple drug resistance has been a consistence finding in the study of antibiogram of enterobacterial isolates. Out of 70 *Escherichia coli* isolates tested 11 (15.71 percent) isolates, 7 (10 percent) isolates and 47 (67.14 percent) isolates were found resistance to 2 antibiotics, 3 antibiotics and 4 or more antibiotics combinations respectively out of 12 antibiotics tested. The authors attributed the pattern of multiple drug resistant to large scale indiscriminate use of different antimicrobials as feed additives and for therapeutic purpose.

Introduction

In recent years *Escherichia coli* has emerged as a more problematic organism causing considerable losses worldwide due to increased susceptibility of birds. Many serotypes of *Escherichia coli* are normal inhabitant of large intestine, caecum and lower part of small intestine of healthy fowl and majority of them are nonpathogenic (Roy *et al.*, 2004). Resistance of *Escherichia coli* to antibiotics is well known, which is a major obstacle in the control of infection. The antimicrobial agents are of great value for devising curative measures against bacterial infections.

However, emerging trend of resistance in bacterial strains against antimicrobial agents has now become one of the major public health concerns in both developing and developed countries (Levy, 1982).

Variability, heritability and genetic advance studies in French marigold (*Tagetes patula* L.)

Anil Kumar, Bhanu Pratap, Dharmendra Kumar Gautam, Vikas Yadav, Gangadhara K, Karam Beer, Ashutosh Kumar Singh and Vivek Kumar Singh

Abstract
A field experiment was conducted at Main Experimental Station of Department of Horticulture, Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya. The experiment was laid out in Randomized Block Design with 10 treatments and replicated thrice. The healthy seedlings were transplanted at a spacing of 30cm X 30cm. The observations were recorded from five plants selected randomly in each genotype per replication for 10 characters namely, plant height (cm), stem diameter (cm), plant spread (cm), number of primary branches, number of secondary branches, days taken to flower bud initiation, duration of flowering (days), number of flowers per plant, flower weight (g) and flower yield per plant (g). Analysis of variance showed highly significant differences for all the ten characters. In general, estimates of phenotypic coefficient of variation (PCV) were found to be higher than their corresponding genotypic coefficient of variation (GCV). High broad sense heritability coupled with high genetic advance was reported for number of flowers per plant (h^2 = 99.62%, GA = 59.78) and flower yield per plant (h^2 = 99.53%, GA = 133.82), showing additive gene effects and shows the effectiveness of selection of these characters.

Keywords: Variability, heritability, genetic advance, french marigold

Introduction
Marigold (*Tagetes spp.*), a member of Asteraceae family. It is one of the most important flower grown commercially in India. It is native of Central and South America especially Mexico. Genus Tagetes consists of 33 species, out of these species, *Tagetes erecta* L., commonly called African marigold, and *Tagetes patula* L. popular as French. Both the species of marigold are suitable for garden display and grown commercially for use as cut flowers and loose flowers. It is highly suitable as a bedding plant in an herbaceous border and is also ideal for newly planted shrubberies to provide colour and to fill the space. It has attracted the attention of flower growers due to its wide spectrum of attractive colours, shape, size and good keeping quality. Flowers of African marigold can be used for extraction of 1-lemoene, ecomene, 1-linylaetate, 1-linauol (Narsude *et al*., 2010) [9]. An extract obtained from the flowers is mixed with other ingredients in the preparation of an obtained which is used in curing ulcer. Orange colour marigold has emerged as rich source of carotenoid pigments namely xanthophyll, which is widely used as dietary supplement in poultry industry to enhance the chicken skin colour and egg yolk pigmentation (Naik *et al*., 2004) [8]. The demand for uniform, medium sized, compact bright colour flowers with more shelf life are very high in domestic flower market (Singh and Misra, 2012) [13]. Therefore, it is realized that under the changing scenario and advancement of floriculture sector, evaluation of marigold germplasm is essential to bring the suitable genotypes with desirable quality parameters and recommended to farmers for exploitation of their potential.

Genetic variation and genetic relationship among genotypes is an important consideration for classification, utilization of germplasm resources and breeding (Kumar *et al*., 2013) [7]. The presence and magnitude of genetic variability in a gene pool is the pre-requisite of a breeding programme (Bhujpal *et al*., 2013) [10]. Heritability provides us information about the additive genotypic variance and phenotypic variance. A knowledge of the estimates of genotypic coefficient of variation (GCV), phenotypic coefficient of variation (PCV), heritability (h2) and genetic advance as percentage of mean (GA) would help the breeder in selection of appropriate breeding methods. Keeping in view its wide importance, a study was conducted to assess the performance of ten marigold genotypes under Ayodhya conditions of Uttar Pradesh.

Abstract. Fusarium wilt (caused by *Fusarium oxysporum* f. sp. *lentis*) is the most crucial limiting variable for decreasing yield levels of lentils (*Lens culinaris* Medik.) around the world. A set of 20 diverse lentil genotypes comprising breeding lines and released varieties was evaluated, along with susceptible controls, for resistance to fusarium wilt through natural incidence for two continuous years (2010–11 and 2011–12) in six diverse lentil-growing environments in India. Analysis of variance showed that the effect of genotype (G) and environment (E) for disease incidence was highly significant. Among the three sources of variation, the biggest contribution in disease occurrence was accounted for by environment (54.68%), followed by G × E interaction (17.32%). The high G × E variation necessitated assessment of the genotypes at different locations (environments). GGE biplot analysis of the studied genotypes revealed that genotype PL 101 and released cultivar L 4076 had low levels of disease incidence. The sources of resistance to fusarium wilt have great potential for use in lentil-breeding programs. Another biplot of relationships among environments demonstrated that, among the test locations, Sehore and Faizabad, were the most effective for differentiation of genotypes. On the basis of discriminating ability and representativeness, the Sehore location appeared an ideal testing site for natural incidence of *F. oxysporum* f. sp. *lentis*.

Additional keywords: disease resistance, genotype × environment interaction, GGE analysis, stability.

Received 2 February 2017, accepted 25 August 2017, published online 27 September 2017

Introduction

Lentil (*Lens culinaris* Medik.) is an important food legume and a reasonable source of protein (22–35%), minerals, fibre and starch for vegetarian people (Srivastava and Vasishtha 2012; Kumar *et al.* 2016). It is mainly grown in western Canada, central India, southern Turkey, West Asia, northern USA, Bangladesh, southern Europe and Australia (Harish 2012). Fungal diseases are serious constraints to lentil production in many parts of the world. Of them, wilt caused by the fungus *Fusarium oxysporum* f. sp. *lentis* is the most crucial limiting factor for reducing lentil yield globally (Taylor *et al.* 2007). The fungus is a warm-weather pathogen generally present in sandy, acidic soil and it can survive in the soil for a decade (Eagling 2009). Fusarium wilt is identified by abrupt drooping of the leaves, leading to drying of leaves and the ultimate death of the seedling. The root system appears sound, but it has decreased expansion and poor nodulation rate (Kraft *et al.* 1981). This fungus generally causes 5–10% yield reduction, but under favourable environmental conditions, the disease severity may cause complete crop devastation (Chaudhary and Kaur 2002). Management is difficult

Summary

Out of eight fungicides and six neem based products, evaluated in field conditions, propiconazole 25 EC @ 0.1 per cent appeared to be most effective which reduced the disease severity by 86.0 per cent and 86.11 per cent and increased yield by 136.06 per cent and 137.20 per cent in *Kharif* 2001 and 2002, respectively. Among the six botanicals evaluated as field spray, Neem azal @ 0.3 per cent was found to be most effective and it reduced 79.07 and 80.0 per cent severity of disease and increased 102.07 per cent and 100.94 per cent crop yield in *Kharif* 2001 and 2002, respectively.

Key words : *Rhizoctonia solani* Kuhn., Sheath blight, Fungicides, Botanicals

How to cite this article : Chandra, Subhash, Kumar, Pankaj and Kumar, Suresh (2018). Field evaluation of fungicides and botanicals against sheath blight, *Rhizoctonia solani* in rice (*Oryza sativa* L.). *Asian J. Soil Sci.*, 11 (1) : 95-97 : DOI : 10.15740/HAS/AJSS/11.1/95-97.

Introduction

Rice (*Oryza sativa* L.) is one of the most important cereal crop of the world. In India it occupies an area of 44.361 million hectares with production of 78.64 million tonnes, and productivity of 1.773 tonnes ha^{-1} (Mishra, 2004). It contributes 20.25 per cent of agricultural G.D.P.

This crop is subjected to attack by many diseases caused by fungi, bacteria, viruses, nematodes and several physiological disorders which caused annual loss to the tune of 12 to 25 per cent of the total production, while fungal diseases alone caused annual damage of 12 to 20 per cent of its production. Among these diseases, the sheath blight caused by *Rhizoctonia solani* Kuhn. earlier considered as minor disease is now regarded as an internationally important. In India, the disease was first reported by Paracer and Chahal in the year 1963 from Gurdaspur (Punjab). It is also designated as a banded blight disease of rice in North India. The pathogen mainly infect leaf sheath but symptoms may be produced on any aerial part of the rice plant.

Thus, sheath blight caused by *Rhizoctonia solani* Kuhn. is most economically important disease and have possessed challenge to the farmers for successful cultivation of rice and ultimately to the plant pathologists. Keeping this fact in view, evaluation of fungicides and botanicals against this pathogen were under taken in field conditions.

Resource and Research Methods

Eight fungicides and six neem based products were tested separately in two different sets of experiments against sheath blight to assess their efficacy. The field trials were conducted during *Kharif*, 2001 and 2002 crop

Efficacy of botanicals, bio-agents and fungicides against *Fusariumudum* causing wilt disease of pigeonpea *In Vitro*

Neeraj Kumar Rajvanshi, Subhash Chandra and Ajay Kumar

Abstract
Pigeon pea is an important pulse crop of India and its production is greatly affected by wilt disease. Pigeon pea wilt is a very destructive soil borne disease caused by *Fusariumudam*. In present research work plant extracts (Garlic, Neem, Tulsi), bio-agents (*Trichodrema viride* and *Pseudomonas fluorescens*) and fungicides (Vitavax, Bavistin and Thiram + Carbendazim) were tested against *Fusarium udum*. Fungicides namely Vitavax Power (0.2%), Bavistin 25SD (0.1%), Thiram + Carbendazim (0.3%) were tested by poisoned food technique *in vitro* and resulted cent per cent restriction of radial growth of *F. udum* up to 96 hrs. The results indicate that the antagonist effect on radial growth of *F. udum* was highest in *Pseudomonas fluorescens* (4.82 to 5.95mm) followed by *T. viride* (5.15 to 6.66mm) in comparison to check (81.00 to 90.00mm). The maximum inhibition was recorded at 10% concentration. The radial growth in plant extracts ranged from 2.32mm (Garlic bulb) to 6.15mm (Neem leaves) at 48 hrs of incubation period. The similar trends were also observed in 5% concentration of all incubation period.

Keywords: Pigeon pea, *Fusariumudum*, bio-agent, fungicide

Introduction
Pigeon pea (*Cajanus cajan* L. Millsp.) is one of the major pulse crops grown in the tropics and subtropics belonging to family Leguminaceae. It has wide adaptability and low input requirements mostly grown in *kharif* season. In India, the crop is mainly grown in Andhra Pradesh, Bihar, Uttar Pradesh, Karnataka, Gujarat, Madhya Pradesh, Maharashtra, Orissa and Tamil Nadu. In Uttar Pradesh, it is grown 311.0 thousand ha area producing 325.0 thousand tons, with an average yield of 1040 kg/ha (Anonymous, 2014) [1]. The poor yield of pigeon pea is mainly due to biotic stress like diseases and insect pests but only few of them like wilt, sterility mosaic, *Phytophthora* blight and *Alternaria* blight are major and destructive ones. Among fungal pathogens, wilt disease caused by *Fusarium udum* Butler is an important disease in India, Kenya, Malawi, Nepal, Tanzania and Uganda (Reddy *et al.*, 1990) [7]. In India, it is the most serious problem all over the pigeon pea growing states especially in U.P, M.P, Bihar and Maharashtra. In Bihar and Uttar Pradesh, 5-10 per cent losses in standing crop are common feature every year (Singh, 2006) [9]. Management of pigeon pea wilt through fungicides applied as soil treatment such as Thiram, Ferbam, Carbendazim and Copper oxychloride have been reported by different workers. In discriminate use of these chemicals has led to development of fungicide resistance strain and more importantly, environmental pollution, posing a potential risk to animal and human health. Hence, for minimizing the losses caused by wilt need inexpensive and environmentally safe management practices. It was therefore considered desirable to evaluate botanicals, bio-agents and fungicides against wilt pathogen for effective management.

Material and Methods
Pigeonpea plants showing characteristic symptoms of *Fusarium* wilt were collected from pigeonpea experimental field, Department of Genetics and Plant Breeding, NDUA&T, Kumarganj, Faizabad for isolation and identification. The infected plant parts were cut in to small pieces and surface sterilized with 0.1 per cent mercuric chloride solution and washed

Evaluation of pigeonpea genotypes against *Fusarium udum* butler under artificial epiphytotic condition

Neeraj Kumar Rajvanshi, Subhash Chandra and Ajay Kumar

Abstract
Wilt of Pigeonpea is a very destructive disease caused by fungus *Fusarium udum* Butler. In India, Pigeonpea crop suffers a great loss due to this disease. The use of resistant variety is one of the best methods of disease management. Therefore, studies were planned to search out the genotypes against *Fusarium* wilt through sick plot technique. Out of 130 genotypes screened, ten genotypes (ICP-8859, ICP8860, ICP8862, ICP8863, ICP89049 ICP12731, BWR254, BWR370, AWR74/15 and Banda Palera were found resistant, 22 moderately resistant, 26 tolerant, 30 moderately susceptible and 42 were highly susceptible to *Fusarium* wilt.

Keywords: Epiphytotic, *Fusarium,* genotypes, resistant

Introduction
Pigeonpea is one of the major grain legume crops grown in the tropics and subtropics and commonly known as Arhar, Tur, Redgram, Cangopea and Gandul, holds an important position in Indian subcontinent. It is a *kharif* season crop that has wide adaptability and low input requirements. The heavy shedding of leaves adds considerable organic matter in to the soil. Pigeonpea is the 4th ranked pulse crop in the world. In India, Pigeonpea is the 2nd most important pulse crop after chickpea. Besides India, it is also grown in South East Asia, Africa, and America. In India, production of Pigeonpea was 3.17mt, on area of 3.88 m ha with yield of 817 kg/ha (Anonymous, 2014) [1]. In India, the crop is mainly grown in Andhra Pradesh, Bihar, Uttar Pradesh, Karnataka, Gujarat, Madhya Pradesh, Maharashtra, Orissa and Tamilnadu. The poor yield of Pigeonpea is mainly due to biotic stress like diseases and insect pests. The maximum number of pathogen has been reported from India (Nene *et al.,* 1996) but only few of them like wilt is the most important, major and destructive ones.

The crop suffers heavily due to *Fusarium* wilt in the major growing areas resulting into huge production losses (Vishwa Dhar *et al.*, 2005). In India, it is the most serious problem all over the Pigeonpea growing states especially in U.P., M.P., Bihar and Maharashtra. In the epiphytotic conditions, disease incidence was recorded 15-25 per cent in general and up to 50 per cent (Butler, 1910). In Bihar and Uttar Pradesh, 5-10 per cent losses in standing crop are common feature every year (Singh, 2006). In discriminate use of chemicals for controlling the disease has led to development of fungicide resistance strain and more importantly, environmental pollution, posing a potential risk to animal and human health. Due to high cost and hazardous effect of used chemical pesticides from last thirty years are not valid today. Hence, for minimizing the losses caused by wilt need inexpensive and environmentally safe management practices.

Materials and Methods
Seeds of one hundred thirty genotypes of Pigeonpea were obtained from the Department of Genetics and Plant Breeding, N.D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) and IIPR, Kanpur. The genotypes were screened under artificial epiphytotic conditions (Sick plot technique) using the methods described by Nene *et al*., (1982) [5]. The plots (sick soil) showed over 90 per cent wilt incidence in susceptible cultivars (Bahar) of Pigeonpea were used for screening the test varieties. After germination, observations were

Abstract. Lentil rust incited by the fungus *Uromyces viciae-fabae* is a major impedance to lentil (*Lens culinaris* Medik.) production globally. Host-plant resistance is the most reliable, efficient and viable strategy among the various approaches to control this disease. In this study, 26 lentil genotypes comprising advanced breeding lines and released varieties along with a susceptible check were evaluated consecutively for rust resistance under natural incidence for two years and at five test locations in India. A heritability-adjusted genotype main effect plus genotype × environment interaction (HA-GGE) biplot program was used to analyse disease-severity data. The results revealed that, among the interactive factors, the GE interaction had the greatest impact (27.81%), whereas environment and genotype showed lower effects of 17.2% and 20.98%, respectively. The high GE variation made possible the evaluation of the genotypes at different test locations. The HA-GGE biplot method identified two sites (Gurdaspur and Pantnagar) as the ideal test environments in this study, with high efficiency for selection of durable and rust-resistant genotypes, whereas two other sites (Kanpur and Faizabad) were the least desirable test environments. In addition, the HA-GGE biplot analysis identified three distinct mega-environments for rust severity in India. Furthermore, the analysis identified three genotypes, DPL 62, PL 165 and PL 157, as best performing and durable for rust resistance in this study. The HA-GGE biplot analysis recognised the best test environments, restructured the ecological zones for lentil-rust testing, and identified stable sources of resistance for lentil rust disease, under multi-location and multi-year trials.

Additional keywords: disease resistance, ideal environments.

Introduction

Lentil (*Lens culinaris* Medik.) is a nutritionally rich, winter food legume crop that is grown in many countries (Negussie and Pretorius 2012; Kumar *et al.* 2016; Parihar *et al.* 2017*a*). The major geographical regions contributing to lentil production are the Americas (55.4%), Asia (36.8%), Africa (2.9%), Oceania (2.9%) and Europe (1.9%). Among countries, Canada, India, Turkey, USA, Nepal, Australia, Ethiopia and China have maximum share (FAOSTAT 2016). Significant improvement has been made in lentil cultivation in the recent past through use of conventional breeding. However, several biotic stresses such as Fusarium wilt, rust, Ascochyta blight, anthracnose and Stemphylium blight are serious constraints to lentil production in many parts of the world (Muehlbauer *et al.* 2006). Therefore, diseases have become major factors limiting yield and quality of lentil seeds. Of them, rust, a foliar disease incited by the fungus *Uromyces viciae-fabae* (Pers.) J.Schröt., is a widely distributed and economically important disease present in major lentil-growing regions such as South America, and countries such as India, Bangladesh, Ethiopia, Nepal, Morocco and Pakistan, and causing 25–100% yield loss under congenial conditions

Management of vascular wilt (*Fusarium Oxysporum* F.SP. *lentis*) of Lentil (*Lens Culinaria* Medic.) through botanicals and bioagents

Subhash Chandra, NK Rajvanshi, Ajay Kumar and Pankaj Kumar

Abstract
Lentil is an important pulse crop and plays very important role in the supply of the protein to under nourished vegetarian population of the country. *Fusarium* wilt of lentil caused by *Fusarium oxysporum* f. sp. *lentis* is one of the wide spread and destructive diseases in India under rice-based cropping system. Use of synthetic fungicides has led to the emergence of several problems like environment pollution, residual effect in grains and killing of non-target organism(s). Hence, for minimizing the losses caused by *Fusarium* wilt, four plant extracts such as Garlic, Neem, Eucalyptus, Tulsi and three antagonistic bio-agents *viz. Trichoderma viride, Trichoderma harzianum* and *Pseudomonas fluorescence* were evaluated. The disease incidence was not much reducing by Neem (40.50 %) and Tulsi (34.45 %) at 10 per cent concentration of 60 days after sowing. The same trends were also found in per cent disease reduction. However, per cent disease reduction in between Eucalyptus (25.50 %) and Garlic (28.00 %), Tulsi (34.45 %) was at par to each other. The Maximum per cent disease reduction was found in Eucalyptus (25.50 %) and Garlic (28.00 %), Lowering the disease incidence and higher per cent disease reduction was also found in *Trichoderma viride* (19.64 %) as compared to *Trichoderma harzianum* (35.50 %) and *Pseudomonas fluorescence* (28.43 %) at 10 per cent concentration of 60 days after sowing.

Keywords: fenugreek, hematological, *O. niloticus*, serum

Introduction
Lentil (*Lens culinaris* Medik.) is an important pulse crop and the second major source of dietary proteins (25%) after soybeans in human and animal diet (Rahman *et al*., 2010) [10]. In India, it is the extensively grown cool season legume crop next to chickpea in terms of quality and quantity (Khan *et al*., 2001) [6]. The crop is infected by a number of fungal plant diseases and out of which vascular wilt is the most devastating caused by several Fusarium species. It is recognized the most important factor in reducing lentil production (Saxena, 1993; Erskine *et al*., 2009) [1]. The wilt disease occurs either at early (seedling) crop stage or at reproductive (adult plant) stage (Stoilova & Chavdarov, 2006) [13]. Presently, lentil production in India is facing continuous decrease as a result of several biotic stresses including wilt (Subhani *et al*., 2007) [14]. A number of management strategies aiming at controlling wilt disease are in practice. The cultural practices like crop rotation is common, however, it is not much effective because the pathogen is of seed or soil-borne nature and can survive in soil for extended period of time. Botanicals and biological management are considered to be the effective in reducing the inoculum present in soil. Among biological control agents, *Trichoderma* species are considered the most effective against several fungal pathogens including *F. oxysporum* (Sarhan *et al*., 1999) [11]. These antagonists are saprophytic filamentous fungi, easily growing and produce conidia having long survival period in large quantities (Mohamed & Haggag, 2006) [8]. Therefore, it is essential to determine the variability in the pathogen regarding its host plant resistance for a successful lentil breeding plan and replacing the low yielding and disease susceptible lentil varieties with those of high yielding and disease resistance ones. Considering these facts, this study was carried out to evaluate the available lentil germplasm, botanicals and bio-control agents against the disease in order to identify sources of resistance, effective botanicals and bio-control agents soil application for the management of lentil wilt

Rust caused by *Uromyces viciae-fabae* is a major biotic constraint to field pea (*Pisum sativum* L.) cultivation worldwide. Deployment of host-pathogen interaction and resistant phenotype is a modest strategy for controlling this intricate disease. However, resistance against this pathogen is partial and influenced by environmental factors. Therefore, the magnitude of environmental and genotype-by-environment interaction was assessed to understand the dynamism of resistance and identification of durable resistant genotypes, as well as ideal testing locations for rust screening through multi-location and multi-year evaluation. Initial screening was conducted with 250 diverse genotypes at rust hot spots. A panel of 23 promising field pea genotypes extracted from initial evaluation was further assessed under inoculated conditions for rust disease for two consecutive years at six locations in India. Integration of GGE biplot analysis and multiple comparisons tests detected a higher proportion of variation in rust reaction due to environment (56.94%) as an interactive factor followed by genotype × environment interaction (35.02%), which justified the requisite of multi-year, and multi-location testing. Environmental component for disease reaction and dominance of cross over interaction (COI) were asserted by the inconsistent and non-repeatable genotypic response. The present study effectively allocated the testing locations into various categories considering their "repeatability" and "desirability index" over the years along with "discrimination power" and "representativeness." "Mega environment" identification helped in restructuring the ecological zonation and location of specific breeding. Detection of non-redundant testing locations would expedite optimal resource utilization in future. The computation of the confidence limit (CL) at 95% level

Evaluation of lentil genotypes against *Fusarium oxysporum* f. sp. *Lentis* under artificial epiphytotic condition

Subhash Chandra, Neeraj Kumar Rajvanshi and Ajay Kumar

Abstract
Wilt of lentil is a very destructive disease caused by fungus *Fusarium oxysporum* f. sp. *Lentis*. In India, lentil crop suffers a great loss due to this disease. The use of resistant variety is one of the best methods of disease management. Therefore, studies were planned to search out the genotypes against *Fusarium* wilt through sick plot technique. Keeping this point in view, one hundred fifty genotypes of lentil were tested for the resistance against *Fusarium oxysporum* f. sp. *lentis* in field condition. It is evident from the result presented in table 2 that out of 150 genotypes, 66 genotypes *viz.*; RLG-109, VL-138, IPL-316, LL-1136, K-75, RLG(105), PL-101, LL-1187, IPL-532, KLB-104, L-4704, IPL-529, LL-1135, KLS-107, IPL-531, DPL-62, IPL-318, SL-28, PLO-98, L-4702, IPL-219, RLG-112, L-4076, LH84-8, HPLC-649, L-1114, L1161, IPL-215, PLO-097, IPL-319, L-4076, DPL-15, IPL-526, IPL-220, VL-142, DL-11-5, IPL-531, KLS-113, VL-143, IPL-325, L-4588, LL-1231, L-4707, PL-129, IPL-325, IPL-324, PL-117, IPL-529, IPL-319, IPL-513, IPL-521, RLG-147, HUL-57, L-4688, L-4147, IPL-315, VL-134, NDL7-402, L-4076, VL-516, RLG-73, IPL-314, VL-133, VL-515, IPL-526, L-4589 and LH07-27 were found resistant, 37 genotypes were found moderately resistant, 34 genotypes were found moderately susceptible, 9 genotypes were found susceptible and 4 genotypes *viz.*; RVL-48, L-4590, HUL-57 and RLGF-109 were found highly susceptible. None of the genotypes was found immune against the disease.

Keywords: Epiphytotic, *Fusarium*, genotypes, resistant.

Introduction
Legumes occupy unique crops in the world by virtue of their high protein content (15-35), carbohydrates, fiber, minerals and nutrients in seeds and it have capability to fix atmospheric nitrogen in symbiotic association with root nodule bacterium (Rhizobium). According to the Indian Council of Medical Research optimum requirement of the pulses for person to maintain his health is 10 µg/days. However not even half of this quantity is available to the people. In India most of the population is primarily vegetarian pulses has a special place in the daily diet about (7-15%) of food grain, of people due to its high protein contents and several uses. India is a major pulse growing country of the world. During 1996-97 pulses occupied 71.4 million hectares of the world with a total production of 57 million tones and average yield of 806 kg /ha. (FAO, 1997), while in India pulses were grown on 1.60 million hectare with the production of 0.94 million tones and average yield 591 kg/ha (Anonymous, 2012) [1, 2]. Lentil (*Lens culinaris*) also known as masoor, is one of the important pulse crop after chickpea and pea among Rabi pulses. In India, it is grown 15 lakh /hectare. With production 9.5 tones' and productivity 633.33 kg/ha and mainly grown in U.P., Bihar, M.P. and West Bengal.
In Utter Pradesh it grown about 0.59 million/hectare with 0.41 million/tones production and productivity 695 kg/hectare (Source Department of Economics 2011-12). Lentil belongs to the order-Rosoles, sub orders- Rosneae, family-Leguminaceae and sub family-papilionaceae. In India, it is grown in winter season. Mostly lentil is grown in India as a rain fed crop by marginal formers in their marginal lands using their local seeds without any input like improved seeds, fertilizers, irrigation and pesticides and consequently economic return is poor. A number of factors are responsible for this low yield. Depredations by diseases are one of them.
The lentil crop is infected by a large number of pathogens such as fungi, bacteria, Virus & nematodes which significantly contribute to poor yields. Among the disease wilt, Anthracnose, Alternaria blight, Ascochyta blight, black root rot, gray mold, rust, powdery mildew and collar rot are important in different part of the country. In this region *Fusarium* wilt caused by *Fusarium oxysporum* f. sp. *lentis*, Rust caused by *Uromyces fabae*, Alternaria blight caused by *Alternaria alternate*, collar rot is caused by *Corticium rofsii* and powdery mildew is caused by *Erysiphe pisi* are widely distributed in Rabi season, The crop suffers heavily due to *Fusarium*

ABSTRACT

Fusarium wilt is major disease in Central India, the major chickpea growing state of country, Madhya Pradesh, Rajsthan, Uttar Pradesh, Jharkhand, Maharashtra, Bihar, Punjab, Haryana, Andhra Pradesh and Chhattisgarh. The disease is soil borne causing heavy loss, development of wilt resistant varieties is most effective means of controlling this disease. Highly resistant sources of wilt in lentil have not been reported from the Indian chickpea breeding programme. Fifty chickpea genotypes including one susceptible check were evaluated in green house against wilt, based on controlled condition - GL 0006, GL 10023, GJG 1208, Avrodhi, NDG 15-2, Udai, NDGK-99-9, NDG-13-14, NDG-13-21, NDG-54, Vijay, Vishal, JG-1 and PG-186 have been identified as highly resistant genotypes. These can be used in hybridization programme for wilt resistance breeding and studying the inheritance of wilt resistance in lentil.

Key words : *Fusarium oxysporum f.sp. ciceris, screening, resistant, susceptible*

Chickpea (*Cicer arietinum* L.) an important pulse crop, which belong to Fabaceae family, ranking third after dry beans (*Phaseolus vulgaris* L.) and dry pea (*Pisum sativum* L.) (1). India the large producer and consumer of pulse accounting for 35 per cent of world area and 25 per cent of the output in India (2). In India, total pulse had the area of 252.43 lakh ha. with production of 187.00 lakh tonnes. and productivity 741 Kg/ha. In India total chickpea had the area of 99.27 lakh ha. with production of 98.80 lakh tonnes and productivity 995 Kg/ha (3). It is grown in Madhya Pradesh, Rajsthan, Uttar Pradesh, Jharkhand, Maharashtra, Bihar, Punjab, Haryana, Andhra Pradesh and Chhattisgarh. However, six major states viz., Madhya Pradesh, Rajasthan, Maharashtra, Uttar Pradesh, Karnataka and Andhra Pradesh altogether contribute 91 per cent of the production and 90 per cent of the area. In U. P. chickpea is grown an area of 5.14 lakh ha. with production of 4.63 lakh ha. and productivity 901 kg /ha. (3). In inspite the barring efforts made by different agencies to boost up it is production. The total production and productivity per unit area is very low among the various factors responsible for yield one of the major factors is the chickpea caused by different pathogens. The pathogen of the disease is soil borne can survive in soil, even in the absence of its host, for six years. It is one of the major diseases of chickpea and at national level, the yield losses encountered was reported about 60 per cent (4). The pathogen of chickpea wilt disease is seed borne (5) as well as soil borne. In India, the incidence of this disease has been reported at seedling, flowering and podding stage at temperature 25°C ± 2°C. Disease management is required to ensure the stable chickpea production. The most sustainable and effective resolution to this problem is the development of resistant cultivars (6). Chickpea germplasm can be screened in field but field screening has limitations such as, confounding effect of drought and other root rot pathogens. While screening under controlled conditions in glasshouse is required. Stable resources are required for breeding wilt resistant varieties. Hence this study was carried out with specific objective of identifying lentil genotypes resistant to *Fusarium oxysporum* f.sp. *ciceris* through pot screening.

MATERIAL AND METHOD

Out of fifty genotypes of chickpea including one susceptible check (K-850) were obtained from the department of Genetics and Plant Breeding, Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Faizabad (U.P.). The genotypes were screened through sick pot techniques in glass house during 2016-17 crop season using the method which described by (7). The seeds were superficially sterilized in 3% sodium hypochlorite for 3 min, then washed in sterile water and then germinated in towel paper for 10 days. Inoculum of pure culture of *Fusarium oxysporum* f.sp. *ciceris*, isolated from naturally wilt infected lentil plants was used for multiplication. Single spore culture of *F. oxysporum* f.sp. *ciceris* was multiplied on 100 gm of 9:1 sand lentil meal medium for 15 days at 28±2°C. Two hundred gram of these inoculums was mixed well with 2.5 kg autoclaved soil and placed in one 25 cm plastic pots. The 10-day-old uprooted seedlings were washed under tap water to remove soil particles. Root tips approximately 1.0 cm long were cut to facilitate the entry of pathogen in to roots. The roots of the seedlings were then immersed in the spore suspension (5×10^6 conidia/ml) for 5 min to enable conidia to stick to the roots. Inoculated seedlings were transplanted into a mixture of equal parts of sterile soil, sand, peat and per liter which had been potted and pre-irrigated 2 days previously. Seedlings were irrigated after their planting in pots, and incubated at 25±2°C. The

Reaction of urdbean (*Vigna mungo*) genotypes against *Cercospora* leaf spot (CLS)

Subhash Chandra, Neeraj Kumar Rajvanshi, Popin Kumar, RM Tripathi and MP Chauhan

Abstract
The present investigation aimed to identify resistance in urdbean (Vigna mungo) against *Cercospora* leaf spot (CLS) in a field condition. The trial was conducted at Genetics and Plant Breeding Farm of Narendra Dev University of Agriculture and Technology, Kumarganj, Ayodhya. Forty six urdbean genotypes were screened in the summer season of the year of 2015- 2016. The severity of was recorded following 0-9 scale. The urdbean genotypes evaluated were grouped into different categories based on disease reaction. The present results indicated that genotype IPU 11-2, PU 10-23, KU 96-7, Pant U 19, TU 94-2, VBG 09-005, KPU 524-65, NIRB-004, DKU 11, Vamban 7, NDUK 13-6, CO 5, KUG 725, PU 10-16, NUL 7, Pant U 30, WBU 108, NIRB-003, Shekhar 3, NDUK 15-9, TU 67, VBG 12-062, RMG 353, IU 05-1, VBG 11-053, IPM 94-1, RUG 55 and TU 22 were resistant to CLS, 6 genotypes *viz*.; AKU 11-15, K 851, KU 96-3, LBG 645, NIRB-002, COBG 11-03 were exhibited moderately resistant, 05 genotypes *viz*.; LBG 623, MU 46, MU 44, KU 14-1, DBG 11 were showed moderately susceptible, 06 genotypes *viz*.; RUG 59, IPU 2-43, Pant U 31, KUG 479, IPU 13-1, KPU 129-104 were susceptible and only one genotype was highly susceptible. None of these genotypes was found free from infection. The urdbean genotypes which were found resistant the could be the choice for resistance against CLS.

Keywords: urdbean, *Cercospora*, *Vigna mungo*, CLS

Introduction
Pulses represent one of the most important foods that have been extensively used to cover basic protein and energy needs in day today life. Pulses have unique property of maintaining and restoring soil fertility through biological nitrogen fixation as well as covering and improving physical properties of soil by virtue of their deep root system. Urdbean or Blackgram (*Vigna mungo* L.) Hepper is the most important pulse crop of the *'vigna'* group. It is considered to have been domesticated in India from its wild ancestral form (*V. mungo* var. *Silvestris* Lukoki, Marechal & Otoul). Center of genetic diversity is found in India (Zeven and de Wet. 1982) [7]. It is an important crop of India and extensively grown over a wide range of agroclimatic zones of the country.

In India, urdbean occupies 4.50 m ha area, production 2.83 mt and productivity 628 kg/ha (Anonymous, 2018) [1]. Highest productivity of urdbean is reported from West Bengal followed by Andhra Pradesh and Uttar Pradesh. Urdbean is prone to several fungal diseases, among which *Cercospora* leaf spot (CLS) caused by *Cercospora* canescens. Eills and Mortin is one of the most important fungal disease of urdbean causing heavy yield losses particularly in Uttar Pradesh and Uttarakhand states. Disease is also reported from other states *viz*., Punjab, Haryana, Bihar, Rajasthan, West Bengal, Himachal Pradesh and Jammu & Kashmir (Saksena and Dwivedi, 1973) [6]. Previously *Cercospora* leaf spot was considered as minor disease. Due to change in cropping system and introduction of yellow mosaic resistant varieties it is becoming an important fungal disease and constraint in production of this crop. Resistance is fundamental attributes of all living systems. Host plant resistance (HPR) is the most efficient and ecofriendly means of management. For exploitation of HPR, reliable field and controlled environment screening techniques are essential. Therefore, the present investigation was undertaken with an objective to identify the sources of resistance in different genotypes of urdbean against *Cercospora* leaf spot.

Evaluation of mungbean [*Vigna radiate* (L.) Wilczek] genotypes for resistance against web blight

Subhash Chandra, Neeraj Kumar Rajvanshi, MP Chauhan and Mukesh Kumar

Abstract
Web blight (*Rhizoctonia solani*) of mungbean is a very destructive disease caused by fungus *Rhizoctonia solani*. In India, mungbean crop suffers a great loss due to this disease.Use of resistant genotypes is the best method of avoiding the occurrence of the disease. Keeping this point in view, fifty two genotypes of mungbean were tested for the resistance against web blight in field condition. Out of fifty two genotypes of mungbean were carried out under field condition of natural infection, where twenty nine genotypes *viz.*; BM 2012-09, Palampur 93/kulu-4, LGC 574, NUL 516, T-44, SGC 20, SML 1082 (SC), IPM 312-19, IGKM 06-42, VG 10-008, MH 921, ML 2412, PUSA 571, RMG 1082, PUSA 1472, ML 2410, ML 2333, COGG-912, KM 2348, AKM 12-17, IPM 312-20, GM 11-02, KM 2241, ML 818, HUM-1, CO6, LGG 460, IPM 02-3 and GM 04-02 were found resistant, five genotypes were recorded moderately resistant, thirteen genotypes were noticed moderately susceptible, four genotypes *viz.*; NVL 825, DUG 5, VBN 4, RMG 1028 were recorded susceptible. Only one genotype K-851was found highly susceptible.

Keywords: Evaluation, mungbean, web blight, *Vigna radiate*

Introduction
Mungbean (*Vigna radiata*) belongs to fabaceae family along with good sources of protein, carbohydrates and vitamins for mankind all over the world. Mungbean (*Vigna radiata* L.) is also known as mung, moong, mungo. In India, the name greengram is more commonly used than mungbean (Chatterjee and Randhawa, 1952) [3]. It is third most important pulse crop of India after chickpea and pigeonpea. Mungbean can grow in all three seasons in India, *viz.*, *Kharif* (July- Oct), *Rabi* (Sept- Dec) and summer (March- June). It is grown under rainfed condition during *Kharif* and on residual moisture during *Rabi* in eastern and southern part of the country. However, *Kharif* season crop occupies maximum area of its cultivation. Intercropping with sorghum, pearl-millet, maize, cotton, castor, pigeonpea etc., are popular. India alone contributes 54% of world production and covers 65% of the world acreage (Singh, 2011) [10]. It is grown in intercropping, catch cropping and relay cropping systems because of its short duration (less than 60 days). It is grown in intercropping, catch cropping and relay cropping systems because of its short duration (less than 60 days). In India, mungbean is grown in an area of 4.32 m ha with production of 2.17 m tones and productivity of 502 kg/ha. Important mungbean growing states are Rajasthan, Maharashtra, Karnataka, Andhra Pradesh, Odisha, Bihar, Tamil Nadu, Madhya Pradesh and Uttar Pradesh (Anon, 2018) [1].

Mungbean has been considered as "poor men's protein". It contains 26% protein, 51% carbohydrate, 4% minerals, 3% vitamins and 10% moisture (Khan, 1981) [7]. The standard worldwide yield of mungbean is very low (389kg/ha) and its production has not increased over the year. The main reason for low yield is the susceptibility of the crop to insects, weeds and diseases caused by fungus, virus and bacteria. Among these, the viruses are the most important group of plant pathogens affecting the production of the crop. They cause severe diseases and economic losses in mungbean and reducing seed yield and quality (Kang *et al.*, 2005) [6]. The crop is infected by a large number of pathogens consisting of (virus, bacteria, fungi and nematodes) which significantly contribute to poor yields. Among the diseases, Yellow mosaic, Web blight, Bacterial blight, Leaf crinkle, Powdery mildew, Cercospora leaf spot, Anthracnose and Macrophomina bight are important in different parts of the country which reducing the yield of mungbean heavily. Previously web blight was considered as minor disease.

Screening of mungbean [*Vigna radiate* (L.) Wilczek] genotypes for resistance against mungbean yellow mosaic virus (MYMV) under field condition

Subhash Chandra, Neeraj Kumar Rajvanshi, Popin Kumar, Mukesh Kumar and MP Chauhan

Abstract
Mungbean (*Vigna radiata* L.) is also known as mung, moong, mungo. In India it is third most important pulse crop after chickpea and pigeonpea. Mungbean is an important short duration grain legume which is grown in different parts of the country, for grain and green manuring. It is an outstanding source of easily digestible proteins with low flatulence, which balances the staple rice diet in Asia. Mungbean yellow mosaic disease (MYMD) caused by whitefly (*Bemisia tabaci*) transmitted mungbean yellow mosaic virus (MYMV) is an important constraint of mungbean in India. Use of resistant genotypes is the best method of avoiding the occurrence of the disease. Keeping this point in view, out of fifty two genotypes of mungbean were tested for the resistance against MYMV during *Kharif* 2015 in field condition. The per cent disease incidence (PDI) of MYMV among 52 mungbean genotypes was worked out up to ninth week after sowing and it varied from 0 to 79.68 %. Out of fifty two mungbean genotypes, five were found resistance, eight were moderately resistant, seventeen genotypes were recorded moderately susceptible and twenty two genotypes were noticed susceptible. Five genotypes namely, PM 10-18, PUSA 1371, BM 2012-09, DGGV-2 and MH 810 found resistant during present investigation which can be used for the development of mapping population for the development of MYMV resistant varieties.

Keywords: mungbean, genotypes, resistance and yellow mosaic virus

Introduction
Mungbean (*Vigna radiata* L.) is also known as green gram, green bean, moong, mash bean, golden gram and green soy (Saminathan 2013) [10]. In India, the name green gram is more commonly used than mungbean (Chatterjee and Randhawa, 1952) [2]. It is third most important pulse crop of India after chickpea and pigeonpea. Mungbean can grow in all three seasons in India, *viz*., *Kharif* (July- Oct), *Rabi* (Sept- Dec) and summer (March- June). It is grown under rainfed condition during *Kharif* and on residual moisture during *Rabi* in eastern and southern part of the country. New sources of resistance against *fusarium oxysporum* f.sp. *Udum* causing wilt of pigeonpea

Subhash Chandra, Neeraj Kumar Rajvanshi, Ajay Kumar, Popin Kumar and Kumari Punam

Abstract
Fusarium wilt is a serious disease in pigeonpea, which causes severe yield losses. The *F. udum* is host specific to pigeonpea and can survive in soil under wilted plant stubble for a long period. The best way of wilt management is by growing resistant varieties. Out of 51 germplasm, screened twelve germplasm *viz.*; AL 1932, BRG 5, CRG 2013-10, GRG 82, GRGK 1, ICP 8863, ICPHL 4989-7, KA 12-3, PT 257, PT 307-1, WRG 293 and ICP 8863 were found resistant, 21 moderately resistant, 2 tolerant, 11 moderately susceptible and 5 germplasm *viz.*; AKT 12-1, AL 1933, ICP 2376, KA 12-2, BAHAR 6424 were highly susceptible to *Fusarium* wilt.

Keywords: Pigeonpea, *Fusarium,* germplasm, resistant

Introduction
Pigeonpea [*Cajanus cajan* (L) Mills.] is major pulse crop grown component of pulses grown in the tropics and subtropics and belongs to family leguminosae. It commonly known as Arhar, Tur, Redgram, Cangopea and Gandul, holds an important position in Indian subcontinent. It possesses high protein content and is consumed in the form of split pulse as dal. It is a *kharif* season crop that has wide adaptability and low input requirements. The heavy shedding of leaves adds considerable organic matter into the soil. Pigeonpea is the 4th ranked pulse crop in the world. In India, Pigeonpea is the 2nd most important pulse crop after chickpea. Besides India, it is also grown in South East Asia, Africa and America. In India, production of Pigeonpea was 42.54 Lac tones on area of 44.31 Lac ha with yield of 960 kg/ha (Anonymous, 2018) [1]. In India, the crop is mainly grown in Andhra Pradesh, Bihar, Uttar Pradesh, Karnataka, Gujarat, Madhya Pradesh, Maharashtra, Orissa and Tamilnadu. The poor yield of pigeonpea is mainly due to biotic stress like diseases and insect pests. The crop is infected by 210 pathogens (83 fungi, 4 bacteria, 19 viruses and mycoplasma and 104 nematodes) reported from 58 countries. The maximum number has been reported from India with 98 pathogens (Nene *et al.,* 1996) [7], but only few of them like wilt, sterility mosaic, phytophthora blight and Alternaria blight are major and destructive diseases. Among these, wilt disease caused by *Fusarium udum* is the most serious problem all over the Pigeonpea growing states especially in U.P., M.P., Bihar and Maharashtra. The *F. udum* is host specific to pigeonpea (Patel *et al.*, 2011) [8] and can survive in soil under wilted plant stubble for a long period. In the epiphytotic conditions, disease incidence was recorded 15-25 per cent in general and up to 50 per cent (Butler, 1910) [3]. In Bihar and Uttar Pradesh, 5-10 per cent losses in standing crop are common feature every year (Singh, 2006) [11]. The best way of wilt management is by growing resistant varieties. For developing resistant varieties, resistant source are the basic requirements. Identification of resistant sources involves testing germplasm under heavy inoculum potential and under conditions conducive for maximum disease development. Sick plot technique has been reported for large scale screenings under field conditions and a sick soil technique (pot screening) for confirming resistance.

Materials and Methods
Seeds of fifty one germplasm of Pigeonpea were obtained from the Department of Genetics and Plant Breeding, N.D. University of Agriculture and Technology, Kumarganj, Ayodhya (U.P.) and IIPR, Kanpur. Entries were sown on the month of late june or early july in the uniform wilt plots with the onset of the man soon (rainy) season. The germplasm were screened under field condition (Sick plot technique) in RBD design with two replications using the methods described by Nene *et al.*, (1982) [6]. After germination observations were recorded regularly up to 60 days for the appearance of wilt symptoms and severity. The number of

Field evaluation of pigeonpea (*Cajanus cajan*) genotypes against fusarium wilt to disease resistance

Subhash Chandra, Neeraj Kumar Rajvanshi, Popin Kumar and Mukesh Kumar

Abstract
The pigeonpea germplasms/genotypes were evaluated to identify the sources of resistance to Fusarium wilt disease. The *F. udum* is host specific to pigeonpea and can survive in soil under wilted plant stubble for a long period. The best way of wilt management is by growing resistant varieties. Out of 54 screened genotypes, twenty one genotypes *viz.* BDN2001-6, BRG2-7, CORG2004-01, CORG990013, H2000-37, H2000-47, IPC7119, IPC8863, IPA14F, JKM186, JKM197, JKM204, JKM205, JKM209, KAWR11, KAWR91, NTL30, PT02-25, PT02-5, PT11-39, and PUSA2005-1 were found resistant, 15 moderately resistant, 13 tolerant, 4 moderately susceptible and 1 genotype were highly susceptible against fusarium wilt. The most susceptible variety Bahar showed 80 per cent wilting.

Keywords: Pigeonpea, *Fusarium,* germplasm, resistant

Introduction
Pigeonpea [*Cajanus cajan* (L.) Millsp.], also referred to as red gram or *arhar,* is a perennial shrub, with its centre of origin located in India. It is an important grain legume crop predominantly grown in the Indian subcontinent as an important source of dietary protein. In India, production of Pigeonpea was 42.54 Lac tones on area of 44.31 Lac ha with yield of 960 kg/ha (Anonymous, 2018) [1]. It is also cultivated in other parts of the world, including sub-Saharan Africa, Latin America, the Caribbean and South-East Asia. Its cultivation is increasing in semi-arid areas because of the crop's ability to thrive under prolonged drought and in degraded lands (Upadhyaya *et al*., 2012) [11]. The crop is mainly grown as annual using cultivars with different durations to maturity: 90 days (Short), 120 days (Medium) and 180 days (Long). It is cultivated as a perennial crop in several regions of India. The shift of pigeonpea cultivation from the traditional *kharif* season to pre *rabi* September sowing in north Bihar has not only shown an increased production potential of this important pulse crop but have also opened altogether a new possibilities in land use pattern of the rain fed areas of Bihar and adjoining states. Fresh pods are consumed as a vegetable; dried mature grains are used for cooking or in processing. Among the several factors responsible for reduction yield and quality deterioration of pigeonpea in India, diseases occupy a vital place. Among the diseases, wilt disease caused by *Fusarium udum* Butler, is the most destructive soil and seed born disease of pigeonpea in India leading to heavy production losses. The disease since been reported from Bangladesh, Ghana, Grenanda, Indonesia, Kenya, Malawi, Mauritius, Tanzania, Thialand, Trinida, Uganda and Zambia. In India it is the most serious problem all over the Pigeonpea growing states especially in U.P., M.P., Bihar and Maharashtra. In the epiphytotic conditions, disease incidence was recorded 15-25 per cent in general and up to 50 per cent (Butler, 1910) [2]. In Bihar and Uttar Pradesh, 5-10 per cent losses in standing crop are common feature every year (Singh, 2006) [10].

Materials and Methods
Seeds of fifty four genotypes of Pigeonpea were obtained from the Department of Genetics and Plant Breeding, N.D. University of Agriculture and Technology, Kumarganj, Ayodhya (U.P.) and IIPR, Kanpur. The genotypes were screened under artificial conditions (Sick plot technique) using the methods described by Nene *et al*., (1982) [5].

In vivo evaluation of bio agents, botanical and fungicides against *Fusarium oxysporum* f. sp. *basilica*

Rajendra Prasad, S.K. Pandey, Subhash Chandra, Neeraj Kumar Rajvanshi and Divya Singh

Abstract
The Holy Basil (*Ocimum sanctum* Linn.) commonly known as Tulsi, is an aromatic perennial plant, belongs to the family Liliaceae. It is native to Indian subcontinent and wide spread as a cultivated plant throughout the south-east Asian tropics. Holy Basil is widely grown in India for medicinal as well as religious purposes. For the management of wilt disease of Holy Basil (*Ocimum sanctum*) the experimental finding depicted in Table no.3 reveal that among 6 treatment which include three bio-agent T_1 *Trichoderma viride*, T_2 *Trichoderma harzianum* and T_3 *Pseudomonas fluorescence* and one botanicals T_4 Neem leaves and two chemicals T_5 Tebuconazole and T_6 Mancozeb. The most effective was Tebuconazole 250 EC @ 0.1% with percent disease control and percent disease intensité, (68.20) and (19.67) respectively. And Mancozeb 75WP @ 0.1%. With PDC and PDI (62.54) and (23.17), respectively where as the bio-agent *Trichoderma viride* Talc based formulation was prepared.cfu-1×10^9/gm and dissolved @ 10gm in 1.0 lit. Distilled water) with PDC and PDI (45.41) and (33.75), respectively. *Trichoderma harzianum* (Talc based formulation was prepared.cfu-1×10^9/gm and dissolved @ 10gm in 1.0 lit. distilled water) with PDC and PDI (37.02) and (38.94) respectively and *Pseudomonas fluorescence* @ 4 gm/kg seed with PDC and PDI (27.76) and (44.62) respectively. and Neem leaves @ 5% with PDC and PDI (16.98) and (51.53).The used fongicide and bio pesticide significantly reduce the wilt of *Ocimum sanctus*.

Keywords: Tulsi, *Pseudomonas fluorescence*, Tebuconazole

In vitro evaluation of bioagents, botanical and fungicides against *Fusarium oxysporum* f.sp. *baisilici*

Rajendra Prasad, SK Pande, Subhash Chandra, Neeraj Kumar Rajvanshiand and Manish Kumar Maurya

Abstract
The Holy Basil (*Ocimum sanctum* Linn.) commonly known as Tulsi, is an aromatic perennial plant, belongs to the family Lamiaceae. It is native to Indian subcontinent and wide spread as a cultivated plant throughout the south-east Asian tropics. Holy Basil is widely grown in India for medicinal as well as religious purposes. *In vitro* studies reveal that highest inhibition was observed in chemical fungicide Tebuconazole (91.81) followed by other fungicide Mancozeb (78.33) followed by bio-agents *Trichoderma viride* (74.82), *Trichoderma harzianum* (71.77) *and Pseudomonas fluorescence* (69.55) *and* one botanical Neem leaves (65.55) in respect to control. All the bio-agents produce toxic volatile metavolatile, which reduced the radial growth of the test fungus. That is *Fusarium oxysporum* f.sp.*baisilici* (7.50) Tebuconazole, Mancozeb (19.57) followed by bio-agents *Trichoderma viride* (22.62) *Trichoderma harzianum* (25.40) *and Pseudomonas fluorescence* (27.40) *and* one botanical Neem leaves (31.00).

Keywords: Tulsi, *Pseudomonas fluorescence,* Tebuconazole.

Screening of lentil genotypes against *Fusarium oxysporum* f. sp. *lentis* in field condition

Subhash Chandra, Mukesh Kumar, Neeraj Kumar Rajvanshi and Virendra Prasad Chaudhary

Abstract
Lentil (*Lens culinaris* Medik) is a member of Leguminosae family and it is commonly known as poor man's meat. Lentil wilt is a very destructive disease caused by fungus *Fusariumoxysporum* f. sp. *Lentis*. In India, lentil crop suffers a great loss due to this disease. The use of resistant variety is one of the best methods of disease management. Therefore, studies were planned to search out the genotypes against *Fusarium* wilt through sick plot technique. Keeping this point in view, one hundred forty three genotypes of lentil were tested for the resistance against *Fusariumoxysporum* f. sp. *lentis* in field condition, out of which 53 genotypes were found highly resistant, 35 genotypes were found resistant, 16 genotypes were found moderately resistant, 18 genotypes were found susceptible and 21 genotypes highly susceptible. None of these genotypes was found free from infection.

Keywords: Lentil, *Fusarium*, genotypes, resistant

Introduction

Lentil *(Lens culinaris* Medik) is a member of Leguminosae family and it is commonly known as poor man's meat. It has a high nutritional value and major source of dietary proteins (25%) after soybeans (Zia *et al.*, 2011) [8]. Lentil (*Lens culinaris* Medik L.) is the most important pulse crop in India and mostly grown in north east plain zone & central part of India. It is a diploid and self-pollinated crop which is grown in winter season and belonging to Order-Rosales, suborder- Rosneae, Family- Leguminaceae (fabaceae), subfamily- papilionaceae, genus- *Lens* and species- *culinaris* with chromosome number 2n=14. Among *rabi* pulses, lentil is next to chickpea. The total area under lentil in India was 1.49 m ha with a total production of 1.61 MT and 1006 Kg/ha productivity (Anonymous, 2018) [1]. In Uttar Pradesh, it is grown on 4.78 lakh hac. area with 4.47 lakh tones production and productivity 936 kg/ha (Anonymous, 2018) [1].

Lentil suffers from attack of a number of diseases such as vascular wilt; collar rots, root rot, stem rot, rust, powdery mildew downy mildew and fusarium wilt which are caused by *Fusarium oxysporum* f. sp. *lentis*. Average yield of lentil is low due to various diseases. Among the disease, foot and root rot of lentil caused by *Fusarium oxysporum* and *Sclerotium rolfisii* are common and the most serious disease in India. The fusarium wilt of lentil caused by *Fusarium oxysporum* f. sp. *lentis* is one of the most important and destructive disease in India wilt pathogen minimize crop yield and deteriorate the seed quality (Khare, 1991) [5]. The disease was first reported from Hungary but in India it was first observed in 1941 from Delhi and Karnal. If infection takes place in early stage the plant do not produced seeds, formed few in number when infection occurred in later stage. Wilt causes more damage at flowering and

ABSTRACT

Tomato crop affected by different fungal diseases in which Fruit rot known as target spot disease incited by *Sclerotinia sclerotiorum* is one of the most destructive disease. Disease severity varied (30.50 to 18.60%) in different locations of Kanpur. Highest disease severity was (30.50%) and the lowest disease severity (18.60%) was noticed at the farmer's field of Billhore, Kanpur. *Sclerotinia sclerotiorum* is a soil borne pathogen which causes symptoms on ripe fruits. Pathogen isolated from infected fruits. Copper oxychloride, Kavach, Tebucanazol, Andrachite, Dithane M-45, Metalaxyl, Roko and Bavistin completely suspected the growth of pathogen*in vitro*. Among eight fungicides, Tebuconazol, Andrachite, Metalaxyl, Roko, and Bavistin were found effective against pathogen under *in vitro* and *in vivo* conditions. However, seven bio-agents (*Trichoderma* spp.), *T. koningii*, *T. virens*are found effective in bothconditions. *In vitro* eight fungicides were tested against pathogen in which Metalaxyl, Roko, Tebucanazol, Andrachite and Bavistin showed 100% growth inhibition. Seven bio-agents (*Trichoderma*spp.) were tested *in vitro* while, among them *T. koningii* showed maximum inhibition followed by *T. virens*, *T. longibrachiatum*, *T. atroviridae*, *T. asperallum*, *T. viridae* and *T. reesei*, respectively. Eight treatments were applied *in vivo* for disease management however, among them T_6 (*Bacillus subtilis* + bavistin) recorded the minimum disease incidence and maximum fruit yield.

Introduction

Sclerotinia sclerotiorum (Lib.) is a serious fungus affecting yield and product quality of many susceptible hosts. It is a widespread soil borne plant pathogen with an extremely wide host range of more than 400 plant species including many of economic importance (Gao *et al.*, 2014). *S. sclerotiorum* is responsible for more than 60 plant diseases (Purdy, 1979). The pathogen produces sclerotia, which survive for long periods and attackroots of growing and mature plants, resulting in root rot, basal stemcanker, and wilt (Duncan *et al.*,

Efficacy of seed dresser fungicides, botanicals and bioagents against *fusarium oxysporum* f. sp. *Lentis in vivo.*

Subhash Chandra, Mukesh Kumar, Neeraj Kumar, Rajvanshi, Virendra Prasad Chaudhary and SKS Rajpoot

Abstract
Lentil (*Lens culinaris* Medik) is a member of Leguminaceae family and it is commonly known as poor man's meat. Lentil suffers from attack of a number of diseases such as vascular wilt; collar rots, root rot, stem rot, rust, powdery mildew downy mildew and fusarium wilt which are caused by *Fusarium oxysporum* f. sp. *lentis*. The highest per cent disease control was found in T_8 Metalaxyl 8% + Mancozeb 64% + Neem leaf extract + *P. fluorescens* (87.75%) followed by T_6 Metalaxyl 8% + Mancozeb 64% + *P. fluorescens* (81.54%), T_7 Metalaxyl 8% + Mancozeb 64% *T. harzianum* (79.62%) T_5 Metalaxyl 8% + Mancozeb 64% Neem leaf extract 10% (73.88%), T_1 Metalaxyl 8% + Mancozeb 64% (71.50%), T_3 *P. fluorescens* (68.83%), T_4 *T. harzianum* (66.88%) and T_2 Neem leaf extract 10% (64.68%). as compared to T_9 control (0.0).

Keywords: Lentil, fusarium, fungicides, evaluation, neem

Introduction
Lentil (*Lens culinaris* Medik) is a member of Leguminaceae family and it is commonly known as poor man's meat. It has a high nutritional value and major source of dietary proteins (25%) after soybeans (Zia *et al.,* 2011) [10]. Lentil (*Lens culinaris* Medik L.) is the most important pulse crop in India and mostly grown in north east plain zone & central part of India. It is a diploid and self-pollinated crop which is grown in winter season and belonging to Order-Rosales, suborder-Rosnee, Family-Leguminaceae (fabaceae), subfamily- papilionaceae, genus-*Lens* and species- *culinaris* with chromosome number 2n=14. Among *rabi* pulses, lentil is next to chickpea. The total area under lentil in India was 1.49 m ha with a total production of 1.61 MT and 1006 Kg/ha productivity (Anonymous, 2018) [1]. In Uttar Pradesh, it is grown on 4.78 lakh hac. Area with 4.47 lakh tones production and productivity 936 kg/ha (Anonymous, 2018) [1].

Lentil suffers from attack of a number of diseases such as vascular wilt; collar rots, root rot, stem rot, rust, powdery mildew downy mildew and fusarium wilt which are caused by *Fusarium oxysporum* f. sp. *lentis*. Average yield of lentil is low due to various diseases. Among the disease, foot and root rot of lentil caused by *Fusarium oxysporum* and *Sclerotium rolfisii* are common and the most serious disease in India. The fusarium wilt of lentil caused by *Fusarium oxysporum* f. sp. *lentis* is one of the most important and destructive disease in India wilt pathogen minimize crop yield and deteriorate the seed quality (Khare, 1991) [6]. The disease was first reported from Hungary but in India it was first observed in 1941 from Delhi and Karnal. If infection takes place in early stage the plant do not produced seeds, formed few in number when infection occurred in later stage. Wilt causes more damage at flowering and pod formation stage of the crop. *Fusarium oxysporum* f. sp. *lentis*. Infection range from 25-95 % depending on the cultivars tested. Lentil wilt caused by *Fusarium oxysporum* f. sp. *lentis* is a major disease in lentil growing areas in the country reported that the annual yield losses 10-15 % due to this disease alone which valued approximately Rs. 2000-2500 crores by (Chaudhary and Amarjit, 2002) [2].

Resistant sources are available against wilt disease of lentil but they are unstable. At present wilt is being managed by using fungicide through seed and soil treatment. However, fungicides are more costly and pollutant to environment. Many plant extract are known to have antifungal activity. Therefore, keeping in view the importance of the crop, seriousness of the disease, non-availability of suitable management practices and gaps in our knowledge

Comparison among botanicals, bio-agents and chemical control against *fusarium oxysporum* f. sp. *ciceris in vitro*

Subhash Chandra, Mukesh Kumar, Neeraj Kumar Rajvanshi and Virendra Prasad Chaudhary

Abstract
Chickpea (*Cicer arietinum* L.) is one of the most important pulse crops, so far its acreage and production is concern. Chickpea has been well recognized for source of protein, nutritive value where majority of the population of India depend on the low priced food for meeting its dietary requirements. The disease is caused by *Fusarium oxysporum* f. sp *ciceris*. Fungicides used for disease management caused by pathogens are known to pollute the environment, soil and water resulting deleterious effects on human health and biosphere. In present investigation, extracts of five plant species namely, Neem (*Azadirachta indica*), Garlic (*Allium sativum*), Onion (*Allium cepa*), Zinger (*Zingiber officinale*), two bioagents *Trichoderma viride*, *T. harzianum* along with two fungicides Carbendazim and Thiram were evaluated for fungi toxicity against *Fusarium oxysporum* f. sp. *ciceris*. The results clearly showed that all fungicides were effective against pathogen to inhibit mycelial growth *in vitro* conditions. Plant extracts and bioagents also more or less inhibited mycelial growth of *Fusarium oxysporum* f. sp. *ciceris in vitro* conditions.

Keywords: Botanicals, bioagents, fungicides, *fusarium oxysporum* f. sp. *ciceris*

Introduction
Chickpea (*Cicer arietinum* L.) commonly known as Gram or Bengal gram belong to the family Fabaceae is an important *Rabi* season pulse crop in India. It is the world's third most important pulse crop, after dry beans (*Phaseolus vulgaris* L.) and dry peas i.e. *Pisum sativum* L. (Vishwadhar and Gurha, 1998) [10]. In India, total pulse had the area of 31.11 mha with production of 24.51 mt. and productivity 788 Kg /ha. In India total chickpea had the area of 10.76 mha with production of 11.16 mt. and productivity 1037 Kg /ha (Anonymous, 2018) [1, 2] However, six major states *viz*., Madhya Pradesh, Rajasthan, Maharashtra, Uttar Pradesh, Karnataka and Andhra Pradesh altogether contribute 91 per cent of the production and 90 per cent of the area. In Uttar Pradesh, chickpea is grown an area of 562 thousand ha with production of 626.00 thousand ton and productivity 1114 kg /ha. (Anonymous, 2018) [1, 2].
The total production and productivity per unit area of chickpea is very low. Among the various factors, different pathogens responsible for yield losses of chickpea. Wilt is one of the major diseases of chickpea at national level; the yield losses encountered was reported about 60 per cent (Singh *et al*., 2007) [9]. Wilt disease of chickpea caused by *Fusarium oxysporum* f. sp. *ciceris* is a complex and destructive in nature. The genus *Fusarium* had many soil borne species which were distributed worldwide and known as plant pathogens since a long time ago. In order to overcome to this disease, a laboratory experiment was conducted to know the efficacy of botanicals and bio-agents against *Fusarium oxysporum* f. sp. *ciceris*.

Materials and Methods
The efficacy of various plant extracts against *Fusarium* wilt of chickpea *viz*., Neem leaves extract (*Azadirachta indica)*, Garlic bulb extract (*Allium sativum)*, Tulsi leaves extract (*Ocimum sanctum*), Onion bulb extract (*Allium cepa*), Zinger rhizome extract (*Zingiber officinale*), two botanicals *Trichoderma viride, Trichoderma harzianum* and two fungicides Carbendazim and Thiram were used. Fresh leaves, rhizomes and bulb were collected and washed thoroughly in clean water. 100 gram of each washed plant material was grinded in pestle and mortar by adding equal amount (100 ml) of sterilized water (1 : 1 v/v) and heated at 80°C for 10 minutes in hot water bath. The materials was filtered through double layered muslin cloth followed by filtering through sterilized Whatman No.1 filter paper and treated as standard plant extract (100%). To study the inhibitory effect of botanicals on mycelial growth

Effect of post-harvest treatments on physiological loss in weight and fungal spoilage of Langra mangoes (*Mangifera Indica* L.) during storage

Kumari Punam, Subhash Chandra, Virendra Prasad Chaudhary, Neeraj Kumar Rajvanshi and Ujjal Kumar Ghosh

DOI: https://doi.org/10.22271/chemi.2021.v9.i1d.11562

Abstract
The effect of calcium salts (calcium nitrate and calcium chloride) and Gibberellic acid on physiological loss in weight (PLW %), spoilage loss (%), economic life (days) and intensity of rotting of fruits during storage of Langra mangoes was studied. The fruits were treated with $Ca(NO_3)_2$ at the concentration of 1,2 and 3 per cent, $CaCl_2$ at the concentration of 1,2 and 3 per cent and GA_3 at the concentration of 50, 100 and 150 ppm. Untreated fruits served as the control. All treatments exhibited significant reduction in PLW and spoilage loss, increased economic life and delay in the onset of pathogenic invasion. At end of experiment, GA_3 100 ppm and $Ca(NO_3)_2$ at 2 per cent proved most promising treatment in these regards and were able to restrict the PLW at 17.86and18.33, Spoilage at 12.00 and 12.65 per cent respectively which was recorded 49.87 and 38.76 per cent respectively in case of control. The economic life under these treatments was 15 and 12 days in comparison to 6 days under control. These treatments were also proved excellent in restricting the invasion of pathogen up to 12th day of storage whereas fruits under control were found heavily infected on this day. The microorganism associated with the decay was identified as *Aspergillus niger*.

Keywords: Mango, Langra, Calcium nitrate, Calcium chloride, GA_3, PLW, Spoilage, Economic life, *Aspergillus niger*

Introduction
Mango (*Mangifera indica* L.), the king of fruits belongs to the family Anacardiaceae. Among the fruits of universal importance, mango is placed on top and is the most popular fruit among millions of people. Mango is fifth widely produced fruit crop of the world after bananas, apples, grapes and oranges. Mango is grown throughout the length and breadth of the country except the temperate and arid regions. The number one mango producing country in the world is India. It contributes approximately 50% of the global mango supply. In India, during 2015-16, it was grown in an area of 2.209 million hectares with a production of 18.643 million tonnes and productivity of 8.4 tonnes/hectare (Anonymous, 2017) [1].

Mango fruit has been found rich source of carbohydrate, minerals and vitamins having moisture 73.0 to 86.7 per cent, carbohydrate 11.6 to 24.3 per cent, protein 0.3 to 1.0 per cent (Kumar, 1999) [3, 10-13]. Among the cultivated varieties of Bihar, the variety Langra is most famous and is one of the most popular cultivars of India (Khara *et al*, 2016) [9]. In domestic market this variety has good demand and is able to fetch highest price in the market of Bihar. However, owing to its highly perishable nature and below average keeping quality, export potential of this variety is yet to be capitalised.

Mango showed highly prominent post-harvest loss because of its high perish ability and climacteric pattern of respiration. This massive reduction in weight of fruits during storage is also very common in mango. The possible cause of weight loss is assigned to moisture loss by process of evapo-transpiration and respiration. As estimated by Lashley (1984) [14], approximately 30 to 50% fruits go waste during post-harvest handling, storage and ripening. Singh *et al.* (1998) [19, 22-24] reported that in India, post-harvest loss of fresh mango fruits due to microbial decay varies from 20-33%.Therefore, a critical examination becomes imperative to prolong the shelf life of the fruits and to know the causes and remedies of post-harvest losses in fresh fruits in order to save the interest of farmer's community and consumers as well.

Effect of post-harvest treatments on quality attributes like total soluble solids, total sugar and reducing sugar of langra mangoes (*Mangifera indica* L.) during storage

Kumari Punam, Subhash Chandra, SKS Rajpoot, Manish Maurya, Rajan Kumar and Ujjal Kumar Ghosh

DOI: https://doi.org/10.22271/chemi.2021.v9.i1d.11581

Abstract
The effect of calcium salts (calcium nitrate and calcium chloride) and Gibberellic acid on quality attributes and consumer's acceptability of Langra mangoes during storage was examined. The fruits were treated with $Ca(NO_3)_2$ at the concentration of 1, 2 and 3 per cent, $CaCl_2$ at the concentration of 1, 2 and 3 per cent and GA_3 at the concentration of 50, 100 and 150 ppm. Water treated fruits were taken as control. Data were recorded in respect of TSS, reducing sugars and total sugars under influence of these treatments. All treatments were found effective in maintaining the higher level of these quality attributes of fruits during entire course of the experiment. At end of trial, $Ca(NO_3)_2$ at 2% was proved as the best treatment in respect of TSS, reducing sugars and total sugars and was able to maintain the level of these up to 24.32%, 9.00% and 20.05% respectively.

Keywords: Mango, langra, calcium nitrate, calcium chloride, Ga_3, TSS, reducing sugar, total sugar

Introduction
Mango (*Mangifera indica* L.) is a tropical, climacteric fruit that is very popular among million of peoples world-wide. Mango, the king of fruits belongs to family Anacardiaceae. Mango is fifth widely produced fruit crop in the world after banana, apple, grape and orange. India ranks first in term of production in the world. It contributes approximately 50% of the global mango supply. In India, during 2015-16, it was grown in an area of 2.209 million hectares with a production of 18.643 million tonnes and productivity of 8.4 tonnes/ hectare (Anonymous, 2017) [2].

Nutritionally, it contains β carotene, β cryptoxanthin, vitamin C, and dietary fibre (Pal, 1998) [12] as well as soluble sugars and various minerals used as good sources of nutrition, and are readily available and easily assumable in human body (Singh *et al.*, 2000) [1, 18, 19]. Approximately 30-50% fruits wasted during postharvest handling, storage, and ripening. Among the fruits mango manifested high postharvest losses because of its high perishability and climacteric pattern of respiration. Mango always decays after harvest, and postharvest losses can be minimized by applying improved storage technology and prolonging the shelf life of fruits. Among the cultivated varieties of Bihar, the variety Langra is most famous and is one of the most popular cultivars of India (Khara *et al*, 2016) [4]. In domestic market this variety has good demand and is able to fetch highest price in the market of Bihar. However, owing to its highly perishable nature and below average keeping quality, export potential of this variety is yet to be capitalised.

Earlier efficacy of pre and post-harvest applications of certain chemicals and growth hormones in maintaining the quality of fruits during storage has been established. Gibberellins as a pre-harvest spray was reported as an efficient growth regulator in enhancing fruit storability and marketability through its action on cell juvenility and retardation of senescence, fruit coloration and softness (Macleod and Millar, 1962) [9]. Post-harvest spray of calcium increases the productivity of mango due to reduction of abscission and it enhances the fruit quality by increasing the fruit firmness and by maintaining the turgidity of middle lamella cells (Ranjan *et al.*, 2005) [17]. Fruits storability was also improved by $CaCl_2$ under cold storage (Ahmed *et al.*, 2000) [1]. Low fruit calcium levels have been associated with reduced post-harvest life and physiological disorders. Pre-harvest sprays of calcium compounds and GA_3 significantly

Lentil wilt caused by *Fusarium oxysporum* f. sp. *lentis* is an important disease and it is a limiting factor to production of lentil. The present study to evaluate the antifungal activity of fungicide, botanicals through food poison technique and bio-agents through dual culture. Results revealed that minimum radial growth was obtained at 500ppm and 1000ppm in metalaxyl 8% + mancozeb 64% (00.00) followed by Neem leaf extract @ 10% (10.90 mm) having per cent inhibition (75.78%), Garlic @ 10% (11.00mm, 75.56%), Onion @ 10% (11.60mm; 74.22%), Neem leaf extract @ 5% (12.4mm; 72.45%). Among bio-agents, *P. fluorescence* showed maximum per cent inhibition (78.92%) followed by *T. viride* (66.82%), *T. harzianum* (60.76%), *B. subtilis* (58.94%), *T. virens* (55.62%).

Introduction

Lentil *(Lens culinaris* Medik) is a member of Leguminaceae family. It has a high nutritional value and major source of dietary proteins (25%) after soybeans (Zia *et al.*, 2011). In India, most of the population is primarily vegetarian. Pulses have a special place in the daily diet of people due to its high protein contents and several uses (Ali and Mishra, 2000). Major lentil growing states in India are Madhya Pradesh (42.50%), Uttar Pradesh (31.25%), West Bengal (9.38%) and Bihar (8.75%). In India, lentil was grown in 1.49 mha with production of 1.61 mt with an average production of 1006 kg/ha (Anonymous, 2018).

Lentil crop is affected by many fungal diseases. Among them *Fusarium* wilt caused by *Fusarium oxysporum* f. sp. *lentis* is one of the major soil borne disease causes an economic loss all over the world (Bayaa *et al.*, 1998 and Taylor, 2007). *Fusarium oxysporum* f. sp. *lentis* infection range from 25-95 per cent depending on the cultivars

ABSTRACT

Lentil is affected by the wilt disease caused by fungus *Fusarium oxysporum* f. sp. *lentil* which causes an economic yield loss. The fungus seed and soil borne in nature and reported from almost all lentil growing areas where this crop is grown. The present study is carried out to find the resistant sources against Fusarium wilt of lentil. 100 genotypes were screened under glass house condition. The genotypes were categorized into Highly resistant (25 genotypes) resistant (11 genotypes), moderately resistant (19 genotypes), susceptible (23 genotypes) highly susceptible (22 genotypes) reaction against the pathogen. Twenty five genotypes were found highly resistant namely, PL 269, PL 4, Pant L – 8(PL 063), PL 252, PL 276, L 4717, LH 84-8, LL 1525, IPL 220, IPL 238, IPL 540, IPL 342, IPL 344, IPL 233, IPL 81, IPL 234, DPL 15, VL 152, VL 156, VL 531, VL 532, VL 157, KLB-1442, KLS 1451, RKL 14-112.

Introduction

Lentil (*Lens culinaris* Medik) ranks third in the world after chickpea and pea (FAO 2015). It is an annual, autogamous, diploid crop (2n=14) and self pollinated crops. Lentil also known as 'Poor man's meat' as it is rich in nutrients, include 60-67% carbohydrates, 20-36% protein, <4% lipid, and 2-3% ash on dry weight basis (Bhatty, 1988). It is widely used in a range of dishes and reputed to have many uses in traditional medicine (Yadav *et al.*, 2007). Major lentil growing states in India are Madhya Pradesh (42.50%), Uttar Pradesh (31.25%), West Bengal (9.38%) and Bihar (8.75%). In India, lentil was grown in 1.49 mha with production of 1.61 mt with an average production of 1006 kg/ha (Anonymous, 2018).

Abstract

The Holy Basil (*Ocimum sanctum* L.) commonly known as Tulsi, is an aromatic perennial plant, belongs to the family Lamiaceae. It is native to Indian subcontinent and wide spread as a cultivated plant throughout the south-east Asian tropics. Holy Basil is widely grown in India for medicinal as well as religious purposes. *In vitro* studies revealed that highest inhibition was observed in chemical fungicide Tebuconazole (91.81) followed by other fungicide Mancozeb (78.33) followed by bio-agents *Trichoderma viride* (74.82), *Trichoderma harzianum* (71.77) and *Pseudomonas fluorescence* (69.55) and one botanical Neem leaves (65.55) in respect to control. All the bio-agents produce toxic volatile met-volatile, which reduced the radial growth of the test fungus.

Keywords: Holy Basil, *Fusarium oxysporum* f. sp. *baisilici*, Evaluation, Tulsi

Introduction

The Holy Basil (*Ocimum sanctum Linn.*) commonly known as Tulsi, is an aromatic perennial plant, belongs to the family Lamiaceae. It is native to Indian subcontinent and wide spread as a cultivated plant throughout the south-east Asian tropics. Holy Basil is widely grown in India for medicinal as well as religious purposes. There are many species of Basil such as *Ocimum sanctum* L. (Tulsi), *Ocimum gratissimum* (Ram Tulsi), *Ocimum canum sims* (Dulal Tulsi), *Ocimum baisilicum* (Ban Tulsi), *Ocimum kilimandscharicum Gureke* (Camphor Basil) *and Ocimum americanum* Linn (Hoary Basil) among them holy Basil *(Ocimum sanctum)* has been well known for its therapeutic potential (Prakash and Gupta, 2005). The chemical constituents present in *Ocimum sanctum* are Oleanolic acid, Ursolic acid, Rosmarinic acid, Eugenol, Carvacrol, Linalool and β-caryophyllene, β-elemene (Kothari *et al*., 2004).

Screening of mungbean [*Vigna radiata* (L.) Wilczek] genotypes for resistance against Cercospora leaf spot under field conditions

Rahul Singh Raghuvanshi, Subhash Chandra, Abhishek singh, Shiv Pratap Singh, Vivek Singh and Neeraj Kumar Rajvanshi

Abstract
Mungbean (*Vigna radiata* L.) is also known as mung, moong, mungo. In India it is third most important pulse crop after chickpea and pigeonpea. Mungbean is an important short duration grain legume which is grown in different parts of the country, for grain and green manuring. It is an outstanding source of easily digestible proteins with low flatulence, which balances the staple rice diet in Asia. The mungbean crop is infected by a large number of pathogens such as fungi, bacteria, virus and nematodes in which mungbean Cercospora leaf spot causes significantly losses. Use of resistant genotypes is the best method of avoiding the occurrence of the disease. Keeping this point in view, one hundred genotypes of mungbean were tested for the resistance against Cercospora leaf spot during *Kharif* 2019 in field condition. Out of total test entries screened 2 genotypes *viz*., SKNM 1502, COGG 13-39 were found highly resistant.

Keywords: leaf spot, cercospora, mungbean, *Vigna radiate* (L.) Wilczek

Introduction
The mungbean (*Vigna radiata* L., Wilczek), alternatively known as the green gram, maash or mungbean, Sanskrit mudga, is a plant species in the legume family. Mungbeans are one of many species recently moved from the genus *Phaseolus* to *Vigna*. The disease starts appearing about 30 days after sowing, depending upon day and night temperature and relative humidity. The main symptom of this disease is formation of angular lesions, on leaves which are grey to brown with radish brown margin. Similar spots also occur on branches and pods. The numbers of leaves spots are more but smaller in case *Cercospora canescens* than *Cercospora cruenta*. In severe case the spots are coalesce and leave are looks like burn. The fungus causes severe leaf spotting and defoliation at the flowering and pod formation. Disease also causes reduction in pod size and grain yield.

Methods and Materials
Seeds of mungbean genotypes were obtained from Indian Institute of Pulses Research, Kanpur and Pulse Section. The field experiment was conducted at Department of Genetics and Plant Breeding, A.N.D. University of Agriculture and Technology. Kumarganj, Ayodhya. Total one hundred genotypes (Table 1) were evaluated in R.B.D. with three replications during *Kharif* season of 2019. Two rows of 4m length spaced 30 cm apart with plant to plant distance of 15 cm., After every genotypes, one row of Kopergoan (*Cercospora* leaf spot susceptible variety of mungbean) was planted and the experimental plot was also surrounded by two rows of Kopergoan to ensure uniform spread of the disease. Observations on disease severity were recorded at 15 days interval, starting with first appearance of symptoms till the maturity of crop using 1-9 rating scale of Mayee and Datar (1986). After germination, observations were recorded regularly up to 30 days for the first appearances of the disease *i.e.* Cercospora leaf spot. The disease was recorded by using 1-9 scale as described in.

Reaction of mungbean [*Vigna radiata* (L.) Wilczek] genotypes against web blight caused by *Rhizoctonia solani* (Kuhn)

Abhishek Singh, VP Chaudhary, Subhash Chandra, Vivek Singh, Rahul Singh Raghuvanshi and Neeraj Kumar Rajvanshi

Abstract
The present investigation aimed to identify resistance in Mungbean [*Vigna radiata* (L.) Wilczek] against Web blight caused by *Rhizoctonia solani* (Kuhn) in a field condition. The trial was conducted at Genetics and Plant Breeding Farm of Acharya Narendra Dev University of Agriculture and Technology, Kumarganj, Ayodhya. One hundred genotypes were screened in the summer season of the year of 2019-2020. The severity of was recorded following 0-9 scale. The Mungbean genotypes evaluated were grouped into different categories based on disease reaction, out of one hundred genotypes were screened for their reaction to web blight (*Rhizoctonia solani*) in the field in field condition. It is clear that out of total test entries screened. One genotype *viz.*, Pusa 1771 was found resistant, while three genotypes *viz.*, Pant M-6, VGG16-055, KMP17-19, were recorded moderately resistant. While twenty three genotypes were noticed moderately susceptible. Twenty two genotypes were found susceptible and twenty one genotypes were documented susceptible. As well as twelve were found highly susceptible. While two genotypes *viz.*, K 851, AKM 12 – 28 were noticed highly susceptible. None of these genotypes was found free from infection. The Mungbean genotypes which were found resistant the could be the choice for resistance against Web blight caused by *Rhizoctonia solani* (Kuhn).

Keywords: Web blight, *Rhizoctonia solani* (Kuhn), Mungbean, *Vigna radiata* (L.) Wilczek

Introduction
Pulses constitute an important ingredient of the predominantly vegetarian diet in Indian. Besides being rich in protein, they also play an important role in sustainable agriculture by enriching the soil through biological nitrogen fixation. These crops lit in various cropping system without disturbing the main crops. Pulses are the main source of protein particularly for vegetarians and contribute about 14 percent of the total protein of an Indian average diet. Production of pulses in the country is far below the requirement to meet even the minimum level of per capita consumption. According to Indian Council of Medical Research (ICMR) optimum requirement of the pulse for a person to maintain his normal health is 104 g per day. However, not even half of this quality is available to people, which is causing malnutrition among the growing people. Therefore, it is necessary that agricultural scientists should evolve the strategy of increasing the production of pulses to meet the protein requirement of increasing population of the country.

Mungbean [*Vigna radiata* (L.) Wilczek] is primarily a rainy season crop but with the development of early maturing varieties, it has also proved to be an ideal crop for spring and summer season. Mungbean is an excellent source of protein (24.5%) with high quality of lysine (460 mg/g N) and tryptophan (60 mg/g N). It has also remarkable quantity of ascorbic acid when sprouted and also contains riboflavin (0.21 mg/ 100 gm) and minerals (3.84 g/100g). Mungbean, being a short duration crop, it is suitable in various multiple and inter-cropping systems. After picking of pods, mungbean plants may be used as green fodder or green manure. Beside these, the crop also enriches soil by fixing atmospheric nitrogen. Among the pulses, mungbean [*Vigna radiate*: (L) Wilczek] also known as green gram or golden gram is one of the most important short duration pulse crops of India and grown in kharif, spring and summer seasons. Mungbean plant possess deep root system which binds soil particles and thus prevent soil erosion. Mungbean is mainly used as dehulled grain, hulled (dal), husked and dehusked dal. Soaked and sprouted grains are used as salad. It is also used for various culinary purposes.

Efficacy of botanicals and bio-agents against web blight caused by *Rhizoctonia solani* (Kuhn) of Mungbean *in vitro*

Abhishek Singh, VP Chaudhary, Subhash Chandra, Shiv Pratap Singh, Rahul Singh Raghuvanshi, Vivek Singh and Neeraj Kumar Rajvanshi

Abstract
Web blight caused by *Rhizoctonia solani* (Kuhn) is one of the most important fungal diseases which appear every year in varying intensity and causes heavy reduction in yield. Though the web blight could be managed by the use of fungicide but due to the emergence of several problems like environmental pollution. Residual effect in grains, killing non targeted organisms its use should be discouraged. Hence, for minimizing the losses caused by web blight need in-expensive and environmentally safe management practices. Several botanicals and Bio-agents have been found effective against web blight of mungbean caused by *Rhizoctonia solani*. The botanicals were tested at different doses like 5.0, 7.5 and 10.0 per cent against web blight of Mungbean. Where 10.0 per cent concentration was found most effective which inhibited maximum per cent growth of fungus *i.e.* Garlic (82.53%) and followed by Ginger, Neem, Onion, Tulsi, Clerodendron and Sadabahar. However Per cent Inhibition in all treatments differed significantly to each other. The maximum per cent inhibition was obtained in 5.0, 7.5 and 10.0 per cent concentration in Garlic. Followed by Ginger after 48 hours of incubation. It was very clear from the studies that effectively of extracts increased with the increase in concentration and time of incubation. The per cent inhibition was also higher in *T. viride* (59.13, 68.47 and 71.78 per cent) and *T. harzianum* (49.35, 57.75 and 56.66 per cent) significantly inhibition the growth of *R. solani* as compared to control at 24, 36 and 48 hours of incubation. *Trichoderma. viride* was better in inhibiting radial growth of *R. solani* as compared to *T. harzianum in vitro*.

Keywords: Botanicals, bio-agents, *Rhizoctonia solani*, Mungbean

Introduction
Pulses constitute an important ingredient of the predominantly vegetarian diet in Indian. Production of pulses in the country is far below the requirement to meet even the minimum level of per capita consumption. According to Indian Council of Medical Research (ICMR) optimum requirement of the pulse for a person to maintain his normal health is 104 g per day. However, not even half of this quality is available to people, which is causing malnutrition among the growing people. Therefore, it is necessary that agricultural scientists should evolve the strategy of increasing the production of pulses to meet the protein requirement of increasing population of the country.

In 1924, web blight was reported for the first time on mungbean from Philippines (Nacien, 1924) [10]. While in India, Dwivedi and Saksena (1974) [4] first reported it on mungbean from Kanpur, Uttar Pradesh. Further, it has also been reported from Assam (Saikia, 1976), Punjab (Bains *et al.*, 1988) [2], Madhya Pradesh (Tiwari and Khare, 1998) [12], Bihar, Rajasthan, Haryana, Himachal Pradesh and Jammu & Kashmir (Anonymous, 2004) [1]. The pathogen causes huge losses in yield of mungbean and urdbean in India (Dubey 2003) [3].

Web blight caused by *Rhizoctonia solani* (Kuhn) is one of the most important fungal diseases which appear every year in varying intensity and causes heavy reduction in yield. Though the web blight could be managed by the use of fungicide but due to the emergence of several problems like environmental pollution. Residual effect in grains, killing non targeted organisms its use should be discouraged. Hence, for minimizing the losses caused by web blight need in-expensive and environmentally safe management practices. Several botanicals and Bio-agents have been found effective for management of different crops including web blight of mungbean caused by *Rhizoctonia solani*.

Effect of post-harvest treatments on quality attributes i.e. titratable acidity, ascorbic acid and Consumers acceptability of Langra mangoes (*Mangifera indica* L.) during storage

Kumari Punam, Subhash Chandra, SKS Rajpoot, Manish Maurya, Rajan Kumar and Ujjal Kumar Ghosh

Abstract
The effect of calcium salts (calcium nitrate and calcium chloride) and Gibberellic acid on quality attributes and consumer's acceptability of Langra mangoes during storage was examined. The fruits were treated with $Ca(NO_3)_2$ at the concentration of 1,2 and 3 per cent, $CaCl_2$ at the concentration of 1,2 and 3 per cent and GA_3 at the concentration of 50, 100 and 150 ppm. Water treated fruits were taken as control. Data were recorded in respect of Titratable acidity, ascorbic acid contents under influence of these treatments. Sensory evaluation was also conducted to assess the consumer's acceptability of treated fruits. All treatments were found effective in maintaining the higher level of these quality attributes as well as the consumer's acceptability of fruits during entire course of the experiment. At end of trial, $Ca(NO_3)_2$at 2% was proved as the best treatment in respect of Titratable acidity and was able to maintain the level of these up to 0.156%. In case of ascorbic acid content and organoleptic scoring GA_3 100 ppm was proved the best. It was able to maintain the level of ascorbic acid up to 27.00 mg/100 gram of pulp and secured an organoleptic score of 83 at the end of experiment.

Keywords: Mango, Langra, calcium nitrate, calcium chloride, ga_3, acidity, ascorbic acid, sensory evaluation

Introduction
Mango (*Mangifera indica* L.), the king of fruits belongs to the family Anacardiaceae. Among the fruits of universal importance, mango is placed on top and is the most popular fruit among millions of people. Mango is fifth widely produced fruit crop of the world after bananas, apples, grapes and oranges. Mango is grown throughout the length and breadth of the country except the temperate and arid regions. The number one mango producing country in the world is India. It contributes approximately 50% of the global mango supply. In India, during 2015-16, it was grown in an area of 2.209 million hectares with a production of 18.643 million tonnes and productivity of 8.4 tonnes/ hectare (Anonymous, 2017) [2].
Mango fruit is an excellent source of Vitamin-A, beta-carotene, alpha-carotene, and beta-cryptoxanthin. It is also a very good source of vitamin-B6 (pyridoxine), vitamin-B9 (folate), vitamin-C (Ascorbic acid) and vitamin-E (Anonymous, 2018) [3]. 100 g of fresh fruit provides 765 IU or 25% of recommended daily levels of vitamin-A. Among the cultivated varieties of Bihar, the variety Langra is most famous and is one of the most popular cultivars of India (Khara *et al*, 2016) [9]. In domestic market this variety has good demand and is able to fetch highest price in the market of Bihar. However, owing to its highly perishable nature and below average keeping quality, export potential of this variety is yet to be capitalised.
Mango showed degradation in quality owing to its high perishability and climacteric pattern of respiration. This massive reduction in the level of quality attributes of fruits is due to fact that sugars along with other organic acids are primary substrate for respiration (Wills *et al*., 1980) [16]. Therefore, a critical examination becomes imperative to slow down the process of respiration and to maintain the quality parameter for an enhance period of time in order to facilitate longer transportation and extended availability of quality fruits in the market.
Earlier efficacy of pre and post-harvest applications of certain chemicals and growth hormones in maintaining the quality of fruits during storage has been established. Pre-harvest sprays of calcium compounds and GA_3 significantly retained more sugar content and ascorbic acid in mango fruits along with better consumer acceptability during storage (Rani and Brahmachari,

USE OF DIFFERENT DOSES OF SYSTEMIC FUNGICIDE (PROPICONAZOL) FOR MANAGEMENT OF FOLIAR BLIGHT DISEASES OF BARLEY

SANTOSH KUMAR, S.P.SINGH, SUBHASH CHANDRA, ASHOK KUMAR AND RAMESH CHAND*
Department of Plant Pathology, Department of Nematology*, Narendra Deva University of Agriculture & Technology Kumarganj, Ayodhya, U.P. 224229.

Abstract

Barley crop suffers from a number of fungal foliar diseases which cause heavy yield loss. Investigations were therefore, conducted to record the disease severity and avoidable yield loss caused by different foliar blight pathogens and fungicidal management against these diseases. Field trial conducted and established 2 sprays of propiconazole (Tilt 25 EC) @ 1.0, 0.75 and 0.50 l/ha each at boot leaf and soft dough stages as most effective for managing foliar blight of highly susceptible barley variety RD 2503. It resulted in 40.55, 48.77 and 59.30 per cent disease severity, 37.13, 36.96 and 32.75q/ha yield and 33.32, 33.03 and 24.42 per cent avoidable yield loss. It was significantly followed by treatments having single spray of propiconazole @ 1.0, 0.75 and 0.50 l/ha at boot leaf stage with disease intensity 56.94, 63.60, 69.99 per cent, yield 34.56, 32.43, 26.13 q/ha and 28.38, 23.70, 0.282 per cent avoidable yield loss.

Keywords: Foliar blight, fungicidal management, propiconazole

Introduction

Barley (*Hordeum vulgare* L.) is one of the important crops of present era due to its superior nutritional qualities and satisfactory yield in problematic soil. It is grown under a wide range of environmental conditions, cooler climates, during the growing seasons, and well drained light to heavy loam soil being most suitable. Barley is a crop of international importance and serve mainly as staple food, feed to livestock and poultry, as malt for manufacture of bear and other liquors like whisky, brandy etc. Foliar blight causing pathogens viz., *Bipolaris sorokiniana, Alternaria alternata, Drechslera graminea* and *Drechslera teres* are most destructive pathogens of barley and cause severe yield loss. The management of foliar blight pathogens is more effective by using different doses of propiconazole (Tilt 25 EC) sprayed at different crop growth stages. The chemical control of these pathogens therefore, is alternative possibility. Propiconazole as a effective chemical against foliar blight diseases after six to some years.

Materials and Methods

The experiment having following details, were conducted with view to work out an effective fungicidal management schedule for the disease. Two sprays of propiconazole (Tilt 25 EC) @ 1.0 l/ha, each at boot leaf and soft dough stages. One spray of propiconazole (Tilt 25 EC) @ 1.0 l/ha, at boot leaf stage. Two sprays of propiconazole (Tilt 25 EC) @ 0.75 l/ha, each at boot leaf and soft dough stages. One spray of propiconazole (Tilt 25 EC) @0.75 l/ha, at boot leaf stage. Two spray of propiconazole (Tilt 25 EC) @ 0.50 l/ha, each at boot leaf and soft dough stages. One spray of propiconazole (Tilt 25 EC) @ 0.50 l/ha, at boot leaf stage. Two spray of water @ 1000 l/ha, each at boot leaf and soft dough stages and untreated (check). Initiation of the disease, disease intensity after 15 and 30 days spray of Tilt following Kumar *et al.*,1998, double digit scale, 1000-grain weight (test weight) and yield (q/ha).

Comparison between all the 8 treatments was made based on means of relevant parameters. Severity recorded on double digit scale, rating was averaged for leaf and next lower leaf as per (Dubin *et al.*, 1998) formula, which served as means of observation. Avoidable yield losses will be calculated by the formula given below:

$$AYL = \frac{YP - YU}{YP} \times 100$$

Where,
YP = Yield under protected condition
YU = Yield under unprotected condition

Per cent disease intensity (PDI) was calculated by employing the formula:

$$PDI = \frac{\text{Sum of total numerical rating}}{\text{Total number of leaves examined} \times \text{highest rating}} \times 100$$

Results and Discussion

Foliar blight of barley caused by *Bipolaris sorokiniana, Alternaria alternata, Drechslera graminea* & *Drechslera teres* was managed by using different doses of propiconazole (Tilt 25 EC) sprayed at different crop growth stages. Disease severity, thousand grain weight, yield quintal per hectare and avoidable yield loss was recorded in each treatment separately. All the treatments except water spray were found significantly effective in reducing the disease severity over untreated check. The propiconazole, with disease intensity of 40.55 per cent proved most effective when sprayed @ 1.0 l/ha, both at boot leaf and soft dough stages. Similar sprays @ 0.75 l/ha with a disease intensity of 48.77 per cent were next to follow. It was significantly followed by treatments having single spray of propiconazole @ 1.0 l/ha, at boot leaf stage and two sprays of 0.50 l/ha, each at boot leaf and soft dough stages (Table 1).

The treatments have their significant impact on the yield of barley grains over untreated check and water spray. The treatment, two sprays of propiconazole @ 1.0 l/ha, each at boot leaf and soft dough stages, with 37.12 q/ha grain yield gave significantly higher yields over rest of the treatments followed by two sprays of propiconazole @ 0.75 l/ha, each at boot leaf and soft dough stages with 36.12 q/ha grain yield, but both were at par. These were followed by single spray of propiconazole @ 1.0 l/ha, at boot leaf stage, two sprays @ 0.50 l/ha, each at boot leaf and soft dough stages, and single spray @ 0.75 l/ha at boot leaf stage with grain yield of 34.56, 32.75 and 32.43 q/ha respectively. Single spray @ 0.50 l/ha at boot leaf stage with a yield of 26.13 q/ha were recorded least effective amongst all the treatments and also at par with untreated check and water sprayed.

Data gathered on account of test weight of barley grains. Approximately similar results were also recorded in case of test weight. Two sprays of propiconazole @ 1.0 l/ha, each at boot leaf and soft dough stages gave significantly best performance (40.52 g) over all the treatments and untreated check followed by two sprays of propiconazole @ 0.75 l/ha, each at boot leaf and soft dough stages but both were at par. Single spray of propiconazole @ 1.0 l/ha, at boot leaf stage, single spray @ 0.75 l/ha and two sprays of propiconazole @ 0.50 l/ha, each at boot leaf and soft dough stage were the second performer which gave 37.91 g, 37.10 and 37.46 g test weight respectively and all were statistically at par. All the treatments of propiconazole were significantly superior over untreated check and water sprays. Maximum loss of 33.32 per cent in grain could be avoided with two sprays of propiconazole @ 1.0 l/ha, each at boot leaf and soft dough stages, followed by two sprays of propiconazole @ 0.75 l/ha, each at boot leaf and soft dough stages which avoided a loss of 33.03 per cent in grains. Minimum avoidance of loss of grains (0.28 per cent) was recorded with single spray of propiconazole @ 0.50 l/ha, at boot leaf stage. All the treatments propiconazole found significantly effective in reducing the disease severity. Propiconazole at concentration of 1.0 l/ha sprayed at boot leaf and soft dough stages, proved significantly superior in managing leaf blight intensity over check and all other treatments. The propiconazole, with disease intensity of 40.55 per cent proved most effective when sprayed @ 1.0 l/ha, both at boot leaf and soft dough stages. Similar sprays @ 0.75 l/ha with disease intensity of 48.77 per cent were next to follow. It was

Abstract

Oat is one of the most important cereal fodder crops of Rabi season. It provides soft and palatable fodder. Its fodder, on dry matter basis contains 10.0 -11.5 % crude protein, 55-63 % neutral detergent fiber, 30-32 % acid detergent fiber, 22.0-23.5 % cellulose and 17-20 % hemicelluloses when harvested at 50 % flowering stage of crop. Oat is also used as straw, hay or silage. Total world area under oats is approximately 13.9 million hectares. The production of oat is not being fully exploited because of the lack of proper information on its optimum fertilizer requirement. Among the different production factors, fertilizer application is one of the most important factors in limiting the production of oat crop.

Introduction

Phosphogypsum is a byproduct of all diammonium phosphate plants. Every matric tons (MT) of phosphoric acid manufactured generates 5 MT of phosphogypsum. There is now an estimated stock of about 125 lakh MT of byproduct phosphogypsum in the country. Its agricultural use started only very recently with the onset of calcium and sulphur deficiency in oat grown mostly in light textured soil. Its utilization is however very much restricted because of lack of knowledge on its use, appreciation of benefit in different crops and anticipated environmental problem associated with its use. Phosphogypsum contains 16% S, 22% Ca and 0.71% P_2O_5. Pure gypsum ($CaSO_4$) contains 18.6% S and 21% Ca, while commercial agricultural grade gypsum of 70-80% purity contains 13-15% S and 40% CaO. Sulphur is now recognized as the fourth major plant nutrient after nitrogen, phosphorus and potassium. Crops in general require as much sulphur as they need phosphorus. Sulphur deficiencies have been reported in soil from several state of India and importance of sulphur fertilization in increasing crop yield and product quality is being increasingly recognized. It performs many important functions in the plants. It is best known for its role on the synthesis of protein and vitamins. It is constituent of amino acids and thus vital for production. Sulphur is associated with the production of crop of superior nutritional quality. Since the quality of forage crop is important for their utilization by live stock, hence sulphur fertilizer is of much important in forage production. It enhances the effects of other nutrients also. The effect of sulphur on yield and crop quality is further enhanced where it interacts positively with other nutrients. Reports on the sulphur phosphorus interaction have been conflicting since both positive and negative interactions have been observed (Kanwar and Mudahar, 1985). The sulphur application can ensure the high production of oat. Keeping facts in view an effort has been made to assess the phosphogypsum level which is a byproduct of phosphoric acid plant and on various cultivar of Oat fodder crop.

Material and Methods

The field experiment was conducted to evaluate the effect of phosphogypsum levels to various cultivar of fodder oat crop at Genetics and Plant Breeding Farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad, Uttar Pradesh, India during *Rabi* season 2015-2016 under the project of All India Coordinated Research Project (AICRP) on forage crops. The experimental soil having silty loam in texture, pH (1:2.5) 8.59, EC 0.38 dSm^{-1}, Organic carbon 3.1 gkg^{-1}, available nitrogen 173.4, phosphorus 14.80 and potassium 195.10 $kgha^{-1}$. The twelve treatment were comprised of one time application of four levels of phosphogypsum on basis of sulphur content (0, 125, 250 and 375 $kgha^{-1}$) with three cultivar viz. NDO-1, NDO-2 and NDO-711 in randomized block design replication each treatment thrice. The plant spacing was row to row 25cm and plant to plant 5cm. The phosphogypsum was applied through broadcast and surface incorporation. The half dose of nitrogen @ 100 kg N ha^{-1} though urea, and full dose phosphorus @ 40 kg P_2O_5 ha^{-1} through Diammonium phosphate applied at the time of sowing of the crop. The remaining half dose of nitrogen was top dressed in standing crop at 25 DAS just after first irrigation of the crop. Representative soil samples at initial and after harvest of the crop (0-15cm) of investigation were drawn from individual treatment plot and analyzed with methods described in *Jackson*, 1973. The cutting was done with the help of sickle at 50% flowering stage at 105 DAS. The chlorophyll contents was estimated following the methods of Arnon and Stout (1949) and expressed as mgg^{-1} fresh leaves. The nutrient uptake was calculated with multiplication of dry matter yield by nutrient content in percentage.

Results and Discussion

Growth and fodder yield

Data pertaining to growth and fodder yield are presented in Table-1. Inherent genetic variability in plant was notice among entries. Among the entries of fodder oat crop, the maximum plant height with NDO-711(113.5cm), tillers m^{-2} (397), dry matter accumulation (1273.27 gm^{-2}), green forage yield (515.28 qha^{-1}), dry matter yield (124.33 qha^{-1}), crude protein yield (13.83 qha^{-1}) and chlorophyll content (1.70 mgg^{-1}) which was found significantly superior in respect of plant height, dry matter accumulation, green forage yield, dry matter yield, crude protein yield and chlorophyll content over rest of the cultivars. Among the phosphogypsum levels the maximum plant height (117.9 cm), tillers (391 m^{-2}), dry matter accumulation (1241.78 gm^{-2}), green forage yield (515.2 qha^{-1}), dry matter yield (124.2 qha^{-1}), crude protein yield (14.2 qha^{-1}) and chlorophyll content (1.78 mgg^{-1}) were received with the application of phosphogypsum 375 $kgha^{-1}$ (60kg S ha^{-1}) which was found significantly superior in respect of plant height, dry matter accumulation, green forage yield, dry matter yield, crude protein yield and chlorophyll content with 125 $kgha^{-1}$ and found statistically at par the level of 250 kg ha^{-1} phosphogypsum. Better growth and development of oat plants due to higher levels of phosphogypsum (sulphur) doses would have been due to multiple role of S in protein and carbohydrate metabolism of plants by activating a number of enzymes which participate in dark reaction of photosynthesis hence increases the plant height and dry matter was observed with increased doses of phosphogypsum (sulphur). Similar finding were also reported by Choudhary *et al.* (2013), Varshney *et al.* (2008) and Tanveer *et al.* (2013) Sulphur play an important role in plant metabolism by virtue of being essential constituent of various metabolically active compounds like amino acid, proteins, nucleic acid, porphyrins (chlorophyll), enzyme and co-enzyme. Constituent of chlorophyll it is important for photosynthesis. It influences the rate of cell division and their enlargement and hence tends to rapid growth of meristemetic tissue. Similar finding were also reported by Shukla and Menhi (2004).

Nutrient uptake

The data with respect to nutrient uptake by oat fodder presented in Table-2 which revealed that among the entries of fodder oat crop, the maximum nutrients uptake (N 22.78, P 25.98, K 213.37 and S 22.60 kg ha^{-1}) were received with the cultivar NDO-711 which was significantly superior over rest of the entries (NDO-2 and NDO-1). This might be due to the genetic characteristics of variety, resulting

Evaluation of Pigeon pea genotypes for resistance to *Fusarium* Wilt

Subhash Chandra, Neeraj Kumar Rajvanshi, Ajay Kumar, Kumari Punam* and Ramesh Chand**

*Department of Plant Pathology, Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya – 224 229 (U.P.), *Department of Botany, J. P. University Chhapra (Bihar)*
***Department of Nematology, ND.U.A.&T., Kumarganj, Ayodhya – 224 229(U.P.), India*
<chandrasubhash75@yahoo.in>

Pigeon pea (*Cajanus cajan* L.) is widely adaptable to wide variety of climate and is one of the important legume crops of tropics and subtropics. It played a major role in nutritional security for the people taking cereal based diet. Beside their dietary value and nitrogen fixing ability, pulses also play an important role in sustaining intensive agriculture by improving physical, chemical and biological properties of soil and are considered excellent crop for diversification of cereal based cropping system.

Wilt disease caused by *Fusarium udum* Butler, is the most destructive soil and seed born disease of pigeon pea in India leading to heavy production losses. The *F. udum* is host specific to pigeon pea (Patel *et al.*, 2011) and can survive in soil under wilted plant stubble for a long period. The best way of wilt management is by growing resistant varieties. For developing resistant varieties, resistant source are the basic requirement. Therefore, the present investigation was undertaken.

Seeds of 58 germplasm of Pigeon pea were obtained from the Department of Genetics and Plant Breeding, N.D.U.A.&T., Ayodhya and ICAR-IIPR, Kanpur. The germplasms were screened under sick plot technique. The plots (sick soil) showed over 90% wilt incidence in susceptible cultivar Bahar of Pigeon pea was used as test variety. After germination, observations were recorded regularly up to 60 days for the appearance of wilt symptoms and severity. The disease was recorded using 1-9 scale for the wilt disease.

Fifty eight germplasms of Pigeon pea were screened for their reaction to *Fusarium udum* in sick plot. It is evident (Table 1) that out of 58, 6 germplasms *viz.*; AKT 201030, IPA 96, IPAF, IPA 204, JSA 59 and WRGE 18 were found resistant, attributing to the higher concentration of phenol as observed by Haldar and Srinivasan (2007), 5 moderately resistant, 10 tolerant, 16 moderately susceptible and 21 germplasm were highly

Lentil (*Lens culinaris* Medik L.) is one of the most important pulse crop in India and mostly grown in north east plain zone and central part. It is a diploid and self-pollinated crop which is grown in winter season. Lentil suffers from attack of a number of diseases such as vascular wilt; collar rots, root rot, stem rot, rust, powdery mildew downy mildew and fusarium wilt which are caused by

ABSTRACT

Fusarium wilt is one of the major diseases in lentil crop which causes a significant yield loss. The present study aimed to manage the *Fusarium wilt* of lentil through seed treatment with fungicide, botanicals and bio-agents alone or in combination which is carried out at Student Instructional Farm of ANDUAT, Kumarganj, Ayodhya. It was observed that Minimum disease incidence was found in T_8 Metalaxyl 8% + Mancozeb 64% + Neem leaf extract (10%) + *T. viride* (14.13 %) with per cent disease control (82.76) followed by T_3 Metalaxyl 8 % + Mancozeb 64 % + *Trichoderma viride* (15.85 %) having PDC (80.67), T_2 Metalaxyl 8 % + Mancozeb 64 % + *Trichoderma harzianum* (22.37%) having PDC (72.71), T_7 Metalaxyl 8% + Mancozeb 64% + Neem leaf extract (10%) (28.84%) having PDC (64.82).

Introduction

Lentil (*Lens culinaris* Medik) commonly known as Masur was among the first crop domesticates and has become an important pulse crop in the farming and food system of many countries globally (Sarker and Erskine, 2006). Lentil also known as 'Poor man's meat' as it is rich in nutrients, include 60-67% carbohydrates, 20-36% protein, <4% lipid, and 2-3% ash on dry weight basis (Bhatty, 1988). Major lentil growing states in India are Madhya Pradesh (42.50%), Uttar Pradesh (31.25%), West Bengal (9.38%) and Bihar (8.75%). In India, lentil was grown in 1.49 mha with production of 1.61 mt with an average production of 1006 kg/ha (Anonymous, 2018).

Among biotic factors disease are major constraint in lentil production. Among the fungal diseases, Fusarium wilt of lentil caused by *Fusarium oxysporum* f.sp. *lentil* is a major threat in lentil production worldwide (Bhalla *et al.*, 1992). In India, this disease causes significant yield losses in various states of India where lentil is grown. The fungus is soil and seed borne and also

Evaluation of insecticides and biopesticides against *Scirpophaga incertulas* (Walker), leaf folder (*Cnaphalocrosis medinalis*) and green leafhopper in basmati rice

SKS Rajpoot, S Dixit, V Prasad, SP Giri, RA Singh, N Parkash, AL Upadhay and Subhash Chandra

Abstract
The field trials were carried out at A.N.D.U.A.T. Crop Research Station, Masodha Ayodhya, during kharif 2019 and 2020 to evaluate the efficacy of four combination modules/treatments consisting of three insecticides Chlorantraniliprole 20% SC, Cartap hydrochloride 50% SC and Triflumezopyrim 10% SC, one commercial neem formulation - Neemazal and two oils - Neem and Eucalyptus oil procured from IIRR, Hyderabad (Telangana) were compared along with untreated control (only water spray). There were significant differences in dead heart damage among the treatments. All insecticides treatment module recorded the lowest mean damage of white ears 1.3% when compared to 28.8% in untreated control. Among other treatments, neemazal, eucalyptus oil and cartap hydrochloride combination showed lowest mean infestation of 4.1% DH. Among modules, all insecticides module was found to be the best with 1.3% mean white ear damage followed by neemazal, eucalyptus oil and cartap hydrochloride module with 4.1% WE. All insecticides module was the most effective treatment showing mean leaf damage of 2.45% followed by treatment with neemazl, Eucalyptus oil and cartap hydrochloride (4.95% DL) when compared to untreated control (17.2% DL). All insecticides combination was the most effective treatment of Green leafhopper showing mean population of 3.0 followed by neeamazal, eucalyptus oil and cartap hydrochloride combination (17.7)) and were superior to control (61.7 hoppers/10 hills). All insecticides treatment Chlorantraniliprole, Cartap hydrochloride, Triflumezopyrim recorded the highest grain yield of 3260 kg/ha with 237.1% increase over control followed by neemazal, neem oil and cartap hydrochloride with 2350 kg/ha (143.01% IOC). All the treatments were significantly superior to control plot which showed a yield of 967 kg/ha. All insecticides combination minimized the yield loss in basmati rice.

Introduction

Rice (*Oryza sativa* L.) is an important staple food crop for more than two third of the population of India and more than 65 per cent of the world population (Mathur *et al*., 1999) [10]. India is the largest rice growing country, it accounts for more than 40% food grain production. Introduction and wide adoption of basmati rice varieties has led to sever incidence of yellow stem borer in addition to the existing leaf folder menace on the rice crop all over India. There are over 70 pests infesting rice in India and 20 are of regular occurrence (Patha, 1975). The pest causes 25-30% damage to rice crop (Lal, 1996) [7]. Almost 20 insects are considered as rice pests of economic importance that include stem borers, leaf folder,gall midge, defoliators and vectors like leafhoppers and plant hoppers that cause direct damages and transmit various diseases Among the major pest attacking rice crop the stem borer, *Scirpophaga incertulas* (Walker) is the number one pest, which attack the crop both at vegetative and reproductive stages (Pasalu *et al*., 2002) [12]. All plant parts of basmati rice are vulnerable to insect infestations from sowing to harvest with an estimated 25-30% yield loss annually (Khan *et al*., 2003) [11]. Scented varieties are comparatively more preferred by insect pests (Khuswaha, 1994) [6]. Among these insect pests stem borers viz., yellow stem borer Scirpophaga incertulas (Walker), white stem borer Scirpophaga innotata (Walker), pink stem borer Sesamia inferens (Walker) and leaf folder Cnaphalocrocis medinalis (Guenee) are important. The rice green leafhoppers (GLH), are one of the most devastating rice pests throughout the rice growing areas of Asia (Q.M.A. Razzaque *et al*. 1985, E.A. Heinrichs, *et al*

Income generation for sustainable development of rural women

Abha Singh, Pragya Ojha, Sumant Pratap Singh and Namita Joshi

Abstract
Women constitute about 50% of total population, yet their status in the society pitiable. They put in 15 hours of work daily but their wages are less than men. The income generation activities undertaken by women are yet to prove its impact on them or it is more a self employment activity rather than a substantial source of income. Therefore there is a need to study if these micro income generating activities provide empowerment to rural women. The objective of this study is to find out if income generating activities under taken by rural women have increased their participation in decision making process. In this study income generating activity has been treated as independent variable and women empowerment as dependent variable. The study was conducted in Sultanpur district of Uttar Pradesh (U.P.) and both income generating and non income generating 150 women from each group were selected as sample. The pace of empowerment may be due to small amount of income generated. As a result of this, U.P. (Uttar Pradesh) government initiated several projects. Under this scheme women are encouraged to undertake some income generating programmes to raise their income which will their self confidence, bargaining power, promote stronger household food security and investment in children's schooling. From review paste researchers and personal experiences the following model is designed to show how women empowerment takes place. A similar model was tested by Estudillo and Esutka 1988, but model differs in measuring empowerment in terms of women participation in decision making. The study revealed that income earned by women has improved their status and empowerment is taken place but the speed of empowerment is slow.

Keywords: decision making, society, economic, farming, labor, village

Introduction
It is paradoxical that women constitute nearly 50 percent of world population and yet their social economic and welfare status is pathetic. Even today only a fraction of rural women are educated and majority is living under poverty, ignorance, and oppression. They still lack the access to information, science and technology, economic resources, political power and employment avenues. Their employment opportunities are dismal. What ever improvement in women employment is being claimed, it is mostly among urban women while rural women are still far behind and living in poor condition. The activity profile of women reveals that they put in 15 hours of work daily and yet their wages are lower than men. Besides this, they contribute nearly 50 to 70 percent of agricultural labour in farming and when working on own farm they are not paid. Although when they work as a labour on the farm of other farmers, they are paid less wages compared to men. The world community is aware of rural women's plight and four world conferences have been organized and truck load of resolutions have been passed. As a result of this, U.P. (Uttar Pradesh) government initiated several projects, notably DWACRA (Development of Women and Children of Rural Areas). Under this scheme women are organized in self help groups and are encouraged to undertake some income generating programmes to raise their income which will raise their self confidence, bargaining power, promote stronger household food security and investment in children's schooling. According to Cornelia Butler Flora Rural women help in income generation either by earning or by saving.

Critical analysis of the studies reflects that income generation activity should be encouraged for empowering the women. However none of these studies clearly state that the impact of income generation is positive and it has empowered the women. The major issue is how empowerment has been measured in these studies. Therefore, in this study woman participation in various decisions making has been measured in as empowerment.

The second aspect which is yet to be tackled is the feeling of improvement of income and

Abstract

The aim of the present investigation was to examine the effect on haematological profile before and after disbudding in calves. The study was carried out at the Instructional Livestock Farm Complex, College of Veterinary Science and Animal Husbandry, NDUAT, Kumarganj, Faizabad and nearby villages. Twenty four cattle calves were utilized to study haematological parameters (Hb (gm/dl), Neutrophil (%), Basophil (%), PCV (%), Lymphocyte (%), Monocyte (%), TLC (103/ µl), Eosinophil (%) and N/L ratio) before and after disbudding in to four groups viz. control (T0), lignocaine (TL), tremadol (TT) and lignocaine + tremadol (TL-T). After medication calves were disbudded by hot iron method. The blood samples were collected for haematological parameters just before (0h) and after disbudding on 6h, 24h and 72h. Haematological responses recorded before and after disbudding. The results showed that, at 24h, T0 group showed significantly lowest Hb (10.66±0.49%) which was statistically similar to TT and TL-T groups but significantly different from TL groups. At 0h, 6h and 72h means of PCV% were significantly different among treatment groups. There was no significant different in eosinophil, neutrophil and TLC among different treatment groups during the whole period of study. The lowest lymphocytes (64.00±1.00) was observed in TT group which was statistically similar with TL-T group but significantly differed with TL and TT groups at 6h. The T0 group showed significantly lowest basophil (0.00±0.00) which was statistically similar to TT and TL-T groups but significantly different from TL group at 6h. At the same interval, T0 group showed significantly lowest monocytes (4.66±0.61) which was significantly different with TL, TT and TL-T groups. At 6h, T0 group showed significantly lowest N/ L ratio (0.15±0.01) which was statistically similar to TT and TL-T groups but significantly different from TL group. It may be concluded that no significant difference was observed in eosinophil%, TLC, neutrophil% and monocyte% counts between control and treatment groups. However Hb%, basophil%, PCV% and lymphocyte% were significantly different between control and treatment groups. N/L ratio was significant only at 6h. Most of the cases TL-T group showed comparatively better performance.

Keywords: *Skin thickness, Lactation stage, Parity, Milk yield, Murrah, Sahiwal, Gir*

Introduction

Dairy animals especially cattle and buffalo play a major role in India because of their higher milk production potential. Moreover, some of the prominent milch breeds are exported to foreign countries like Italy, Brazil etc. for maintaining the people's daily milk needs. In India, milch cattle and buffalo breeds like Sahiwal, Gir, Red Sindhi, Deoni, Murrah, Surti, Mehasana etc. are well adapted to the prevailing environmental conditions. Among all the milch breeds, Sahiwal is considered to be one of the important cattle milch breeds and thrives well in many parts of India. Animals of this breed are known for their ability of heat tolerance, disease resistance and adaptability to low input system. The average milk yield of this breed has been reported between 2,725 and 3,175 kg in a lactation period of 300 days and certain individual cows have been reported to produce as high as 4,535 kg of milk (Sastry and Thomas, 2016). Mostly, dairy breeds of the tropics and subtropics are slow maturing and low milk producers. This is because of partly inherited and partly due to the malnutrition, management and environment to which they are exposed (Das *et al.*, 2003).

Buffaloes play very important role in Indian agriculture. They are the main source of milk, meat and draft power in many parts of the world. In India, the total buffalo population is recorded 108.70 million and about 51% of total milk production is shared by these animals (Livestock Census, Govt. of India, 2019). As there has been an immense increase in the human population, buffaloes therefore hold the greatest promise and potential for milk production. Murrah breed is the most important breed that is known for its high milk yield potential. Murrah breed has been used extensively to improve the milk production of dairy buffalo in other countries like Brazil, Italy, Bulgaria and Egypt. Average milk production in Murrah buffalo varies from 1360 to 2270 kg in a lactation period of 310 days (Sastry and Thomas, 2015). The average milk yield is reported to be 6.5 kg/day while a few individual animals yield as much as 19.1 kg/day. However, the Murrah buffalo named Rani of Lakshmi Dairy Farm in Punjab set a new record by producing 26.33 kg of milk in the 2016 National Livestock Competition and Expo (Watts, 2016). Physical features of Murrah breed such as body size, coat colour, horn shape, udder shape & size, and skin thickness are said to be related with milk production (Mondal and Pandey, 1995; Bhuiyan *et al.*, 2004). The skin of an animal in good condition is relatively thick and skin thickness may indicate an animal's ability to thrive in a given area. Histological structures determining the expand ability, elasticity and density of the skin are associated with milk yield. Moreover skin has a major importance as an organ of adjustment between the animal and its climatic environment. Skin thickness of cattle and buffalo has been measured by various workers (Hossain *et.al.*, 2016; Bharati *et.al.*, 2017). The considerable differences of result by various workers appear to be both biological and metrical in origin. However, the value of measuring cattle skin thickness and examining its relationship with other characters cannot be properly assessed unless skin thickness itself can be measured within reasonable limits of error (Hayman *et al.*, 1966).

Very few reports have been published regarding the relationship of skin thickness with parity and stage of lactation, but it is essential to study further about the skin thickness of dairy breeds. The present study has been, therefore, undertaken to impact of skin thickness in relation to parity and lactation stage on milk yield in dairy animals (Sahiwal, Gir cows and Murrah buffalo).

Impact of stocking density on gait score and mortality in broiler chickens

KD Singh, PS Pramanik, Subodh Kumar, Rajesh Kumar, AK Srivastav and MK Verma

Abstract
The research was conducted to investigate the impact of stocking density (i.e., I.C.A.R., Venky's and Amrit recommendations) on gait score & mortality in broiler chickens. A 500 day-old straight run commercial broiler strain "VENCOB" chicks were divided in two batches. Each batch was subdivided in 3 equal groups namely Gr 1 (I.C.A.R.), Gr 2 (Venky's) and Gr 3 (Amrit). All the birds were raised on pucca floor with saw dust as litter material providing equal managemental practices. Walking ability was accessed at weekly interval up to 6 weeks of observation. The gait scoring system followed in the present study was Modified gait scoring system developed by Garner *et al.* (2002). Daily mortality of birds was recorded in morning hours &mortality rate was calculated weekly. The lowest and highest% of birds showing GS 0 under I.C.A.R. recommendation of stocking density have been found to be 83.93±0.64% (week 4) and 92.86±0.40% (week 6) respectively. Similarly the corresponding proportion of birds showing GS 1 were 6.07±0.78% (week 1) and 13.93±0.64% (week 4) respectively. Comparatively lesser % of birds show GS 2 and the lowest and highest L.S. means % of this were 0.00±0.40% (week 6) and 3.21±0.82% (week 3) respectively. Venky's & Amrit's observation were also similar as I.C.A.R. recommendation has been observed. Overall it has been observed that% of birds showing GS 0 was significantly more in I.C.A.R. followed by Amrit and Venky's during this study. However, highest% of birds showing GS 1 was recorded in Venky's recommendation followed by Amrit and I.C.A.R. Whereas, less than 5% birds exhibited GS 2 in this study in respective of stocking densities. There was no significant difference regarding% of birds with GS 2 in three stocking densities during all the weeks except at week 4. The overall mortality (%) was less than 5% over weeks under each placement densities. No significant difference was observed among mortality rates of broiler chickens under these three stocking densities during all the weeks studied. From present study, this can be concluded that leg health and walking ability was comparatively better under I.C.A.R. recommendation followed by Amrit and Venky's. However, effect of stocking density on mortality was non significant among three stocking.

Keywords: gait score, foot pad lesions, stocking density, mortality and walking ability

Introduction
The total poultry population in India is 729.2 million, which is 12.39 percent higher than numbers in the previous census (Livestock Census, 2012) [21]. Poultry is one of the fastest growing sectors of Indian agriculture today, with annual growth rates of 5.57 percent and 11.44 percent in egg and broiler production, respectively. The value of output from the poultry sector was US$10 billion in 2014 (Rajendran *et al.*, 2014) [25]. Broiler production has been more vibrant than layer production within the poultry sector, with an annual growth rate of 11.44 percent, production of 3.725 million tons and employment of 4.29 million people (Index Mundi, 2015) [15]. India is the fourth largest producer of poultry meat in the world, valued at US$ 6.6 billion. Poultry production accounts for about 0.66 percent of India's GDP and 7.72 percent GDP from the livestock sector (Rajendran *et al.*, 2014) [25]. Poultry meat production increased from 0.069 million tons in 1961 to 3.725 million tons in 2014. The per capita availability of poultry meat is 2.8 kg; against recommended level of 11 kg (Rajendran *et al.* 2014 [25]; Index Mundi, 2015 [15]). The main reasons for improved broiler poultry production (Kalamkar, 2012; SAPPI.PP, 2009) [17, 29] are: modernization of production practices; import of pure lines/grandparent stock; least-cost feed formulation; vaccines against major diseases; provision of EAS and other input services; improved quality breeder management; developments in poultry processing; and private sector partnerships through Contract Broiler Farming. It is estimated that 37 percent of broiler production in India is under contracts, and about 78 percent of those contracts are concentrated in southern India (Rajiajwani, 2012) [26].
Gait scores (GS), a parameter used to evaluate walking ability (Kestin *et al.*, 1992; Garner *et*

Studies on relationship between milk yield and skin thickness of dairy animals

Durgesh Nandan, PS Pramanik, KD Singh, RP Diwakar, Gaurav Pandey and Vipin Yadav

Abstract
The aim of the present investigation was to examine the relationship between skin thickness and milk yield. The experiment was conducted at Livestock Farm Complex, C.V.Sc. & A.H., ANDUAT Ayodhya, Ram Newaj Singh Dairy Farm, Kumarganj, Ayodhya (UP) and Gorakhnath Singh Dairy, Baijnathpur Gorakhpur (UP) as per availability of lactating animals (Murrah buffalo, Gir and Sahiwal cows) which was 32 animals of each breed. A total of 96 dairy animals were studied in this experiment in which 32 Murrah buffaloes, 32 Sahiwal cows and 32 Gir cows ranging from first to fourth lactation periods. The dairy animals were selected on daily milk yield and total milk yield were recorded from the records over an average period of 120 days of lactation length. The skin thickness was measured from seven sites or regions namely neck, chest, abdomen, rump, hind quarter, udder and flank of each animal. The result shows that, in Murrah buffaloes the highest average DMY was 8.16 ± 0.52, 8.62 ± 0.55, 8.29 ± 0.78, 8.15 ± 0.55, 8.69 ± 0.77 and 7.86 ± 0.39 litres by animals under thin skin thickness of neck, chest, abdomen, hind quarter, udder and flank regions respectively. In Sahiwal cows, it was observed that the highest average DMY was 7.26 ± 0.31, 7.47 ± 0.65, 7.63 ± 0.48, and 7.69 ± 0.76 litres by animals under low skin thickness of neck, chest, abdomen and udder regions respectively. Where as in Gir cows it was observed that the highest average DMY was 6.23 ± 0.46, 6.06+0.41, 5.96 ± 0.51, 5.06 ± 0.36 and 6.03 ± 0.65 litres by animals under low skin thickness of neck, abdomen, hind quarter, udder and flank regions respectively. However, it was also observed that all the Murrah buffaloes, Sahiwal and Gir cows having thick skin of different regions were found to produce lowest milk yield per day. Least square analysis showed that the relation between DMY and skin thickness of thin, moderate and thick in different regions was found to be statistically non-significant except in flank regions where different types of skin thickness found significant ($p<0.01$). Further it was observed TMY and type of skin thickness in different regions were not found significant ($p<0.01$) except udder and abdomen regions where thick skin TMY were found to be statistically highly significant ($p<0.01$). It may be concluded that, the udder skin thickness was minimum followed by that in ascending order in the neck, chest, abdomen, hindquarter, flank and rump regions of the animals. Further it was evident that Murrah buffalo, Sahiwal and Gir cows under their skin thickness were found to produce more milk, while moderate skin thickness produced more milk and then thick skin thickness produced milk.

Keywords: Skin thickness, murrah, sahiwal, gir, parity, milk yield

Introduction
Dairying is an important enterprise for many countries of the world. As a result it has been an important source of income generation for rural families in the developing countries. With the increase in human population, the demand for milk has also been increased (Tollens *et al.*, 2004) [17]. In India, milch cattle and buffalo breeds like Sahiwal, Gir, Red Sindhi, Deoni, Murrah, Surti, Mehasana etc. Are well adapted to the prevailing environmental conditions. Among all the milch breeds, Sahiwal is considered to be one of the important cattle milch breed and thrives well in many parts of India. Animals of this breed are known for their ability of heat tolerance, disease resistance and adaptability to low input system. The average milk yield of this breed has been reported between 2,725 and 3,175 kg in a lactation period of 300 days and certain individual cows have been reported to produce as high as 4,535 kg of milk (Sastry and Thomas, 2016) [15].
In India, majority of buffalo population belong to the riverine group and the milk production is the main function of these animals. It is reported that about 73.77 % of world buffalo population are found in South Asia. In India, the total buffalo population is recorded 108.70 million and about 51% of total milk production is shared by these animals (Livestock Census, Govt. of India, 2019).

Abstract

The aim of the present investigation was to examine the haematological profile and oxidative stress before and after disbudding in calves. The study was carried out at Livestock Farm Complex, College of Veterinary Science and Animal Husbandry, ANDUAT, Kumarganj, Ayodhya and nearby villages. Twenty four cattle calves were utilized to study haematological parameters that are Haemoglobin (Hb (gm/dl), Neutrophil (%), Basophil (%), PCV (%), Lymphocyte (%), Monocyte (%), TLC (10^3/ µl), Eosinophil (%), N/L ratio) and oxidative stress before and after disbudding in to four groups viz. control (T_0), lignocaine (T_L), tremadol (T_T) and lignocaine+tremadol (T_{L-T}). After medication calves were disbudded by hot iron method. The blood samples were collected for haematological parameters & for estimation of LPO (lipid peroxides) as per method described by [1] just before (0h) and after disbudding on 6h, 24h and 72h. The results showed that, at 24h, T_0 group showed significantly lowest Hb (10.66±0.49%) which was statistically similar to T_T and T_{L-T} groups. At 0h, 6h and 72h means of PCV% were significantly different among treatment groups. The lowest lymphocytes (64.00±1.00) was observed in T_T group at 6h. The T_0 group showed significantly lowest basophil (0.00±0.00) which was statistically similar to T_T and T_{L-T} groups but significantly different from T_L group at 6h. At the same interval, T_0 group showed significantly lowest monocytes (4.66±0.61) which was significantly different with T_L, T_T and T_{L-T} groups. At 6h, T_0 group showed significantly lowest N/ L ratio (0.15±0.01) which was statistically similar to T_T and T_{L-T} groups but significantly different from T_L group. At 0h, 6h and 24h LPO was significantly different among groups. At 0h, T_0 group showed significantly highest (106.59±0.63) which was significantly different from T_L, T_T and T_{L-T} groups. It may be concluded that no significant difference was observed in eosinophil%, TLC, neutrophil% and monocyte% counts between control and treatment groups. However, Hb%, basophil%, PCV% and lymphocyte% were significantly different between control and treatment groups. N/L ratio was significant only at 6h. Most of the cases T_{L-T} group showed comparatively better performance. At 0h, 6h and 24h LPO was significantly different among groups. At 0h, T_0 group showed significantly highest (106.59±0.63) which was significantly different from T_L, T_T and T_{L-T} groups.

Impact of blue and green monochromatic light in comparison to white LED on the stress reaction and mortality rate of broiler chickens

P Gautam, PS Pramanik, KD Singh, MK Verma, S Gautam, AK Verma, VN Gupta and B Singh

Abstract
The present experiment was conducted to investigate the impact of blue and green monochromatic light in comparison to white LED on the stress reaction and mortality rate of broiler chickens. For a period of 42 days study two hundred forty day old Vencobb 400 straight run commercial broiler chicks were randomly divided into three groups with 2 replicates of 40 in each at the poultry unit of livestock farm complex, College of veterinary sciences and animal husbandry, A.N.D.U.A.T. Kumarganj, Ayodhya, (U.P). In first green-blue group (T_{GB}), the birds were kept on green LED light (GL) and blue LED light (BL) from 1-21days and 22-42 days, respectively. The broiler birds of Group T_W and T_C were kept in white and incandescent LED lights for 42 days, respectively. The findings revealed that the heterophil % differed significantly ($P<0.05$) at 6th week of age when broiler finished their light treatment duration (after shifting from green LED to blue LED at 4th week of age). The ratio of blood heterophil to lymphocyte was also significantly differed ($P<0.05$) at the 6th week of age. The H/L ratio was higher in T_C group (0.37±0.008) whereas, it was lowest in T_{GB} group (0.33±0.456) than T_W group (0.35±0.120) birds at 6th of age. This study indicated that birds were minimum stress level in T_{GB} group than other treatment groups. The mortality rate of broiler chicks was highest in T_W group (6.25%) and lowest in T_{GB} group (3.75%) than T_C group (5%) birds. The results of the present study concluded that, broiler birds under green-blue (1-21d in GL and 22-42d in BL) LED bulb treatment group had significantly ($p<0.05$) lower stress as drawn by a ratio of Heterophil: Lymphocyte, which was highest in incandescent bulb treatment groups followed by white LED groups.

Introduction
For the large section of poultry meat consumers, the comprehensive mechanization of the poultry segment has made the broiler meat available in the recent years. Now the broiler meat is far most globally famous animal food product due to its nutritional, sensory and economical properties. It has a high potential to generate foreign exchange earnings through export of poultry products to neighboring countries. The Poultry industry has emerged as the fastest growing segment of the livestock sector both globally as well as in India (Iisa Augustine and Ruchira Shukla, 2015) [6]. Broiler production is one of the most dynamic and fastest growing animal husbandry sub-sectors in India. The total poultry population has increased by 16.81% over in the recent census and the total poultry in the country is 851.81 million. However, in previous census 2012, it was 729.21 million in numbers (Livestock census, 2019) [14]. Due to increasing population growth, urbanization and rising income there is an increasing demand of animal protein source so that chicken meat has shown its fastest growth in last two decades.
Lighting is an important environmental cause in poultry production that is known to affect performance and behavior. Chickens are visually well equipped, and therefore light plays very important role in their wellbeing and productivity. Light is constituted of a wide spectrum of electromagnet (EM) waves. The visible part of the electromagnetic (EM) spectrum is relatively small and is formed of wavelengths from approximately 350 to 800 nm. The eyes of broilers seem to be more sensitive to the broader spectrum than humans and these can perceive ultraviolet and infrared as well.

Components of Light in Poultry Management
Artificial light can be described by distribution of light (photoperiod), colour (wave length)

Influence of herbal mixture, exogenous enzymes and butyric acid supplementation on nutrient digestibility, carcass characteristics and economics of broiler chickens

DK Chaudhari, Sachin Gautam, VK Singh, Ruma Devi, KD Singh, SP Singh, S Tewari and S Rao

Abstract
Three hundred commercial straight run, day old Ven Cobb 400Y chicks were divided into six groups with 5 replicates of 10 birds in each to assess the efficacy of herbal mixture, exogenous enzymes and butyric acid on their performance. The chicks were placed on basal diet with no supplement in negative control (NC) and basal diet supplemented with antibiotics, alcoholic extract of 0.5% herbal mixture, 0.5% herbal mixture (alcoholic extract) + 0.1% butyric acid, 0.5% herbal mixture (alcoholic extract) + 0.03% exogenous enzymes and combination of 0.5% herbal mixture (alcoholic extract) + 0.03% exogenous enzymes + 0.1% butyric acid in PC, HE, HEB, HEE and HEBE groups, respectively. The results of the analyzed data showed that DM and CP digestibility coefficient of herbal based non-antibiotic feed additive groups were similar to NC and PC group birds. Drawn weight yields were not affected by any additive supplements. The abdominal fat was significantly ($P<0.005$) lower in HEB and HE group birds as compare to NC and PC groups. Profit/bird live weight, benefit cost ratio and profitability of HEB group was significantly ($P<0.05$) better than NC, but ($P<0.05$) lower to PC group. It was concluded that, supplementation of alcoholic extract of 0.5% herbal mixture along with 0.1% butyric acid had no adverse effect on nutrient digestibility and carcass characteristics; however, profitability was higher than negative control birds.

Keywords: Herbal mixture, butyric acid, nutrient digestibility, carcass characteristics and economics

Introduction
Now a days poultry sector is one of the most popular and fastest growing livestock sector in India, contributing 10% of livestock and 0.7% of total GDP. The demand for low cost and processed quality chicken meat is growing by 15-20% annually. The aim of poultry production is to get proper growth rate, better feed conversion efficiency and maintaining optimal health to maximize production in terms of meat and egg. In poultry diet, antibiotic growth promoters (AGPs) are used for the protection against some diseases, toxins, improvement in nutrients absorption in intestines etc. However, the efficacy of antibiotics reduced due to development of resistance in pathogenic bacteria; besides this residues of antibiotics in meat have negative impact on public health. In most of the countries AGPs has been either regulated or banned (Lesson *et al.*, 2015) [14]. So, there is need of finding alternatives to growth-promoting antimicrobials without affecting their production. Several substances like essential oil of herbs, organic acids, probiotics, prebiotics, exogenous enzymes etc. have been investigated in recent years, which are able to support productive performance and prevent the incidence of some diseases in poultry (Huyghebaert *et al.*, 2011) [10].

Phytogenic feed additives are plant derivatives of plant extraxts, herbs and spices with extended activities viz., endogenous secretions in the gut, stimulation of feed intake and better growth. Herbs like aloe vera (*Aloe barbadensis*), ashwagandha (*Withaniasomnifera*), mangrail (*Nigella sativa*), turmeric (*Curcuma longa*), methi/fenugreek (*Trigonellafoenum-gracium*), neem (*Azadiractaindica*), punarnava (*Bhoeraviadiffusa*), tulsi (Ocimum sanctum), bhuiamla (*Phyllanthus emblica*) and garlic (*Allium sativa*) are commonly used as medicinal herbs in India and have antibacterial, antifungal, anti-inflammatory, antioxidant, growth promoting, hepatoprotective and immuno-stimulatory activities. Non starch polysaccharides (NSP) present in corn and soybeans are poorly digested by monogastric animals; represent a potential source

Abstract: A number of inorganic elements are essential for the growth, production and reproduction of animals. In addition, mineral requirements are also influenced by age, parity, stage of pregnancy and stage of lactation. Adequate quantity of minerals are utmost important for proper functioning of various physiological functions in animals. Deficiency and excess both have detrimental effects on production and reproduction; thus significantly affecting the economics of animal husbandry.

Key words: Domestic Animals · Macrominerals · Production · Reproduction

INTRODUCTION

A number of inorganic elements are essential for the growth, production and reproduction of animals [1]. In addition, mineral requirements are also influenced by age, parity, stage of pregnancy and stage of lactation. The inorganic elements are classified according to their requirements in animal body. Those required in greater quantities are referred as macrominerals (calcium. phosphorus, sodium, chloride, potassium, magnesium and sulfur). Macrominerals required in large amount each day and their concentration in diet is expressed as percentage of diet or in grams per kilogram of diet. Macrominerals has role in different physiological functions. Other elements required in much smaller amounts are referred as trace minerals (microminerals) i.e. copper, cobalt, iodine, iron, manganese, molybdenum, selenium, zinc, chromium and fluorine. Their concentration in diet is expressed as parts per million (ppm), which is equivalent to milligram per kilogram of diet or in some cases as parts per billion (ppb), which is equivalent to microgram per kilogram of diet. Adequate quantity of minerals are utmost important for proper functioning of various physiological functions in animals. Deficiency and excess both have detrimental effects on production and reproduction; thus significantly affecting the economics of animal husbandry.

Role of Various Macro Minerals in Animal Reproduction

Calcium (Ca): Calcium is an essential component of skeleton and plays a pivotal role in maintaining homeostasis of vertebrates [2]. The maximum portion of calcium present in the bone as hydroxyapatite (99%) and small fractions present in the cell membrane or endoplasmic reticulum (0.9%), extracellular fluid or serum (0.1%) and in cytosol (0.00002%) [3]. Extracellular calcium exist in three forms i.e. ionized (50%), complexes to anions (5%) such as citrate, bicarbonate, phosphate, or lactate and protein bound (45%). Ionized calcium involved in array of physiological processes such as muscular

Pre-Lambing behaviour of Muzzafarnagri sheep

B Singh, PS Pramanik, KD Singh, N Singh, VN Gupta, P Gautam and G Pandey

Abstract
The peri-parturient behaviour of 10 Muzzafarnagri ewes were observed at Livestock Farm Complex, A.N.D.U.A.T., Kumarganj, Ayodhya. All the ewes, in advance stages of pregnancy, that is one or two days prior to lambing, there were relaxation of pelvic ligament; the udder enlargement distended and tightened and waxy; vulva became oedematous and flabby, showing mucus discharge. The restlessness in ewes generally observed 152.25 ± 16.565 min before actual birth of lamb. Onset of intermittent abdominal straining in ewes started 76.66±8.223 min before actual birth of lamb and it was repeated at an interval of 10-12 min, during peak stage of labour. Intense and regular straining in ewes, started on an average 6.33±0.69 min, before actual birth of lambs. The appearance and rupture of chorio-allantoic sac occurred on an average 4.73±0.532 min, before actual birth of lamb. The average time taken by lamb to appear vulva was 3±0.362 min before actual birth of lamb.

Keywords: Muzzafarnagri ewes, pre-parturent behaviour, lambing presentation

Introduction
Sheep raising in India is one of the traditional occupation of some people popularly known as shepherds or Gadariya. People of some regions of our country are raising sheep as a domestic animal for fulfilling family nutrition demand and business purpose from the ancient time such as in Kashmir region sheep is reared for delicious mutton and for beautiful and warm woollen clothes, sheep reared in Uttarakhand and other Himalayan region used as food for scarcity season. Sheep is a small sized, ruminant, calm animal and grows fast and the raising system is very easy and simple. There are various sheep breeds are available in our country which are suitable to the particular region and climate. Now a day, many people are taking the opportunities of sheep farming as business to grow family income. Sheep with its multi-facet utility for wool, meat, milk, skins and manure, form an important component of the rural economy particularly in the arid, semi-arid and mountainous areas of the country. It provides a dependable source of income to the shepherds through the sale of wool and animals.
Sheep is an important species of farm livestock. There is a vast genetic diversity in sheep and out of about 200 breeds listed in the world, 43 breeds of sheep are found in India. The Indian subcontinent is a rich source of diverse ovine germplasm, and only very few countries have such a large number of breeds with wide genetic diversity. In India Sheep make a valuable contribution to the livelihood of the economically weaker sections of the society. Amongst the livestock owners, the shepherds are the poorest of the lot. The export earnings from different woollen products and mutton are also noticeably contributing to the National income. Sheep-skin in the form of leather and leather products is also exported.
The breed Muzzafarnagri is distributed in Muzzafarnagar, Bulandshaher, Saharanpur, Meerut and Dehradun districts of Uttar Pradesh, Uttarakhand and parts of Delhi and Haryana. The animals are medium to large in size. Face line is slightly convex. Ears and face are occasionally black. Both sexes are polled. Males occasionally show rudimentary horns. Ears are long and drooping. The tail is extremely long and reaches fetlock. The fleece is white, coarse and open. Belly and legs are devoid of wool. The overall least square means for lambs 1st and 2nd six monthly and adult annual clips were 582.17, 538.75 and 1217.62g, respectively under farm conditions. The overall averages were 3.63, 15.59, 23.52, 27.14 and 30.76kg, respectively at birth, 3, 6, 9 and 12 month age. Least square means of wool quality attributes viz. fibre diameter, hetro fibres, hairy fibres, medullation and staple length were 38.39±1.36µ, 14.35±1.37%, and 46.89±3.42%.
Knowledge of animal's natural behaviour is essential in ensuring to create an environment, manage and care for individual animals and flocks in a manner that enables them to express

Post-Lambing behaviour of Muzzafarnagri Ewes and Lamb

B Singh, PS Pramanik, KD Singh, J Singh, VN Gupta, P Gautam and G Pandey

Abstract
The post-parturient behaviour of 10 Muzzafarnagri ewes were observed at Livestock Farm Complex, A.N.D.U.A.T., Kumarganj, Ayodhya. All the ewes, in most of the cases, the lamb appeared at vulva whilst the ewes were in recumbent position. In most of the lambing the presentation of foetus was anterior (about 75%). Post lambing behaviour of ewes seen important in establishing of mother-neonate bond to accept or reject of the lambs by ewes. Most of the ewes initiated licking immediately after parturition. The duration of licking and grooming behaviour up to 6 hr post lambing was 24.6±1.28 min., complete expulsion of placenta after birth of lamb was 113.3 ± 4.30 min. There was no case of any dystocia found in Muzzafarnagri ewes. During after birth process the maternal orientation of ewes toward lambs were anterior (70%) and posterior (30%). Maternal rejection was observed 10% in relation to ewes after lambing and 90% ewes accepted their lambs. Placentophagia was absent in Muzzafarnagri ewes. The average time taken in delivery of foetus from anterior to posterior or posterior to anterior was 2.25±0.26 min. The total duration of resting up to 6 hr post lambing was 114.6 ± 4.31 min. The lamb started attempt to stand 4.08 ± 0.34 min after birth. The lambs made 9.42 ± 0.45 numbers of attempts to stand after birth. The average time taken by lambs to first stand was 25.75 ± 0.51 min after birth. Most of the lamb (75%) showed preferences of left teat for their first suckle and about 25% lamb preferred right teat for their first suckle.

Keywords: Post-parturient behaviour, lambing presentation, dystocia, placentophagia

Introduction
Indian climate is very suitable for setting up sheep farming as business or a livelihood in India. Sheep farming requires little investment of land and money, able to get the returns of investment within a very short period. Sheep farming in India can be a great source of good income for the marginal and landless farmers. Sheep is an important species of farm livestock. There is a vast genetic diversity in sheep and out of about 200 breeds listed in the world, 43 breeds of sheep are found in India. The Indian subcontinent is a rich source of diverse ovine germplasm, and only very few countries have such a large number of breeds with wide genetic diversity. Knowledge of animal's natural behaviour is essential in ensuring to create an environment, manage and care for individual animals and flocks in a manner that enables them to express themselves naturally and to remain healthy with a high quality of life. The behaviour of sheep is likely to be a complex interaction between their genetics and the fundamentally important early life experiences with their dam, further complicated by their association with their peers, particularly around weaning, and the quality and availability of grazing (Lawrence and Dwyer, 2000) [11].

Maternal Behaviour
Maternal behaviour is key to ensuring the survival of lambs, particularly when a ewe has two or more offspring. Newborn lambs need milk and immunological protection shortly after birth, and early interactions between the mother and the young are critical in this respect. Bonding, and consequently survival, of twins, can be considerably improved if the ewe remains at the birth site for a minimum of 6 hours, and this can be encouraged in part through feeding management. Two major factors contribute to the formation of this early bonding: postnatal vocal communication and sucking (Nowak, 1996) [14]. The ewe makes a low-level bleating noise, standing so as to encourage the lamb to find the udder and start suckling (Dwyer, 2014) [4]
The ewe and lamb maintain a close spatial relationship over the first week of life. After this period lambs gather into peer play groups and up to 4 weeks of age they go increasingly longer

Effect of different litter materials on growth performance of broiler chickens

VN Gupta, PS Pramanik, KD Singh, S Gautam, P Gautam, B Singh, G Pandey and D Nandan

Abstract
Two hundred forty day old Vencobb 400 straight run commercial broiler chicks were randomly divided into three groups with two replicates of 40 chicks in each to assess the effect of different litter materials on growth performance of broiler chickens. The broiler chicks were kept on rice husk, 50 % rice husk + 50 % paddy straw and wood saving in Tc, T_{MIX} and Tws groups, respectively for a period of 42 days. The results of the experiment showed that broiler chicks kept under T_{mix} ($3027.20^{b}\pm80.50$g) i.e. combinations of paddy straw with rice hulls were heavier as compared to the other litter treatments. The overall body weight gain was numerically higher in T_{mix} as compared to the other litter treatments. It was also evident that feed intake was higher in T_c groups as compared to T_{MIX} and Tws groups. The overall FCR was superior in T_{mix} group ($1.84^{a}\pm0.21$) as compare to other group T_{ws} ($2.22^{ab}\pm0.15$) and T_c (2.42 ± 0.11). The results of the present experiment concluded that the growth performance indicated that final body weight, body weight gain, FCR were better in T_{mix} group than wood saving and the control group broiler birds however, feed intake was higher in T_c group.

Keywords: litter materials, paddy straw, rice hulls, broiler chicken

Introduction
The Poultry industry has emerged as the fastest growing segment of the livestock sector both globally as well as in India (Iisa Augustine and Ruchira Shukla, 2015) [7]. Now a days poultry meat is available for huge groups of consumers due to revolutionary mechanization of the poultry sector in recent years. The higher nutritional, sensory and economical characteristics of poultry meat have made it, far most famous animal food product globally. It has a high potential to generate foreign exchange earnings through export of poultry products to neighboring countries (Iisa Augustine and Ruchira Shukla, 2015) [7]. Broiler production is one of the most dynamic and fastest growing animal husbandry sub-sectors in India. The total poultry population has increased by 16.81% over in the recent census and the total poultry in the country is 851.81 million. However, in previous census 2012 it was 729.21 million in numbers (Livestock census, 2019) [12]. Due to increasing population growth, rising income and urbanization there is an increasing demand of animal protein source so that chicken meat has shown its fastest growth in last two decades.

The type of bedding can affect performance of broiler birds (Billgilli *et al.*, 1999b) [2]. The litter type affects litter bacteria and litter consumption which may influence the immunity and performance of broilers (Lien *et al.*, 1992) [10]. Common bedding materials include rice husk, paddy straw, wood shavings, sawdust, peanut hulls, shredded sugar cane, straw, and other dry, absorbent, low-cost organic materials. Sand is also occasionally used as bedding. The efficiency of litter type can be influence by various factors such as physical properties of the material used, particle size, build up moisture content and rate of caking. In many areas sawdust and wood shavings are most commonly used bedding materials for commercial poultry production. The higher cost, poor supplies and unavailability of these litter materials has encouraged the search for suitable substitute litter materials. Good bedding materials should absorb the moisture from body wastes, limiting the production of harmful pathogenic micro-organisms and ammonia, provide a dry, comfortable medium to broilers for dusting themselves in and rest upon. Therefore, it should be soft, compressible, absorbent and capable of drying quickly.

In this context the use of crop and wood residues as poultry litter seems to be promising. Hence, the present experiment was designed to assess the effect of different litter materials on

ABSTRACT

Chakravati, R.K., Pramanik, P.S., Singh, K.D., Singh, M.K. and Manoj, J. 2019. Effect of litter treatment on growth, carcass traits and immunity status of broiler chickens. Indian Journal of Poultry Science, 54(2): 151-154.

The aim of the present study was to evaluate the effect of various strengths of alum as litter amendment on broiler performance, carcass traits, litter quality and immunity status of broiler birds. About 200 day old Vencobb chicks were divided in to four equal groups, having 50 chicks in each group. The groups T_1, T_2 and T_3 were reared on litter material which is treated with various alum concentrations and the control group without any litter amendment. The present study revealed that the broiler litter group which is amended with alum at a concentration of 0.095 kg/bird,enhanced theoverall body weight gain of broilers with superior carcass traits. The immune level of the broilers were also found better as evidenced from reduced heterophils lymphocytes ratio of litter treated groups. Therefore, it is concluded that alum at a concentration of 0.095 kg/bird can be safely used for broiler litter treatment without any detrimental effects on environment.

Key words: Alum, Broiler, Carcass, Immunity, Growth performance, Litter

INTRODUCTION

Poultry is one of the rapidly growing segments of the agricultural sector in India with an annual growth rate of 6 to 8 percent in broiler meat and 5 to 7 percent in egg production today. Their growth rate has been rising at 8 to 10 percent per annum (Bhanja, 2019). As a result, India is now the world's third largest egg producer and the fifth largest producer of broilers.Rearing of birds in deep litter system of housing is common practice in India for broiler production. The poultry litter quality and status influence bird's performance and also influences economic status of producers and integrators (de Oliveira*et al.*, 2015). The poultry litter used for broiler rearing is a source of released ammonia and its amlioration is an important factor which influences the performance and health status of birds (Rashid *et al.*, 2017). Keeping litter in a dry condition is a critical part of management of poultry farmssince the wet litter causes increased release of ammonia, which negatively affects the productive performance of broilers (Ritz *et al.*, 2006; Nagaraj *et al.*, 2007; Sahoo *et al.*, 2017). Kristensen *et al.* (2000) observed that the intake of feed and overall body weight gain of broilers was decreased when ammonia concentrationwas increased in poultry sheds. The ammonia emission can also affect the atmospheric gaseous balance and biodiversity (Rashid *et al.*, 2017).

Dry litter helps to control the ammonia level, providing the healthy flock environment and reduces condemnations due to various leg ailments and breast blisters (de Oliveira *et al.*, 2015). Dry litter is also important for health and wel being of labourers working at poultry farms (Kristensen and Wathes 2000; Miles *et al.*, 2004; Sahoo *et al.*, 2015). Different chemical compounds are being studied by numerous scientists for making litter dry. The application of alum ($Al_2(SO_4)_3.14H_2O$) as poultry litter amendment for decreasing the release of ammonia from poultry litter in sheds is an economical method (Gilmour *et al.*, 2004; Choi and Moore, 2008).Rashid *et al.* (2017) suggested that application of acidic litter amendments should be encouraged for beneficial broiler production. The alum also lowers water soluble phosphorous and therefore the alum treated litter had beneficial effects on field application as fertilizer (Moore *et al.*, 2000; Sahoo *et al.*, 2015). The present studywas plannedto compare the effect of different concentrations of alum as litter quality improvement on broiler performance, carcass traits, litter quality and immunity status of broiler chickens.

A B S T R A C T

The aim of the present investigation was to examine the man-power utilization pattern of milking operation in dairy animals. The present study was conducted on 23 selected milch animals at Instructional Livestock Farm Complex, College of Veterinary Science and Animal Husbandry, N.D.U.A.T., Kumarganj, Faizabad, U.P. The loose housing system was followed in the farm and animals were maintained within the enclosure having covered area on and around the feed manger. Hand methods of milking were performed in separate milking byre in two shifts following single row system. Man-min required under hand milking operations were recorded by a stop watch and observations were taken for 30 days. The results showed that, that time required in unit operation (sec/ Litre milk) decreased with increase in milk yield of animals. Man-second utilized for unit operation of 0-2, 2-4 and 4-6 litre milk yield group was 166.94, 90.59, and 75.80 second respectively. The average total milking time required for milk yield groups of 0-2, 2-4, and 4-6 litre was 268.77±11.10, 307.09±9.23 and 390.4±10.95 second respectively. These groups had an average yield of 1.61, 3.39 and 5.15 litre milk respectively. Similarly, for evening milking, milk yield group studied were 0-2, 2-4 and 4-6 litre which has an average production of 1.52, 3.25 and 5.08 litre milk respectively. The time required for the milking of per litre of milk for these groups was 188.76, 94.21 and 65.51 second respectively. It was observed with increase in milk yield the time required in unit operation was observed to be in decreasing order. The total time required in milking operation increased from 286.92±9.73, 306.17±12.13 and 332.8±11.84 second respectively. From the present study it may be concluded that total average time spent in hand milking operation of animals was found maximum in morning milking followed by evening milking.

Introduction

The dairy farming is a two-stage production system, i.e., cultivation of fodder crops and management of milch animals, currently contributes about 132.4 million tones (Department of Animal Husbandry, Dairying & Fisheries, Ministry of Agriculture, GOI) of milk and acts as a substrate to channelize energies of 143 million men and 35 million women farm workers to participate in the production process in India (Patel and Mehla, 1988). Man-power is the most critical resources

STUDY THE PHYSIO-HEMATOLOGICAL RESPONSE BEFORE AND AFTER DISBUDDING IN CALVES

Shiv Swaroop[1], P.S. Pramanik[1], K.D. Singh[2*], A.K. Verma[2], Vishuddha Nand[2] and A.K. Srivastav[2]
[1]Department of Livestock Production Management, College of Veterinary Science and Animal Husbandry NDUAT, Kumarganj, Faizabad- 224229, Uttar Pradesh, India [2]Department of Livestock Farm Complex, College of Veterinary Science and Animal Husbandry NDUAT, Kumarganj, Faizabad- 224229, Uttar Pradesh, India

Abstract

The aim of the present investigation was to examine the effect on Physio-haematological profile before and after disbudding in calves. The study was carried out at Livestock Farm Complex, College of Veterinary Science and Animal Husbandry, NDUAT, Kumarganj, Faizabad and nearby villages. Twenty four cattle calves were utilized to study Physio-haematological parameters that are Respiration Rate (RR), Pulse Rate (PR), Rectal Temperature (RT), Haemoglobin (Hb (gm/dl), Neutrophil (%), Basophil (%), PCV (%), Lymphocyte (%), Monocyte (%), TLC (10^3/ µl), Eosinophil (%) and N/L ratio) before and after disbudding in to four groups viz. control (T_0), lignocaine (T_L), tremadol (T_T) and lignocaine+tremadol (T_{L-T}). After medication calves were disbudded by hot iron method. The physiological parameters recorded just before (0h) and after disbudding on 1h, 6h and 24h. The blood samples were collected for haematological parameters just before (0h) and after disbudding on 6h, 24h and 72h. The results showed that, at 0h, 1h, 6h and 24h RR were significantly different among treatment groups. Only at 0h PR was significantly different among different treatment groups and during rest of the period up to 24h there is no significant different among groups. There was significant difference for RT only at 24h among different treatment groups. At 24h, T_0 group showed significantly lowest Hb (10.66±0.49%) which was statistically similar to T_T and T_{L-T} groups. At 0h, 6h and 72h means of PCV% were significantly different among treatment groups. There was no significant different in eosinophil, neutrophil and TLC among different treatment groups during the whole period of study. The lowest lymphocytes (64.00±1.00) was observed in T_T group at 6h. The T_0 group showed significantly lowest basophil (0.00±0.00) which was statistically similar to T_T and T_{L-T} groups but significantly different from T_L group at 6h. At the same interval, T_0 group showed significantly lowest monocytes (4.66±0.61) which was significantly different with T_L, T_T and T_{L-T} groups. At 6h, T_0 group showed significantly lowest N/ L ratio (0.15±0.01) which was statistically similar to T_T and T_{L-T} groups but significantly different from T_L group. It may be concluded that generally physiological responses like RR, PR and RT were higher in control groups than treatment groups before and after disbudding. No significant difference was observed in eosinophil%, TLC, neutrophil% and monocyte% counts between control and treatment groups. However Hb%, basophil%, PCV% and lymphocyte% were significantly different between control and treatment groups. N/L ratio was significant only at 6h. Most of the cases T_{L-T} group showed comparatively better performance.

Introduction

Disbudding is painful yet common husbandry practice in the cattle industry, especially on dairy farms, because hornless cattle are safer (ALCASDE, 2009) and injuries to cattle and other animals are reduced (Prayaga, 2007). Dehorned cattle are safer to handle and cause fewer injuries to workers, other cattle, and farm animals (Stafford and Mellor, 2005). Cattle are also dehorned to reduce bruising and hide damage and to meet transport requirements (Goonewardene and Hand, 1991; Faulkner and Weary, 2000: Prayaga, 2007). Several disbudding methods exist, including cautery, the use of caustic paste, and hot iron. All of these methods involve tissue damage and have been described as painful (Stafford and Mellor, 2005; 2011). The *Model Code of Practice for the Welfare of Animals: Cattle*, however, strongly advises against caustic disbudding (PISC, 2004).

Despite this knowledge, dehorning is commonly performed without pain relief because of the costs and impracticalities associated with researched methods (Petherick, 2005). The breeding of polled cattle eliminates the need for dehorning and because horns are inherited as an autosomal recessive with polledness being dominant (Long and Gregory, 1978). The legislation pertaining to dehorning and disbudding differ between countries like in Sweden, disbudding without local anaesthesia and sedation was banned in the 1992 Animal Rights Act (Bengtsson *et al.* 1996), but calves may be dehorned in Denmark without local anaesthesia until they are 4 weeks of age (Grondahl-Nielsen *et al.* 1999). The Council of Europe recommends the use of anesthesia for the dehorning of calves over 4 wk of age (Oliver, 2009). Pain control is also required for all calves under the *Canadian Code of Practice for the Care and Handling of Dairy* Cattle (NFACC, 2009). Furthermore, the Australian *Model Code of Practice for the Welfare of Animals: Cattle* recommends the use of local analgesics for dehorning calves over 6 month of age (PISC, 2004). Thus, the need to meet industry standards and the availability of suitable dehorning pain relief regimens for commercial production remain a challenge. Very little work has been done on the disbudding distress in Indian dairy animals particularly in indigenous animals.

Materials and Methods

The aim of the present investigation was to examine the Physio-hematological response before and after disbudding in calves. Study was carried out at the Instructional Livestock Farm Complex of the college of Veterinary Science and Animal Husbandry, NDUAT, Kumarganj, Faizabad and around the campus. Twenty four (24) farm born cattle calves of 2 to 3 weeks were randomly divided into four groups within each comprising of 3 males and 3 females, Control (T_0), Lignocaine hydrochloride (2%) @ 1 ml/ bud (T_L) (Tramadol @ 0.25 mg/ kg body weight I/M) (T_T) and Lignocaine + Tramadol at above dose rate (T_{L-T}). Medication was done 5-10 minutes before disbudding. Two doses of ligocaine per bud were injected for cornual nerve block in calves.

(a) Physiological responses

Physiological responses recorded before and after disbudding were as follows-

Respiration rate (no./ minutes)	Pulse rate (no./ minutes)	Body temperature (^{0}F)

(b) Haematological parameters

Haematological responses recorded before and after disbudding were as follows

a) Hb (gm/dl)	d) Neutrophil (%)	g) Basophil (%)
b) PCV (%)	e) Lymphocyte (%)	h) Monocyte (%)

Abstract

The aim of the present investigation was to examine the behavioural response pre and post disbudding in calves. The study was carried out at Instructional Livestock Farm Complex, College of Veterinary Science and Animal Husbandry, NDUAT, Kumarganj, Faizabad. Twenty four (24) farm born cattle calves of 2 to 3 weeks were randomly divided into four groups within each comprising of 3 males and 3 females. Control (T_0), Lignocaine hydrochloride (2%) @ 1 ml/ bud (T_L), Tramadol @ 0.25 mg/ kg body weight I/M (T_T) and Lignocaine (2%) @ 1 ml/ bud + Tramadol @ 0.25 mg/ kg body weight I/M. After medication calves were disbudded by hot iron method. The behavioural parameters recorded just before (0h) and after disbudding on 1h, 6h and 24h. The results showed that, at 24h, $T_{L\text{-}T}$ group showed significantly lowest (0.00±0.00/min) which was statistically similar with T_0, T_L and T_T groups. Sleeping activity was significantly different only at 6h among different treatment groups. At 0h and 24h standing were significantly different among treatment groups. At 0h, 1h, 6h and 24h walking was significantly different among treatment groups. There was no significant difference in feeding, whereas at 1h and 24h drinking was significantly different among groups. At 1h and 6h urination was significantly different among groups. At 1h and 6h, T_0 group showed significantly highest head rubbing with hind foot activity (1.83±0.30/min and 1.16±0.16/min, respectively) which was significantly different from T_L, T_T and $T_{L\text{-}T}$. At 1h, 6h and 24h head rubbing with inanimate object was significantly different among groups. At 1h and 6h head shaking was significantly different among groups. At 1h, T_0 group showed significantly highest (1.83±0.30/min) which was significantly difference from T_L, T_T and $T_{L\text{-}T}$ groups. There was no significant different in biting among different treatment groups, whereas at 6h, T_0 group showed significantly highest (0.66±0.21) which was significantly different from T_L, T_T and $T_{L\text{-}T}$ groups. In this study vocalization, sitting activity were significantly higher in control than treated groups. No significant differences were observed in feeding and biting activities during the whole period of the study. In present study it may be concluded that the calves of T_T group shows comparatively better performance in pain alleviation behavioural activities.

Introduction

Disbudding is a painful yet important routine husbandry procedure in the global dairy and beef industries. Dehorned cattle are safer to handle and cause fewer injuries to workers, other cattle, and farm animals (Stafford and Mellor, 2005). Cattle are also dehorned to reduce bruising and hide damage, to minimize trough space requirements, and to meet transport requirements (Prayaga, 2007). Removal of the horn before its attachment to the skull (disbudding) tends to create a more superficial and less traumatic wound, likely resulting in less pain and bleeding and a shorter healing time (Petherick, 2011). Topical anaesthesia may be a practical and more affordable option for pain alleviation. Administered postoperatively, local anaesthetic agents are fast-acting and highly effective when applied to open wounds or mucosal tissues (Lomax *et al.*, 2008). The preoperative injection of local anaesthetics (cornual block; Weaver *et al.*, 2005) has been found to be effective in reducing pain (cortisol concentrations) for up to 2 h (lignocaine) and 4 h (bupivacaine) following dehorning (McMeekan *et al.*, 1998a). Changes in animal behavior, including increased frequency of head shaking, ear flicking, tail flicking, and reduced rumination, is also suggestive of a painful experience that persists for up to 6 h following dehorning (Sylvester *et al.*, 2004). The Council of Europe recommends the use of anesthesia for the dehorning of calves over 4 wk of age (Oliver, 2009). Pain control is also required for all calves under the *Canadian Code of Practice for the Care and Handling of Dairy Cattle* (NFACC, 2009). Furthermore, the Australian *Model Code of Practice for the Welfare of Animals: Cattle* recommends the use of local analgesics for dehorning calves over 6 month of age (PISC, 2004). Thus, the need to meet industry standards and the availability of suitable dehorning pain relief regimens for commercial production remain a challenge.

Materials and Methods

The study was carried out at Instructional Livestock Farm Complex, College of Veterinary Science and Animal Husbandry, NDUAT, Kumarganj, Faizabad. Twenty four (24) farm born cattle calves of 2 to 3 weeks were randomly divided into four groups within each comprising of 3 males and 3 females, Control (T_0), Lignocaine hydrochloride (2%) @ 1 ml/ bud (T_L), Tramadol @ 0.25 mg/ kg body weight I/M (T_T) and Lignocaine (2%) @ 1 ml/ bud + Tramadol @ 0.25 mg/ kg body weight I/M. Medication was done 5-10 minutes before disbudding. Two doses of ligocaine per bud were injected for cornual nerve block in calves.

After medication calves were disbudded by hot iron method. Hairs around each horn bud were clipped and Vaseline was applied around each bud to protect damage or burning of surrounding tissues. The disbudding is considered sufficient when the corium of the horn is completely cauterized and rough surface is encountered, then relation of red hot iron is stopped. After disbudding, antiseptic Soframycin skin cream® and Topicure Herbal spray® as fly repellent were applied on each bud till complete healing of wound.

Table 1: Description of behaviours recorded during and after disbudding in calves

S.No.	Behavior	Description/ definition
1	Sitting	Lying on group with open eye
2	Sleeping	Lying on ground with closed eye
3	Standing	Erect on all four legs
4	Walking	Movement of all four legs at least once
5	Feeding	Head in feeder whether taking feed or not

ABSTRACT

The aim of the present investigation was to examine the effect on haematological profile before and after disbudding in calves. The study was carried out at the Instructional Livestock Farm Complex, College of Veterinary Science and Animal Husbandry, NDUAT, Kumarganj, Faizabad and nearby villages. Twenty four cattle calves were utilized to study haematological parameters (Hb (gm/dl), Neutrophil (%), Basophil (%), PCV (%), Lymphocyte (%), Monocyte (%), TLC (10^3/ µl), Eosinophil (%) and N/L ratio) before and after disbudding in to four groups viz. control (T_0), lignocaine (T_L), tremadol (T_T) and lignocaine + tremadol (T_{L-T}). After medication calves were disbudded by hot iron method. The blood samples were collected for haematological parameters just before (0h) and after disbudding on 6h, 24h and 72h. Haematological responses recorded before and after disbudding. The results showed that, at 24h, T_0 group showed significantly lowest Hb (10.66±0.49%) which was statistically similar to T_T and T_{L-T} groups but significantly different from T_L groups. At 0h, 6h and 72h means of PCV% were significantly different among treatment groups. There was no significant different in eosinophil, neutrophil and TLC among different treatment groups during the whole period of study. The lowest lymphocytes (64.00±1.00) was observed in T_T group which was statistically similar with T_{L-T} group but significantly differed with T_L and T_T groups at 6h. The T_0 group showed significantly lowest basophil (0.00±0.00) which was statistically similar to T_T and T_{L-T} groups but significantly different from T_L group at 6h. At the same interval, T_0 group showed significantly lowest monocytes (4.66±0.61) which was significantly different with T_L, T_T and T_{L-T} groups. At 6h, T_0 group showed significantly lowest N/ L ratio (0.15±0.01) which was statistically similar to T_T and T_{L-T} groups but significantly different from T_L group. It may be concluded that no significant difference was observed in eosinophil%, TLC, neutrophil% and monocyte% counts between control and treatment groups. However Hb%, basophil%, PCV% and lymphocyte% were significantly different between control and treatment groups. N/L ratio was significant only at 6h. Most of the cases T_{L-T} group showed comparatively better performance.

Abstract

The research was conducted to investigate the effect of stocking density (i.e., I.C.A.R., Venkys and Amrit recommendations) on stress reaction & foot pad lesions in broiler chicken. A 500 day-old straight run commercial broiler strain "VENCOB" chicks were divided in two batches. Each batch was subdivided in 3 equal groups (i.e., I.C.A.R., Venky's and Amrit). All the birds were raised on pucca floor with saw dust as litter material providing equal managemental practices. The blood samples were collected at 4th, 5th and 6th week of the study. H: L ratios were calculated by dividing the number of heterophils by the number of lymphocytes counted. Daily observations for foot pad lesions of birds were recorded. Twenty birds from each group were scored for foot pad lesions (FPL). The results showed that, number of lymphocytes decrease and the number of heterophyl increase in response to stressors. The heterophyl and lymphocyte count (%) was significant (P<0.01) in all the weeks under study. Higher HET count (%) was observed under Amrit followed by Venky's and I.C.A.R. floor space recommendation during last three weeks. The almost similar but reverse pattern of LYM count (%) have been observed like HET count (%) of broiler chickens under three stocking densities at week 4, 5 and 6. At week 4, H: L ratio under I.C.A.R. (00.67±0.015) significantly (P<0.01) higher than that of both Venky's (00.52±0.009) and Amrit (00.52±0.005) recommendations which did not differ each other. At week 5 the H: L ratio in Amrit (00.66±0.012) recommendation was significantly (P<0.01) more than rest recommendations. At week 6 the highest and lowest H: L ratio was 0.71±0.008 (Amrit) and 0.50±0.005 (I.C.A.R.) respectively. There were significant (P<0.01) differences among all the three ratios. The FPL score 0 (no lesion) was significantly higher in I.C.A.R. followed by Amrit and Venky's at 2 & 3 week. At 4th week, L.S. means of FPL score 0 was significantly lower in I.C.A.R. than Venky's and Amrit. At 6 week, it was significantly higher in I.C.A.R. &Amrit than Venky's. The FPL score 1 (mild lesion) was significantly higher in Venky's followed by Amrit& I.C.A.R. at 2 and 3 week. At 4th week, it was higher in I.C.A.R. than other two groups. However, at 6 week, it was significantly higher in Venky's than I.C.A.R. and Amrit. The FPL score 2 (severe lesion) was significantly higher in Venky's and Amrit than I.C.A.R. at week 2. At week 4, it was statistically higher in I.C.A.R. than other two groups. This can be concluded that H: L ratio was higher under Amrit's recommendation than those in Venky's and I.C.A.R., whereas higher the stocking density higher the incidence of foot pad lesions in broiler chickens.

Introduction

The total poultry population in India is 729.2 million, which is 12.39 percent higher than numbers in the previous census (Livestock Census, 2012). Poultry is one of the fastest growing sectors of Indian agriculture today, with annual growth rates of 5.57 percent and 11.44 percent in egg and broiler production, respectively. The value of output from the poultry sector was US$10 billion in 2014 (Rajendran *et al.*, 2014). Broiler production has been more vibrant than layer production within the poultry sector, with an annual growth rate of 11.44 percent, production of 3.725 million tons and employment of 4.29 million people (Index Mundi, 2015). India is the fourth largest producer of poultry meat in the world, valued at US$ 6.6 billion. Poultry production accounts for about 0.66 percent of India's GDP and 7.72 percent GDP from the livestock sector (Rajendran *et al.*, 2014). Poultry meat production increased from 0.069 million tons in 1961 to 3.725 million tons in 2014. The per capita availability of poultry meat is 2.8 kg; against recommended level of 11 kg (Rajendran *et al.* 2014; Index Mundi, 2015). The main reasons for improved broiler poultry production (Kalamkar, 2012; SAPPLPP, 2009) are: modernization of production practices; import of pure lines/grandparent stock; least-cost feed formulation; vaccines against major diseases; provision of EAS and other input services; improved quality breeder management; developments in poultry processing; and private sector partnerships through Contract Broiler Farming. It is estimated that 37 percent of broiler production in India is under contracts, and about 78 percent of those contracts are concentrated in southern India (Rajiajwani, 2012). The term "stress" is commonly used to describe the detrimental effects of a variety of situations on the health and performance of poultry (Moberg, 2000). Birds have limited body resources for growth, reproduction, response to environmental changes, and defense mechanisms. The adaptation process due to stress causes the release of hormones and requires the redistribution of body reserves including energy and protein at the cost of decreased growth, reproduction, and health (Estevez, 2007). After extended or repeated periods of stress, birds become fatigued and weak; they often succumb to starvation and infectious diseases (Heckert *et al.*, 2002; Estevez, 2007). In several studies, it has been determined that psychological and physical stressors such as fasting, frustration, water deprivation and crowding, increase the ratio of Heterophil to Lymphocyte (H/L) (Dozier *et al.*, 2006; Buijs *et al.*, 2009). The H/L ratio has been shown to be highly heritable (al-Murrani, *et al.*, 1997) and a reliable index for determining stress in poultry (Heckert *et al.*, 2002). Stocking density in general is a significant factor in broiler performance (Feddes *et al.*, 2002; Heckert *et al.*, 2002; Tablante *et al.*, 2003). Recently, chicken paw prices have escalated due to an insatiable demand for high-quality paws in export markets. This demand has turned paws into the third most important economic part of the chicken behind the breast and wings, with paws accounting for approximately $280 million a year (US Poultry & Egg Export Council, 2009). The lesions that are caused by FPD are a concern to the poultry industry as a cause of animal welfare, food safety, and product downgrade issues. Animal welfare audits in Europe often use foot, hock, and breast burns-lesions as an indicator of housing conditions and the general welfare of the birds (Haslam *et al.*, 2007). In fact, the occurrence of FPD is now used as an audit criterion in welfare assessments of poultry production systems in Europe and the United States (National Chicken Council, 2010). Foot-pad lesion is an important aspect of bird welfare. In severe cases, the foot-pad lesions may cause pain which together with a deteriorated state of health constitutes a welfare issue. Harms and Simpson (1975) reported that birds with foot-pad dermatitis had an unsteady walk, and Hester (1994) described how foot-pad dermatitis causes birds to walk with a hobbling gait.

The research was conducted to investigate the effect of stocking density (I.C.A.R., Venky's and Amrit recommendations) on stress reaction and mortality in broiler chicken. A 500 day-old straight run commercial broiler strain "VENCOB" chicks were divided in two batches, each containing 3 equal groups (i.e., I.C.A.R., Venky's and Amrit). The blood samples were collected at 4th, 5th, and 6th week of study and mortality were recorded every day. After May-Grunwald–Giemsa staining, H: L ratios were calculated. The results showed that, LYM and HET numbers decrease and increase respectively in response to stressors. The HET and LYM count (%) was significant ($P<0.01$) in all the weeks of study. At week 4, H: L ratio under I.C.A.R. (00.67+0.015) significantly ($P<0.01$) higher than that of both Venky's (00.52+0.009) and Amrit (00.52+0.005) recommendations which did not differ each other. At week 5 the H: L ratio in Amrit (00.66+0.012) recommendation was significantly ($P<0.01$) more than rest recommendations which, however did not differ each other. At week 6 the highest and lowest H: L ratio were 0.71+0.008 (Amrit) and 0.50+0.005 (I.C.A.R.) respectively. All the three ratios differ significantly ($P<0.01$). This can be concluded that H: L ratio was higher under Amrit's recommendation than those in Venky's and I.C.A.R. No significant difference was observed among mortality rates of broiler chickens under these three stocking densities during all the weeks studied.

Introduction

Archaeological discoveries in the Indus Valley suggest that chickens were probably domesticated from the red jungle fowl (*Gallus gallus*) as early as 5400 B.C. (West and Zhou, 1988). The total poultry population in India is 729.2 million, which is 12.39 percent higher than numbers in the previous census (Livestock Census, 2012). Poultry is one of the fastest growing sectors of Indian agriculture today, with annual growth rates of 5.57 percent and 11.44 percent in egg and broiler production, respectively. The sector is providing direct or indirect employment to 6.5 million people. About 80 percent of the employment is generated directly by poultry farms; the rest by the feed, pharmaceutical, equipment and other support services required by poultry. The value of output from the poultry sector was US$10 billion in 2014

ABSTRACT

The present investigation was carried out at Deep Frozen Semen Laboratory, Department of Veterinary Gynaecology and Obstetrics, C.V.Sc.&A.H., N.D.U.A.&.T., Kumarganj, Faizabad (U.P.) with the aim to examine the effect of ascorbic acid on epididymal spermatozoa of Murrah bull on freezability. A total 56 pair (8 pair of testicle in each groups) of testicle were utilize and semen was collected at 6hrs (G1), 12hrs (G2), 24hrs (G3), 36hrs (G4), 48hrs (G5), 72hrs (G6) and 96hrs (G7) after slaughter. All testicles were stored at refrigerated temperature (4^0C) till semen collection. Basic extender used in this research was Tris-buffer and ascorbic acid. Semen dilution & addition of ascorbic acid to maintain addition of concentration in the dilution in the group T1, T2 & T3 @ 1mM, 2mM & 3Mm respectively along with a control group. Post thawed evaluation of refrigerated semen done after 24 hrs storage at the parameters like % progressive motility, %of live count, % of sperm abnormality and % HOS reactive spermatozoa test. The results showed that, mean (±SE) of percent post thaw motility in Epididymal semen collected indicates a significant ($P<0.05$) improvement in sperm motility was reported in T2 and T3 in all the groups (6, 12, 24, 36, 48, 72 & 96 hrs after slaughter). The mean (±SE) of percent live count in post thaw Epididymal semen collected 6, 12, 24, 36, 48, 72 & 96 hrs after slaughter have a significant ($P<0.05$) improvement in sperm livability in T2 and T3. The results showed that, mean (±SE) of percent post thaw sperm abnormalities in Epididymal semen collected indicates a significant ($P<0.05$) improvement in sperm abnormalities reported in T2 and T3 in all the groups (6, 12, 24, 36, 48, 72 & 96 hrs after slaughter). The mean (±SE) of percent Hypo osmotic swelling test in post thaw Epididymal semen collected after 6, 12, 24, 36, 48, 72 & 96 hrs after slaughter shows a significant ($P<0.05$) improvement in Hyper osmotic swelling test in T2 and T3. It may be concluded that the 6hrs and 12hrs collection of Epididymal semen of Murrah bull critically evaluated from storage point of view and ascorbic acid (@ 2mM) in semen additive appears to provide promising results.

Abstract

The present investigation was carried out to evaluate the dairy and carcass parameters of lesser known Gang-Fatehpuri sheep in its breeding tract for a part of their recognition and registration as a new sheep breed. A total of 100 lactating ewes for dairy traits and 92 lambs of either sex were surveyed and evaluated. The overall means of daily milk yield, lactation length, fat contents and solid-not-fat contents were 260.25±5.14 g, 113.15±1.43 days, 8.04±0.22 % and 10.73±0.15 %, respectively. The effect of ewe's parity was significant ($p<0.05$) on daily milk yield. The overall averages of age at slaughter, pre slaughter weight, carcass weight and dressing percentage were 208.24±5.74 days, 24.51±0.59 kg, 11.09±0.31 kg and 45.18±0.29 %, respectively. The gender of lambs affected significantly ($p<0.05$) on all the carcass traits except age of slaughter.

Keywords: *Gang-Fatehpuri, dairy traits and carcass traits. (words in alphabetical order)*

Introduction

Indian ovine gene pool is quite diverse with 74.26 million populations. Sheep husbandry strengthen the rural economy of north-western arid habitats because of uncertainty of agricultural crop production due to less rainfall, limitation of irrigation facilities and low productivity of soil. In spite of two recognized sheep breeds in Uttar Pradesh, several unrecognized lesser known sheep genetic groups distributed in different geographic locations. The lesser known sheep are an important asset because they have best responds to their agro-climatic conditions. The Gang-Fatehpuri sheep distributed in Fatehpur, Kaushambi and Raebareli districts of Uttar Pradesh and contributed a significant proportion in livelihood of Pal/Gadariya communities of Uttar Pradesh.

The dairy and carcass performances are important economic aspects of sheep husbandry. The carcass parameters are directly correlated with growth parameters, which in turns affected by various genetic and non-genetic factors. Indeed, the dairy and carcass performances are important determinants, which directly shape the trading value of a sheep. The knowledge about the various performances of a genetic group is important necessities for their recognitions in animal genetic resources. Keeping these views, the present study was aimed to quantify the dairy and carcass characteristics of Gang-Fatehpuri sheep.

Materials and Methods

The total of 100 ewes for dairy parameters and 92 lambs of either of the sex for carcass traits were taken in the present study. The work was approved by Institutional Animal Ethics Committee (IAEC) for animal experiment of Acharya Narendra Dev University of Agriculture and Technology, Kumarganj, Ayodhya, Uttar Pradesh wide reference no. IAEC/CVSc/2/P-37/2020/31. The dairy parameters *viz.* daily milk yield, (DMY), lactation length, (LL), milk fat % (Fat %), solid-not-fat % (SNF %) and carcass traits namely age at slaughter, (AS), pre slaughter weight (PSW), carcass weight (CW) and dressing percentage (DP) were studied. The data regarding traits under study were collected by face to face interview method using pre tested questionnaire from farmer's flocks in Fatehpur district. The 40 randomly selected milk samples were tested for their quality parameters at by auto milk analyzer at the Namaste Co-operative dairy milk collecting centre. The data of dairy parameters were divided into two season of lambing (1st: Jan.-Jun.; and 2nd: Jul.-Dec.) and three parity (1st, 2nd and 3rd). The animals were slaughtered after 24 hour fasting at Aldua food processing unit, Aligarh, Uttar Pradesh. The data of carcass traits were divided according to sex. All the data of dairy and carcass traits were analyzed by SPSS 20 software programme.

Results and Discussions

Dairy performances

The dairy performances under study were presented in table 1. The present results of daily milk yield of Gang-Fatehpuri ewes were more or less consistent with Muzaffarnagari and Jalauni sheep (Acharya *et al.*, 1982). Conversely, the lower daily milk yield was reported in Jaisalmeri sheep (Arora *et al.*, 2007). Moreover, the higher daily milk yield observed in Malpura (Karim *et al.*, 2001; Mishra, *et al.*, 2009; Saha *et al.*, 2009), Malpura x Awassi halfbreds (Narula *et al.*, 1999), Pattanwadi (Saha *et al.*, 2009; Mohapatra, *et al.*, 2020).

The present finding of lactation length was in close agreement with the observations in and Jalauni (Acharya *et al.*, 1982) and Awassi sheep (Jawasreh *et al.*, 2019). Unlike to present finding, lower lactation length were observed in Awaasi sheep (Haile *et al.*, 2019), and higher lactation length was observed in Madgyal sheep (Tekede *et al.*, 2020).

As comparable to present finding, the lower fat % observed in Awassi (Jwasreh *et al.*, 2019), Lacune (Giambra *et al.*, 2004), Cres x Awassi crossbreds, however, BoroMiac *et al.*, 2009 reported higher fat% in Cres sheep.

Like to present observation, similar SNF % was reported by BoroMiac *et al.* (2009) in Cres and Cres x Awassi genotypes. Conversely, the lower SNF% were observed in Malpura and Awassi sheep by Karim *et al.* (2001) and Jawasreh *et al.*, (2019), respectively. Furthermore, Gimbra *et al.*, (2004) reported higher SNF% in Lacune sheep.

The parity of ewes was significantly affected the daily milk yield of Gang-Fatehpuri ewes. Similar significant effects of ewe's parity on daily milk yield were mentioned by in Malpura and its crosses with Awassi sheep (Arora *et al.*, 2004; Sharma *et al.*, 2009).

(correct the red marks)

Carcass performances

The carcass characteristics under present study were depicted in table 2.

Our finding of age at slaughter was in agreement with the observations reported by Santoshkumar *et al.* (2018) in Mecheri lambs and Hussain *et al.* (2019) in Bannur, Kenguri and Yalaga lambs. Conversely, the lower age at slaughter was observed in Malpura (Singh *et al.*, 2003; Kumar *et al.*, 2008) and Madgyal lambs (Tekede *et al.*, 2020).

The present finding of PSW was compared well with observations in Muzaffarnagari (Kumar *et al.*, 2015) and Kenguri lambs (Hussain *et al.*, 2019). Unlike present findings, the lower estimates were reported in Malpura (Kumar *et al.*, 2008), Mandya (Kumar *et al.*, 2018) and Madgyal lambs (Tekede *et al.*, 2020). Moreover, the

SHORT COMMUNICATION

Evaluation of Body Weight and Body Measurements of Lesser-known Gang-Fatehpuri Sheep of Uttar Pradesh, India

Manoj K. Verma[1]*, Vindhyavashini K. Singh[1], Jaswant Singh[1], Ajeet K. Verma[2]

Abstract

The present study was aimed to evaluate morphometric characteristics of lambs of less known native sheep of Gang-Fatehpuri of Fatehpur district of Uttar Pradesh during different growth stages in its breeding tract for breed recognition and registration with NBAGR, Karnal, India. A total of 365 lambs of either sex of different age groups (94, 102, 95, and 74 heads of 3, 6, 9, and 12 months of age, respectively) were surveyed in 15 villages of Fatehpur district. The overall values of body weight and body measurements, *viz.*, body length, height at withers, chest girth, tail length, and ear length recorded at 12 months of age (sexual maturity) were 29.62 ± 0.46 kg, 73.47 ± 0.46 cm, 73.54 ± 0.51 cm, 77.63 ± 0.43 cm, 40.08 ± 0.23 cm, and 18.29 ± 0.13 cm, respectively. The mean values of all the traits, except ear length, of male lambs, were significantly ($p < 0.05$) higher/larger than female lambs. The differences gradually increased significantly ($p < 0.01$) with advancing age from 3 months to 12 months. The values were generally comparable with the earlier known sheep breeds like Muzaffarnagari, and Kajali of the region.

Keywords: Body measurements, Body-weight, Gang-Fatehpuri, Mutton type breed.

Ind J Vet Sci and Biotech (2021): 10.21887/ijvsbt.17.4.17

Introduction

India has vast biodiversity of ovine genetic resources with multipurpose utility for wool, mutton, milk, skin, and manure. The livestock population develops through unique adaption to their agro-climatic environments and their survival over a prolonged duration. Sheep rearing is a valuable component of the rural economy of India's arid, semi-arid and hilly areas. A systematic attempt to characterize and conserve animal breeds were started after establishing the National Bureau of Animal Genetic Resources (NBAGR) at Karnal, India. In addition to 44 well-recognized sheep breeds, many unrecognized, uncharacterized, and lesser-known sheep genetic populations are disseminated in the entire country. The biometric measurements of different body parts have a significant relationship with the body-weight of animals (Nayak *et al.*, 2008; Mishra *et al.*, 2016; Dass *et al.*, 2019).

The body measurements (body length, height at withers, chest girth) and body weight are used as an indicator of adult size, feeding requirements, and physiological maturity of animals. Furthermore, based on body measurements, an association can be established between body conformation and functionality of animals. Thus, body measurements can assist in the evaluation of growth performance as well as the meat production potential of Gang-Fatehpuri sheep. In view of the facts above, the present study aimed to evaluate the body weights and body morphometric measurements during the growth period of one year of this breed, as part of its recognition and registration with the Animal Genetics Bureau.

STUDIES ON REPRODUCTIVE TRAITS OF JAUNPURI GOATS

Pawan Kumar, V. K. Singh, Jaswant Singh*, N.S. Singh and M. K. Verma
Department of Animal Genetics and Breeding
College of Veterinary Science & A.H., N. D. University of Agri. & Tech.,
Kumarganj, Faizabad, U.P. (India)

Abstract

The present study was conducted to evaluate the various reproductive traits of the Jaunpuri female and male goats under the field condition during 2009-10. Data on 104 does and 34 bucks were collected for evaluation of female and male reproductive traits, respectively in its two native districts viz. Jaunpur and Sultanpur of eastern Uttar Pradesh.

Data on reproductive performance such as breeding methods, age at first estrus, age at first kidding, service period, number of service per conception, kidding interval and gestation length were recorded on 293 Jaunpuri goats of various age groups in its two native districts viz., Jaunpur and Sultanpur of Eastern U.P. during 2009-10. The average age at first estrus in Jaunpur and Sultanpur district were 12.396 ± 0.292 and 12.451 ± 0.300 months, respectively. The estrus duration was 23.962 ± 0.060 and 23.686 ± 0.125 hours, respectively for both the districts. The estrus cycle length, service period, kidding interval and gestation length for both the district were 21.056 ± 0.049, 21.627 ± 0.108, 54.357 ± 7.265, 56.875 ± 7.976, 204.687 ± 7.408, 206.041 ± 8.136 and 149.687 ± 0.146, 149.75 ± 0.113 days, respectively.

Keywods: Reproductive traits, Kidding interval, Age at first estrus, Jaunpuri goat

Introduction

Total goat population has been declined by 3.82% over the previous census and as per the 19th livestock census (2012) total goat population in the country is 135.17 million. It contributes 26.40% of total livestock population. It owes the ability to live under the most diverse condition of natural habitat and its flexible integration into dissimilar socio-economic situation for having quite definite physiological characteristics associated with high economic viability. There has been no serious attempt for description, evaluation, conservation and genetic improvement of goat breeds.

Jaunpuri goat, one of the neglected goat breed of India is found in the belt between Ganga and Gomati rivers of Eastern Uttar Pradesh. Jamunapari breed of goat was used to evolve this breed by crossing with the local non-descript goats of the region (Saraswat, 2001). It is not yet considered as a well-established goat breed of the country due to lack of scientific literature about this breed (Acharya, 1982). Systematic evaluation and characterization of their performance in its native tract is the pre-requisite for its inclusion in the list of the established breed. It will also prevent degeneration of this important indigenous goat of the country. Therefore, the present study was envisaged to evaluate the reproductive performance of Jaunpuri goats in its native tract.

Materials and Methods

The present study was conducted in two districts of eastern Uttar Pradesh viz. Jaunpur and Sultanpur. Seven villages from Jaunpur and eight villages from Sultanpur have been randomly selected. 17 farmers and 53 goats from Jaunpur and 15 farmers and 51 goats from Sultanpur district, as well as 34 bucks from both the district were selected for present investigation.

Data was subjected to statistical analysis using standard formulae (Snedecor and Cochran, 1994).

Results and Discussion

The mean values of various reproductive traits in female Jaunpuri goats from its home tract are presented in table1.

Age at first estrus: The mean value of age at first estrus of Jaunpuri does was 12.42±0.21 months. The findings indicated that the does of the two districts had almost similar age at first estrus. Rahman *et al.* (1977) also reported almost similar age (10.26±1.78 months) at first estrus in Black Bengal goats. However, Khan *et al.* (1981) and Giri *et al.* (2009) observed higher mean values (16 months) of this trait in Jamunapri and Black Bengal goats, respectively.

Estrus cycle and its duration: The mean value of first estrus cycle length of Jaunpuri does was 21.34±0.06 days. No significant difference was observed in the estrus cycle length of the does between the two districts. The mean value of estrus duration of this goat was 23.83±0.07 hrs. The findings indicated no significant difference between the does of the two districts in their average estrus duration.

Age at first tupping and Kidding: The age at first tupping and kidding of Jaunpuri goats averaged 13.12±0.22 and 18.21±0.23 months, respectively. The does of the two districts show no significant differences in these two traits. Saraswat (2001) reported the average age at first kidding in Jaunpuri goats maintained at the farm condition as 678 days. The present estimate of average age at first kidding in Jaunpuri goats is lower than that in Barbari (Dutt, 1968) and Jamunapri (Roy, 1995 and Roy *et al.*, 1989). However, Giri *et al.* (2009) observed lower age at first kidding as 12.3±0.01months in Black Bengal goats.

Service period: In Jaunpuri goats, the average service period was 55.63±5.36 days. The results suggested that the goats of the two districts studied has almost similar service period.

Number of services per conception: The number of services per conception of Jaunpuri goat averaged 1.85±0.07. The findings revealed that the does of the two districts requires almost two services for a successful conception.

Kidding interval: The mean value of kidding interval of Jaunpuri goat was 205.36±5.46 days. The does of the two districts did not show any significant difference in this trait. However, in Jaunpuri goats, Saraswat (2001) reported the average kidding interval as 235 days. The present findings is comparable with those in Black Bengal (206.7±3.12 days) (Giri *et al.*, 2009) and Jamunapari (229.30±26.76 days) (Khan *et al.*, 1981) goats. However, higher mean values were reported by Roy (1995) in Jamunapari (335±0.80 months) and Alam *et al.* (2009) in Beetal (332.81±6.80 months).

Gestation length: The gestation length of Jaunpuri goats averaged 149.72±0.05 days. Does of both districts studied had almost similar duration of gestation. Saraswat (2001) reported it as 146 days in Jaunpuri goats maintained at organized farm.

Type of Kidding: The results revealed that in Jaunpuri goats, twinning was the highest (61.48 %), followed by single (36.58 %), indicating that twinning is very common in this native breed of goat. The incidence of triplet was very rare (1.95 %). Acharya (1982) also reported similar twinning percentage of 64.12±9.4 % in Barbari goats, but lower in Jamunapri goats (27.8±6.46 %) than the present estimate. In Black Bengal goats, Giri *et al.* (2009) observed higher twinning rate (50.4 %) than single births (45.2 %) as observed in the present study.

Male Reproductive Traits

The mean values of various reproductive traits in male Jaunpuri goats collected from its home tract are presented in table 2.

Age at first tupping: The results revealed that the mean value of age at first tupping of Jaunpuri buck was 12.46±0.37 months. No significant difference was observed between the bucks of the two districts in their average first tupping age.

Scrotum Circumference: The scrotum circumference of male goats of the age groups 0-3, 3-6, 6-9, 9-12 and >12 months averaged 1.70±0.08, 3.50±0.50, 16.17±0.73, 16.88±0.88 and 18.00±0.70 cm,

STUDY ON MORPHOMETRIC, WOOL AND REPRODUCTIVE TRAITS OF LOCALLY NON-DESCRIPT SHEEP OF FAIZABAD DISTRICT OF UTTAR PRADESH

Vikash Chand, V.K. Singh* and M. K. Verma

Department of Animal Genetics & Breeding, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad, U.P.

Abstract

The present study was conducted to evaluate the morphometric traits such as physical characteristics, production and reproduction performance of locally available non-descript sheep in Faizabad district in field condition. A suitable questionnaire was used as per breed descriptor to collect various informations. Eighteen farmers and 611 non-descript sheep from district Faizabad were selected for investigation. Information about morphometric traits, production and reproduction performance, various socioeconomic such as land holding capacity, family size, numbers of family members and female engaged in sheep farming income from sheep farming etc. and managemental practices followed by sheep farmers were collected by personal interaction with farmers. As the sheep were of different ages, the data for body weight and measurement have been classified into various groups viz., 0-3, 3-6, 6-9, 9-12, 12-24, and above 24 months. The data collected during the study were subjected to statistical analysis using suitable formulae(Snedecor and Cochran, 1994) & Wool evaluation had perform at CSWRI, Avikanagar, Rajasthan. The common coat colour of locally available non-descript sheep of Faizabad district were white, white with black/brown face with black and white colour of hoof &horn. Ear were small or ill developed (Rudimentary). Horn is present only in male, prominent with backward & downward in direction. The overall average body weight of male sheep of age groups 0-3, 3-6, 6-9, 9-12, 12-24, >24 months was found to be as 12.60 ± 0.24, 15.90 ± 0.13, 19.00 ± 0.18, 21.12 ± 0.10, 30.94 ± 0.76 and 34.50 ± 0.76 kg respectively. The corresponding values for females are 10.04 ± 0.23, 13.62 ± 0.12, 16.34 ± 0.11, 19.26 ± 0.10, 24.01 ± 0.91, and 28.03 ± 0.57 kg respectively. Wool quality is falling in coarse grade having higher percentage of hairy fibers, average quality for carpet/Durry application. The estimated value of wool diameter(micron), Hetero fiber%, Hairy fiber%, total medullation%, staple length(cm), bundle strength tenacity(g/tex), bundle strength elongation% are 39.42, 14.49, 45.44, 59.93, 5.3, 13.07, 11.5 respectively. The reproductive performance of sheep in male age at first mating(months), in female age at first mating(months), age at first oestrous(months), age at first lambing(months), lambing interval(months), estrous cycle duration(days) and service period(months) were 20.58± 0.30, 13.81±0.20, 8.41±0.25, 19.42± 0.29, 8.02 ±0.16, 17.13±0.12 and 3.06 ±0.11.

Key Words: Non-descript sheep, Morphometric traits, wool and Reproductive traits.

Introduction

India is a rich source of diverse ovine germplasm with 74 million sheep which is 6.8% of world sheep population (FAOSTAT 2010). There are 43 documented descript breeds of sheep in India by NBAGR in year 2018. Sheep with its multi facet utility (for meat, wool, skin, manure and to some extent milk) play an important role in the Indian agrarian economy. They are better adapted to arid and semi-arid tropics with marginal and sub-marginal lands, otherwise unfit for crop production. They are perhaps the most suitable small ruminants to utilize the sparse vegetation available in dry land areas through range land management and reseeded pastures. They have an excellent ability to survive over a prolonged period of drought and semi starvation and are less prone to extreme weather conditions, ectoparasites as well as other diseases.

The Indian Council of Agricultural Research (ICAR), India has established a National Bureau of Animal Genetic Resources (NBAGR) at Karnal to take up description, evaluation and conservation of the livestock genetic resources and suggest strategies for their long-term conservation. Efforts are being made at NBAGR Karnal to determine the latest status by compiling information on characteristics of indigenous breeds of sheep through surveys on native tracts. Additional activities on molecular characterization of indigenous sheep breeds are also well under way at NBAGR (Arora and Bhatia, 2003; Sodhi *et. al.*, 2003) in view of worldwide recognition of the need for analysis of genetic structure and relationships of sheep populations/breeds to conserve ovine diversity (Arranz *et. al.*, 1998, 2001; Saitbekova *et. al.*, 2001; Sun *et. al.*, 2004). Conservation of sheep genetic resources, not only national but an international issue, therefore, needs more attention to the present status of sheep biodiversity and outlining measures that are necessary if the goals of sheep diversity conservation and self-reliance are to be combined. Local & non-descript sheep in Faizabad district is white in colour and some sheep is white with black patches. The head is black or brown with white patches. The forehead is slightly convex. The female is polled, but male has prominent horns that is backward and downward direction. The ears are small or rudimentary in70%population. The litter size is mostly single but sometimes twin occur. The fleece is course. However, no proper scientific study has been so far to evaluate the genetic potential of local & nondescript sheep of Faizabad district. Due to this, no standard breed characteristics & phenotypic performance of this breed is yet to be established thus not included in the list of established breed of sheep in the country. Therefore, the present investigation was planned to draw the attention of scientist & shepherd towards the specialist of this sheep for providing recognition as an Indian sheep breed with the objectives to study the geographical distribution and the morphometric, wool and reproductive characteristics of local and non-descript sheep in Faizabad district.

Materials and Methods

The present study was conducted to evaluate the morphometric traits such as physical characteristics, production and reproduction performance of local and non-descript sheep in district Faizabad in the field condition. The survey was conducted in district Faizabad of its native tracts. Seven villages from Faziabad district had been randomly selected for the present investigation. Eighteen farmers and six hundred eleven sheep from Faizabad were selected for investigation. The data collected during the study were subjected to statistical analysis using suitable formulae (Snedecor and Cochran, 1994)

Results and Discussion

1.Morphomretric Traits:

1.1. Coat colour and colour of body extremities of non-descript sheep of Faizabad district

The proportions of five coats colours viz., White, white with black spots, white with brown spots, Black and Brown are 81.44, 6.12, 5.24, 4.09, and 3.11% respectively. There were two types of hoof and horn colours namely black and brown. The white, black and brown tails witch colours were 81.44, 11.26 and 7.20% respectively.

1.2. Body weight:

The overall average body weight of male sheep of age groups 0-3,3-6,6-9,9-12,12-24,>24 months was found to be as 12.60 ± 0.24, 15.90± 0.13, 19 .00± 0.18, 21.12 ± 0.10, 30.94 ± 0.76 and 34.50 ± 0.76 kg respectively. The corresponding values for females are 10.04 ± 0.23, 13.62 ± 0.12, 16.34 ± 0.11, 19.26 ± 0.10, 24.01 ± 0.91, and 28.03 ± 0.57 kg respectively. The estimates obtained in present study were close agreement with those reported by Taneja, (1968) in Marwari sheep. However, the estimates were lower than those reported by Bhat

Non-genetic factors, Murrah buffalo, Four weekly test day milk yields, Peak yield

A B S T R A C T

The aim of present study was to find out the effect of various non-genetic factors on four weekly test day yield (WTDY), 305 days or less lactational milk yield (305MY) and peak yield (PY) in Murrah buffaloes. The data on 172 WTDY records of Murrah buffaloes calved from 2002 – 2011, collected from the dairy farm of NDUAT, Kumarganj, Faizabad Uttar Pradesh. To study the effect of non-genetic factors on WTDY, 305MY and PY, fixed model, least square maximal likelihood analysis was used for the analysis of data. The least square means for 305MY and PY were found to be 1931.37 ± 30.52 Kg and 11.15 ± 0.33 Kg respectively. The least square means of overall WTDY ranged from 3.37 ± 0.12 Kg (WTDY-11) in 40th week test day to 9.11 ± 0.15 Kg (WTDY-3) in 8th week test day. Analysis of variance showed that the difference were statistically significant ($P<0.05$) for the effect of season on 305MY and PY. The effect of period was significant ($P<0.05$) and PY and highly significant ($P<0.01$) on 305MY. The effect of lactation was significant ($P<0.01$) on 305MY.

Introduction

Dairying has become an important secondary source of income for millions of rural families and has assumed a most important role in providing employment and income generating opportunity. Now a days many countries adopts test day milk yields records in genetic genetic evaluation in place of 305 days or less lactational milk yield (305MY) and Total lactational milk yield of dairy animals. Presently India is the largest milk producing (approx 155.5 million tons) country (DAHD 2016). In Indian Dairying buffaloes play a vital role contributing about 51% of total milk produce in country. Murrah is the best buffalo breed with superior genetic potential for milk production. The total lactational milk yield is an old form of record keeping. The test day milk yield recording is an alternative and new form of record keeping, which is an economic and time saving proposition in field condition. Various advantages of using test day milk yield records are individual test day effect, more number of records per animal. The interval between records can be used for reducing generation interval, better adjustment of non genetic factors influencing the milk yield resulting to more accurate genetic evaluation of dairy animals. Although test day milk

ABSTRACT

The present study was carried out on 172 lactation records of Murrah buffalo maintained at Livestock farm, NDUAT, Kumarganj, Faizabad under Network Project on Buffalo Improvement (AICRP) from 2002-2011. The four weekly test day milk yield were used to develop the best lactation curve for the 305 days lactation milk yield in Murrah buffaloes using four models viz. Gamma type function (Wood, 1967), Exponential function (Wilmink, 1987) and Quadratic model (Dave, 1971). The average weekly test day milk yield increased from 7.11 kg in 1st week to a peak yield of 9.91 kg in 8th week, and subsequently to 4.17 kg in 40th week according to Exponential function for overall records. The average weekly test day milk yield increased from 8.77 kg in 1st week to a peak yield of 11.55 kg in 8th week, and subsequently to 5.81 kg in 40th week as per Quadratic model for overall records. The gamma type function was observed slightly higher test day yield in first lactation than the least squares mean. However it was observed lower value in other lactations than the least square mean. The different lactation curve of lactation wise showed gamma function type gave the best fit results in all the lactations.

Key Words: *Lactation curve, Four weekly test day milk yield, ascending phase and descending phase.*

Introduction: There is different trends of milk secretion throughout the lactation of an animal, which can be invariably represented mathematically in the form of the lactation curve. In simple term the lactation curve can be defined as the graphical representation of milk yield against the time (Broody *et. al.*, 1923). There are three different stages of lactation curve. The ascending phase indicates the initial steep rise in the milk yield, which is usually linear. The peak yield along with persistent phase is the largest phase of the lactation, which represent the inherent capacity of animal for suitable milk production. The third phase is the decline phase, which is comparatively short. This phase is usually associated with the drying off stage of the animal. Various lactation curve models have been tried by different workers to fit the lactation curve in different cattle breeds (Singh *et. al.*, 2002; Cilek and Keskin, 2008; Rashia, 2010). The three models (Gamma function, Exponential Function and Quadratic function model) have been used for modeling of lactation curve in present study. The lactation curve models are also used to predict the yield of lactation at any point of the lactation. This property of the model can prove beneficial in case of incomplete records. Getting the test day information from field is not easy and there is every chance of missing the data due to certain inevitable reasons. In such cases these lactation models may prove very beneficial for prediction of these incomplete records. Lactation curve is a valuable tool in designing suitable breeding and managemental strategies for lactating animals. Hence, the present study is carried out on the four weekly test day milk yield data of Murrah buffalo maintained at NDUAT, Kumarganj, Faizabad under Network Project on Buffalo Improvement (AICRP) with objective to identify the best fit lactation curve model to test day milk yield data of Murrah buffalo.

Material and Method: the data utilized in present study was spread over a period of nearly 10 years from 2002 to 2011. The data of 172 four weekly test day milk yield (1st weekly test day milk yield-WTDY 1; 4th weekly test day milk yield-WTDY 2; 8th weekly test day milk yield-WTDY 3; 12th weekly test day milk yield-WTDY 4; 16th weekly test day milk yield-WTDY 5; 20th weekly test day milk yield-WTDY 6; 24th weekly test day milk yield-WTDY 7; 28th weekly test day milk yield-WTDY 8; 32th weekly test day milk yield-WTDY 9; 36th weekly test day milk yield-WTDY 10 and 40th weekly test day milk yield-WTDY 11) distributed in different parities as given as first lactation (44 records), 2nd lactation (29), 3rd lactation (34), 4th lactation (32) and 5th lactation (32). Selection of models were selected and fitted to the lactation curves for the five parities to determine the best model for each of the parity. The models used were as follows-

1. Gamma function model - Model 1 (Wood, 1967)
   $Yt = at^b e^{-ct}$
2. Exponential Function model –Model 2 (Wilmink, 1987)
   $Yt = a + bt + c\exp^{(-0.05t)}$
3. Quadratic model –Model 3 (Dave 1971)
   $Yt = a + bt + ct^2$

   Where,
   Yt = average test day milk yield in the t^{th} week
   a = appropriate initial milk yield just after calving
   b = incline slope parameter upto peak yield
   c = decline slope parameter
   t = time of test day yield

the above mentioned models were fitted to milk yield for different parities. The most suitable model for different parities was identified on the basis of highest coefficient of determinant (R^2) value.

Result and Discussion: the 172 WTDY of different lactation were used to predict different WTDY by these above mentioned lactation curve models. The results are presented in table 2 for different lactation. The average four weekly test day milk yield increased from 6.17 Kg in 1st week (WTDY 1) to a peak yield of 8.91 Kg in 8th week (WTDY 3) and subsequently to 3.30 Kg in 40th week (WTDY 11) by Gamma function model (Model 1). The average four weekly test day milk yield increased from 7.11 Kg in 1st week (WTDY 1) to a peak yield of 9.91 Kg in 8th week (WTDY 3) and subsequently to 4.17 Kg in 40th week (WTDY 11) by Exponential function model (Model 2). The average four weekly test day milk yield increased from 8.77 Kg in 1st week (WTDY 1) to a peak yield of 11.55 Kg in 8th week (WTDY 3) and subsequently to 5.81 Kg in 40th week (WTDY 11) by Quadratic model (Model 3) for overall records presented in table 1.

The Gamma function (Model 1) was observed slightly higher WTDY in first lactation as compare to the least squares mean of actual observations. However it was observerd lower value in all other lactations than the least squares mean of actual observations. Quadratic model (Model 3) gave the highest value in all the lactation than the least square mean of actual observations. The Gamma function (Model 1) gave the best fit results in all the lactation with higher R^2 value. Similaraly Dongare *et. al.*, 2012, Cilek, and Keskin., 2008, singh and bhat., 1978, pande, 1983, olori *et. al.*, 1999, Yadav *et. al.*, 1977 and Kellong *et. al.*, 1977 found good fit Model 1 in different breeds of

Factors Affecting Average Milk Protein Percentage in Sahiwal Cattle and Murrah Buffalo

M. K. Verma, G. K. Sachdeva, Alok Kumar Yadav, Chandra Prakash, Ajeet Kumar Verma

Received 10 May 2016; Accepted 16 June 2016; Published online 23 July 2016

Abstract India is a mainly agriculture country. In Indian agriculture, the vast and diverse livestock population plays a vital role in the rural economy. The present investigation was carried out using data on performance records spread over a period of 6 years (2005-2010), on 188 Sahiwal cows and 94 Murrah buffaloes maintained at ICAR-NDRI, Karnal, Haryana. The research was conducted to study the effect of various factors on average milk protein percentage in sahiwal cows and Murrah buffaloes. Least squares analysis was carried out to assess the effect of non-genetic factors namely season, period and parity on average milk protein percentage. The effect of season was found significant in sahiwal cows whereas non-significant in Murrah buffaloes; the effect of period was found to be significant in both species; the effect of Parity was found to be non-significant in both species.

Keywords Sahiwal, Murrah, Average milk protein percentage, Non-genetic factors.

Introduction

Sahiwal cattle and Murrah buffalo play a vital role in the rural economy. There are various step has been taken for increasing lactational milk yield, however, other important aspect of milk production i.e. milk constituents received little attention in livestock imrovement programs. Presently to establish a profitable and sustainable dairy industry, we must have producer animal in term of quantity and quality of milk. Although Sahiwal cows and Murrah buffaloes are very good milk producing dairy animals but their milk production, composition and reproduction efficiency varied under different management and environment regime [1]. Therefore, quality of milk should be considered in present day breed inprovement programme. To enhance quality milk production of a dairy animal, it is necessary to de-

ABSTRACT

The present study was carried on milk production and milk constituents of 444 lactations of 176 Murrah buffaloes over a period of 10 years from 2001 to 2010 with the objective to find out the effect of various genetic and non-genetic factors on milk yield and milk constituents traits in Murrah buffaloes. Data on total milk yield, milk yield in 305 days or less, lactational average fat per cent and lactational average solid not fat percent (LSA) were collected and compiled purposely and analyzed with suitable statistical tool. Overall least square mean for all lactation traits of total milk yield (TMY), milk yield in 305 days or less (305MY), lactational average fat % (LFA) and lactational average solid not fat % (LSA) were 2253.88 ± 70.15 Kg, 2097.11 ± 59.12 Kg, 7.97 ± 0.02 % and 9.64 ± 0.01 % respectively. The period has significant effect on milk yield and milk constituent traits. Sire and parity affects significantly to TMY and 305MY, however, seasons were affecting to TMY only. Hence it is concluded as milk constituents (LFA and LSA) not affected by sire, parity and season. Although, sire and parity has affect on TMY and 305MY whereas season affects only TMY, therefore, due importance should be given to sire and parity during selection and genetic improvement of Murrah buffalo. Analysis among the parities also revealed that there were no significant (P≥0.05) difference among the second, third and fourth parity hence, at the time of selection second lactation (305MY) milk yield is equally important as fourth lactation in which highest milk yield has been reported in present study.

Key words: Genetic factors, LFA, LSA, Mixed model, Non-genetic factors, TMY, 305MY.

INTRODUCTION

Murrah buffalo is a pride of nation and best in the world. Although, India's buffaloes population are increasing steadily however, it possess only 20.49 million out of 105.34 million of total buffalo population (Livestock census, 2008). Murrah buffalo plays a vital role in the rural economy through milk, meat and animal power. Although Murrah is best and highest milk producing breed of buffalo but its milk production, composition and reproduction efficiency varied under different management and environment regime (Bishnoi and Singh 2009). Although, higher milk yield and quality milk is a key factor for successful and profitable dairy farming however, genetic improvement to increasing the milk productivity of dairy animals through augmenting the lactational milk yield has been emphasized so far. But, milk constituents have equal importance, nowadays, for consumer and processing industries. Therefore, quality of milk should be considered in present day breed improvement programme. To enhance productivity of a dairy animal, it is necessary to develop an understanding of the factors affecting its milk production and composition. Milk production and composition traits affecting by genetic and non-genetic factor therefore, determining the genetic and non-genetic estimate and correlation of parameters might be helpful in determining the method of selection to predict direct and correlated response to selection, choosing a breeding system to be adopted for future improvement as well as in the estimation of genetic response. Several studies have reported genetic parameter estimates for buffalo milk yield (Afzal *et al.* 2007, Sahoo *et al.* 2014) but, literature in Murrah buffalo milk components is scanty therefore, the present investigation was undertaken with the objective to study the effect and influence of genetic and non-genetic factors on milk yield and milk constituents traits of Murrah buffalo.

MATERIALS AND METHODS

Data pertaining to milk production and milk constituent traits were collected from history sheets and milk constituent's registers of 176 Murrah buffalo comprising 444 lactations spread over a period of 10 years from 2001 to 2010 from Dairy Cattle Breeding division, NDRI Karnal, Haryana. Milk production and milk constituent traits considered in the present study were total milk yield (TMY), milk yield in 305 days or less (305MY), lactational average fat % (LFA) and lactational average solid-not-fat % (LSA). Collected data were classified in Five periods [1st (2001-2002), 2nd (2003-2004), 3rd (2005-2006) 4th (2007-2008) and

Effect of weather variables on the yield of wheat crop in District Jaunpur, Eastern Uttar Pradesh, India

Piyush Kumar Singh, VN Rai, Neeraj Singh, Sunil Kumar and Vishva Deepak Chaturvedi

Abstract
India is an important centre of wheat cultivation. The wheat is cultivated on the largest areas in India. wheat is the major crop of Uttar Pradesh, which covers about 32.5 per cent area of total gross-cropped area in Uttar Pradesh. The present study mainly deals with the effect on weather variables. The study has been undertaken for wheat crop in the district Jaunpur, Eastern Uttar Pradesh, India. The present study is formulated to determine the individual effect of weather variables on wheat yield. On the basis of R^2, we found that individually Maximum Temperature is more important with 62.7 followed by sunshine (hr.), rainfall, wind velocity and Minimum Temperature with 61.3, 52.0, 30.4 and 27.9 respectively.

Keywords: Weather variables, significant Correlation & Regression, Yield, wheat crop, R^2.

Introduction
In India, wheat crop is grown mainly in the northern states, with Uttar Pradesh being the top-most contributor of wheat with a total production of 25.22 million tonnes, followed by Punjab (15.78 MT) and Madhya Pradesh (14.18 MT). It is interesting to know that despite being the highest producer of wheat and having the largest land under wheat cultivation in India (9.85 million hectares), Uttar Pradesh productivity (2561 kg/ hectare) is still less than the national average. But Punjab with 4491 kg/ hectare beats every other state in terms of productivity!
Wheat crop is usually sown from months of September to December in various states of India depending upon the suitable climate, and the harvesting is done from February to May depending upon the climate as well as the time it is seeded. The temperature required for sowing ideally should be the winter temperature of 10°C-15°C and summer temperature of 21°C-26°C. The temperature at sowing needs to be low while at the harvesting time, higher temperatures are necessary for the proper ripening of Wheat.
Being a plant, pests and diseases have always been a problem, although, with the use of pest and disease resistant varieties and pesticides, the yield has increased phenomenally. Some common pests that affect the wheat cultivation are Stripe Rust /Yellow Rust, Powdery Mildew, Aphids, Head Scabs, Army Worm, Termites etc. Most of them can be taken care of with some added vigil and judicious use of pesticides.
Environment plays an important role in crop production. The eastern U.P. has different environment and ecology as compared to other parts of the state and country. The study has been undertaken for wheat crop in the district of Jaunpur, Uttar Pradesh, India. The district of Jaunpur is situated in the North-West part of Varanasi Division. The rivers Gomti and Basuhi divide the district into nearly four equal landmasses. The soils are mainly sandy, loamy and clayey. Jaunpur district is often affected by the disaster of floods that is why there is a paucity of minerals. Excavations at some places yield to some rocks which are burnt to make lime. The lime obtained from sand and gravel is used in buildings construction work. The economic development of the district is mainly dependent on agriculture.

Material and Methods
The time series data on yield for wheat crop of Jaunpur district of eastern Uttar Pradesh pertaining for the period from 2000-01 to 2017-18 have been procured from the website.

Abstract
India is an important centre of rice cultivation. The rice is cultivated on the largest areas in India. Rice is the major crop of Uttar Pradesh, which covers about 36.5 per cent area of total gross-cropped area in Uttar Pradesh. The present study mainly deals with the effect on weather variables. The study has been undertaken for rice crop in the district Jaunpur, Eastern Uttar Pradesh, India. The present study is formulated to determine the individual effect of weather variables on rice yield. On the basis of R^2, we found that individually Maximum Temperature is more important with 57.8 followed by sunshine (hr.), rainfall, Minimum Temperature, and wind velocity with 54.2, 52.2, 30.1 and 5.32 respectively.

Keywords: Weather variables, correlation & regression, yield, rice crop, R^2

Introduction
In India rice is grown in 43.86 million ha, the production level is 104.80 million tones and the productivity is about 2390 kg/ha (Agricultural Statistics at a glance- 2015). It is grown under diverse soil and climatic conditions the productivity level of rice is low compared to the productivity levels of many countries in the world. Also, about 90% of the cultivated land belongs to Marginal, Small and Medium farmers which is another constrain in increasing the productivity of rice in the country. It is, therefore, there is ample scope to increase the productivity of rice in the country. The highest productivity is 6710 kg per ha of China followed by Vietnam (5573 kg /ha), Indonesia (5152 kg/ha), Bangladesh (4375 kg/ha) etc There are improved technologies and various interventions which could be adapted to increase the productivity in the country. Cultivation of hybrid rice has potential to increase the productivity and needs to be promoted. A lot of work has been done by IASRI, New Delhi in this direction in different locations of the country. The discriminant function has also been used to forecast Preharvest yield of rice by Agrawal (2002) using weather variables.
The majority of the agriculture land is used to grow major cereal crops; rice and wheat. Rice is the major crop in Uttar Pradesh and is grown in about 5.90 Mha which comprises of 13.5% of total rice in India. Uttar Pradesh has favorable and suitable climate, vast areas of fertile soils, sunshine and adequate water resources. Te cropping intensity is 153% of the Uttar Pradesh. Uttar Pradesh ranks 3rd in the country in production of rice.
Environment plays an important role in crop production. The eastern U.P. has different environment and ecology as compared to other parts of the state and country. The study has been undertaken for rice crop in the district of Jaunpur, Uttar Pradesh, India.

Material and Methods
The time series data on yield for rice and wheat crop of Jaunpur district of eastern Uttar Pradesh pertaining for the period from 2000-01 to 2017-18 have been procured from the website http://updes.up.nic.in/spatrika/spatrika.htm by Economics and Statistics Division, Planning Department, Government of Uttar Pradesh.
Weekly weather variables data for rice and wheat crop in the district of Jaunpur, Eastern Uttar Pradesh have been obtained from the National Data Centre, India Meteorological Department, Pune for the study period 2000-01 to 2017-18.

Effect of weather variables on the yield of wheat crop in District Azamgarh of Eastern Uttar Pradesh, India

Neeraj Singh, Piyush Kumar Singh, VN Rai and BVS Sisodia

Abstract
Wheat (*Triticum aestivum* L.) is the major crop of Uttar Pradesh, which covers about 36.5 per cent area of total gross-cropped area in Uttar Pradesh. The present study mainly deals with to determine the effect of weather variables on the yield of Wheat crop in Azamgarh district of Eastern Uttar Pradesh, India. On the basis of correlation and regression analysis, we found that rainfall is most important variable which effects the yield of Wheat crop positively followed by minimum temperature while rest variables show negative effects on the yield of Wheat crop.

Keywords: Azamgarh, wheat, yield, weather variables, correlation, regression, r-square

Introduction
Wheat (*Triticum aestivum* L.) is the major crop of Uttar Pradesh, which covers about 32.89 per cent area of total gross-cropped area and contributes 31.92 per cent production of India in 2017-18, (DAC&FW, 2018). Wheat is mostly grown in Rabi (December-April) season. This crop is also studied under the FASAL programme of the Department of Space (Parihar & Oza, 2006). Due to importance of this crop in the national agricultural scenario, it is important to study the impact of climate change on this crop.

Azamgarh district (Eastern Uttar Pradesh, India) which falls under middle gangetic agro-climatic region and 8th eastern plain agro-climatic zone in the eastern part of Uttar Pradesh at a distance of about 270 km from Lucknow. Azamgarh district lies between latitude 26° 03' N and longitude 83° 13' E and it is bounded by the districts of Mau in east, Gorakhpur in the north, Ghazipur in south-east, Jaunpur in the south-west, Sultanpur in the west and Ambedkar Nagar in the north-west.

The present study has been undertaken for the yield of Wheat crop in the district Azamgarh, Eastern Uttar Pradesh, India.

Material and Methods
The time series data on yield for Wheat crop of Azamgarh district of eastern Uttar Pradesh pertaining for the period from 2000-01 to 2017-18 have been procured from the website http://updes.up.nic.in/spatrika/spatrika.htm by Economics and Statistics Division, Planning Department, Government of Uttar Pradesh.

Weekly weather variables data for Wheat and wheat crop in the district of Azamgarh, Eastern Uttar Pradesh have been obtained from the National Data Centre, India Meteorological Department, Pune for the study period 2000-01 to 2017-18. The data for Wheat crop have been collected up to the first 16 weeks of the crop cultivation which include 44th Standard Meteorological Week (SMW) to 7th SMW of the next year. The data on six weather variables *viz*. Maximum Temperature, Minimum Temperature, Rainfall, wind-velocity and Sun-shine hours have been used in the study.

Individual effect of weather variables
The statistical models have been proposed by expressing effect of changes in weather variables on yield in wth week as a linear function of respective correlation coefficients between detrended yield and weekly weather data (Agrawal *et al*., 1986). Trend effect on yield is also removed from yield while calculating correlation coefficients of yield with weather variables to be used as weights.

The present paper attempts to analyze the growth rate for Area, Production and Productivity of Rice crop in Varanasi Division of Eastern Uttar Pradesh. The time series data on area, production and productivity of wheat crop pertaining from "Sankhyakiya Patrika" to the period 2000-01 to 2014-15 were used for the study. The per cent change was estimated on the basis of triennium average for area, production and productivity which is increased substantially with 5.19, 15.90 and 10.20 per cent respectively. Graphical presentations have shown the trends in area, production and productivity of Rice. The growth rate was examined by Compound Annual Growth Rate (CAGR), which is 0.307 per cent for area, 1.559 per cent for production and for its productivity 1.247 per cent. Decomposition analysis shows the dominant effect of productivity for the growth in rice production.

Introduction

Varanasi division is an administrative geographical unit of Uttar Pradesh of northern India. Varanasi is the administrative headquarter of the division. Division consists of district of Varanasi, Jaunpur, Gazipur and Chandauli Varanasi district lies between latitude 25 20' N and longitude 83 00' E. The district covers an area of 1535 square kilometers. It is bounded by Jaunpur district to the north Ghazipur and Ballia district in the east, Mirzapur and Chandauli district to the south and Gyanpur to the west. According to the Department of National Economics and Statistics (2015) during 2012-13 and 2013-14,

The paper analyses the growth and instability in terms of area, production and productivity of potato in Eastern Uttar Pradesh. The growth was examined by Compound growth rate and Simple growth rate. The study relates to 1980-81 to 2014-15 which is further divided into four sub-periods. The area under potato registered positive growth rate throughout the period in Vindhyan Zone. The productivity of potato was found to be highest in North Eastern Plain Zone where as lowest in Eastern Plain Zones.

Introduction

Agriculture in India has a significant history. Today India ranks second worldwide in farm output. India has shown a steady average nationwide annual increase in the kilograms produced per hectare for various agricultural items, over the last 60 years. These gains have come mainly from India's green revolution, improving road and power generation infrastructure, knowledge of gains and reforms. The state is divided into 9 agro-climatic zones - Tarai Region, Western Plain Region, Central Western Region, South Western Region, Central Plain Region, Bundelkhand Region, North Eastern Plain Region, Eastern Plain Region and Vindhyachal Region. The study relates to the Eastern Uttar Pradesh which covered different three Agro- climatic zones viz. North Eastern Plain Zone, Eastern Plain Zone, and Vindhyan Zone. North Eastern Plain Zone constitute 11 districts viz. Basti, Bahraich, Balrampur, Deoria, Gorakhpur, Gonda, Mahrajganj, Kushinagar, Siddhartha Nagar, Sant Kabir Nagar and Shravasti. Eastern Plain Zone constitute 11 Districts viz. Azamgarh, Ambedkar Nagar, Barabanki, Ballia, Chandauli, Faizabad, Ghazipur, Mau, Jaunpur, Sultanpur, and Varanasi. In Vindhyan Zone constitutes three districts viz. Mirzapur, Sonbhadra, and Sant Ravidas Nagar.

In the agro-climatic zones of eastern Uttar

Effect of zinc sulphate and gibberellic acid on chemical attributes of winter season guava (*Psidium guajava* L.) *Cv.* Allahabad safeda

Neeraj Kumar Maurya, Bhanu Pratap, Abhinav Kumar, Dheeraj Yadav, Shiv Praksh Shrivastav and Abdul Mazeed

Abstract
The present investigation was carried out at the Effect of Zinc sulphate and Gibberellic acid on Chemical attributes of Winter Season Guava (*Psidium guajava* L.) cv. Allahabad Safeda" at the Main Experiment Station, Department of Horticulture, Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj), Faizabad (U.P.) during the year 2015-2016. The experiment was conducted in Randomized Block Design with seven treatments and replicated in three times, considering one plant as a unit. The observations were recorded for chemicals attributing characters of guava fruits. The maximum fruit size (6.30), weight (110.21), volume (110.35) and diameter (6.87) were recorded with foliar application of GA_3@150ppm. Better quality fruits with respect to highest specific gravity (0.998) were recorded with GA_3@150ppm. The fruit yield was also recorded maximum with the combined spray of GA_3@150ppm. Overall it can be concluded that application of GA_3@150ppm judged the best for higher fruit yield, production and better fruit quality of guava.

Keywords: zinc sulphate, gibberellic acid, total soluble solid, acidity, ascorbic acid and total sugars

Introduction
Guava (*Psidium guajava* L.), "the apple of the tropics", is one of the most common fruits in India. The guava belongs to the family 'Myrtaceae'. It is originated from tropical America and is a subtropical, hardy, evergreen fruit tree. The Guava covers an area of 2.20 Lac ha. Bihar has largest area covering about 29.2 thousand ha. followed by Uttar Pradesh (39.9 thousand ha.) and Karnataka (7.2 thousand ha.) The average productivity of guava is 12 mt/ha. The productivity is higher in M.P, i.e. 29 mt/ha (Misra and Singh, 2005). Guava produced in Allahabad region of U.P. is best in the quality in the world (Chadha, 2001). It is highly tolerant to alkaline and saline soils and it can be grown successfully even upto pH 8.5, it can withstand to the maximum temperature at 46°C, even with scantly rainfall of less than 25 cm. Guava in one of the cheapest and good source of Vitamin-C and pectin. The ripe guava contains 86.9% moisture, 19.3% dry matter, 0.76% ash, 0.40% crude fat, 1.13% crude protein and 6.2% crude fiber but its composition varies widely with cultivars, stage of maturity and season (Ghosh and Chattopadhyay, 1996) [4]. They also content 8.2 to 10.5 0Brix total soluble solids, 4.9 to 10.1 per cent total sugar content, 0.22 to 0.39 per cent acidity and 260 mg/100g of fruit pulp content ascorbic acid (Mitre, 1999) with good amount of iron, calcium and phosphorus. In northern India, guava flowers mainly twice in a year, April-May which provides the crop in. rainy season, whereas, August-September flowering gives the winter season crop. In Maharashtra and Tamil Nadu, there is a third crop produced with flower appearing in October-November. The natural fruits setting in guava are quite high (80-86%) of which only 34-36% fruit reach maturity. Guava fruits are consumed either fresh or processed in the form of product like jam, jelly, nectar and good quality RTS beverages. The rainy season crop of guava is rough, insipid, poor in quality, less nutritive and it is attacked by several insect-pest and diseases. On the other hand, winter season crop is superior in quality, free from the pest and diseases, having long storage life. It further needs improvement in nutritive value, market value and demand so that it fetches more prices in market as compared to the rainy season crop. Recently it was observed that foliar application of plant growth regulator (GA_3) exerted favorable effect on the physico--chemical characters of guava fruits at harvest (Kher *et al*., 2005) [5]. Micronutrients such as Zinc play important role in growth and development of fruits, vegetables and cereals. It is one of the essential elements for the formation of chlorophyll and hence useful towards photosynthetic activity. Zinc is a constituent of some enzymes and possibly takes part in synthesis on Indol Acetic Acid in plant. The objective of study is to find out the effect of

Integrated Effect of Bioagents along with FYM on Pokkah Boeng Disease of Sugarcane

*Seweta Srivastava[1], Vinit Pratap Singh[2], Meenakshi Rana[1], Pavithra G.[1], Debjani Choudhury[1]**

[1]School of Agriculture, Lovely Professional University, Phagwara, Punjab, India
[2]College of Agriculture, Azamgarh Campus, ANDUA&T, Faizabad, Uttar Pradesh, India

Abstract

Sugarcane production in various regions of the country is affected by different biotic and abiotic stresses. Among the biotic constraints, there are many diseases such as red rot, wilt, grassy shoot, pineapple disease, smut, leaf scald and pokkah boeng disease. Amongst the foliar diseases, the pokkah boeng disease is becoming a major disease of sugarcane. Pokkah boeng is frequently associated with sett rot or stem rot disease as both are caused by the same causal organism that is, Fusarium moniliforme. The pathogen affects the economically valuable stalk tissues. This is an air-borne disease; it is primarily transmitted through the air currents and secondary transmission is through the infected setts, irrigation water, splashed rains and soil. Trichoderma spp. and Chaetomium globosum have been frequently used for biocontrol of aerial pathogen. Microorganism selected for the management of pokkah boeng should be aggressive competitor, well adapted to the agro-ecosystem and may be easily applied under field conditions. The selected bioagent enhances or maintains already existing defense mechanisms operating in the environment. Inhibitory effect on the growth of F. moniliforme was studied with five biocontrol agents viz., Trichoderma harzianum, Trichoderma hamatum, Trichoderma viride, Aspergillus flavus and Aspergillus niger. Soil application with bioagents enriched farmyard manure (FYM) in different plots was done before sowing. The data revealed that all the bioagents suppressed the colony growth of F. moniliforme. The suppression of the growth of the pathogen is significantly higher with T. viride and T. harzianum which were at par among themselves. The minimum inhibition was observed in T. hamatum, A. niger and A. flavus. The study also showed that soil application with Trichoderma-enriched FYM gives an additive effect in reducing the incidence of pokkah boeng disease of sugarcane in comparison to those of bioagents alone.

INTRODUCTION

Sugarcane (*Saccharum* spp.) is an economically important cash crop of many tropical and subtropical countries that is used to produce sugar and biofuels [1]. It is the world's largest sugar-producing crop and leads second in production quantity in India [2]. The crop is affected by many biotic and abiotic stresses challenging the sugar production in India. Among the biotic stresses and diseases such as red rot, wilt, grassy shoot, pineapple disease, smut, leaf scald and pokkah boeng have been considered as serious constraints. Among the foliar diseases, pokkah boeng was recorded to range from 1% to 90% during 2007–2017 in the most affected cultivars leading to serious threats for commercial sugar production in U.P. Although the disease has been a minor problem, the epidemiological threats during last few years indicated the growing concern for this disease [3]. Nowadays, the incidence and severity of the disease has been reported from Uttar Pradesh, Maharashtra, Punjab, Haryana, Assam, Tamil Nadu and Bihar—the major sugarcane growing states in India and many other sugarcane-growing countries (Whittle and Irawan, 2000).

Pokkah boeng, derived from a Javanese term, describes a disease affecting the sugarcane tops. It was first recorded in Java by Walker and Went in 1886 and later reported by Edgerton and

ABSTRACT

Guava (*Psidium guajava* Linn.) is a popular fruit crop grown commercially around the world. In India, it is grown almost in all the states. Guava wilt is extremely severe and soil borne disease, *i.e.*, difficult to control once the symptoms appear on the plant foliage. This disease can better be called as guava wilt complex because several pathogens viz., *Fusarium oxysporum* f. sp. *psidii*, *F. solani*, *F. proliferatum*, *F. chlamydosporum*, *Macrophomina phaseoli*, *Rhizoctonia bataticola*, *Cephalosporium* sp. *Gliocladium vermoesenii*, *G. roseum*, *Verticillium alba-atrum*, *Acremonium* sp. and *Nalanthamala psidii* are involved to cause guava wilt. Traditional culturing methods take a long time for identification of pathogenic isolates. A protocol has been developed for the detection of *Fusarium* from soil samples in the early stage of infection. The present chapter emphasize on various molecular detection techniques used to facilitate the rapid detection of pathogen from infected soil samples collected from rhizospheric zone of guava. The disease is soil-borne and is difficult to control. Numerous approaches are used to manage this disease which cause major financial loss have been proposed, including cultural, physical, biological and chemical treatment including host plant resistance. In this context, this chapter is also critically based on the different control measures of guava wilt that have been used in laboratory studies as well as in the guava fields.

Key words: Gauva, wilt, pathogen, detection, management

INTRODUCTION

Guava is grown in tropical and subtropical climates that are conducive to its development (Mohan *et al.* 2020). It is high in calcium, vitamin C, nicotinic acid, phosphorus, and soluble fibre, providing an important source of food for many less developed countries. Guava is thought to have originated in South America (Mexico to Peru) (Amusa *et al.* 2005). South Asian nations, the Hawaiian Islands, Cuba, Brazil, Pakistan, and India produce most of it (Almadhor *et al.* 2021).

Wilt disease is a major limiting factor for the productivity and production of guava (Pereira *et al.* 2017). Rhizosphere soils contain a wide variety of microbes *viz.*, fungi, viruses, nematodes and bacteria, etc. Different type of interaction may take place in the rhizosphere, which include effect of microflora on plant growth and different type of interactions like symbiosis, antagonism, synergism between the rhizosphere microfloras. Rhizosphere and rhizoplane microbial population can influence the various aspects of plant growth and development like root morphology, root to shoot weight ratio, physiological process and crop yield, etc (Hakim *et al.* 2021). Rhizosphere microorganisms, directly or indirectly effects the plant growth by making the nutrients available to the plants and by being antagonistic to phytopathogens. They

Standardization of optimal moisture level on population density, longevity and multiplication of drought tolerant *T. harzianum* isolates on de-oiled cake of Neem

Prashant Singh, Ramji Singh, Madhu GS and Vinit Pratap Singh

Abstract
Trichoderma species naturally occurring antagonistic microorganisms has performed great potential to antagonize plant pathogens. Hence, biocontrol involving the use of such beneficial microorganisms for plant protection is being considered as a viable substitute to reduce the use of chemical pesticides. These microorganisms need to be multiplied and kept viable often for long period under storage. This study aim to study multiplication and longitivity of *Trichoderma* isolates on de-oiled neem cake at different moisture regimes. Fifteen isolates of *Trichoderma* were isolated in different region of Utter Pradesh state of India and one isolate IRRI 1 was collected from Internation Rice Research Institute. Neem cake was able to support the highest population dynamics of *T. harzianum* strains at 70 per cent moisture level up to 21 days. Increasing the moisture beyond 70 per cent resulted in declining the population dynamics of *T. harzianum*. These findings suggested that 70 per cent additional moisture in the de-oiled cake of Neem is most appropriate for increasing the population dynamics of *T. harzianum* strains. *T. harzianum* strains *i.e.* IRRI-1, TH-28, TH-26, TH-21, TH-30, TH-3, TH-29 and TH-7 were found to be best performer with regard to their rate of multiplication. Even without additional moisture, the two strains *i.e.* IRRI-1 and TH-28, could sustain their viability at the cake.

Keywords: *Trichoderma harzianum*, cake, neem, strains

Introduction
Trichoderma species are effective antagonists with biocontrol abilities against economically significant plant parasitic soil-borne infections and are found in nearly all soil types (Shahid *et al.*, 2014) [6]. It's a free-living fungus found in soil and root ecosystems, and it's extremely interacting in root, soil, and foliar environments. It inhibits pathogen growth, survival, and infections through a variety of methods including antibiosis, mycoparasitism, hyphal contacts, enzyme release, induced host cell resistance, and nutrition and space competition. (Yedidia *et al.*, 2003) [7]. Trichoderma spp. are not only effective pathogen antagonists, but they also promote plant growth and root development by colonizing roots as endophyte symbionts, solubilizing minerals and increasing the availability of insoluble nutrients, secreting siderophores, plant growth regulatory materials (phytohormons), vitamins, and enzymes, and so on (Harman *et al.*, 2006) [8]. Trichoderma penetrates the epidermis to colonise root surfaces in a robust and long-lasting manner, increasing plant drought tolerance. Drought avoidance through morphological adaptations, drought tolerance through physiological and biochemical adaptations, and accelerated drought recovery are some of the mechanisms involved in Trichoderma's modulation of drought response (Malinowski *et al.*, 2000) [5].
Several microorganisms have been floated in the market as biocontrol agents (formulations) over the last few decades, and many low-cost materials have been used as carriers, but the problem is that they do not perform as well in the field as they do in lab and glasshouse experiments, and appear to be less effective. They also have limitations in terms of viability and population reduction during storage and transportation. As a result, there is a demand for low-cost materials that are nutrient-rich, biodegradable, and compatible with other ingredients along with biocontrol agents support. These materials can be used as substrates for mass multiplication and help to sustain the viability and survival of BCAs for longer periods of time during storage and transit. They can also supply nutrition if applied to soil (field & pots) conditions.

The world Health Organization (WHO) has declared the corona virus disease 2019 (COVID-19) a pandemic disease. Although the virus can infect people of all ages, evidence suggested that older people (those of 60 years old), pregnant women and small children have more probability of disease occurrence. This may be due to age which is associated with a decline in immunity, higher risk of co-morbidities like Diabetes, Heart disease, Lung conditions, Cancer and people with disability may be a greater risk of contacting COVID-19. In India the situation is getting severe day by day. Here people facing the problem of poverty, malnutrition, unemployment and this pandemic disease make the situation more burst. So it is necessary that we must have to protect ourselves from the COVID-19 which can be fulfilled by improving the immunity level of our body. We know that India is an agricultural country. Most of the people depend on agriculture for its livelihood. There are many agricultural products which can help us to build up strong immunity system out of them one important product is mushroom. Mushroom cultivation can convert the huge lignocellulosic waste materials into a wide diversity of products (edible or medicinal food, feed and fertilizers), protecting and regenerating the environment. Cultivated edible mushrooms are the fruiting bodies of basidiomycetes with a saprobic life style. These basidiomycetes can be divided into primary, secondary, and tertiary decomposers (1). Primary decomposers such as the oyster mushrooms (*Pleurotus* spp.) and shiitake (*Lentinula edodes*) degrade hemi-cellulose, lignin, and other components of plant material. Unlike secondary and tertiary decomposers, they do not depend on other organisms and their metabolites. Secondary decomposers such as the button mushroom typically colonize composted materials, while tertiary decomposers such as

Fusaric Acid: A Potent Vivotoxin

Seweta Srivastava, Vinit Pratap Singh, Meenakshi Rana

[1]School of Agriculture, Lovely Professional University, Phagwara, Punjab, India
[2]College of Agriculture Campus, Azamgarh, ANDUA&T, Ayodhya, Uttar Pradesh, India

Email: meenakshi.20557@lpu.co.in

Abstract: ***Vivotoxin designates a secondary metabolite produced by the pathogen and/or its host during infection, produces disease symptoms, but is not oneself the initiating causal agent of the infection. Out of all, Fusaric-acid is the most studied pathogen produced wilt toxin classified as a non-specific vivotoxin. It does not produce all the symptoms of wilt. Many scientists all over the world including India were of the belief that, out of all other toxins involved in the infection process of wilting, fusaric acid was the most potent one. Infected tissue shows a marked increase in respiration process which is contrary to the host tissues doped with fusaric acid because it is a best-known respiratory depressant.***

Key words: ***Fusaric-acid, Fusarium oxysporum, Potent, Vivotoxin, Wilting***

1. INTRODUCTION

Dimond and Waggoner, 1953 gave the term "vivotoxin" to denominate "a substance produced in the infected host by the pathogen and/or its host, which functions in the production of disease, but is not itself the initial inciting agent of disease." They also notified that "a vivotoxin is a disease-producing entity and therefore a pathogenic agent." They enlisted 3 major criteria as the nominal need to set up vivotoxicity. These were -
(a) reproducible segregation from the infected host plant,
(b) purification, and
(c) re-production of at least a fraction of the disease symptoms by allocating the toxin in a same healthy plant.

Dimond, 1955 subsequently altered their criteria by defining that vivotoxin "not be present in the healthy host" because it produces during the host-pathogen interaction. Dimond as well explained that, instead of refinement, the toxin be defined chemically. Dimond & Waggoner seemed to be cognizant of this in consideration that vivotoxicity could be incontestable by observing only the 1st and 3rd of their criteria. Paradoxically, they said that "just as it is usually necessary to know the identity of a parasite to establish it as a cause of disease, so it is also necessary to purify and identify a vivotoxin to prove its complicity." We disagree with the postulate expressed in the first section or with the assumption attained in the last. What is required in both the cases is indicated in the conclusion that the parasite or the toxin perform a significant causative function during the occurrence of biotic infection. Here we want simply signalize that criteria which stipulate the requisite evidence are more adequate than those which prescript the processes by which the information is to be received. First step of Dimond & Waggoner's, which shows segregation of the toxin from the infected host plant, is based on the aforementioned criticism. Separation of most potent, coseismal toxin, existing in little bulk, seems impracticable, but tolerable illustration is that it utilizes in the creation of infection symptoms may be acquired by some different ways (Braun and Pringle, 1959). Despite the fact that these considerations betoken that the criteria of Dimond & Waggoner are little idealistic because they don't explain straight on the query of their

Character association and path analysis of yield contributing traits and quality parameter in chickpea (*Cicer arietinum* L.)

Vartika Singh, SC Vimal, Shiv Prakash Shrivastav, Virendra Maurya and Nidhi Singh

Abstract

Forty genotypes along with three check varieties of chickpea (*Cicer arietinum* L.) were assessed to work out the association of different seed yield traits, direct and indirect effects of their various attributes on seed yield. Seed yield per plant showed significant and positive correlation with pods per plant, seed yield per plant showed highly significant and negative correlation with days to 50% flowering and non-significant correlation with other characters. The characters showing significant positive correlation among yield and important characters would be highly effective and efficient in improving respective traits. Path analysis identified pods per plant and seedling length as important components having high order of direct effect to secondary branches per plant and vigour index as important components having high order of indirect effect on seed yield per plant. The characters identified above as important direct and indirect yield components merit due consideration in formulating selection strategy in chickpea for selection of high yielding varieties.

Keywords: Chickpea (*Cicer arietinum* L.), Character association, Path analysis, Seed yield, Quality parameters

Introduction

Chickpea is an important pulse crop in India. It is grown in *Rabi* season in India. Globally, the pulses are the second most important group of crops. These are used for food for human and other animals. Pulses are an important food crop due to their high protein and essential amino acid (methionin, cystein and trypltophan) required for the proper growth and development of human body. On an average pulse contain 20-25 *per cent* protein and dry seed. Chickpea (*Cicer arietinum* L.) belongs to genus *Cicer*, tribe Cicereae, family Fabaceae, and subfamily Papilionaceae. It originated in south-eastern Turkey. The *Cicer* is of Latin origin, derived from the greek word 'kikus' meaning force or strength. Among pulse, chickpea occupies a premier position in respect of area and production in the world. It is grown in an area 13.20 m ha and the production is around 11.60 m tonnes with an average productivity of 880 kg per ha. India is also greater consumer as well as importer of chickpea in the world. In India, chickpea is grown about 9.93 m ha area and producing 9.53 m tonnes grain with productivity of 960 kg per ha. In Utter Pradesh, it is cultivated on area of 577 thousand ha with grain yield production is 475 thousand tonnes and productivity of wheat crops is 824 kg per ha respectively 2013-14 (Anonymous, 2015) [1]. It is cultivated throughout the country excepting high altitude and costal region. However, the major chickpea producing state are Madhya Pradesh, Rajasthan, Maharashtra, Karnataka and Andhra Pradesh. Which contribute more than 90 per cent of the national production.

At germination levels it not only involves speed and totality germination but also punching power of the seedling at different range of environmental condition. Thus study of correlation and direct and indirect effects of seed traits provides the basis for successful plant. The objective of this study was to determine the correlation and path analysis of yield and yield contributing characters in chickpea to assess their suitability in a breeding plant.

Materials and Methods

The study was designed to work out the status of association of different seed yield traits and direct and indirect effects of these different traits on seed yield per plant among forty chickpea genotypes at field experiment under present investigation was conducted during *Rabi* 2014-15 at the Student's Instructional Farm and lab experiments were conducted in Seed Testing Laboratory, Seed Technology Section, N. D. University of Agriculture and Technology,

Enhancement of yield components and seed quality parameters by growth regulators in lentil (*Lens culinaris* Medik.)

Pankaj Kumar, SC Vimal, Sarvjeet and Jai Prakash Gupta

Abstract

The present study were carried out in the Department of Genetics and Plant Breeding, N. D. University of Agriculture and Technology, Kumarganj Faizabad during *rabi* season 2015-16 and 2016-17 entitled "Enhancement of yield components and seed quality parameters by growth regulators in lentil (*Lens culinaris* Medik.)" The objective of the study was To standardize growth regulators optimization seed germination and vigour potential, with the selection of GA_3, Kinetin and NAA for exploitation of its, maximum grain yield in lentil under the agro-climatic conditions. The 19 treatments of growth regulators and seed priming for lentil variety (NDL-1) was evaluated following 13 quantitative characters *viz.*, Days to 50% flowering, Days to maturity, plant height on 30 and 60 days, number of branch on 30 and 60 days number of pods per plant, number of seeds per pod, 1000 seed weight biological yield/plant harvest index (%), seed yield per plant (g), seed germination, seedling length vigour index. The treatment T_3 (GA_3 150 ppm (priming) was found best in, all the treatments. Maximum number of pods per plant (46.69) and seed yield/plant (2.68 g) was recorded with T_3 (GA_3 150 ppm (seed priming).

Keywords: lentil, growth regulator, Priming

1. Introduction

Pulses are the cheapest and most widely consumed source of protein in countries like India, having predominantly vegetarian population. On an average pulse contain around 20-25% protein, which is 2.5 to 3.0 times higher than that of cereals and are correctly called as "poor man's meat". Besides protein, pulses are also rich source of calories, vitamins and minerals essential for human nutrition.

Lentil (*Lens culinaris* Medik) is one of the most nutritious amongst cool season legumes, and belonging to family, *leguminoseae* and sub-family- *papilionaceae*, genus- Lens and species- culinaris with chromosome number 2n = 14. It is of very ancient origin and its native home is regarded to be the countries in eastern Mediterranean littoral, such as Asia Minor, Greece and Egypt, from where it extended eastwards to India. The valleys in the Hindukusk Mountains in India are also claimed as its native regions. It was later introduced in Europe, Africa and America. It is known by at least 30 common names in various parts of the world *viz.*, Masoor, Mangu/ Margu, Masura, Renuka, Mangalaya *etc.*

Seed priming is a pre-sowing treatment which involves a controlled hydration of seeds, sufficient to allow pre-germinative metabolic events to take place while insufficient to allow radicle protrusion through the seed coat. This technique has been used to increase yield components and seed quality parameters under unfavorable environmental conditions Treatments were various doses of growth regulators alone and along with foliar spray of growth regulators. Besides, seed priming technique is used for lentil production in some area. Priming can enhance crop establishment, vegetative growth and seed yield of lentil. The factor attributed for low yield of pulses in India as compared to the world productivity are non-availability of quality seeds of improved and short duration varieties, growing of pulses under marginal and less fertile soil with low input and pest and disease management growing of pulses.

Materials and Methods

The field experiments under present investigation were conducted during 2015-16 and 2016-17 at Student Instructional Farm and lab experiments were carried out in Seed Testing Laboratory of Seed Technology Section, N. D. University of Agriculture and Technology, Kumarganj, Faizabad (U. P.). Geographically, Narendra Nagar situated between 26.47^0 N latitude, 82.12^0 longitude and at an altitude of 113 meters above the mean sea level. The climate of district Faizabad is semi-arid with hot summer and cold winter.

Determination of best combination of bio-fortification and hydro-priming for yield and its quality parameters in chickpea (*Cicer arietinum* L.)

Sarvjeet, SC Vimal, Jai Prakash Gupta and Ashish Singh

Abstract
The field experiments under present investigation were conducted during *Rabi* 2014-15 and 2015-16 at Student Instructional Farm and lab experiments were carried out in Seed Testing Laboratory of Seed Technology Section, N. D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) with objective of to determine best combination of biofortification and hydropriming for yield contributing traits and seed quality parameters *i.e.* days to 50% flowering, Days to maturity, Plant height (cm) 30 and 60 DAS, No. of branches per plant 30 and 60 DAS, number of pod/plant, number of seed/pod, Biological Yield (g), harvest index, 100 seed weight (g), seed yield kg/ha, germination (%), seedling length (cm), vigour index, seed yield/plant (g). The experiments were conducted in factorial RBD design with three levels of biofertlizer (*Rhizobium* 7.5g, 10g, 12.5g, *Trichoderma* 5g, 7.5g, 10g and PSB 7.5g, 10g, 12.5g) and seed priming (13, 16, 18 hrs) in chickpea variety (Pant G-186), result revealed that inoculation of biofertilizers significantly improved plant height at 30 and 60 days, number of branches per plant on 30 and 60 days, number of pods per plant, number of seeds per pod, biological yield, harvest index, 100-seed weight, seed yield, seed germination, seedling length, vigour index and seed yield per plant. Overall the treatment of *Rhizobium* dose 12.5g with 16 hrs hydropriming produced higher seed yield (2170.08 Kg) in first year and (2083.17 Kg) in second year, respectively. On the basis of present study it was concluded that nodulation and seed yield of chickpea can be improved by inoculation with *Rhizobium* and hydropriming 16 hrs which could be economically feasible to increase chickpea production.

Keywords: bio-fortification, hydro-priming, *Cicer arietinum*

Introduction
Chickpea (*Cicer arietinum* L.) belongs to genus-*Cicer*, family-*Leguminosae or Fabaceae*, and sub family-*Papilionaceae*. It's origin is considered in South Eastern Turkey (Ladizinsky, 1975). In India, total production of chickpea was 9.53 million tones from of 9.93 million ha area with average yield of 960 kg/ha in year 2013-14. In area, production and productivity of Uttar Pradesh possessed 577 thousand ha. 475.4 thousand tones, 824 kg ha^{-1} respectively in year 2013-14 (Anonymous, 2015). Seed priming, several processes including storage, material handling, activation and synthesis of a number of enzymes and nucleic acids, repair and build up, Several biochemical and physiological changes have been observed in seeds during ageing membrane disruption is one of the main reason of seed deterioration the major cause of membrane disruption are increase in free fatty acid level and free radical productivity by lipid peroxydation. Different techniques could be used to enhance crop yield. Priming is also thought to increase free radical scavenging enzymes activity and counteract the effect of lipid peroxidation and reduce leakage of metabolites. The early improvements may increase the rate of unifofmity of seed germination and seedling emergence. (Afzal *et al.*, 2013) [1]
The present experiment entitled Determination of best combination of biofortification and hydropriming for yield and its quality parameters in chickpea (*Cicer arietinum* L.)

ABSTRACT

Spinach is a good source of vitamins riboflavin and calcium and dietary fiber. Now a day plant growth regulators are playing a very important role in increasing yield, growth and improving the quality of crops. The experiment comprised seed treatments of plant growth regulators *viz.,* Gibberllic Acid (GA_3), Indole Acetic Acide (IAA), 2,3,5 Trido Benzoic Acid (TIBA) the observations were recorded on characters *viz.,* germination (%), abnormal seedling (%), shoot length (cm), root length (cm), seedling length (cm), seedling dry weight (g) and seedling vigour index-I. The study revealed that the different PGRs effects significant for all parameters. The application growth regulators GA_3 @ 50 ppm improved root length (7.37 cm), shoot length (7.91 cm), seedling length (15.28 cm) and seedling vigour index -1(976.81). While, the application of GA_3 @ 100 ppm recorded maximum germination (64.72 %) and dry weight (0.570 g). Among varieties, variety Allgreen was found superior for improved root length, shoot length, seedling length and seedling vigour index -1. It may be concluded that germination, seedling growth and vigour of partially aged seed of spinach can be significantly improve with the Application of GA_3 @ 50 ppm on variety Allgreen.

Introduction

Spinach (*Spinacia oleracea*) is an edible flowering plant in the family Amaranthaceae. It is native to central and south western Asia. It is an annual plant (rarely biennial) which grows to a height upto 30 cm. Spinach may survive over winter in temperate regions. The leaves are alternate, simple with ovate to triangular, variable in size from about 2-30cm long and 1-15cm broad with larger leaves at the base of the plant and smaller leaves higher on the flowering stem. The flowers are inconspicuous, yellow –green, 3-4 mm diameter, maturing into a small, hard, dry, lumpy fruit cluster of 5-10 mm across containing several seeds. Common spinach / palak were long considered to be in the family chenopodiaceae, but in 2003, that family was merged into the family amaranthaceae in the order caryophyllales. Within the family amaranthaceae, amaranthoideae and chenopodioideae are now subfamilies for the amaranths and the chenopods, respectively.

Spinach is thought to have originated in ancient Persia (modern Iran and neighboring

ABSTRACT

The present study were carried out in the Department of Genetics and Plant Breeding, N. D. University of Agriculture and Technology, Kumarganj Faizabad during *Rabi* season 2014-15 and 2015-16 entitled "Standardization of hydropriming duration for enhance seed yield and its quality parameters in chickpea (*Cicer arietinum* L.)" The objective of the study was to standardize the hydro priming duration Seed priming is a simple and cheap method but is acceptable in different areas. In order to the effect of hydropriming treatment on germination percentage in caraway (Carum carviL.), this experiment was conducted by randomized block design (Factorial) design with three replications. The factor was including hydro priming 13(P_1), 16(P_2), and 18(P_3) hours. The results showed that the effect of hydropriming was significant on germination percentage, seedling length, and seedling vigour index. Mean comparison showed that the highest germination percentage, seedling length were achieved by P_2 and also the highest seedling dry weight and seedling vigour were achieved by P_2 and lowest germination percentage, seedling length, seedling dry weight and seedling vigour were achieved by P_1. The results of this experiment showed that hydro priming method can improve the germination percentage in field condition and lab condition.

Introduction

Chickpea (*Cicer arietinum* L.) is the most important pulse crop in India with an average yield of 1500-2000 kg/ha. Chickpea is a diploid species with a chromosome number 2n = 16. It belongs to subfamily Papilionaceae of the family Leguminaceae. It's seeds contain 16.4-31.2% protein, 3.0% fibre, 38.1-73.3% carbohydrates, 1.6-9.0% cellulose, 0.2% Ca, 0.3% P, 3.0% ash, vitamins (C and B) and minerals (Mg, Zn, K, Fe) (Huda *et al.*, 2003 and Ozer *et al.*, 2010). Combined inoculation of *Rhizobium* with *Pseudomonas striata* or *Bacillus polymyxa* and with *Bacillus megaterium* have shown increased dry matter, grain yield and phosphorus uptake significantly over the uninoculated control in legumes (Elkoca *et al.*, 2008). Phosphate solubilising bacteria (PSB) plays an important role in making phosphorus available to crop plants.

The present study was undertaken comparative study of biofertilizers and seed priming on seed yield and quality of chickpea (*Cicer arietinum* L.). Seed priming, several processes including storage, material

An experiment was carried out during *Rabi,* 2015-17 at Students Instructional Form, Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Faizabad (U.P.) to study the simple correlation coefficients among 13 quantitative characters with genotype NDL-1 in three replications using RBD Factorial design. Estimates of simple association coefficients among 13 quantitative characters estimated during 2015-16 and 2016-17 displayed that seed yield per plant exhibited highly positive significant associations with vigour index, biological yield per plant, seedling length, seed germination, harvest index, 1000 seed weight, number of seeds per pod, number of pods per plant, No. of branches/plant 60 days, No. of branches/plant 30 days, plant height (cm) 60 days, plant height (cm) 30 days, days to maturity and days to 50% flowering. All the other characters under study also displayed highly significant associations with each other besides seed yield per plant in both the years.

Introduction

The pulse is an annual leguminous crop yielding from one to twelve seeds of variable size, shape and color within a pod. Pulses are used for food for humans and other animals. Pulses are very important sources of protein in Indian diets as majority of population are vegetarian. Pulses are the third most important group of crops after cereals In the pulses includes; chickpea dry beans like pinto beans, kidney beans and navy beans; dry peas; and others among which lentil is a most important food legume. Lentil is eaten as *Dahl*, either whole or split. Lentil (*Lens culinaris* Medik) is of the important *Rabi* pulse, sown from October to December all over India either as a pure culture or as a mixture with sugarcane, linseed, rapeseed and mustard etc. The crop is harvested from February to April, depending upon the time of sowing. It can be grown on all kinds of soil. It can be successfully grown on poorer soil of moderate alkalinity. It can also tolerate drought. In the world India's rank 2nd in respect of production as well as acreages followed by Turkey. In India it is grown in about 1.48 m ha with total production 1.03 mt, and productivity 697 Kg/ha. Uttar Pradesh occupies 0.59 m ha area with 0.48 tones

HETEROSIS AND INBREEDING DEPRESSION IN MUNGBEAN [*VIGNA RADIATA* (L.) WILCZEK] UNDER PROBLEMATIC SOIL

S.C. Vimal, Pankaj Kumar and K.K. Srivastava
Seed Technology Section, N.D. University of Agriculture and Technology, Kumarganj, Faizabad-224 229 (U.P.) India
E-mail: scvimalndgpb@gmail.com

ABSTRACT

Estimation of heterosis over better parent may be helpful in identifying real heterotic crosses, while their practical value may be known of through estimation of over the standard or the best variety of the area. The present investigation aims at estimating the magnitude of heterosis over better and standard parent and inbreeding depression for F_1 to F_2 were calculated in six set of crosses of mungbean in Khari and zaid seasons for seed yield and its related components. Marked hetrosis for seed yield and its important components were observed. The hybrid EC-393407× ML-550 be the most promising cross for seed yield and some other desirable traits. The study reveals good scope for commercial exploitation of heterosis as well isolation of pure lines among progenies of heterotic F_1 for improvement of yield level in mungbean.

Key words : *Mungbean, hetrosis, inbreeding depression, segregating generation, yield and yield components.*

Among the various pulses grown in our country, mungbean (*Vigna radiate*(L.)Wilczek) is one of the most important pulse Crops. Mungben also know as greengram, botanically belongs to family leguminosae and sub-family papillonaceae. It is a highly self-pollinated crop having somatic chromosome number (2n=2x) of 22. Mungbean is grown principally for its proteineous seeds that are used as human food. Prior knowledge of the nature of heterosis and inbreeding depression are paramount significance in crop improvement. Exploitation of heterosisis considered to be one of the outstanding achievements of plant breeding. In self-pollinated crops like mungbean, the scope for utilization of heterosis depends mainly upon the direction and magnitude of heterosis. In the present investigation the objective is to asses extent of hetrosis present in F_1 hybrid and to know the possibility of exploiting hetrosis in hybrid breeding programe. The estimates of hetrosis and inbreeding depression can gave a preliminary idea about the genetic control of particular character. It helps also in choosing suitable crosses to be used in combination breeding programmes.

MATERIALS AND METHODS

The experimental materials comprised of F_1, F_2, BC_1 and BC_2 generations of six crosses (EC-393410 X NDM-1, EC-393410 X Pant M-3, EC-393407 X ML-550, EC-393407 X NDM 5-3, NDM-1 X ML-287 and NDM 98-1 X NDM-1) along with eight homozygous and genetically diverse varieties/genotypes *i.e.* EC-393410, EC-393407, NDM-1, Pant M-3, ML-287, NDM5-3, ML-550 and NDM 98-1 and their subsequent crossed generations were grown in a Randomized Compact Family Block Design with three replications during *Kharif* and *Zaid* seasons at Genetics and Plant Breeding Research Farm, N.D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P.). At the time of raising the crop, the soil was partially reclaimed saline-sodic soil with pH=8.9-9.1 and EC= 4.0-4.6 mmhos/cm. All F_1 populations were planted in rows spaced 45 cm apart. Seed-to seed distance was kept approximately 10 cm. Fifteen competitive plants in non-segregating populations, 60 plants F_2 population and 45 plants in segregating population were selected for each entry to record observations on days to maturity, plant height, primary branches per plant, clusters per plant, pods per cluster, pod length, seed per pod, 100-seed weight, biological yield per pant, harvest-index and seed yield per plant. Heterosis and inbreeding for all the characters were estimated as usual.

RESULTS AND DISCUSSION

Highly significant and very high estimates of heterosis in positive direction over better-parent (Table 1) as well as standard parrent (Table 2) were exhibited by all the six crosses for seed yield for plant in *Kharif* and *Zaid* season. Heterobeltiosis for seed yield per plant ranged from 71.13% (cross V) to 178.01% (cross III) in *Kharif* season and from 60.09% (cross III) to 126.58% (cross VI) in *Zaid* season. Standard heterosis for seed yield varied from 82.10% in cross II to 248.90% in cross III in K*harif* season and from 52.32% in cross II to 157.14% in cross IV in *Zaid* season. Besides seed yield, very high heterobeltiosis and standard heterosis values of highly significant and positive nature were also recorded for pods per plant, followed by harvest-index and biological yield per plant in all the six crosses in both seasons expect highly significant and negative heterobeltiosis found in cross V for harvest-index in *Zaid* season. However, degree of both types of heterosis was comparatively lower for biological yield, in general, across the six crosses in both seasons. These six crosses also possessed high mean performance for seed

LATION AND PATH ANALYSIS OF SEED YIELD, ITS CONTRIBUTING TRAITS AND SEED QUALITY ETERS IN INDIAN MUSTARD [*Brassica juncea* (L.) Czern & Coss.]

S.C.Vimal, Nitin Kumar and Himanshu Singh
Department of Genetics and Plant Breeding
N.D.University of Agriculture & Technology, Kumarganj, Faizabad-224229 (U.P.) India

Abstract

riment on thirty genotypes along with three check varieties of Indian mustard was carried out during Rabi 2014-15 in Randomized sign with three Replications at Genetics and Plant Breeding Farm and Lab experiment was conducted in Seed Testing Laboratory &T, Kumargang, Faizabad (U.P.).The seed yield per plant exhibited significant and positive correlation with no. of silique on main lant height, no of primary branches per plant and seed germination. Existence of highly significant positive correlation amongst its important components. Path coefficient analysis identified highest positive direct effect on seed yield per plant was exhibited by ength followed by no. of seeds per siliqua and negative direct effect on vigour index followed by days to 50% flowering and days to

s: Indian mustard, Correlation Coefficient, Path analysis, Seed yield, Vigour index.

ustard (*Brassica juncea* L.) is one of the most important rops of India.Indian mustard or brown mustard (rai) was introduced from China into north-eastern India, from where ead to Afghanistan via Punjab, eastern Afghanistan, together ining north-western India. It is predominantly cultivated in , Uttar Pradesh, Haryana, Madhya Pradesh and Gujarat. Its is also being extended to non-traditional areas of southern *ssica* also performs well on neglected sites where problems acidity, low available nutrient content, poor drainage, nd soils with topographical limitations exist.

ny plant breeding programme is to develop high yielding vith better quality superior over existing one. The variability on of superior type can be obtained through screening and of germplasm. The knowledge of association between and their direct and indirect contribution towards of seed yield characters are additional help to plant deciding the selection criteria. Germplasm collections ie richest source of variability. Path analysis may be of lity to a plant breeder, but it definitely gives an insight into relationship among different characters in a biological d provides information whether the observed correlation is direct influence or through other variables. Thus, path ecifies the causes and also gives the relative importance of cters. Considering the above aspects, the present on was under taken to estimate correlation coefficients ious seed yield and yield contributing traits and to find out and indirect effect of seed yield with other quantitative and traits.

And Methods

nt investigation was designed to work out the status of of different yield traits and direct and indirect effects of rent traits on seed yield among the thirty Indian mustard at Field and Seed Testing Laboratory (STL) of Seed y Section, Narendra Dev University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) India. The experiments were conducted in Randomized Block Design with three replications. The observations were recorded on eleven characters *viz.* days to 50% flowering, days to maturity, plant height, no. of primary branches per plant, no. of silique on main raceme, no. of seeds per siliqua, 1000-seeds weights, seed germination, seedling length, vigour index and seed yield per plant. Standard statistical techniques such as correlation between different characters Searle (1961) and Path coefficient analysis by Dewey and Lu (1959) in which seed yield was kept as dependant character. Germination test was conducted in three replications 100 seeds each by adopting Top on paper methods as described by ISTA procedures. The vigour index was calculated as per the method prescribe by Abdul-Baki and Anderson (1973) expressed in whole number.

Results And Discussion

The grain yield or economic yield in almost all the crops is a complex character, which manifests from multiplicative interaction of several characters that are termed as yield components. The genetic architecture of seed yield in Indian mustard as well as others crops is based on the balance or overall net effect produced by various yield components interactive with one another. Therefore, selection would not be better as such unless accompanied by the selection for various component characters responsible for conditioning it. Thus, identification of eleven yield components and information about their association with yield and with each other are very useful for developing effective breeding strategy for evolving high yielding varieties. The correlation coefficient measures the degree of symmetrical association between two variables or characters, which helps in understanding the nature and magnitude of association between yield and its component traits.

In the present study, correlation coefficients were computed among the 11 characters in Table-1. Seed yield per plant exhibited highly significant and positive

stimates of phenotypic and genotypic correlation coefficients among different characters in Indian mustard

CHARACTER ASSOCIATION OF YIELD COMPONENTS AND SEED QUALITY PARAMETERS IN CHICKPEA (*CICERARIETINUM* L.)

Sarvjeet, S. C. Vimal and Jai Prakash Gupta

Department of Genetics and Plant Breeding, (Seed Tech. Section), NDUAT, Kumarganj, Faizabad (UP)

Abstract

An experiment was conducted to study the character association of yield components and seed quality parameters in chickpea *i.e.* days to 50% flowering, Days to maturity, Plant height (cm) 30 and 60 DAS, No. of branches per plant 30 and 60 DAS, number of pod per plant, number of seed per pod, biological Yield (g), harvest index, 100-seed weight (g), seed yield kg/ha, germination (%), seedling length (cm), vigour index, seed yield per plant (g). The experiments were conducted in factorial RBD design with three levels of biofertlizer (*Rhizobium* 7.5g, 10g, 12.5g, *Trichoderma* 5g, 7.5g, 10g and PSB 7.5g, 10g, 12.5g) and seed priming (13, 16, 18 hrs) in chickpea variety (Pant G-186). Association studies revealed that During 2014-15 seed yield per plant showed highly significant and positive correlation with number of branches per plant on 30 days (0.801), number of branches per plant on 60 days (0.645) number of pods per plant (0.508) while significant and positive correlation with the number of seeds/pod (0.479), seed yield kg/ha (0.416), plant height on 30 days (0.402). During 2015-16 seed yield per plant showed highly significant and positive correlation with harvest index (0.866), biological yield (g) (0.717), plant height on 30 days (0.652), number of branches per plant on 60 days (0.641), vigour index (0.629), seedling length (0.595) plant height on 60 days (0.552) while significant positive correlation with seed yield kg/ha (0.587).

Key words : *Cicerarietinum* L., Yield components, Seedling length, Plant height

Introduction

Chickpea (*Cicerarietinum* L.) is the most important ılse crop in India with an average yield of 1500-2000 /ha. The gram is mentioned in Sanskrit which indicates at it is cultivated in India since a longer period than in y other country in the World. Chickpea (*Cicerarietnium*) gram is an important *Rabi* season self pollinated gume crop having extensive geographical distribution. ıickpea is known by different names in various countries ch as Gram, Chana, Bengal gram etc. Chickpea is a ploid species with a chromosome number 2n = 16. It longs to sub family Papilionaceae of the family guminaceae

Investigations on characters association between rious agronomical and seed quality traits are important crop production, not only from theoretical consideration quantitative inheritance of the characters but also from ıctical view of point. Selection is usually conceded with ange in two or more characters simultaneously. This ormation may be used in the prediction of correlated ponse to directional selection in the construction of selection indices and in the detection of some characters which may have no value by themselves but are useful as indicators of the more important ones under consideration.

The correlation coefficients help us in understanding the relative importance of various yield influencing characters. So that the most important yield component can be identified. The identification of the few most important components is necessary for planning and execution of a successful crop production strategy because it is almost impossible and impractical to practice selection for large number of characters along with grain yield. Correlation coefficient analyses were carried out to determine the relative importance of consumer quality and seedling vigour traits related to seed yield in chickpea. Seed index was positively and significantly correlated with seed volume, seed density and volume expansion. Association of volume expansion was also positive and significant with seed volume, seed density and water absorption capacity. Germination relative index showed significant positive association with water absorption

Standardization of biofortification for enhance seed yield and its quality parameters in chickpea (*Cicer arietinum* L.)

Sarvjeet, SC Vimal and Anurag Kumar

Abstract

The objective of the study was to standardize the biofertilizer doses with the selection of Rhizobium strain for exploitation of its natural symbiosis with chickpea for effective nodulation, maximum grain yield in chickpea under the agro-climatic conditions. The 27 treatments of bio-fertilizers and seed priming for chickpea variety (Pant G-186) were evaluated following 12 quantitative characters *viz.* Days to 50% flowering, Days to maturity, plant height on 30 and 60 days, number of branches on 30 and 60 days number of pods per plant, number of seeds per pod, biological yield per plant harvest index (%), seed yield (kg/ha), 100 seed weight (g). The treatment P_2 T_{12} (*Rhizobium* 12.5 g) was found best in, all the treatments. Maximum number of pods per plant (75.38) and seed yield (Kg/ha) (2170.08) was recorded in Inoculation with Biofertilizer (*Rhizobium*).

Keywords: chickpea, bio-fertilizers, priming

Introduction

Pulses are the cheapest and most widely consumed source of protein in countries like India, having predominantly vegetarian population. On an average pulse contain around 20-25% protein, which is 2.5 to 3.0 times higher than that of cereals and are correctly called as "poor man's meat". Besides protein, pulses are also rich source of calories, vitamins and minerals essential for human nutrition. Among the various pulses grown in our country, chickpea (*Cicer arietinum* L.) is the most important pulse crop in India with an average yield of 2500-3000 Kg/ha. This crop is mentioned in Sanskrit which indicates that it is cultivated in India since a longer period than in any other country in the world. Gram is an important *Rabi* season self pollinated legume crop having extensive geographical distribution. Chickpea is known by different names in various countries such as Gram, Channa, Bengal gram *etc.* Chickpea (*Cicer arietinum* L.) crop is self-pollinated and diploid (2n=2x=16) species. It is belongs to genus *Cicer,* tribe Cicereae, family *Fabaceae*, and subfamily *Papilionaceae.* It originated in South-Eastern Turkey. The *Cicer* is of Latin origin, derived from the Greek word 'kikus' meaning force or strength. Similarly bio-fertilizers such as *Rhizobium* and Phosphorous Solubilizing Bacteria (PSB) also have beneficial influence on plant growth, seed yield and quality as they fix large quantity of biological nitrogen. The application of micronutrient and bio-fertilizers through seed treatment not only economies the cost of nutrients but also are readily available to the young seedlings for their vigorous growth and this initial early benefit would help to obtain higher seed yield and quality. However, studies on influence of seed treatments with micronutrients and bio-fertilizers on plant growth, seed yield and quality in chickpea (Ravindra *et al.*, 2007) [10].

Materials and Methods

The field experiments under present investigation were conducted during *Rabi* 2014-15 and 2015-16 at Student Instructional Farm and lab experiments were carried out in Seed Testing Laboratory of Seed Technology Section, N. D. University of Agriculture and Technology, Kumarganj, Faizabad (U. P.). Geographically, Narendra Nagar situated between 26.47° N latitude, 82.12° longitude and at an altitude of 113 meters above the mean sea level. The climate of district Faizabad is semi-arid with hot summer and cold winter. Nearly 80 per cent of total rain fall is received during the monsoon. The treatment details are presented in Table 1. Plant to plant distance and row to row distance was kept 10 and 30 cm, respectively. Fertilizer was applied @ 20:40:40 (kg ha $^{-1}$) N:P:K at the time of sowing. The chickpea crop was cultivated using standard agronomic practices. The observations were recorded at days to plant

Optimization of seed technological parameters and micronutrients supplementation on yield contributing characters, seed recovery and quality in rice (*Oryza sativa* L.)

Jai Prakash Gupta, SC Vimal, Ajay Kumar, GD Kushwaha and Pankaj Kumar

Abstract
The present investigation were conducted during *Kharif* 2015 and 2016 at Student Instructional Farm and lab experiments were carried out in Seed Testing Laboratory of Seed Technology Section, N. D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) India with objective of the study was to optimization of seed technological parameters and micronutrients supplementation on yield contributing characters, seed recovery and quality in rice (*Oryza sativa* L.) for yield contributing traits and seed quality parameters *i.e.* days to 50% flowering, no of tillers per plant, productive tillers per hill, Plant height (cm), panicle length, Days to maturity, spikelet fertility, harvest index, seed recovery, seed yield (q/ha), 1000 seed weight (g), germination (%), vigour index and electrical conductivity. The experiment was laid out in Split Plot Design with three replications keeping two methods of transplanting *viz.* C_1 (Normal method) and C_2 (SRI method) in the main plot and three foliar spray of micronutrient doses *viz.* M_1 (Zn, Fe and Mn @0.25%, 0.50%&0.25%), M_2 (Zn, Fe and Mn @0.50%, 1.00%&0.50%) and M_3 (Zn, Fe and Mn @0.75%, 1.50%&0.75%) in sub plot. The two transplanting spacing *viz.* S_1 (15×20 cm) and (25×25 cm) were also applied in the sub plots with three genotype *viz.* NDR 97, NDR359 and BPT 5204. The result revealed that inoculation of transplanting method, spacing and foliar spray of micronutrients doses significantly improved days to 50% flowering, no. of tillers per plant, productive tillers per hill, Plant height (cm), panicle length, Days to maturity, spikelet fertility, harvest index, seed recovery, seed yield (q/ha), 1000 seed weight (g), germination (%), vigour index and reduce electrical conductivity. Overall the treatment of findings revealed that rice crop should be transplanted on 25×25 cm under SRI method with the foliar spray application of Zn, Fe and Mn @0.75%, 1.50%&0.75%, for obtaining high seed yield potential of the variety producing good quality seeds.

Keywords: Micronutrients supplementation, Foliar spray, SRI method, Transplanting spacing, seed recovery, Rice seed.

1. Introduction
Rice (*Oryza sativa* L.) is a semi-aquatic annual grass plant belongs to the genus *Oryza*, tribe Oryzeae and family Poaceae. It is the second largest principal food crop in the world after wheat and is one of the main staple food crop in India. Besides being the staple food crop, it has been the cornerstone of food and culture for our people. Among seven billion people on the earth, more than half of them depend on this crop for principal source of energy in their daily diet. Rice is distributed over a wider range of latitude from 50 ^{0}N to 40 ^{0}S and is being grown up to an altitude of 2500 meters. It evolved in humid tropics as a semi aquatic plant and it has got unique adaptive nature to hot humid environment, which is not seen in any other major cereal crop.

Rice yield in India fluctuate greatly in time and space on account of its cultivation under diverse weather, ecological and socio-economic conditions. Out of the total 43.86 million ha. under rice, 20 million ha. area is irrigated and the remaining 23.86 million ha. area is cultivated in rainfed conditions. Rice can be grown under different agro-ecological environments.

Seed quality plays a crucial role in realizing the full genetic potential of varieties as well as benefits of other agricultural inputs (Seshu and Dadlani, 1993) [21]. The use of quality seeds alone increases the productivity to the extent of 15-20 per cent (Dahiya *et al.*, 1993) [7]. Only seeds with assured genetic and physical purity can be expected to response to the other inputs in agriculture. Among the inputs used by the farmers for agriculture production seed is the cheapest one and it forms only part of the cultivation expenses. All the efforts and investment would be unremunerative if farmer does not get good quality seeds. Only seed with good

To optimize doses of Zn, Fe and Mn in different combinations and its effect on yield contributing characters, seed recovery and quality in rice (*Oryza sativa* L.) varieties

Jai Prakash Gupta, SC Vimal, Ajay Kumar, GD Kushwaha and JP Srivastava

Abstract
The present investigation were conducted during *Kharif* 2015 and 2016 at Student Instructional Farm and lab experiments were carried out in Seed Testing Laboratory of Seed Technology Section, N. D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) India with objective of the study was to optimize doses of Zn, Fe and Mn in different combinations and its effect on yield contributing characters, seed recovery and quality in rice (*Oryza sativa* L.) varieties for yield contributing traits and seed quality parameters *i.e.* days to 50% flowering, no of tillers per plant, productive tillers per hill, Plant height (cm), panicle length, Days to maturity, spikelet fertility, harvest index, seed recovery, seed yield (q/ha), 1000 seed weight (g), germination (%), seedling vigour index and electrical conductivity. The experiment was laid out in the three foliar spray of micronutrient doses *viz.* M_1 (Zn, Fe and Mn @0.25%, 0.50% & 0.25%), M_2 (Zn, Fe and Mn @ 0.50%, 1.00% & 0.50%) and M_3 (Zn, Fe and Mn @0.75%, 1.50% & 0.75%) with three varieties *viz.* NDR 97, NDR359 and BPT 5204. The result revealed that inoculation of foliar spray of micronutrients doses significantly improved days to 50% flowering, no. of tillers per plant, productive tillers per hill, Plant height (cm), panicle length, Days to maturity, spikelet fertility, harvest index, seed recovery, seed yield (q/ha), 1000 seed weight (g), germination (%), vigour index and reduce electrical conductivity. Overall the treatment of findings revealed that among doses of foliar spray of micronutrient, Zn, Fe and Mn @ 0.75%, 1.50% & 0.75% may be utilized in rice for seed production as it produced higher seed yield, maintained the seed recovery and other yield contributing quality of seeds.

Chapter - 4

Doubling Farmer Income through Different Agriculture Sources

Shalini Srivastava, R.N. Kewat, S.C. Vimal and S.K. Chakravarti

Abstract

In agriculture, multiple cropping is the practice of growing two or more crops in the same piece of land in same growing seasons. It is a form of polyculture. It can take the form of double-cropping, in which a second crop is planted after the first has been harvested, or relay cropping, in which the second crop is started amidst the first crop before it has been harvested. Multiple cropping systems can help to get maximum production and ultimately maximum foreign exchange which is necessary for developing countries.

Keywords: Cropping system, season, marketing, income

Introduction

A related practice, companion planting, is sometimes used in gardening and intensive cultivation of vegetables and fruits. One example of multi-cropping is tomatoes + onions + marigold; the marigolds repel some tomato pests. Mixed cropping is found in many agricultural traditions. In the Garhwal Himalaya of India, a practice called baranaja involves sowing 12 or more crops on the same plot, including various types of beans, grains, and millets, and harvesting them at different times. In the cultivation of rice, multiple cropping requires effective irrigation, especially in areas with a dry season. Rain that falls during the wet season permits the cultivation of rice during that period, but during the other half of the year, water cannot be channeled into the rice fields without an irrigation system. The Green Revolution in Asia led to the development of high-yield varieties of rice, which required a substantially shorter growing season of 100 days, as opposed to traditional varieties, which needed 150 to 185 days. Due to this, multiple cropping became more prevalent in Asian countries.

Doubling Farming: The substantive points are: one, what is the period and targeted year for doubling the farm income; two, what is to be doubled,

STUDIES OF GENETIC VARIABILITY, HERITABLE AND GENETIC ADVANCE *IN LINSEED (LINUM USITATISSIMUM L)*

Ram Jeet, R.K. Srivastava, S.C. Vimal, Vidya Sagar, Bitthal, S.P.Singh and Vinay Kumar
Krishi Vigyan Kendra Panti, Ambedkar Nagar, KVK, Barabanki and NDUAT Kumarganj, Ayodhya-224229 (UP)

Abstract

ıetic variability is basic requirement of crop improvement programme and effectiveness of selection depends upon its nature and magnitude vailable genetic material. In other words, genetic variability is fundamental to selection and to a great extent to the breeding methodology uch. The genetic variation is heritable one and hence, important in any selection programme. Heritability is one of the most important ct selection parameters which determine whether the phenotypic differences observed among the various individuals are due to differences heir genetic makeup or simply the results of environmental factors. Heritability is an index of transmissibility of traits from parents to r offspring's.Lush (1940) suggested the following uses of heritability estimates:When heritability in narrow sense is high, emphasis should olaced mainly on mass selection and if it is low, more pressure should be given on pedigree, sib tests and progeny tests. In case where stemic variance is relatively high emphasis should be placed on selection between families and line breeding.If over-dominance is strong, reeding programme is to be emphasized with an objective of commercial bybrid production. When the variance due to interaction between iotype and environment is relatively large, breeding programme should be stream lined on the development of superior varieties for ferent agro-climatic regions.Heritability in narrow sense could be utilized for estimation of expected improvement based on selection. iereas, the genetic advance in another parameter which helps breeders in estimation of he gain through selection pressure.Comstock and oinson (1952) defined that genetic advance as an improvement in the genotypic value in the new population as compared to the original : and depends upon the following three factors: The amount of genetic variability such as the magnitude of the differences among different ividuals in the base or initial population. The magnitude of the masking effects of the environmental and interaction components of iability on the genetic diversity.The intensity of selection which is being applied.

y words:-Line× tester, Genetic variability, heritability and genetic advance, linseed

roduction

the breading programme the Genetic variability heritability and ietic advance play the key role in the characterization of traffic. The icept of genetic variability heritability and genetic advance reported Gupta and Godwat (1981) studied 8 parents, 56 F_{2^s} and 28 F_{2^s} and orted high genetic coefficient of variation, heritability and genetic ance as percentage of the mean for 1000 seed weight, indicating t variation in due to additive gene effect. High heritability in jugation with low genetic advance as a percentage of the mean was ained for all characters except 1000 seed weight indicating the iation of these characters in due to non-additive gene effects. Patil l. (1981) reported high broad sense heritability estimates in two ieration for number of days to 50 per cent flowering, plant height, n number per plant, 1000-seed weight and seed yield per plant. ietic advance was highest for number of capsules per plant and d yield in both generation. Number of capsules pert plant and 1000- d weight were positively and significantly correlated with yield in h generations as reported by Kumar and Chauhan (1982) observed h narrow sense heritability for plant height and 1000-seed weight ile, moderate for seeds per capsule, tillers per plant and branches plant. They further reported substantial genetic gain for capsules plant, plant height and branches per plant, suggesting that these iracters are useful for selection if considered simultaneously. Rao l Singh (1984) studied the genotypic coefficient of variation broad ise heritability and genetic advance for seed yield per plant and the ld characters and reported that non-additive gene effects were portant for the most of the characters. Average broad sense itability value were moderate or high. For all traits (range 0.62- 8)indicating scope for improvement by breeding. Srivastava and gh (1984) reported high estimates of heritability for days to turity, plant height, number of primary and secondary branches per nt. Genetic gain was highest for plant height, secondary branches l capsules per plant.

terials and Methods

e present investigation was conducted at Main Experiment Station l Student's Instructional Farm of Narendra Deva University of riculture and Technology, Narendra Nagar Kumarganj, Faizabad .P.) during rabi 1999-2000 and 2000-2001. This place is graphically situated at 26.47^{0}E latitude, 82.12^{0}E longitude and at tude of 113 meters above the mean sea level. This area falls under nid subtropical zone which is characterized by hot and dry nmers with cold winters. The experimental material used in present investigation consisted of 44 Fis and 15 parental lines. These 44 F_{2^s} were developed by crossing 11 elite strains of diverse origin as lines (Females), with 4 released/widely adopted varieties as males, viz. Neelam, Garima, Subhra and Gaurav.Experimental material consisting of 59 treatments (44 F_{2^s} +15 parents) was sown in Randmozed Block Design with three replications. These entries were sown in single rows of three meter long with 30 cm row to row and 10 cm plant to plant spacing. All the recommended cultural practices were followed to raise a good crop.Observations on the following characteristics were recorded on five plants randomly selected and tagged from each row except the days to 50 per cent following and days to maturity, which were recorded on line basis. Plant height (cm), Days to maturity, Number of primary branches/plant, Number of secondary branches/plant, Number of capsules/capsule, 1000-Secd Height (g), Secd yield/plant (g).

Statistical analyses:-

The experimental data were compiled by taking the mean of sampled plants in a plot of each treatment in respect in respect of characters under study. Average of data were subjected to analysis of variance according to experimental design used. The data obtained from the set of 11 lines ×4 testers viz. Neelam, Garima, Subhra and Gaurav resulting (44 F_{1^s} and their 15 parents were used for combining ability analysis (Kempthorne, 1957) and estimation of hererosis (hayes et al 1955).

Coefficient of variability, heritability and genetic advance:-

The phenotypic, genotypic and environmental confidents of variability for all the nine characters has been given in Table 4.3. The magnitude of phenotypic coefficient of variability (PCV) was higher than the genotypic coefficient of variability (GCV) and environmental coefficient of variability (ECV) for all the characters under study. Higher estimates of PCV and GCV were prerecorded for number of capsules per plant, The character which exhibited moderate estimates (between) (12% to 18%) of PCV and GCV were number of primary branches per plant, 1000 seed weight and number of seeds per capsule. Remaining characters viz. plant height, days to 50 per cent flowering and days to maturity recorded low (<12%), estimates of PCV and GCV. Lowest value of ECV was recorded for days to maturity (0.98%) days to 50 per cent flowering (1.70%) and plant height (3.36%) High estimates of ECV were observed in primary branches per plant (10.90%) and seed yield per plant (7.99%).

Heritability in broad sense (h^2b), genetic advance (Ga) and genetic advance in per cent of mean (Gs%) were estimated for all characters

COMBINING ABILITY STUDIES FOR CERTAIN QUANTITATIVE CHARACTERS IN LINSEED *LINUM USITATISSIUM L.**

Ram Jeet, S.C. Vimal, P.K. Singh, Vinay Kumar, Vidya Sagar, Shiv Nath & Pradeep Kumar
Krishi Vigyan Kendra Panti, Ambedkar Nagar U.P., N.D.U.A.T.Kumarganj, Ayodhya & C.S. Azad University Kanpur, U.P.

Abstract

mbining ability for 10 characters was studied using 7 lines viz. BAU-610A, EC-384154 JRF-3, JRF-4, Polf-34, H-25 and H-22 as females d 4 testers Padmini, Parvati, Shubhra and LCK-3003 as male crossed in line × tester mating design. Analysis of combining ability revealed existence of highly significant variation among crosses for all characters in F_1 and F_2 generations, respectively. The lines BAU-610A was nd to be good general combiner for days to maturity, plant height, number of primary branches/plant, 1000-seeds weight, seed yield/plant, content days to 50% flowering and incidence of Allternaria blight in F_1 generation. However, BAU-61A had significantly positive gca ect for days to 50% flowering and incidence of Alternaria blight and poor general combiner in Seed Yield/plant and oil content in F_2 nerations. The variance due to line × tester were significant for all the characters, suggesting the presence of non-additive gene effect for se traits. The crosses BAU 610-A× Shubhra, JRF-3x Padmini, JRF-4x Padmini in F_1 generation and EC-384154×Shubhra, JRF-Parvati in F_2 generation were to most promising for improvement of seed yield and one or more of its component traits.

ey words- Line × tester, gca, sca, linseed.

troduction

any breeding programme the appropriate selection of parents based their combining ability not only provides necessary information garding the choice of parents but also simultaneously illustrate the ture and magnitude of gene action involved. The line × tester ating design helps in realising the objective to estimate the mbining ability of parents and by their selecting superior parents as ell as cross combinations. Accordingly, the present investigation s undertaken to have the knowledge about the yield and other yield ributing characters of nature of combining ability for some newly veloped male and female lines of linseed (Linum usitatissium L.) d gene action for yield and other yield attributing characters.

aterials and Methods

e experimental materials used in present investigation consisted of crosses derived thought line × tester design were grown during bi 2004-05 for advancement of generation and promising 14 F_1s re back crossed to their respective parents for inheritance studies F_2 eds were also harvested. The experiment comprising of 67 notypes (28 F_1s+28 F_2s+11 parents) was conducted in a ndomized Block Design with three replications during rabi 2005- at Oilseeds Research Farm, Kalyanpur of chandra Shekar Azad niversity of Agriculture and Technology, Kanpur, These entries re sown in single row of three meter length with 30 cm row to row d 5 cm plant to plant spacing. The observations were were recorded 10 characters, namely, days to 50% flowering, days to maturity, ant height (cm), number of seeds per capsule, 1000-seeds weight, ed yield/pant, oil content and incidence of Alternaria blight.

mponents of variance estimates of phenotypic and genotypic efficient of variation (PCV and GCV) were evaluated by the rmula suggested by Burton (1952). Heritability in the broad sense s calculated following Hanson (1963). Whereas, expected genetic vance was estimated by the method suggested by Johnson et at 955).

esults and Discussion

e analysis of variance for combining ability in respect of 28 crosses r the 10 characters have been presented in Table-1. The variances ong the lines in respect of their general combining ability were ghly significant for all of the characters in F_1 and F_2 generations. e differences among the testers arising primarily due to their gca re highly significant for the characters in F_1 and F_2 expect days to aturity, number of seeds per capsule, 1000-seeds weight and cidence of Alternaria blight in F_2. The variances among the crosses e to line × tester interaction component indicating their sca, were ghly significant for all the characters in F_1 and F_2 except number of eds per capsule and 1000-seeds weight in F_2 and incidence of ternaria blight in both generations.

timates of gca effects showed that it was not possible to pick up a od general combiner for all characters because the combining ility effects of parents were not consistent for all the yield components. The lines BAU-610A was found to be good general combiner for days to maturity, plant height, number of primary branches/plant, number of capsules per plant, 1000-seeds weight, Seed yield/plant and oil content days to 50% flowering and least incidence of Alternaria blight in F_1 generation. However, BAU 610A had significantly positive gca effects for days of 50% flowering and incidence of Alternaria blight and poower general combiner in Seed yield/plant and oil content in F_2 generation. JRF-4 was found to be a good general combiner for plant height, oil content and more incidence of Alternaria blight in both F_1 and F_2 generations. H-25 and H-22 were identified as poor general combiner for days to 50% flowering and number of capsules per plant in F_1 and F_2 generations. The lines EC-384154 was a good general combiner for days to 50% flowering and days to maturity in respect of late maturity duration in both F_1 and F_2 generations. Among the testers Parvati proved to be a good general combiner for delayed maturity and tallness in bood F_1 and F_2 generations whereas, Padmini was best general combiner for earliness and dwarfness, seed yield, oil content and least incidence of Alternaria blight in F_1 generation Shubhra was identified as average general combiner for days to 50% flowering and number of primary branches/plant and number of capsules per plant in both F_1 and F_2 generations. H-22 was adjudged to be good general combiner for least incidence of Alternaria blight whereas, JRF-3 and LCK-3003 for Seed yield/plant in both F_1 and F_2 generations.

In the present investigation, the crosses exhibiting higher estimates of desirable sca effects common in both the generations were BAU 610A×Parvati for days to 50% flowering and EC-384154×Padmini for number of capsules per plant. These common crosses over the generations indicate additive ×additive type of gene action for the expression of concerned traits.

The cross combinations H-25×Parvati, BAU 610A×Padmini, H-25×Shubhra and EC-384154×Parvati, Polf-34×Padmini, JRF-4×LCK-3003 for days to maturity, JRF-4×Parvati, EC-384154×Parvati, BAU 610A×LCK-3003 and Polf-34×Parvati, H-25×Parvati, H-22×CK-3003 for plant height; Polf 34×Parvati, JRF-4×Padmini, BAU610A×LCK-3003 and EC-384154×Padmini for number of primary branches/plant; H-25×LCK-3003, EC384154×Padmini, BAU-610A×LCK-3003 and JRF-4×Parvati, EC-384154×Shubhara and H-22LCK-3003 for number of seeds per capsules; BAU610A×Shubhra, JRF-3×Padmini, H-22×Parvati and EC384154×Shubhra for 1000-seeds wight; BAU 610A×Shubhra, JRF-3×Padmini, JRF-4×Padmini and EC-384154×Shubhra, JRF-3×Parvati, H-25×Parvati for Seed yield/plant; Polf-34×Parvati H-22×LCK-3003, BAU 610 A×Shubhra and EC-384154×Padmini, JRF-3×Shubhra, Polf-34×LCK-3003, EC-384154×Padmini and H-22×Padmini, EC-384154×Padmini and H-22×Parvati, EC-384154×Shubhra for incidence of Alternaria blight were the good specific combinations for F_1 and F_2 generations, respectively.

Association and path analysis of yield attributes and physiological parameters in rice (*Oryza sativa* L.) under problematic soil conditions

Suraj Kumar Hitaishi, SC Vimal and Amit Kumar Chaudhary

Abstract
The present investigation were assessed to work out the association of different grain yield attributes and physiological parameters, direct and indirect effects of their various traits on grain yields. Observations were recorded for yield its contributing traits and physiological parameters. The grain yield having positive and strong correlation with chlorophyll content (0.871), harvest index (0.864), grains per panicle (0.632), spikelet per panicle (0.555), leaf temperature (0.553), and panicle length (0.513) and 1000-grain weight (0.493) showed positive and strong significant association with grain yield per plant at phenotypic level where as plant height and days to 50% flowering possessed significant negative correlation with grain yield per plant. Spikelet per panicle (0.580), biological yield per plant (0.570), harvest index (0.331), flag leaf area (0.164), protein content (0.142), days to maturity (0.129), chlorophyll content (0.107), spikelet fertility (0.098) and leaf temperature (0.045) exhibited direct effect on grain yield. Considering the correlation and path analysis flag leaf area, grains per panicle, 1000-grain weight and harvest index are important characters be considered for yield improvement.

Keywords: Rice, character association, path analysis, physiological parameters, grain yield

Introduction
Rice (*Oryza sativa* L.) is the most important staple food crop of the world because of being the major source of calories of more than half of the total global population. The importance of rice is not only as a fundamental commodity and primary food source for more than half of the world's population, but also influences issues of global concern such as food security and development. More than 90 per cent of the world's rice is grown and consumed in Asia, known as rice bowl of the world, where 60 per cent of the earth's people and two third of world's poor live. Rice being the staple food for more than 70 per cent of our national population and source of livelihood for 120450 million rural households is backbone to the Indian Agriculture.

Rice (*Oryza sativa* L.) is a semi-aquatic annual grass plant belongs to the genus *Oryza,* tribe Oryzeae and family Poaceae. It is the second largest principal food crop in the world after wheat and is one of the main staple food crop in India. Besides being the staple food crop, it has been the cornerstone of food and culture for our people. Among seven billion people on the earth, more than half of them depend on this crop for principal source of energy in their daily diet. Rice is distributed over a wider range of latitude from 50 0 N to 40 ° S and is being grown up to an altitude of 2500 meters. It evolved in humid tropics as a semi aquatic plant and it has got unique adaptive nature to hot humid environment, which is not seen in any other major cereal crop.

Rice yield in India fluctuate greatly in time and space on account of its cultivation under diverse weather, ecological and socio-economic conditions. Out of the total 43.86 million ha. Under rice, 20 million ha. Area is irrigated and the remaining 23.86 million ha. Area is cultivated in rainfed conditions. Rice can be grown under different agro-ecological environments.

Protein content of milled rice is 6-7 per cent, rice however, compares favorably with other cereals in amino acid content. The biological value of protein is high, the fat content of rice is low (2.0-2.5%) and much of the fat is lost during milling. Rice grain contains as much B group vitamin as wheat. Milled rice losses valuable proteins, vitamins and minerals in the milling process during which embryo and aleurone layer are removed and much of the loss of nutrients can avoided through parboiling process. The by-products of rice milling are used for a variety of purposes. Rice bran is used as cattle and poultry feed. Rice hull can be used in manufacture

Heterosis and inbreeding depression for yield, its contributing characters and physiological parameters in rice (*Oryza sativa* L.) under stress condition

Suraj Kumar Hitaishi, SC Vimal and Amit Kumar Chaudhary

Abstract
Heterosis and inbreeding depression studies in rice were carried out on seventeen characters against two crosses: Cross I (NDRK 5004 × NUD 3) and Cross II (PANT 10 X IR 28) at Student's Instructional Farm of Acharya Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Ayodhya-224229 (U.P.), India. Heterosis of F1 hybrids over Standard parent and better parent varied from character to characters in the two crosses. Significant positive heterosis was observed for harvest index and grain yield per plant in both the crosses. Highest inbreeding depression was observed for grain yield per plant and lowest for biological yield per plant in Cross I. While highest inbreeding depression was observed for harvest index and lowest for leaf nitrogen in Cross II. Grain yield per plant in Cross I and spikelet per panicle in Cross II recorded high level of heterosis and inbreeding depression. Significance of dominance gene effects and epistatic interactions for most of the traits in six crosses indicated that exploitation of heterosis through hybrid varieties appears to be a potential alternative. The positive and significant heterobeltiosis was noted for panicle length and grain yield per plant in sodic conditions. Above studies suggested that for crop improvement it would be desirable to follow different selection methods/breeding methods to be improve varieties and yield also.

Keywords: rice, heterosis, inbreeding depression, segregating generation, grain yield, physiological parameters

Introduction
Rice is the important cereal food crop and serves as the primary source of staple food for more than half of the global population. Because of higher population growth rate than crop productivity, there are food shortages in most of the area of India. Use of hybrid variety is an important strategy to meet the demand of increasing population. Hybrid rice is an economically viable option to increase cultivars yield potential. Heterosis in yield contributing traits ultimately brought about yield improvement in F1 hybrid rice (Vanaja and Babu, 2004) [7]. The superiority of F1 hybrid over both its parents in terms of yield and some other characters is known as heterosis. Both positive and negative heterosis is useful in crop improvement, depending on the breeding objectives and nature of the traits. Heterosis is useful for deciding the direction of future breeding programme and to identify the superior cross combinations. Knowledge on heterosis together with inbreeding depression would be helpful for identification of poor crosses in early generations. In the present study two crosses were made in rice to study the manifestation of heterosis for yield and its components as well as to estimate the inbreeding depression.

Materials and Methods
The present investigation was conducted during *Kharif*, 2017, 2018 and 2019 at Student's Instructional Farm of Acharya Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya-224229 (U.P.), India. The experimental material was based on generation mean analysis set of 2 hybrids (F1), 2 segregant (F2), 2 BC1 and 2 BC2 developed by crossing of six parameters. Six genetically diverse genotypes *viz.*, NDRK 5004, NUD 3, Pant 10, IR 28, CSR 10, Sushk samrat were inter crossed in generation mean analysis fashion were evaluated in Randomized Block Design with three replication during *Kharif* 2019 each plot was consisting of a double row of 3 meter long beds with intra row spacing spaced 20 cm apart. Seed to seed distance within a row will be kept 15 cm. Similar planting distance will be maintained for P1, P2, F1's, F2's, and B1 and B2.The desired observation will be recorded on five randomly selected plants for parents, 10 plants for F1's, 15 plants for B1, B2 and 20

ABSTRACT

The experiment on forty genotypes along with three check varieties of chickpea (*Cicer arietinum* L.) were assessed to work out the genetic variability, heritability and genetic advance effects of their various attributes on seed yield. The high magnitude of genotypic and phenotypic coefficients of variation were observed for seed yield per plant, 100- seed weight, seeds per pod, primary branches per plant and pods per plant, indicating thereby, substantial scope for improvement in this character after hybridization and subsequent selection and the high estimate of heritability with high genetic advance in per cent of mean were observed for 100-seed weight, seed yield per plant and seeds per pod. The highest seed yield per plant was produced by KWR 108 (18.84 g), while the lowest seed yield per plant were given by BGD 1081 and Phule G 0405 (6.60g). High heritability and genetic advance indicate that the additive nature of gene action and reliability of those characters for selection and emerged as ideal traits for improvement through selection.

Introduction

Chickpea (*Cicer arietinum* L.) crop is self-pollinated and diploid (2n =2x = 16) species. It is belongs to genus *Cicer*, tribe Cicereae, family Fabaceae, and subfamily Papilionaceae. It originated in south-eastern Turkey. The *Cicer* is of Latin origin, derived from the greek word 'kikus' meaning force or strength. Among pulse, chickpea occupies a premier position in respect of area and production in the world. It is grown in an area 13.20 m ha and the production is around 11.60 m tonnes with an average productivity of 880 kg per ha. India is also greater consumer as well as importer of chickpea in the world. In India, chickpea is grown about 9.93 m ha area and producing 9.53 m tonnes grain with productivity of 960 kg per ha. In Utter Pradesh, it is cultivated on area of 577

YIELD GAP ANALYSIS THROUGH FRONT LINE DEMONSTRATION IN WHEAT CROP

R.L. Singh* ,Pradip Kumar **, S.N.Singh*and O.P.Verma******
Krishi Vigyan Kendra, Gonda UP

Abstract

Front Line Demonstrations were conducted to find out the yield gap on wheat crop. Krishi Vigyan Kendra, Basti conducted 80 demonstrations with a total area of 32.0 ha. on high yielding wheat variety PBW-502 during two consecutive years 2008-09 and 2009-10 . Demonstraions were conducted in twelve villages covering five blocks of the district. Each demonstration area was 0.4 ha. Line sowing through seed drill machine was done in FLD plot while broadcast sowing of seed was done in Farmer's practice. Prevailing farmer's practices were treated as control for comparison to recommended practices. Wheat variety PBW-343 was sown under Farmer`s practice. The average yield of demonstrated plot was obtained 55.78 q / ha. over control (44.75 q / ha.) with an additional yield of 11.03 q/ha having an increase of 24.65 percent. The average Extension gap was 11.03 q / ha. Technology gap 9.22 q / ha. while technology index was found 14.18 percent.

Key word: Front Line Demonstration, Transfer of Technology, Recommended practices, yield gap, Wheat

Introduction

Rice-wheat is a predominant crop rotation of district Basti. Wheat (Triticum aestivum) is the second most important cereal crop in India after rice contributing substantially to the national food security by providing more than 50% of the calories to the people who mainly depend on it. In historical perspective India has made spectacular advancement in productivity and sustainability of wheat and wheat-based cropping system. The scenario of the past ten years has clearly indicated that the wheat production in the country has soared ahead despite area remaining the same. The wheat programme has released 399 wheat varieties, comprising 355 bread wheat, 54 durum, 5 dicoccum and 5 triticale for cultivation under different zones. (Anonymous, 2012).

Wheat is an important cereal crop of Basti district of Uttar Pradesh. The district has been considered as productive potential of wheat crop due to assured irrigation facilities and favorable soil and climatic conditions. In the district wheat is grown in an area of 1.19 lac ha. with a production of 3.79 lac tons having productivity of 31.79 q/ha while in UP total area is 98.85 lac ha. with a production of 349.71 lac tons having productivity of 35.38 q/ha (Faslotpadan ki ranneeti,Rabi Abhiyan 2016-17, Deptt. Of Agric. UP). However, there is still a wide gap between the production, potential and the actual production obtained by the farmers. This may be due to partial adoption of recommended package of practices by the wheat growers. Technology gap is a major problem in increasing wheat production in Basti district of U.P State. So far, no systematic effort was made to study the technological gap existing in various components of wheat cultivation.

Materials and Methods

The study was carried out by Krishi Vigyan Kendra Basti during rabi 2008-09 and 2009-10 on the farmer's field of 12 adopted villages covering five blocks of the district. Front Line Demonstrations were conducted under National Food Security Mission. Seed of Wheat variety PBW-502 was procured from Agriculture Deptt. of the district. Demonstration plot was sown under the supervision of KVK scientists. A total of 32.0 ha. area with each plot size 0.4 ha was under Front-line demonstrations using Wheat variety PBW-502 with active participation of 80 farmers. Before conducting FLDs, farmers were selected for group meeting and conducting FLDs. A specific skill training was given to the selected framers regarding package of practices of wheat. The difference between Demonstration package of practices and Existing farmers practices are given in Table 1.

In general, the soils under study were sandy loam in texture with a PH range in between 7.0 to 7.5. The available nitrogen, phosphorous and potassium varied between 100-250, 26-60, 150-300 Kg/ha, respectively. However, the soils were deficient in micro nutrients particularly in zinc.

In demonstration plots use of quality seed of improved variety, timely sowing, weeding, need based use of pesticides, herbicides as well as balanced fertilization, and irrigation were emphasized. First irrigation was given at 21 days after sowing at CRI stage, second was given at tillering stage at 40-45 DAS, third at knot formation at 60-65 DAS, fourth at heading and fifth at milking stage while in Farmer practice four irrigations were given. The traditional practices were maintained in case of local check. The data were collected from both FLD plots as well as control plot and finally the extension gap, technological gap, technological index (Samui et al,2000) along with the benefit-cost ratio were calculated as given below.

Technology gap= Potential yield- Demonstration yield

Extension gap= Demonstration yield – Farmers practice yield

Technology index= (Potential yield- Demonstration yield) X100 / Potential yield

Table-1: Comparison between demonstration package of practices and existing Farmer practices in wheat crop

Sl. No.	Particulars	Demonstration practices	Farmer Practice
1.	Farming situation	Irrigated	Irrigated
2.	Variety	PBW-502	PBW-343
3.	Time of sowing	November	November
4.	Method of sowing	Line sowing through seed drill	Broadcast
5.	Seed treatment	Use of treated seed by carbendagym @ 2 g/kg of seed	Without seed treatment
6.	Seed rate	100 kg/ha	125 Kg/ha
7.	Fertilizer dose	NPK (150:60:60)	NPK (150:60:00)
8.	Plant Protection	Application of bio fungicide Beuvaria bassiana	Injudicious use of pesticide and fungicides
9.	Weed management	Spraying of Sulfosulfuron 75% @ 32 ml/ha. + metsulfuron methyl 5% @ 40 g/ha. during 30-35 days after sowing	Use of Isoproturon 75 % @ 1.0 kg / ha.at 30-35 days after sowing

YIELD PERFORMANCE OF COLLECTED WILD MILKY MUSHROOM (*CALOCYBE* SP.)

Vivek Singh, Pradip Kumar*, Sanjeev Kumar and Ketan Kumar

Department of Plant Pathology, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad - 224 229 (U.P.), India.

Abstract

Milky mushroom (*Calocybe indica*) is an indigenous tropical edible mushroom becoming popular among people these days during summer and rainy season. The morphological characters like pileus size, stipe size, gills, spore print colour and colonies characters of a wildly collected *Calocybe* sp. (DMRO-600) were found as 4.50- 6.16 cm, 7.5- 8.5cm, distinctly formed crowded with emarginated, white and circular with creamy white, respectively. Out of five grain substrates evaluated for spawn production, wheat grains proved as best substrate followed by sorghum grains, pearl millet grains and soybean product (Nutrella). For cultivation of this mushroom, five locally available substrates in pure form and in combinations with wheat straw were evaluated. Out of these, wheat straw substrate gave highest yield (1052.50 g), maximum number of fruiting bodies (40.75), early spawn run (21.50 days) along with early first harvest (33.25 days), followed by yield obtained from wheat straw + paddy straw (932.50 g), paddy straw (841.25 g), wheat straw + sugarcane bagasse (840.56 g), sugarcane bagasse (825.0 g), maize straw (703.75 g), wheat straw + maize straw (596.25 g), wheat straw + dehulled maize cobs (543.75 g) and dehulled maize cobs (503.75 g). Hence this study confirms the suitability of locally wild strain DMRO-600 for cultivation to mushroom growers by using wheat grains for spawn production and wheat straw as substrate for its cultivation for achieving higher yield.

Key words : *Calocybe* sp., spawn, substrates, yield.

Introduction

Milky mushroom (*Calocybe indica* P & C) was first reported in India by Purkayastha and Chandra in 1974. It belongs to the kingdom Fungi, phylum Basidiomycota, class Agaricomycetes, order Agaricales and family Lyophyllaceae. This is an indigenous tropical mushroom, suitable for cultivation during summer and rainy season. It naturally grows on the humus rich soil under road side tree, in garden and forest during rainy season. Wildly collected species of *Calocybe* were sold in Kolkata, Tamil Nadu and Rajasthan and their nutritional and medicinal quality were confirmed by Purkayastha and Chandra (1974), Doshi *et al*. (1989) and Krishnamoorthy (1995). In India, mushrooms vernacularly known as "*Khumbi*", "*Chhatra*", "*Kukurmutta*", "*Dhengri*", "*Dharti ka phool*", "*Doodh chatta*" etc.

A substrate is an important substance for making spawn and growing mushrooms. Various kinds of agricultural wastes including wheat straw, paddy straw, maize, bajra, cotton stalks and leaves, sugarcane bagasse, dehulled maize cobs, tea and coffee waste and coconut coir substrate can be utilized for cultivation of *Calocybe indica*. There is no need to compost the substrate for its cultivation as the mycelium can degrade the cellulose, hemicelluloses and lignin by secretion of various extracellular enzymes. This mushroom requires a temperature of 30-35ºC and relative humidity of 70-80% for cultivation which is conducive to environmental conditions of most part of India (Singh *et al*., 2009; Amin *et al*., 2010; Upadhyay, 2010 and Gitte *et al*., 2014). During last decade milky mushroom has become a major commercially cultivated species in south India particularly Tamil Nadu, Andhra Pradesh and Karnataka and during last 4-5 year its cultivation has become popular in north India as well. Its high biological efficiency (100%), better keeping quality, white attractive colour, suitable for pickle and chutney, can be grow on wide range of agricultural wastes and simple cultivation technique are major factors

Yield Loss Assessment due to Alternaria Blight Disease in Rapeseed and Mustard

H K SINGH[1*], PRADIP KUMAR[1] AND S K SINGH[2]

ABSTRACT

An experiment was conducted to assess the yield losses due to Alternaria blight in different released cultivars of rapeseed-mustard during Rabi 2016-17 and 2017-18 planting 15 varieties of the rapeseed-mustard namely RH-749, Pusa gold, KBS-3, GSL-5, GSL-2, Pusa mustard-27, Jhumka, Anuradha, PT-30, T-27, PM-25, Pusa aditya, PT-303, Sheetal, TMLC-2 in six replications. The minimum disease severity on leaves and pods were recorded in protected and unprotected conditions in the variety GSL-5 (2.65% and 16.26%), (1.75% and 6.32%) followed by GSL-2 (3.20% and 19.72%), (1.89% and 6.75%) Pusa aditya (6.91% and 19.89%), (2.18% and 7.20%) and Sheetal (7.99% and 23.13%), (3.21% and 7.43%), respectively. On the basis of mean values the minimum infection rate on pods was recorded GSL-2 (0.083 and 0.042) followed by Pusa aditya (0.089 and 0.045), respectively. The minimum AUDPC on leaf under protected and unprotected was recorded on cultivar GSL-5 (76.40 and 496.20) followed by GSL-2 (88.80 and 596.85), Pusa aditya (205.35 and 588.25), Sheetal (241.70 and 717.30) and RH-749 (244.95 and 950.85), respectively. Whereas the minimum AUDPC on pod was recorded with variety GSL-5 (32.10) and Pusa aditya (200.25) followed by [GSL-2 (34.65) and Sheetal (206.65)], [Pusa aditya (39.35) and RH-749 (566.41)] and [Sheetal (60.95) and Pusa mustard-27 (741.75)], respectively. The maximum yield avoidable loss (%) was recorded T-27 (46.67%) followed by Jhumka (44.53%, Anuradha (40.00%), KBS-3 (38.77%) and Pusa gold (34.13%), respectively. Minimum avoidable loss (%) was recorded on cultivar GSL-5 (11.09%) followed by Anuradha (14.36%), GSL-2 (17.73%), RH-749 (17.90%) and Pusa aditya, respectively. In present investigation out of 15 genotypes examined for blight resistance, GSL-5, Pusa Aditya, Sheetal and GSL-2 exhibited good level of partial resistance i.e. moderately resistance. Other 11 varieties RH-749, Pusa gold, Pusa mustard-27, Jhumka, Anuradha, PT-30, PT-303, T-27, KBS-3, TMLC-2 and PM-25 were susceptible based on the mean basis severity (PDI), reduced apparent infection rate and lesser value of AUDPC.

INTRODUCTION

Rapeseed-mustard is one of the major oilseed crops cultivated in India and around the world. It is extensively grown traditionally as a pure crop as well as intercrop (mixed crop) in marginal and sub-marginal soils in the eastern, northern and north-western States of India (Singh *et al*, 2017). Rapeseed and mustard belong to family Brassicaceae, Indian mustard commonly known as *rai* is the most important member of Cruciferous oil seeds occupying nearly 70 per cent of the total area under rapeseed-mustard (Singh *et al*, 2014b). The leaves of young plants are used as green vegetable and whole plants as green fodder. The seeds are highly nutritive containing 38 to 57 per cent erucic acid, 4.7 to 13 per cent linoleic acid and 27 per cent oleic acid (Singh *et al*, 2011). The rapeseed and mustard group dominates among oilseed crops in area and production on global level. India is one of the largest rapeseed-mustard growing countries in the world, occupying the third position in area and production after China and Canada sharing 12 per cent of world's total production. At global level, rapeseed-mustard is cultivated on 5.96 million hectares with production of 8.32 million tonnes and productivity of 1397 kg/ha (Anonymous, 2018). Rapeseed-mustard is the second most important oilseed crop after groundnut and accounts for nearly 30.7 per cent of the total oilseed production in the country. There are several diseases known to affect the mustard crop but foliar diseases like Alternaria leaf spot, white rust (blister), downy and powdery mildews cause heavy yield losses to the crop. Alternaria blight caused by Alternaria brassicae (Berk.) Sacc and Alternaria brassicicola (Schw) Wiltshere is a world-widely distributed and economically important disease on rapeseed (Brassica napus), mustard (Brassica campestris) and other brassicas (Singh *et al*, 2014a), Tewari and Conn (1993) , Kumar (1997), Meah *et al* (2002), Meena *et al* (2010). The characteristic symptom is the development of circular spots on leaves and pods with concentric ring. Later on spots coa-

Study on genetic variability in germplasm of coriander (*Coriandrum sativum* L.)

Rang Nath Pandey, CN Ram, Pradip Kumar and OP Rao

Abstract
The present investigation was conducted during *Rabi* season 2019-20 at Main Experimental Station of Vegetable Science, Acharya Narendra Deva University of Agriculture & Technology, Kumarganj, Ayodhya (UP). The field experiment was layout in Augmented Block Design with 70 genotypes with 3 check in 5 blocks. The character studied were days to 50 per cent flowering, plant height (cm), branches per plant, fruiting nodes per plant, inter-nodal length (cm), umbel diameter (cm), number of umbels per plant, number of fruits per umbel, number of umbellates per umbel, number of fruit per umbellate, 1000 seed weight (g), seed yield per plant (g). Analysis of variance due to the block were highly significant for all character except day to 50 per cent flowering, fruiting nodes per plant and test weight. Highest genotypic and phenotypic coefficient of variation was recorded for branches per plant. High estimate of heritability was expressed for plant height and fruit per umbel, while high genetic advance in per cent of mean observed for branches per plant (23.60).

Keywords: Coriander, heritability, variability, PCV, GCV and genetic advance

Introduction
Coriander *(Coriandrum sativum* L, 2n=2x=22) is an annual herb and grown for both green leaf and dried seeds. It is extensively grown in Andhra Pradesh, Tamil Nadu, Karnataka, Punjab, Rajasthan, M.P. and Uttar Pradesh. Rajasthan is the main growing state and contribute about 40 per cent production in India. In India it is grown in 6,29,000 ha area with annual production of 7,56,000 MT and 1.20 MT per hectares productivity (Anonymous 2020) [2].
The coriander plant has a fragrant odour and pleasant aromatic taste. Dry seeds contain 0.1- 1 percent essential oil which impart odour and taste. The principle constitute of essential oil is dextro- linalool. The volatile oil is used in cosmetics products and beverages. Dried seeds are used in flavouring sauces and meat product, some bakery and confectionary items. It is also used as major ingredient in most of the curry product. The fruit are considered as carminative, diuretic, anti-bilious, refrigerant andaphrodisiac. Coriander belongs to the family Apiaceae, which is consisting of 300 genera and more than 3,000 species. It is an annual herb with thin stem bushy appearance and 90-100 cm in height. Leaves are alternate, compound and petiole has a pair of stipules sheathing the stem base. The lower leaves are broad pinnate and have long petiole with crenately lobed margins. The upper leaves are cut with linear lobes and bi or tri- pinnate. The flowers are pink or white. The seeds are green round (botanically fruit) attain greyish brown colour at maturity.
Genetic variability is a pre-requisite for any improvement in a crop. The success of any crop improvement programme depends on the magnitude of genetic variability and extent to which the desirable characters are heritable. The ultimate goal of breeding programme aims to improve the characteristic of plants so, that they become more desirable. The survey of genetic variability with the help of suitable genetic parameters like genotypic and phenotypic coefficient of variations, heritability estimates and genetic advance as percentage of mean are indispensable in breeding programmes aimed at improvement of seed yield.

Materials and Methods
The present investigation entitled "Study on genetic variability for growth, yield and its attributing traits in coriander (*Coriandrum sativum* L.)" carried out at the Main Experiment Station, Department of Vegetable Science, Acharya Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya (U.P.) India, in Augmented Block Design during *Rabi* season 2019-20 using Seventy genotypes with three checks (Hisar Anand, NDCor-1 and NDCor-2) of coriander collected from Department of Vegetable Science, Acharya Narendra

(Received: August 09, 2016; Revised received: January 18, 2017; Accepted: January 21, 2017)

Abstract: An experiment was conducted at Krishi Vigyan Kendra, Basti (UP) with two high yielding rice varieties to standardize the System of Rice Intensification (SRI) method including the age of seedling and variable spacing. The SRI standardized package was compared with the conventional production system of rice at farmer's field. Maximum grain yield (66.80 q/ha) along with all the contributing traits i.e. plant height (130.0 cm), root depth (30.0 cm), root spread (20.66 cm), root biomass (16.75 g/m²), number of tillers (36), spikes (27), spike length (32.66 cm), grains/spike (285), test weight (37.3 g) and grain yield (66.80 q/ha) were recorded in variety NDR-359 with 10 days of seedling age planted at 25 X 25 cm spacing. Similar trend of observations were also recorded through this spacing in case of variety PNR-113, where, plant height (120.33 cm), root depth (27.0 cm), root spread (16.66 cm), root biomass (16.80 g/m²), number of tillers (33), spikes (26), spike length (28.60 cm), number of grains/spike (282), test weight (35.25 g) and grain yield (65.70 q/ha) witnessed. At farmer's field in demonstration trial 14.44 per cent increase in grain yield through SRI practice was remarkable. It is an eco-friendly approach because it helps in resource conservation owing to its need of less exploitation of ground water, no use of any weedicide and minimum use of other hazardous chemicals (insecticide/ fungicide).

Key words: Rice, SRI, Seedling age, Spacing

Introduction

Rice (*Oryza sativa* L.) being the most important staple cereal crop providing one third of calorie requirement for more than 70 per cent of Indian population. Globally, India ranks first in area and second largest producer next to China in rice production. The diverse agro-ecological situation demand location specific management technology for the realization of full yield potential. The current global population of more than 7.5 billion is expected to reach 9.0 billion by 2050 AD. Most of these population increases will occur in developing countries of Asia and Africa where rice is a staple food. To meet the increasing demand an annual increase of 2.0 million tons in deteriorating resource base and climate change affecting adversely is indeed a harculum task. Improvement and strengthening of genetic base, adoption of hybrid rice and refinement of production technology packages are some of the options on which the emphasis is being given. The semi-aquatic nature of rice and high water requirements for its cultivation make it much more prone to losses from drought during reproductive phase. Indian agriculture largely depends upon monsoon rainfall where about two third of the arable land lack irrigation facilities and is termed as rain fed. The most immediate consequence of drought is a fall in crop production due to inadequate and poorly distributed rainfall. Also the weeds are major constraints in rice production because they compete with crop plants for moisture, light, nutrients and space. Both these problems (Better water as well as weed management) are addressed under SRI system. Although, in SRI fields weeds intensification is higher as compared to traditional transplanting system due to wetting and drying of fields. A little increase in production (4.31mt.) was witnessed during 2013-14 as compared to its previous year but again there was a backdrop (Anonymous, 2015).

The system of rice intensification (SRI) which was developed by father Henri de laularie in 1980s in Madagascar (Barkelaar, 2001) has already been adopted in many countries. The pronounced effect of the system has been recorded in more than 26 countries including China, Japan and other big players of rice production. Usually, under this system a package has been developed including seed rate (2 kg/acre), age of seedling (8-12 days), Khusral and Aminus (2009), number of seedlings (single / hills), spacing (25 X 25 cm) with moist field avoiding flooding, weeding (Cano weeder) and supplementations of organic manuring etc. (Krishna and Biradar Patil, 2009). The average yield thus recorded by more than 20 countries including China ranging between 7-8 t / ha and even more (12 t / ha). As per report from Anant Pur district of Andhra Pradesh, the average yield ranged from 6.5 to 8.5 t / ha. As a strategy, the seed replacement rate may be increased and the

Management of powdery mildew of rapeseed-mustard

H.K. SINGH[1]*, KETAN KUMAR[1], PRADIP KUMAR[1], SUNITA SINGH,* R.B. SINGH[1], K.N. MAURYA[2] AND M.P. CHAUHAN[2]
[1]Department of Plant Pathology, [2]Department of Genetics and Plant Breeding, B-72, University Campus, N.D. University of Agriculture and Technology, Kumarganj, Faizabad 224 229, Uttar Pradesh, India

ABSTRACT: Out of 200 genotypes screened, 20 genotypes, namely, EC-414309, PBC-9221, NPC-14, BAUSM-92-1-1, PBC-2004-1, EC-339000, EC-338997, GSL-1, HNS-004, ONK-1, NRCDR-515, PBC-2002-2, NPC-15, OCN-3, EC-399299, NUDB-26-11, CAN-133, NPN-1, RGN-55, NRCR-837 showed consistently resistant reaction in both the years, while nine genotypes *viz.*, EC-399296, EC-399301, EC-399313, PHR-2 , CAN-130, RAURD-101, RH-9301, SKM-9328, IJWHJ-001 were moderately resistant. Besides these, 30 genotypes exhibited moderately susceptible, 71 susceptible and 70 highly susceptible reactions. Three sprays of aqueous suspensions of Triademefon (0.1%), Wettable sulphur (0.3%), Dinocap (0.1%) and Myclobutanil (0.1%) at 15 days intervals, after disease appearance, controlled the disease effectively and increased seed yield. The maximum per cent disease control was recorded with spray of Triademefon upto 76.88 per cent. Wettable sulphur, Dinocap, Myclobutanil, Water spray inhibited the disease upto 74.50, 73.11, 67.66, 63.78 per cent, respectively. The significantly higher mean seed yield of 1435kg/ha was recorded with treatment Triademefon 0.1% followed by Wettable sulphur @ 0.3% (1330 kg/ha) and Dinocap @ 0.1% (1250 kg/ha). Similar trends were also recorded in case of test weight.

Key words: Powdery mildew, Resistance, Fungicide, Rapeseed and mustard

Rapeseed and mustard is the major oilseed crop of Uttar Pradesh, which is severely affected from powdery mildew disease caused by *Erysiphe cruciferarum* Opiz. Ex Junnel, a minor disease earlier, this, has become major one during recent years in late sown crops and cause heavy yield losses up to 42.4% (Singh and Singh, 2003; Singh and Singh, 2004). Disease occurs between second weeks of February to first week of March. The resistance breeding is one of the most economical methods for the management of the diseases. Therefore, investigations were conducted to identify sources of resistance and fungicides for effective in managing the disease.

MATERIALS AND METHODS

Field experiments were conducted at the University Experiment Station at Kumarganj (26°47'N, 82°12'E, 113 msl), Faizabad, Uttar Pradesh during *rabi* 2012-13 and 2013-14 crop seasons following recommended agronomic practices (120Kg N, 60Kg P, 60Kg/ha).

Varietal screening

Two hundred genotypes of rapeseed-mustard were evaluated for their response to powdery mildew under late sown condition at the Research Farm of Genetics and Plant Breeding of this University. The trial was conducted in the third week of December in single row of 3m length having 30 x 10 cm spacing in augmented design. Susceptible check Varuna was sown after every five test genotypes and flanked the trial all around with paired rows to serve as infector. Disease severity was recorded on three leaves one each from top, middle and bottom from ten randomly selected plants from each genotype, after the appearance of for about a month according to 0-5 scale. The disease was scored, following the scale, 0: Free- apparent symptoms absent; 1: Resistant - 1-10% leaf area mildewed; 2: Moderately resistant - 11-25% leaf area mildewed; 3: Moderately susceptible-26-50% leaf area mildewed; 4: Susceptible - 51-75% leaf area mildewed; 5: Highly susceptible - Over 75% leaf areas mildewed.

Fungicidal management

The cultivar 'Varuna' was sown in last week of December in randomized block design having 4m x 3m plot size with 30 x 10 cm plant spacing in three replications. The effectiveness of different fungicedes *viz.* Triademefon (Bayleton) 25WP @ 0.1%, Wettable sulphur (Sulfex) 80WP @ 0.3%, Dinocap (Karathane) 48EC @ 0.1% and Myclobutanil 0.1% concentration along with water spray were tested against the disease severity and seed yield of the crop. The required amount of each chemical was calculated, weighed and the spray solution was prepared and then volume was made up to desired level and was sprayed by using high volume Knap-sak sprayer of 10 litre capacity. Three sprays of each chemical, first at appearance of the disease and remaining two after 15 days intervals were given. Highest severity grades obtained on individual sample plants were used for evaluating % disease index (PDI) following formula given by Singh and Singh (1982). Over all seed yield, 1000-grain weight and avoidable seed yield loss (%) for individual treatments were also recorded in respect to each treatment.

POSSIBILITIES OF HIGH YIELDING HYBRID AND SCENTED RICE VARIETY PRH-10 THROUGH FRONT LINE DEMONSTRATIONS

R.L. Singh*, Pradip Kumar ** S.N.Singh*and O.P.Verma******

Abstract

Front Line Demonstrations were conducted to find out the yield gap on rice crop. Krishi Vigyan Kendra, Basti conducted 35 demonstrations with a total area of 7.0 ha. on hybrid and scented Rice variety PRH-10 during two consecutive years Kharif 2010 and Kharif 2011. Demonstraions were conducted in thirteen villages covering three blocks of the district. Each demonstration area was 0.2 ha. Transplanting was done in FLD as well as in Farmer's practice. Scented rice variety Type-3 was transplanted under Farmer`s practice. The average yield of demonstrated plot was obtained 44.78 q / ha. over control or Farmer`s practice (35.57 q / ha.) with an additional yield of 9.21 q/ha having an increase of 25.89 percent. The average Extension gap was 9.21 q / ha. Technology gap was 20.22 q / ha. while technology index was found 31.09 percent. In reference to economics, Net returns and Benefit-Cost ratio were 27964 and 1.92 in demonstration and 16741 and 1.57 in farmer's practice respectively. Net returns and Benefit –Cost ratio both were higher in case of demonstration over farmer's practice.

Key word: Front Line Demonstration, Transfer of Technology, Recommended practices, yield gap, Rice

Introduction

Rice-wheat is a predominant crop rotation of district Basti. Rice (Oryza sativa) is the most important cereal crop in India contributing substantially to the national food security. Rice provides 21% global human per capita energy and 15% of per capita protein. Although rice protein ranks high in nutritional quality among cereals, protein content is modest. Rice also provides minerals, vitamins and fiber, although all constituents except carbohydrates are reduced by milling.

The world average consumption of rice in year 1999 was 58 kg with the highest intake in some Asian countries. Mayanmar has the highest annual consumption i.e. 211 kg per capita. Rice eaters and growers constitute the bulk of the world. In India annual rice consumption was 74 kg per capita, Total calories per capita per day was 2417 in which rice calories was 736 which accounts 30%. (FAO online database update 31 may 2001)

Rice is an important cereal crop of Basti district of Uttar Pradesh. The district has been considered as productive potential of rice crop due to assured irrigation facilities and favorable soil and climatic conditions. The district lies in North Eastern Plain Zone under nine Agro climatic zones of UP. In year 2016-17 the district Rice is grown in an area of 1.02 lac ha. with a production of 2.11 lac tons having productivity of 20.64 q/ha while in UP total area is 59.66 lac ha. with a production of 143.96 lac metric tons having productivity of 24.13 q/ha (Kharif Faslon ki saghan padhyatiyan, Krishi Vibhag Uttar Pradesh, 2018).

However, there is still a wide gap between the production, potential and the actual production obtained by the farmers. This may be due to partial adoption of recommended package of practices by the rice growers. Technology gap is a major problem in increasing wheat production in Basti district of U.P State. So far, no systematic effort was made to study the technological gap existing in various components of rice cultivation. Now many farmers have adopted hybrid rice due to higher yield but quality of rice is poor. Keeping this view in mind the Hybrid and scented rice variety PRH -10 was taken under study. This variety was released in year 2001.It is suitable for irrigated conditions. It has excellent aroma, extra-long grains. It possesses tolerance for shattering. It is resistant to gall midge, brown spot and moderately resistant to leaf folder and blast. Its maturity period is 125-130 days.

Materials and Methods

Front Line Demonstrations were conducted. Seed of hybrid and scented Rice variety PRH-10 was procured from Agriculture Deptt. of the district. Demonstration plot were transplanted under the supervision of KVK scientists. The study was carried out by Krishi Vigyan Kendra Basti during kharif 2010 and Kharif 2011 on the farmers field of 13 adopted villages covering three blocks of the district. A total of 7.0 ha. area with almost each plot size 0.20 ha was under Front-line demonstrations using Rice variety PRH-10 with active participation of 35 farmers. Before conducting FLDs, farmers were selected for group meeting and conducting FLDs. A specific skill training was given to the selected framers regarding package of practices of wheat. Prevailing farmer's practices were treated as control for comparison to recommended practices. The difference between Demonstration package of practices and Existing farmers practices are given in Table 1.

In general, the soils under study were loam in texture with a pH range in between 7.0 to 7.5. The available nitrogen, phosphorous and potassium varied between 100-250, 26-60, 150-300 Kg/ha, respectively. However, the soils were deficient in micro nutrients particularly in zinc.

In demonstration plots use of quality seed of improved variety, timely sowing, weeding, need based use of pesticides, herbicides as well as balanced fertilization and irrigations were emphasized. Irrigations were given at just after transplanting, heading, flowering and grain filling stages. Gap filling was done after 7-10 days after transplanting in demonstration plot. The traditional practices were maintained in case of local check. The data were collected from both FLD plots as well as control plot and finally the extension gap, technological gap, technological index (Samui et al,2000) along with the benefit-cost ratio were calculated as given below.

Technology gap= Potential yield- Demonstration yield

Extension gap= Demonstration yield – Farmers practice yield

Technology index = $\frac{\text{(Potential yield- Demonstration yield) X100}}{\text{Potential yield}}$

Table-1: Comparison between demonstration package of practices and existing Farmer`s practices in rice crop

Sl. No.	Particulars	Demonstration practices	Farmer`s Practice
1.	Farming situation	Irrigated	Irrigated
2.	Variety	PRH-10	Type-3
3.	Time of sowing nursery	Mid-June	Mid-june
4.	Method of sowing	Transplanting	Transplanting
5.	Seed treatment	Use of treated seed by carbendagym @ 2 g/kg of seed	Without seed treatment
6.	Seed rate	15 kg/ha	30 Kg/ha

STUDY AND ANALYSIS OF INCOME AND EXPENDITURE LEVEL OF POTATO (*SOLANUM TUBEROSUM*) UNDER DIFFERENT SIZE OF HOLDINGS

Ajit Verma[1], Sarita Srivastava[2], Pradip Kumar[3] and Vinod Singh[4]

[1]Department of Farm Management, Krishi Gyan Kendra, Baribag, Ghazipur (U.P.), India.
[2]Department of Home Science, Krishi Gyan Kendra, Deoria (U.P.), India.
[3]Department of Plant Pathology, Krishi Gyan Kendra, Baribag, Ghazipur (U.P.), India.
[4]Department of Farm Management, Crop Research Station, Baribag, Ghazipur (U.P.), India.

Abstract

The main objective of the present study was to work out the income and expenditure level of potato by the use of bio fertilizer along with organic and inorganic fertilizer also in randomly selected villages of district Ghazipur, U.P. during 2011-12. It was found that yield and net return was increased from smaller to large farm ranges increasing trends under demo and local checks. Benefit cost ratio also ranges increasing from smaller to larger ones. The study concludes that yield and net return was increased only due to proper use of organic and bio fertilizer management, this study further concludes that in future more better use of organic and bio fertilizer management produces more yield and better net return in all size groups.

Key words: Yield, bio fertilizer, increasing trends.

Introduction

The potato crop has a special value as food. Potato belongs to the family Solanaceae. It occupies the largest area under any single vegetable in India. The consumption of potato per head in our country is not very much highered in comparison to others. This crop needs irrigation at frequent intervals. Five to six irrigations are sufficient. Potato tubers are planted either whole or cut into pieces sowing time is mid of September to the first week of January. Where crop has been sown in plains of the Northern area. Two successive crops can be raised on the same land. Organic manures as play very much important role in the production of yield and quality. This should be put into the soil 3 to 4 weeks before planting 80 Kg. of Nitrogen, full dose of phosphorus and full dose of potash will be incorporated into the soil as basal dressing, rest 40 Kg. of nitrogen should be apply as top dressing at the time of first earthing. Use of proper planting measures resulted to protect the crop from late blight and insect pest etc. Application of good quality of organic manure or FYM along with recommended doses of NPK provides significantly higher yield and better quality reported by Emin Caliskan *et al.* (2004). Organic manures not only been responsible for adding the natural sources of NPK but it play an important role to improve the physical and chemical properties of nutrient, deficiency in the Soil which improves higher tuber yield said by Roust and Neyround (2003). The tuber and their size has been increased when they have got sufficient amount of nitrogen because this is one of the very much most important food as well as Vegetable (crops in our country which is responsible for producing better calories and weight in comparison to others, Application of herbicides or hand weeding resulted higher tuber yield.

Materials and Methods

The present study was conducted along with farmers scientist collaboration in randomly selected village and block namely Sepah of Kasimabad Block. The study has been taken during the Season of 2011-12 in Ghazipur district of Uttar Pradesh. Three farmers have been selected on random basis under small, medium and large size of holdings. The main motto was to increase their production with better quality and also suggested them to compare the advance practices along with local ones.

Abstract

To judge the income level of the sorghum was the main objective of the present study which has been taken on the farmer's field during 2011-2012 in Ghazipur district of Uttar Pradesh at different from levels in comparison with local checks. It was formed the yield and net income was higher in demo. groups in Comparison to local checks, because all the advance package of practices has been applied properly and timely while local checks are only based on traditional practices, by virtue of lacking the knowledge local checks are suffered. The study has finely been concluded that there should be a wide range in future to increase their productivity and income by applying more and more advance technologies of cultivating the crop.

Key words: Farmers, yield, increasing trends, size groups.

Introduction

Sorghum, popularly known as Jowar. It grain is primarily as human food in various farms, such as Roti or is cooked like rice. Sorghums are also malted, popped and several local preparations are made. Green and dried fodder is the most important roughage for feeding cattle throughout the country. The utilization of grain sorghum as a cattle not very significant, although considerable scope exists. *Rabi* sorghums are wholly confined to black cotton soils, the *Kharif* Sorghums are grown on light soils also on a limited scale. Medium and deep black soils are predominantly suitable for this crop.

Sorghums are grown during in *Kharif* last week of June to July. The differed spread of high yielding varieties tends to enhance the attack of shoot fly on in this verities and the increased midge incidence on the locals, particularly during the *Kharif* Season. Wheat crop yield formed significantly higher after *Kharif* Sorghum, cowpea grain etc. Yield of wheat will be go down only after sorghum by using not a proper dose of organic fertilizer and cost of other sources of factors of production on higher side Sinsinwar (1994). Cultivation of cereal forages along with legumes makes an increased quantity and nutrition's fodder resulted a greater improvement in soil quality. Green forage and dry matter yields formed significantly higher where maize and cow pea has been taken in consequent lines. The increase in the yield of green and dry matters in the intercropping system might be owing to the nutrient sparing effect of leguminous fodder, Tripathy *et al.* (1997). Nutrients requirement of the crop increasing day by day due intensive cropping system etc.

Materials and Methods

The present study has been taken on the field through farmers-scientist collaborations during the year 2011-12 in randomly selected village Nasirpur, Block Devkali of Ghazipur District of Uttar Pradesh Two farmers from each-groups ranging small, medium and large sizes has been randomly selected. The sorghum (Jowar) has been taken on the farmers field during last week of June to first week of July. Suggested the variety C.S.B.-15, Seed rate 15 Kg./ha. along with for better yield NPK application was put into the soil @ 40:20:20 Kg. per hectare. All the recommended package of practices has been applied to the crop during at the time of their needs for better yield and income. A comparative study has also been made through local check from same groups

MANAGEMENT OF ISARIOPSIS LEAF SPOT OF BER (*ZIZYPHUS MAURITIANA* LAMK.) THROUGH FUNGICIDES

Sanjeev Kumar*, Pradip Kumar, Divya Singh, Prashant Mishra and Sukhvindar Singh

Deparment of Plant Pathology, Narendra Deva University of Agricult. and Tech., Faizabad - 224 229 (U. P.), India.

Introduction

Ber [*Zizyphus mauritiana* Lamk. (Syn. *Z. jujuba* L.)], the Indian jujube is a tropical fruit tree species belonging to the family *Rhamnaceae*. It is also known as Narkelikul, Boroi, Bor, Beri and Indian plum. Indian jujube is one of the two *Zizyphus* species that have considerable horticultural importance. The other one is Chinese jujube. Being native to India, it is now widely naturalized in Africa, Afghanistan, China, Malaysia, Australia and in some Pacific regions. In India it is commonly grown in Rajasthan, Haryana, Punjab, Madhya Pradesh, Bihar, Uttar Pradesh, Maharashtra, Assam and Gujrat. It is a hardy crop that tolerates extreme temperature and thrives under rather dry condition with annual rainfall of 15-225cm. Ber fruit is very nutritious having rich in minerals and vitamins. The fruit is eaten raw or as pickles or used in beverages. In India, the ripe fruits are mostly consumed raw but are sometimes stewed.

Ber crop suffers from a number of fungal diseases. Among them, some important fungal diseases are powdery mildew (*Oidium erysiphoides* f. sp. *zizyphi*), rust (*Phakospora zizyphus vulgaris*), leaf spot (*Tandonella zizyphi*, *Alternaria* sp.) *Cercospora zizyphi*, *Cladosporium zizyphi* and *Phoma* sp.) and mouldy leaf spot (*Isariopsis indica* var. *zizyphi*). However mouldy leaf spot or Isariopsis leaf spot appears in severe form on various ber cultivars and causes maximum yield loss. Gupta *et al*. (1977) reported Isariopsis leaf spots disease for the first time from Haryana. Verma and Kumar (1992) reported that Cloudy weather with moderate temperature during October-November is favourable for the disease development. Black spots, which are sooty, tuft like circular to irregular black spots develop on leaf surface. During advanced stage, the lower surface of leaves also covered in longer area and corresponding upper surfaces show brown discolouration. Thus, the present research was done to find out effective fungicides for management of Isariopsis leaf spot of ber.

***Author for correspondence :** E-mail: drsanjeev44@gmail.com

Materials and Methods

The experiment was conducted during 2010-2013 at Main Experimental Station, Horticulture, N.D.U.A. & T., Kumarganj Faizabad (U.P.), India; on Cultivar 'Gola' to assess the efficacy of fungicides for management of Isariopsis leaf spot of ber. There were 4 replications for each treatment. The spray of fungicides/botanicals @ 10 liter/plant was scheduled just after initiation of the disease under field condition. The fungicides/botanical used for treatment were Mancozeb 0.2%, Carbendazim 0.1%, Copper oxychloride 0.2%, Propiconazole25EC 0.1%, Difenconazole 10WP 0.1% and Neem oil 3.0%.

Observations were recorded on disease incidence/ intensity and yield (kg/ha). The observations in respect of disease intensity on leaves were recorded after 20 days after last spray. Hundred leaves (25 from each side of tree) were observed following 0-5 grade scale of Mckinney (1923) as given in table 1.

Yield data were recorded at the time of harvesting of fruits. The per cent disease index (PDI) and per cent disease control (PDC) were calculated by using following formula.

$$PDI = \frac{\text{Sum of all numerical rating}}{\text{Total no. of leaves examined} \times \text{highest rating}} \times 100$$

$$PDC = \frac{\text{\% disease control} - \text{\% disease in treatment}}{\text{\% disease in control}} \times 100$$

All the treatments were arranged in randomized block design and data were statistically analyzed. Percentage data of disease index and disease control were

MANAGEMENT OF RUST DISEASE (*RAVENALIA EMBLICAE* SYD.) OF AONLA (*EMBLICA OFFICINALIS* GAERTN.)

Sanjeev Kumar*, Pradip Kumar, Prashant Mishra, Santosh Kumar and Sukhvindar Singh

Department of Plant Pathology, Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj), Faizabad - 224 229 (U.P.), India.

Abstract

Indian goosberry (*Emblica officinalis* Gaertn) commonly known as aonla is one of the important fruit crop in arid and semi-arid growing regions. To test the effect of bioagents and fungicide alone and in combination against aonla rust, a field experiment was conducted at Main Experimental Station Horticulture, Narendra Deva University of Agriculture and Technology, Faizabad during 2010-2013. The result showed that minimum PDI (9.16) with maximum PDC (74.25) and yield 104.75 kg/tree was recorded with (0.2%) chlorothalonil treatment followed by 1% *T. viride* + 0.1% chlorothalonil (14.40 PDI), (59.52 PDC) and yield 91.31 kg/tree. Bio-agents *Trichoderma viride* & *Pseudomonas fluorescens* were found less effective to control the disease.

Key words : *Emblica officinalis*, aonla, *Ravenalia emblicae,* rust, fungicide, bioagents.

Introduction

Aonla (*Emblica officinalis* Gaertn) is an important indigenous fruit of India. The commercial cultivation of aonla is expended from the "Home Land" of Uttar Pradesh to almost all the states of India including Maharashtra, Gujarat, Rajasthan, Madhya Pradesh, Jharkhand, Chhattisgarh and Andhra Pradesh. Among the diseases, aonla rust (*Ravenalia emblicae*) is a serious and economically important disease not only in Uttar Pradesh but also in other states like Rajasthan, Andhra Pradesh, Tamil Nadu, Haryana etc. It was first observed in Rajasthan by Tyagi (1967). In India, Rawal (1993) has observed that this causes considerable loss in major aonla growing tracts of Uttar Pradesh, India. The disease is characterized by appearance of brown pustules on lower side of older leaves of new graft which are brown, circular and raised. On fruits, initial few brown to black pustules appear which develop in the ring. At later stage pustules join together and cover big area of the fruits (Tyagi and Pathak, 1988; Jat and Goyal, 2004). Plants with a severe attack on fruits show no symptoms on the leaves and vice-versa (Tyagi, 1967). Owing to expansion of aonla orchards, working out of management strategies is also equally important to sustain the yield and quality of aonla fruits and hence the present study was conducted to the effect of environment, test of different bio-agents, fungicide alone and in combination with following objectives.

- Symptomatological study under natural condition
- Management with fungicide and bio-agents

Author for correspondence : E-mail: drsanjeev44@gmail.com

Materials and Methods

A field experiment was conducted on cultivar Chakaiya at Main Experimental Station, Horticulture, Narendra Deva University of Agriculture & Technology, Faizabad in Randomized Block Design with three replications during the year 2010-2013. For the management of aonla rust with fungicide and bio-agents, ($\mathbf{T_1}$ = 1% *P. fluorescens,* $\mathbf{T_2}$ = 1% *P. fluorescens* 1% + 0.1% Chlorothalonil, $\mathbf{T_3}$ = 1% *T. viride*, $\mathbf{T_4}$ = 1% *T. viride* + 0.1% Chlorothalonil, $\mathbf{T_5}$ = 0.1% Chlorothalonil, $\mathbf{T_6}$ = 0.2% Chlorothalonil, $\mathbf{T_7}$ = Unsprayed) one tree per replication were maintained for each treatment. Three foliar applications were given at 15 days intervals first spray was done just after initiation of disease. The data on the development of rust on aonla fruits were recorded on the four marked fruiting branches per plant. Disease fruits were graded into six categories of disease incidence *i.e.* 0 = healthy, 1 = 1-10, 2 = 10.1-25, 3 = 25.1-50, 4 = 50.1-75, 5 = >75%. The percent disease index (PDI) and percent disease control (PDC) were recorded

Estimation of direct and indirect association of independent traits with seed yield in bottle gourd (*Lagenaria siceraria* (Mol.) Standl.)

CM Gupta, GC Yadav, CN Ram, Pradip Kumar, Raja Bhaiya and Anoj Yadav

Abstract
An experiment was executed at Main Experiment Station of Department of Vegetable Science, Acharya Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Ayodhya (U.P.) during *Zaid* 2019, path analysis among different character. Experimental material for the study consisted of 36 genotypes including two checks (Pusa Naveen and Narendra Rashmi). The experiment was conducted in Randomized Complete Block Design with three replications. Single row plot of 3 m length spaced 3 m apart with 50 cm plant to plant distance was maintained. Observations were recorded on 14 quantitative traits *viz.* days to first staminate flower and pistillate flower anthesis, node number to first staminate and pistillate flower appearance, days to first fruit harvest, green fruit length (cm), green fruit circumstances (cm), mature fruit length (cm), mature fruit circumstances (cm), mature fruit weight(kg), seed weight per fruit(g), number of seed per fruit(g), 100-seed weight(g), seed yield per plant(g). Seed weight per fruit and days to first fruit harvest, node number to staminate flower appearance were identified as most important traits with positive direct effect on seed yield per plant. However, no of seed per fruit and mature fruit weight were found as important indirect contributor towards high seed yield per plant via seed weight per fruit at both phenotypic and genotypic level.

Keywords: path coefficient, direct and indirect, bottle gourd or *Lagenaria siceraria*

Introduction
Bottle gourd [*Lagenaria siceraria* (Mol.) Standl.) is one of the most valuable member of family cucurbitaceae having somatic chromosome number 2n=22. The bottle gourd or white flowered gourd is commonly known as Lauki or Ghiya in India. It is an annual plant with very large leaves and branched tendrils, spreading or climbing up to 15 meters. The study of extent of correlation of various traits with each other is an important strategy designated to break genetic barriers of yield. This study is helpful in determining the components of a complex trait like yield. However, only correlation does not provide an exact magnitude of direct and indirect effect towards the yield. In this context, path coefficient analysis is an important tool to partition the correlation coefficient into direct and indirect effect of the independent variables on the dependent. This information may be useful to breeder in selecting high yielding genotypes in a crop. Keeping this in view, the present investigation was conducted to determine the characters and their direct and indirect effects on yield.

Material and Methods
The present investigation was conducted during *Zaid*, 2019-20 at Main Research Station, Department of Vegetable Science, Acharya Narendra Deva University of Agriculture and Technology, Narendra Nagar, (Kumarganj) Ayodhya (U.P.). Narendra Nagar is situated at 26.470N latitude and 82.120E longitude at an altitude of 113 metres above the mean sea level. The soil type of experimental site was sandy-loam. The experiment was laid out in completely Randomized Block Design with three replications on March 4th, 2019. Each genotype was planted in 3m x 3m plot size. The distance between rows and plants was kept at 3m and 50cm, respectively. Six plants were maintained in each plot. The recommended agronomic practices were followed to raise a good crop. Observations were recorded on six randomly selected plants from each replication on 14 quantitative traits such as days to first staminate flower and pistillate flower anthesis, node number to first staminate and pistillate flower appearance, days to first fruit harvest, green fruit length (cm), green fruit circumstances (cm), mature fruit length (cm), mature fruit circumstances (cm), mature fruit weight(kg), seed weight per fruit(g), number of seed per fruit(g), 100-seed weight(g), seed yield per plant(g). The data were subjected to analysis of variance as per the procedure described by Panse and Sukhate (1967).

"FAULT DIAGNOSIS AND REMEDIES C ROTATING MACHINES"

[1]Satyendra Singh Kuntia, [2]Ram Bahadur Singh, [3]Seema
[1]M. Tech Scholar, [2&3]Guest Faculty
[1]NIT Bhopal, [2&3]Mahamaya College of Agricultural Engineering & Technology Ambedkar Nagar (UP), India

Abstract: It is natural for a machine to vibrate. Nowadays, machines used everywhere in the industry. By using the specific way, the vibration data can be collected, the data can be very useful to control the behavior of machines. This thesis presents the way of collecting the vibration signals from different rotating machines by using condition monitoring tools. Machine fault diagnosis in machines has been a key concern for which many methods have been devised such as Fast Fourier Transform (FFT) band spectrum analysis, Signature analysis. Shaft misalignment, rotor unbalance and bearing fault are the main sources of vibration in rotating machines. These methods may be useful for large systems like in turbine shafts, gearboxes, induction motors and the like. Such a method has enormous potential in are automated diagnostics process whereby the measurement of the responses, the fault condition and location can be detected. In present work, Fault diagnosis by employing vibration signals is done. Vibration signals data obtained from spectrum analysis has been carried out for finding different parameters of machines such as velocity, acceleration etc. The vibration parameters are computed from spectrum, and analyzed the effect of vibration on health of machines.
Index Terms – Fault Diagnosis, Fast Fourier Transform, Signature Analysis, Condition Monitoring.

1. Introduction

Condition monitoring is the method to determine the condition of machinery while in operational. The key to a useful condition monitoring techniques includes:
i. Knowing what to concentrate for.
ii. A way to interpret it.
iii. When and how to put this knowledge to use.
Successfully using these techniques permits the repair of downside elements prior to failure. Condition monitoring not only helps plant personnel decrease the possibility of catastrophic failure, but also allows them to order parts in prior, schedule manpower, and plan other repairs during the downtime period. According to Maintenance Resources, the development of condition monitoring technique can be divide into three generations ranging from the 1930s to the 1980s and up to recent time. During the primary generation of evolution, through '30s and '40s, most industrial machinery was comparatively basic and there was not as much focus on failure. In addition, because these tools were less complicated, repairs were relatively easy, carried out in faster way, fixes taking place in establishments these days. As equipment's became more sophisticated and complicated, organizations became increasingly dependent on their industrial machines. This allows the initiations of the second generation of machine monitoring from the decades of '50s to '70s. During this time, experts made condition monitoring a higher priority and efforts to decrease failure became more prominent. Then, during the third generation that ranges from the '80s till now, machine reliability became a prime focus within any industry that counts on the availability of large equipment's. As such, when equipment now-a-days suffer breakdowns and failure, it can affect the overall process and operation of a industry. Whole time Reliability stated that machine monitoring presently fulfills a variety of purposes within industries, including acting a means to find changes in machinery condition, as well as providing opportunities for predictive maintenance. Additionally, experts these days utilize these methods to find impending failures and determine methods to mitigate these unnecessary breakdowns. Meanwhile, it is important to note that condition monitoring does not by itself prevent catastrophic failures, as the methods only detects and predicts them. Experts and employees must take action based on to data leveraged from machine monitoring systems to avoid failure.

1.1 FFT Analysis

The Fast Fourier Transform is an algorithm optimization of the DFT—Discrete Fourier Transform. The "discrete" part just means that it's an adaptation of the Fourier Transform, a continuous process for the analog world, to make it suitable for the sampled digital world. Most of the discussion here addresses the Fourier Transform and its adaptation to the DFT. When it's time to implement the transform in a program, will use the FFT for efficiency. The results of the FFT are the same as with the DFT; the only difference is that the algorithm is optimized to remove redundant calculations. In general, the FFT can make these optimizations when the number of samples to be transformed is an exact power of two, for which it can eliminate many unnecessary operations. From Fourier we know that periodic waveforms can be modeled as the sum of harmonically-related sine waves. The Fourier Transform aims to decompose a cycle of an arbitrary waveform into its sine components; the Inverse Fourier Transform goes the other way—it converts a series of sine components into the resulting waveform. These are often referred to as the "forward" (time domain to frequency domain) and "inverse" (frequency domain to time domain) transforms. For most people, the forward transform is the baffling part—it's easy enough to comprehend the idea of the inverse transform (just generate the sine waves and add them). So, will discuss the forward transform; however, it's interesting to note that the inverse transform is identical to the forward transform (except for scaling, depending on the implementation). One can essentially run the transform twice to convert from one form to

EFFECT OF CRYOGENIC HEAT TREATMENT ON MECHANICAL PROPERTIES AND MACHINABILITY OF TOOL STEEL D3

[1]Dharmendra Kumar, [2]Ram Bahadur Singh, [3]Seema
[1] Asst. Professor, [2&3] Guest Faculty,
[1]MCS Group of College Lucknow, [2&3]MCAET, Ambedkar Nagar, (UP), India.

Abstract: This paper evaluates the resultant effects of Cryogenic heat treatment on machinability properties of cutting tool on material Tool Steel D3. Mechanical property changes before and after Cryogenic heat treatment are compared. Result of tool wear & chip morphology are measured with different machining factors and magnified and compared through scanning electron microscopy technique. Optimum setting for cutting speed and feed rate are is determined using Response Surface Method Technique. Machining properties are enhanced for tool and are better when compared to conventional machining process results.
Index Terms – Machining, Cryogenic Heat Treatment, Tool Steel D3.

1. Introduction

Tool steel is used to prepare cutting tool for dies and mold preparation and other materials. There are different classifications for tool steel based on specific grate and composition. Tool steel has different properties for different compositions. These properties can also be improved with Heat treatment. Cryogenic heat treatment is one specific process which brings out the improved properties when compared to that general heat treatment.

In heat treatment process, many process are used one by one such as heating process, annealing process, cooling process and hardening process etc. sometime one more type of treatment process is used in heat treatment process which one is cryogenic treatment, sometime cryogenic process work as additional process and sometime cryogenic process work separately. Cryogenic treatment process is latest treatment process of material in which material is cooled to very low temperature up to 77K and many gases are used in cryogenic treatment process such as nitrogen, oxygen, neon, hydrogen, helium, carbon die oxide etc. nitrogen gas is most widely used in cryogenic treatment process because nitrogen gas can reach to -196 °C (77K) but if we want temperature up to -268 °C (5K) then neon gas is used because 5K temperature cannot be obtain by use of nitrogen gas. Cryogenic treatment process relieve internal stress/internal crack of material.

1.1 Cryogenic Heat Treatment

Cryogenic treatment modifies the properties of metal by use of cryogenic temperature and change the crystal structure of material. Cryogenic treatment process works on third law of thermodynamics. Thermodynamics third law states that entropy at absolute zero temperature is zero, cryogenic treatment follow this principle for relieving the stresses in material. In cryogenic treatment, material is subjected to very low temperature for long time period. Cryogenic treatment do not substitute the heat treatment process, it is additional process for tool steel. Hardness of Most of material does not change by use of cryogenic treatment therefore we need to Tempering before cryogenic treatment to gain toughness and hardness of material and it affect the entire material.

1.2 Classification of cryogenic treatment

Cryogenic treatment process is mainly divided into two parts which depend on the temperature such as

(i) Shallow cryogenic treatment (SCT)

(ii) Deep cryogenic treatment (DCT)

In shallow cryogenic treatment, tool steel keep at almost 190K temperature then brings to room temperature while in deep cryogenic Treatment, tool steel keep at almost 70K temperature then brings to room temperature. During the conventional heat treatment, we cool the materials till room temperature and then some austenite leave in material. Then this retained austenite is transferred into martensite by use cryogenic treatment. Liquefied gases are used in cryogenic treatment such as liquid neon, liquid nitrogen, liquid helium etc. nitrogen gas is most widely used in cryogenic treatment and easy purchasable in the world. Boiling temperature of gases used in cryogenic (cryogens).

2. Literature Review

Machining of tool steel is difficult problem for any researcher because tool steel D3 is very strong material. After reading the many research paper, I found that strength of insert tool used in turning operation should be higher than strength of material used for machining [1-3]. Many researchers studied on machinability of tool steel D3 but most accurate values are not obtain yet. Therefore my focus is on to measure the roughness of tool steel after and before the heat treatment process, finishing of machining should be best because many tools are manufactured by using the tool steel D3. These tool made by tool steel are used in forming, rolling, punching, piercing, insert tool and other tools. Therefore roughness and strength of tool steel is important to know for any researchers. In this research I focused on roughness, wear of tool and chip morphology [4]. For machining the tool steel D3, turning operation is used. Machining of tool steel D3 can be increased by heat treatment process and some cooling technique [5-8]. And many researchers have complete different experiment to find the tool life in turning operation using CBN insert tool and experiment data are carried out at several cutting parameters. To find the best result of roughness of material, selection insert tool should be proper because improper selection of insert tool

EXPERIMENTAL AND COMPARATIVE STUDY OF COMPRESSIVE STRENGTH OF CONCRETE MADE OF NATURAL AGGREGATE AND RECYCLED AGGREGATE

[1]Seema,[2]Dheeresh Kumar Nayak,[3]Surendra singh parmar,[4]Ram Bahudur Singh
[1]Guest Faculty,[2]Research Scholor IIT BHU,[3]Assistant Engineer,[4]Guest Faculty
Civil Engineering,
[1]Mahamaya College of Agricultural Engineering &Technology ,AMBEDKAR NAGAR(UP),India

ABSTRACT

In this study compressive strength of concrete produced using recycled aggregate and concrete produced using natural aggregate has been compared. The recycle aggregate is obtained after crushing already cast concrete cube in the laboratory. After crushing the aggregate has been run in L.A. abrasion machine for 6 minutes or 200 rounds with 12 iron balls inside it. This process removes sand and cement which are attached with the aggregate after the crushing. The obtained aggregate has been passed through a sieve to remove sand and cement. Now the aggregate is washed with water,so that remaining sticking materials also removed from the aggregate.

The properties of recycled aggregate are different from natural aggregate like specific gravity, water absorption etc. Using a laboratory test method these properties of recycled aggregate is determined. As water-cement ratio effect the compressive strength of concrete so cube has cast at six different water-cement ratio. Concrete cube has been cast with use of recycle aggregate with six different water-cement ratio as .5, .475, .45, .425, .40 and .38. Concrete cube of natural aggregate has been cast with three different water-cement ratios as .5, .45 and .40. Concrete cube tested on 7, 28 and 60 days. Comparison of compressive strength of concrete has been done between concrete cube produced using natural aggregate and concrete cube produced using recycled aggregate.

Key Words:- Recycle Concrete Aggregate, Compressive Strength, Natural Aggregate

INTRODUCTION

Concrete recycling is becoming an increasingly popular way to utilize aggregate left behind when structures or roadways are demolished. In the past, this rubble was disposed of in landfills, but with more attention being paid to environmental concerns, concrete recycling allows reuse of the rubble while also keeping construction costs down.

Several advances have made recycling more economical for all types of concrete pavements in recent years. These include:

1. Development of equipment for breaking concrete pavements be they plain, mesh-and-dowel or continuously reinforced.
2. Development of methods to remove steel that minimizes hand labour.

Use and application of crushing equipment that can accommodate steel reinforcement.

Recycle Concrete Aggregate (RCA) is the main components of old concrete and for many reasons, there is a need to re-use them. It is better to the reuse of waste aggregates as recycled aggregates in structural concrete, instead of throwing out as a total waste material. Thus in recent years, the use of recycled concrete aggregate has gained tremendous momentum in constructional engineering. Utilization recycling of waste concrete would benefit into two folds. First, reduce the environmental problem and second reduce the utilization of natural resources. By the production and use of RCA, these advantages include lower environmental pollution, reduction in valuable landfill space, and savings in natural aggregate resources.

Demolition of old and deteriorated buildings and traffic infrastructure, and their substitution with new ones is a frequent phenomenon today in large part of the world. The main reasons for this situation are changes of purpose, structural deterioration, rearrangement of a city, expansion of traffic directions and increasing traffic load, natural disasters (earthquake, fire and flood), *etc.* For example, about 850 millions oftones of construction and demolition waste are generated in the EU per year, which represent 31% of the total waste generation [1]. In the USA, the construction waste produced from building demolition alone is estimated to be 123 million tons per year [2].

LITERATURE REVIEW

In 1978 **P.J. Nixon** presented a review report on recycling concrete aggregate (RA) also known as the first state of the art development. In this review he mentions various work done on recycle concrete aggregate between 1945-77. **Gomezinvestigates** the use of waste concrete as an aggregate in Russia in 1946. He found out RA has a lower specific gravity and lower compressive strength as compared with the natural aggregate(NA). At equal compressive strength, the flexural strength of RA is greater than

"STABILITY OF WASTE DUMP: SLOPE STABILITY ANALYSIS"

[1]Seema, [2]Ram Bahadur Singh, [3]Dheeresh K Nayak,[4]Rakesh Babu Gautam,[5]Akash Deep Gupta
[1]Guest Faculty, [2]Guest Faculty, [3]Research scholor IIT BHU,[4]Assistant Professor,[5]Guest Faculty

Abstract : Open dumping is the most usually utilized strategy received in India as strong waste administration. In any case, slant disappointments of open dump destinations lead to ecological contamination as the vast majority of the open dumps are situated close water bodies. Hence, breaking down the steadiness of open dumps is vital in executing mitigatory estimates where required. Wilderness bahadur ali open dump site which is situated close Mahesra, Gorakhpur (U.P.), India was considered as a contextual investigation to examine the dependability of its inclines comprising of old and new waste speaking to various degrees of deterioration. Shear quality parameters of the waste examples of the old and new waste destinations were resolved utilizing box tests at various profundities with molecule measure under 9.5 mm. Explicit gravity test, Oedometer test and Standard Proctor compaction test were performed to get Gs, essential and auxiliary solidification parameters, most extreme dry thickness and the ideal dampness content. Furthermore, direct shear test was completed to decide the shear quality parameters of the fill. Slant strength examination was done utilizing Slope/W and Plaxis-2D programming considering Mohr Coulomb and delicate soil creep models separately for waste material. Thought of essential and auxiliary combination settlement inside the landfill in the Plaxis-2D investigation brought about an expansion in the Factor of safety (FOS). Along these lines, FOS esteems acquired from the incline soundness investigation of the old site, was higher than that in the new waste si.

Index Terms – Open dumping, Solidification, Dampness

I. Introduction

Metropolitan strong waste is a kind of strong waste created from network, business and agrarian tasks. This incorporates squanders from families, workplaces, stores, enterprises and other non-fabricating exercises. City strong waste evacuation is a noteworthy issue in everywhere throughout the world. There are a few techniques accessible to expel strong squanders, for example, designing landfill, open dumping, reuse and reuse and sea dumping. Truly, landfills have been the most widely recognized technique for sorted out waste transfer and remain so in numerous spots the world over. A few landfills are likewise utilized for waste administration purposes, for example, the impermanent stockpiling, solidification and exchange, or preparing of waste material (arranging, treatment, or reusing). An open dumping is characterized as a land transfer site in which strong waste is discarded in a way that does not secure nature and helpless to open copying, presented to the components, scroungers, and so forth. There have been various landfill disappointments on the planet with high loss of lives and properties. Dependability of an incline is assessed by the equalization of shear pressure and shear quality. A formerly steady slant might be influenced by numerous components, making the slant unsteady. Activating elements of an incline disappointment can be a climatic occasion that can make a slant flimsy prompting mass developments. Mass developments can be brought about by increment in shear pressure, for example, stacking, parallel weight and transient powers. Then again, shear quality might be diminished by enduring, changes in pore water weight and natural material. In slant solidness examination, essential trouble with investigation is finding most likely slip plane for some random circumstance, on the grounds that the vast majority of the disappointment cases are dissected after the genuine disappointments. In any case, these days slant observing utilizing radar innovation has been utilized. Steadiness can be altogether improved by introducing seepage way to lessen the destabilizing powers.

On the off chance that the open dump locales experience disappointments they can influence adjacent water assets. There are number of landfill disappointments happened in world with high loss of lives and properties, for example, landfill disappointment happened in Ohio, USA on ninth March, 1996, Landslide at the Payatas dumpsite, Philippines on eleventh July 2000 (Jafari et al.2013, [7]), Hiraya avalanche in Iran on 1997. There are no slant disappointments in open dumpsites experienced in Gorakhpur (U.P.), India, yet the vast majority of them are situated close waterway banks. Consequently, investigating the solidness of this landfill is essential. In this exploration, a civil strong waste landfill site at Jungle bahadur ali is considered as a contextual investigation. This site is nearby the "Rapti River". It for the most part comprises of two particular regions, for example, new site and old site. Old site comprises of MSW dumped at beginning periods of its activity and the new site comprises of MSW dumped after the old site is completely filled. Following couple of long stretches of activity dumping of MSW was ceased and the whole site was relinquished. These two destinations comprising of MSW which have experienced distinctive level of disintegration are at risk to experience slant disappointment which could prompt extreme ecological contamination for the most part because of its nearness to the stream. Along these lines, the exploration point is to assess the dependability of the slants of old and new destinations joining the spatial variety of shear quality properties inside the fill.

1.2Specific Objectives:

The primary objective of this project is to evaluate the stability of the slopes constructed due to dumping of the waste materials (especially the sub-grade materials). It has the following specific objectives:

- Critical review of the available literature to understand the issues involved.
- Collection of samples from field or an operating mine.
- Analysis of the samples to find out parametric variations (as the cohesion, angle of friction, density, moisture content, grain sizes, etc.) affecting the stability.
- Prediction of safety factor based on the geotechnical data.

Design and development of self-propelled onion (*Allium cepa* L.) digger

VISHAL PATEL[1], DHARMENDRA KUMAR[2] and ANSHU SAXENA[1]

[1]Department of Farm Machinery and Power Engineering, College of Technology, G. B. Pant University of Agriculture and Technology, Pantnagar-263145 (U.S. Nagar, Uttarakhand), [2]Indian Institute of Technology Kharagpur-721302(West Bèngal)

ABSTRACT: In this study, an effort has been made to design and develop an onion digger for the onion field in India. The onion digger has four wheels and a two-wheel drive machine. The digging system consists of a blade made up of high carbon steel material (EN45), which was the central digging part of the machine having dimensions 1000mm*250mm*10 mm. Fingers of the reaper binder are also provided to protect the blade from obstacles like heavy rocks and tough metals. The spacing of fingers is 180 mm, and the width of each finger is 100mm. Fingers are fastened on the blade with the help of nuts and bolts, and they are easily replaceable when got damaged. The forward operating speed of the machine is 3-5 km/h, and the maximum speed is10 km/h, having a field capacity of 0.2 hectares per hour. The working depth of the machine is 100mm. Depth is suitable for the field with practically no damage to the onion bulb. The fuel consumption of the machine is 3.5 litres per hour when working at full capacity.

Key words: Digger, development, farm machinery, onion harvester

India is the second-largest onion-producing country in the world (Kumar *et al.*, 2006). Indian onions are available round the year and have two seasons, first harvested from November to January and the second harvesting from January to May. The onion is a biennial but is usually grown as an annual crop. The bulb can be white, yellow, or red and require 80 to 150 days to reach harvest. The optimum time of harvesting is one week after 50% of leaves have fallen. Onions of an early harvest maturity had a higher storability than other maturities of harvest (Maw *et al.*, 1997). Maturities symptoms include yellowing of leaf and dry at the top; bulbs turn red and attain their optimum varietal size (Talokar *et al.*, 2014).The onion root system is fibrous, spreading just beneath the soil surface to a distance of 45cm (Al-Jamal *et al.*, 2001). In India, most of the onions are harvested manually, and it is a time-consuming and labour-intensive job. When producing bulb onions from sets, the cost of manual labour on tending, harvesting, and postharvest treatment amount to 60–70% in the production cost structure (Laryushin and Laryushin, 2009). Matured bulbs are harvested by hand shovel (khurpa), which requires 21.4 % of the total expenditure of onion cultivation (Kawale and Ramappa, 2019). A lot of research has been done in the past to develop machinery for the harvesting of onions in India as well as in other parts of the world. In this study, an effort has been made to develop a self-propelled onion digger suitable for the Indian field.

MATERIALS AND METHODS

The onion digger was developed for digging the onion between the tyres of the machine, the track width of the machine is 1560 mm, and the width of the blade is 1000 mm. The inclination of the blade was kept between 15-20° for better penetration (Kanafojski and Karwowski, 1976), the angle between 15-20° is best for cutting soil with less resistance. The angle of the blade is adjustable, it can be adjusted by two nuts and bolt assembly. After the blade, there is a conveyor that conveys the dug onion and removes the extra soil. After conveying, onions are dropped on the soil and later pick-up by the labour easily.

COMPONENT OF MACHINE

ENGINE: For providing power to the digger, we use the Kirloskar CC418, 8-horse power Diesel Engine. Air-cooledengine works in the clockwise direction. A single-cylinder internal combustion engine is with

Summary

Designing an efficient, short, and secure authentication algorithm for resource-constrained sensor nodes of wireless sensor networks (WSNs) is a challenging task. Authentication in WSNs is mainly performed by the digital signature algorithm. In this paper, we propose an efficient, short, and secure pairing computation-free ID-based authentication algorithm (signature scheme) ESS-IBAA for WSNs which completely follows the rule of identity-based cryptosystem. Identity-based schemes, unlike traditional public-key infrastructure (PKI)-based schemes, remove the need for public-key certificates for public-key validation. It also removes extra costs associated with the public-key certificate and traffic management. Further, due to the requirement of low power and fast authentication, bilinear pairing computation-free identity-based signature schemes are applicable in WSNs. Keeping this in mind, ESS-IBAA scheme is proposed, which is pairing computation free and uses a general cryptographic hash function in the place of a costly map-to-point hash function. The proposed scheme ESS-IBAA is secure against existential forgery on adaptive chosen message and ID attack in the random oracle model under the hardness of the elliptic curve discrete logarithm problem (ECDLP). Moreover, comparative performance analysis shows that the proposed scheme ESS-IBAA is much more efficient in both communication cost and computation cost from the existing related schemes.

Abstract: The experiment conducted at Mahamaya College of Agricultural Engineering & Technology, Ambedkarnagar (U.P.). The pump tested for analysis performance is ELGIMACE model no. LLO3022 single acting reciprocating pump equipped with 2HP three phase induction electric motor with 1440rpm. A hose measuring of water source of 4.12x3.25x1.23. G.I.20 mm size, suction pipe was used. The delivery pipe was high density pliable reinforced rubber pipe to withstand abundant pressure (up to 25kg/cm^2.). Stop watch was measuring discharge of 1/100sec. of least count. For three different speeds of 242 rpm, 285 rpm and 344 rpm with five dissimilar pressures are 1.5 kg/ cm^2, 5.7 kg/cm^2,10.3kg/cm^2, 15kg/cm^2 and 24kg/cm, pump was tested. Track record of all pipe pressure used for this testing was measured by a pressure gauge having adequacy 0-35kg/cm. In motor shaft a V(twin) belt the electric connection was energized and a pulley with minimum diameter 6.25cm was fitted. The outcomes based on the exploratory observation showed that the efficiency rises when pressure is rises. At speed of 344 rpm the efficiency is detected 90% and at dupe speed the volumetric efficiency is 77% for least pressure 1.5kg/cm and volumetric efficiency is 95% for maximum pressure 24 kg/cm^2. The discharge increases as pressure goes up and it is showed by the average discharge and pressure, which is almost linear. The relationship sequence is mostly same for all above circumstances; this stated that discharge is mutual to the pressure for a reciprocating pump.

Index Terms: Discharge, Efficiency, Volumetric efficiency, Pressure, rpm, Static head, Reciprocal and Pressure head.

I. INTRODUCTION

Reciprocating pump is a pneumatic machine which gets converted in hydraulic energy from mechanical energy. A cylinder containing a reciprocating piston absorbs liquid which expend a thrust (impel) force on the liquid and hike its hydraulic energy (pressure energy of liquid). It's a kind of positive displacement pump which comprises of piston or plunger. It is used at a place where relatively small amount of water is to be delivered at high pressure. Water in cylinder is displaced by the movement of piston for the functioning of reciprocating pump. Valves control the flow. A piston or plunger is cylindrical piece which moves backward and forward inside hollow cylinder. Reciprocating pump's capacity depend on the sizes of cylinder chamber, piston length and piston stroke. Electric motor engine operate a pump which have to come into prominence in a large lift irrigation schemes, high output levels can be quickly attained and managed by this process. Reciprocating pump generates high head, but their capacity is smaller compared to other types of pump. Reciprocating pump works on single acting independent suction and discharge strokes works on double acting suction and they discharge in both the direction. Although, recommendation of specific purpose pumps is very tough due to the inaccurate figures about scientific information such as efficiency discharge, head relation and other characteristics .Understanding all this circumstances, under laboratory conditions a study was approached for evaluation of volumetric efficiency, pressure discharge relationship and speed-power-discharge.

A prototype of an electrostatic nozzle was developed for spraying cotton crops in a project titled 'Design and development of an electrostatic nozzle for agricultural applications'. The study was carried out to evaluate the locally-developed electrostatic nozzle and compare its performance with an imported electrostatic nozzle and solid cone nozzle (conventional knapsack sprayer) in the cotton crop at the departmental research farm of Punjab Agricultural University, Ludhiana, India. Different spray performance parameters, *i.e.* number median diameter (NMD), volume median diameter (VMD), uniformity coefficient, droplet density, the volume of spray deposition, and area covered with droplets were determined with the help of water-sensitive paper (WSP) method of deposition collection. There was comparatively less variation in uniformity coefficient with the imported and locally-developed electrostatic nozzles than the solid cone nozzle at a 5 % level of significance. The average droplet density obtained with both the imported and locally-developed electrostatic nozzles was significantly more compared to the solid cone nozzle. The area covered by the droplets of the locally-developed prototype of the electrostatic nozzle was more than the solid cone nozzle. The volume of spray deposition differed significantly for all three treatments at a 5 % level of significance. Overall, there was no significant difference in the performance of both electrostatic sprayers, but they were found to be more effective than the solid cone nozzle.

Key words: electrostatic nozzle, uniformity coefficient, droplet density, volume of spray deposition.

INTRODUCTION

Cotton is one of the most important textile fibres in the world, accounting for about 35 % of the total worldwide fibre usage. It is the single most cash crop that is cultivated extensively throughout the world. India, China and the United States of America are the major cotton-producing countries and together account for approximately two-thirds of total world cotton production (Anon 2015a). India is the largest cotton-producing country in terms of total production with an average of 6.10 Mt per year on a total sown area of 11.8 Mha. However, it has the 33rd ranking in the world in terms of yield per hectare because of a low average yield of about 517 kg/ha as compared to the world's average of about 566.27 kg/ha (Anon. 2015b).

Although cotton production and yield increased by introducing new crop varieties and production practices, still significant yield loss was observed as 4.1, 6.5, and 8.8 % in the cotton crop in three districts of India, namely Firozpur, Mansa, and Bathinda, respectively (Dhawan *et al.* 2008). Crop loss due to different insects has been reported to run to 18.0 to 50.0 % (Dhaliwal *et al.* 2010). In an another study the range of yield loss due to cotton leaf curl virus disease was reported to be from 81.4 to 88.4 % in all northern cotton-growing states of India (Monga 2014, as cited in Kumar Sain *et al.* 2019)

There are several spraying methods to protect crops from pests and diseases. Based on the volume application rate, there are three types of sprayers: high volume sprayer, low volume sprayer, and ultra-low volume sprayer. The high volume sprayer leads to loss of spray due to the larger size of droplets and more liquid application

Abstract

This research investigation was undertaken in ANDUAT, Kumarganj, Ayodhya, Uttar Pradesh, India to study the numerical optimization of natural convection heat suppression in a solar flat plate collector with straight fins. Optimal characteristics of an array of thin fins attached on the absorber plat were obtained by Particle Swarm Optimization algorithm (PSOA). Free convection considered dominant in the cavity. Governing equations contained continuity; momentum and energy are discretized by finite volume method. The medium is considered incompressible, whose free convection is dominant and Boussinesq approximation is applied. A simplified model of real systems is applied with free convection. Free convection problem is solved by SIMPLER algorithm. Two confined cavities with aspect ratios 30 and 60 are considered as flat plate solar collectors. The results indicate that significant reduction on the free convection heat loss can be obtained from solar flat plate collector by using plate fins, and an optimal plate fins configuration exit for minimal natural convection heat loss for a given range of Rayleigh number. Reduction of up to a maximum of 25% at 0 inclination angle was observed in aspect ratio 30. Results showed PSOA is able to obtain characteristics of attached adiabatic fins on the absorber plate also it can obtain optimal inclination angle of cavity to decrease heat losses from solar collectors. The results obtained provide a novel approach for improving design of flat plate solar collectors for optimal performance.

Keywords: Particle swarm optimization algorithm, solar collectors, natural convection

1. Introduction

Flat plate solar collectors are technique to utilizing solar energy. The flat plate absorbs incoming solar radiation and converts it in to heat and also transfers this heat to a fluid flow. Glazing cover plate prevents from heat loss by force convection but when temperature difference between flat plate and glazing cover plate exceeds to a critical value, natural convection will exist between absorber and cover plate. In present work of heat loss from absorber plate is reduced by investigating optimal characteristics of an array of thin fins are considered. Grossman et al. (1977) expanded a model for heat transfer in a flat plate solar collector with a rectangular channel for water or air fluid flow. The analysis was performed for temperature and heat flow distributions in both dimensions of the collector to investigate the thermal boundary layer development. Overall efficiencies are calculated for uniform solar

Abstract

The development of simulation model is a powerful tool for prediction of performance and can help designers to optimize the dryer geometry at various operating conditions. Commercialization of any drying technology for agro-processing or industrial use needs thorough performance prediction and evaluation of system in techno-economic perspectives.

Estimation of solar radiation at Hisar with the help of ASHRAE model has been in close agreement with the observed values taking 5% as level of significance. Thus the model can safely be used to predict isolation at Hisar. The calculated efficiency of the flat plate solar collector using the data at different point in the solar dryer during testing has been consistent.

Introduction

Drying is one of the essential unit operation performed to increase the shelf life of agricultural / horticultural produce and it is one of the most practical methods of preserving food and the quality of horticultural produce. Use of proper drying techniques can significantly reduce the post-harvest losses of fruits and vegetables (Attkan and Alam, 2018). There exist many technical problems associated with open sun drying namely cloudiness and rain, insect infestation, high level of dirt and atmospheric pollution and intrusions from animals and men. In addition to this there is no control on the drying process (VijayaVenkata Raman et al., 2012). Hence, developing countries, receiving significant amount of solar radiation must realise the importance of controlled drying using solar energy. Traditional method for fruits and vegetables drying in rural areas in India is to spread the products on the ground with exposure to the sun in the open air. Sun-drying method may be efficient and cheap process but has disadvantages such as contamination by dirt, insects and bacteria and loss due to wetting by rain squirrels (Esper and Muhlbauer, 1998). These are usually accepted as an inherent part of the method of processing. In order to protect the products from above mentioned disadvantages and also to accelerate the time for drying the products, control the final moisture and reduce wastage through bacterial action. Solar energy is fast becoming an alternative source of energy because of the high rate of depletion of the conventional energy sources. It has many advantages over other alternative source of energy such as wind because of its abundant, inexhaustible, renewable and non-polluting nature. Equally, it can be tapped at a relatively low cost. The associated danger of fire or other hazards are less (Ekechukwu and Norton, 1999).

Whereas, controlled solar drying system leads to faster rate of drying and exposure of products against rain, dust, storm, birds, rodents, insects and pests are avoided. This ensures better quality of dried products which would fetch higher prices (Hossain and Bala, 2007). In solar drying method, faster drying takes place which result a significant reduction in drying time. Product dried in solar dryer are superior in quality (colour and flavour). Though the same superior quality product can be obtained by using electricity or electric power, but the electric operations are expensive and are not within the reach of our rural and tribal population. There is also inadequate supply of electricity in rural areas. In such conditions solar-energy crop dryers appear increasingly to be attractive as commercial propositions (Das and Kumar, 1989).

The development of simulation model is a powerful tool for prediction of performance and can help designers to optimize the dryer geometry

ENERGY INPUT FOR FODDER CROP PRODUCTIONS UNDER DIFFERENT TYPES OF FARMING SYSTEMS

Pramod Kumar Mishra*, Sunny Sharma, Himanshu Tripathi and Dharmendra Pandey

Lovely Professional University, Phagwara, Punjab, India

Abstract

The pattern of energy utilize in cultivation of fodder crop was studied under traditional and partially mechanized farming system. It was observed that the total operational energy was found to be 6883.83 MJ/ha and 7298.73 MJ/ha in traditional and partially mechanized farming system respectively. Out of which 48.52 and 56.21 percent was utilized by direct source of energy in different farming systems, whereas 51.48 and 43.79 percent was utilized by indirect sources of energy. The total energy cost in traditional farming system was Rs 86450 /ha. Similarly, the cost of energy in partially mechanized system was Rs 93201 /ha. This difference clearly indicates that traditional farming system can be replaced by partially mechanized farming system with more return.

Key word: Partially mechanized farming system Energy ratio, energy productivity etc.

Introduction

Energy is integral part to national development process and to provide major vital services that improve human requirements; fuel for cooking, light for living, motive power for transport, and electricity for modern communication. In agricultural sector, its use is in every form of inputs, seed, fertilizer, agro-chemical for plant protection, machinery use for various operation, housing, transport, and processing. Apart from solar energy, production agriculture uses basic additional energy inputs, soil, water, tractive power, chemicals for growth of plants. The amount of energy invested through these inputs and quantity actually used by the plant govern the crop growth and yield during their life cycle.

Singh *et al.* 202 has estimated that total energy input Indian agriculture increased by 3.6 times. In modern agriculture, commercial energy sources (fuel, machinery and chemicals) contribute bulk of the energy supplies to the production system. Commercial energy use in agriculture has been increasing since revolution with increasing use of diesel and electricity in farm operations. The share of agriculture in electricity consumption has increased from 3.9% of the total consumption in 1950-51 to 29.6% in 1993-94. Total commercial energy use in agriculture increased nearly fivefold with growth rate of 11.8% between 1980-81 to 1994-95. The share of agriculture in total consumption in the country increasing marginally from 3.2 to 5.2% during the same period. Increase in land productivity and efficient diversification of agriculture for better economic return to the producers will call for significantly higher level of input to agriculture (Mahapatra, 1991).

India is presently under heavy stress on account of a large-scale exploitation for fuel wood, timber and fodder, mismanagement of forest resources and frequent fires. There is acute shortage of fodder especially green nutritious fodder, which is major cause of low productivity of livestock, especially in hilly area (Deb Roy *et al.*, 1989). The main reasons for low productivity is insufficient and low quality fodder and feed including grazing facilities (Deb Roy, 1993). Therefore, India has been the home of major draught, milch and dual-purpose breeds of cattle. Indian dairy production system is complex and generally based on traditional and socioeconomic considerations. However, there has been a rapid change in way of agriculture (*i.e.* cropping system, water resources, diversification of crop, intensification of agriculture), increasing use of mechanical power, transformation from

Precision attributes based index for the selection of efficient agricultural machinery

Manjeet Singh[1], Karun Sharma[2*], Pramod Mishra[1], Bharat Patel[1] and S K Singh[1]

[1]Department of Farm Machinery and Power Engineering, Punjab Agricultural University, Ludhiana, India.
[2]Krishi Vigyan Kendra, Samrala, Punjab Agricultural University, Ludhiana, India.

Received 5 May, 2016; Accepted 25 January, 2017

Development and introduction of high capacity, precise, reliable and energy efficient machinery/equipment is the need for judicious use of inputs. Manufacturing of agricultural machinery in India is varied in nature and starts from village artisans, tiny units, cottage to small scale industries, organized tractor and agricultural machinery manufacturers including energy and processing machinery industry. Precision in application rates for higher input-use efficiency can be achieved only by improving the designs of the existing machinery/equipment. Precision index (PI) of machine/equipment is based on its capability to perform a given task in accurate manner. It is a worthwhile attribute to compare the performance of different equipment and operations to enhance the productivity of a given farm. The purpose of study was to propose an index, that is, PI to select efficient and precise machine/equipment for the farmers. PI values were calculated for three types of machinery namely zero seed cum fertilizer drills, planters and spraying machines. It was concluded that drill Make 2, tested in the year 2004, was having the highest PI value, that is, 0.95 or 95% followed by drill Make 1 having PI value 0.95 or 95% tested in the same year. Drill Make 5 tested in the year 2013 was having minimum PI value, that is, 0.80 or 80%. PI value for happy seeder was 0.88 or 88%. During the testing of multi-crop planter in year 2014, the variability of double dropping was more, that is, 28% followed by missing having 20% value and produced influence on PI value observed to be 0.83 or 83%. PI of semi-automatic and automatic potato planter was found to be 0.84 and 0.80, respectively. The value was not much satisfactory and could be ranked under average category. PI of electrostatic sprayer mounted with single as well as twin nozzle was observed the highest, that is, 0.89 followed by PI of air assisted sprayer with single and double nozzle (0.85 and 0.84, respectively.

Key words: Precision index, zero till seed cum fertilizer drill, happy seeder, spraying machines, planting machines.

INTRODUCTION

Mechanization imparts capacity to the farmers to carry out farm operations, with ease and lesser drudgery. It helps the farmers to achieve timeliness, precisely meter and apply chemicals for better efficacy and efficiency. Efficient machines help in increasing productivity by about 30% (Singh et al., 2014) besides enabling the farmers

■ **ABSTRACT :** Mahua stamen remover was evaluated for its performance. It was tested at four moisture levels (11.9, 13.17, 15.64 and 17.66 % d.b.) and three feed rates (15, 21, 27 kg/h). The stamen removal efficiency and whole flower recovery were determined to optimize feed rate and moisture content of mahua flower for better performance of the machine.The present study revealed that the optimum flower moisture content and feed rate were found to be 13.17 per cent and 15 kg/h, respectively with stamen removal efficiency of 88.23 per cent and whole flower recovery of 81.2 per cent.

■ **KEY WORDS :** Mahua stamen remover, Stamen removing efficiency, Whole flower recovery ans deseeder

Mahua *(Madhuca indica)* of Sapotaceae family is a large tree found inthe deciduous forest of India. Every part of the mahua tree is used by the tribals for their livelihood. Its flower is used as foods and can be fermented to alcoholic drinks due to its high sugar content. It is a multipurpose tree providing food, fuel, timber, green manure, oil, oil cake, liquor and raw materials for several products and is one of the most important trees of Indian forest. It also has a religious and a high bio-asthetic value in the tribal culture. It is one of those multipurpose forest tree species that provide an answer for the three major Fs *i.e.,* food, fodder and fuel (Banerji and Mitra, 1996). It is very important from the point of view that it can help inpromoting nutritional and economic security in backward areas.

The estimated annual production of mahua flower is around 2 lakh tonnes (*www. jhamfcofed.com*) in Jharkhand. Mahua tree produces edible flowers and fruits. The ripe flowers, which fall from the tree, are collected. The yield per tree ranges from 100-200 kg. Mahua is also famous for its seed oil.

Mahua flower can be utilized in a variety of ways in home, as animal feed and also as raw material for industrial products. They can be used as a sweetener inpreparation of many local dishes like *Halwa, Kheer, Puri* and *Burfi* (Patel and Naik, 2008). It is also used for preparation of bakery and confectionary goods. Tribal people also use it for brewing alcohol. It contains tannin as tannins are excellent antioxidant that helps in giving the structure, texture and flavour to wine. Mahua flowers are also considered good for cooling and are used as a tonic and demulcent. However, an estimated 90 per cent of the production goes into brewing beverages. Mahua has various types of medicinal uses due to its tannin content. It is used as anti-diabetic, antiulcer, hepato protective, anti-pyretic, anti-fertility, analgesic, anti-oxidant, swelling, inflammation, piles, emetic, dermatological, laxative, tonic, anti-burn, anti-earth worm, wound healing headache and many more problems (Patel *et al.,* 2012). On account of various advantages of mahua

PIPE WATER NETWORK DISTRIBUTIONVERSUS CANAL FOR IRRIGATION - A CASE STUDY OF KHANGAON BRANCH OF LOWER WARDHA PROJECT

[1]SEEMA, [2]RAM BAHADUR SINGH, [3]SHASHI PRABHA ANAN

[1]Civil Engineering,
[1]Mahamaya college of agricultural engineering & technology,Ambedkar nagar, India,

Abstract In This case study of Khangaon branch of Lower Wardha shows comparision and difference in the pipe water distribution system and canal system. Irrigation is a vital input in the agricultural productivity and agricultural growth. More than 70% of available inland water resources worldwide are being presently utilized for irrigation purposes. From the source the water is carried through open channels or close conduits to the irrigation areas. There is no doubt that modernization of irrigation system like concrete lining to the inner surface of the open channel and canal automation etc. will save water. However, still there are significant losses due to theft, evaporation & seepage. Further, contamination of water takes place due to people using water for bathing and cloth washing. On this background it is appropriate to adopt innovative, simple, easy to adopt, water distribution system using pipe lines. The paper discusses the need to adopt pipe line network for water conservation for irrigation projects, and a case study of Khangaon Minor of Lower Wardha project in detail. The findings show that such water distribution network using pipe lines shall be implemented in irrigation projects so as to achieve good water management with high water conservation comparatively with canal by maintaining the proper residual pressure/head and velocity

Key words: Pipe Distribution Network; Water conservation; Water distribution system

I. INTRODUCTION

1. INTRODUCTION

As we progress into the 21st century, water guarantees to be one of our most valuable assets. Insightful administration and legitimate preservation of this asset will be progressively vital, and imaginative strategies should be utilized to spare water. Robotization combined with astute plan has significantly expanded assembling efficiency around the world, while cutting the undesirable and along these lines enhancing the quality. Water system network give important water to agriculturists who have the ability to expand the monetary estimation of water to a decent degree to the extent they can, by legitimate usage of the water. The water from the source to the interest territories can be passed on under gravity through Canal networks or Pipe appropriation networks. These networks have their own points of interest and burdens that may happen amid various phases of structure, examination and development. Canal network is favored over pipe network on financial premise despite the fact that water misfortunes amid progress are high. In any case, considering restricted accessibility of water, expanding cost of land that should be get for canal development, and plausibility of keeping up adequate heads to specifically utilize present day water system strategies like dribble and sprinkler with or without extra vitality, improves pipe dissemination network a decision both as far as in general expense and water use proficiency.

This paper centers about the correlation of canal and pipe networks by choosing certain factors such as residual pressure, land acquisition, water conservation, water quality and total cost of projec. Khangaon part of Lower Wardha Irrigation Project is considered for the investigation. The task was at first intended to be actualized in customary method for canal network. Be that as it may, before execution a substitute is worked out using pipe distribution network. This paper gives a correlation of various parameters in two distinct plans.

2. STUDY AREA: KHANGAON MINOR -1

Figure 1 demonstrates the whole Khangaon minor branch alongside its laterals and chak division proposed. It is situated in Deoli, a residential area and a civil committee in Wardha region in the territory of Maharashtra, India. The investigation territory with scope 20038'35.14" N and longitude 78015'45.94" E is all around associated through State and National highway. The gross direction zone is 555.46 ha, out of which 538 ha is cultivatable order territory. The absolute discharge prerequisite for this zone is determined as 0.295 cumec. The length of the Khangaon Minor-1 without considering the laterals is 6.6

Abstract: The study was made in order to establish correlation between rainfall and ground water fluctuation of Ambedkar Nagar District in Uttar Pradesh through regression analysis. To study the trend in ground water level in eastern U.P. Ambedkar Nagar a model was fitted known as regression model with data for every year from 2008-2017 .The developed model equation is $Y' = -3.59 \times 10^{-3}X + 13.767810$ .The coefficient of correlation between water table and rainfall was observed as − 0.5735. The result of study had been evaluated through r^2, RMSE and EC were found to be -0.574, 1.23 & 96.6% respectively. The above empirical equation may be useful in prediction of water table depth from rainfall for base line for boring of tube well for timely irrigation of crop.

Index Terms: Rainfall, Regression Analysis, Correlation, Groundwater, Fluctuation.

I. INTRODUCTION

In 1959-60 the area underground water irrigation which is less than six million hectare but went up to 18 million hectare in 1980-81 to 33 million hectares in 1999-2000. More than half of the total irrigation is based on ground water, the share of ground water in area increasing from 30% in 1960-61 to 58.77% in 1999-2000. The area underground water is increasing progressively because it the most reliable and cost effective source of irrigation (Joshi, 2002).

The rainfall contributes to the annual increment in the ground water reserve which in turn is reflected in the rise of water table during the post monsoon period. Estimation of water table is needed for planning and developing the resources. With increasing demand for water for both agricultural and industrial use, the need to develop ground water resources to maximum possible extent has gained importance. The main component of recharge of ground water is precipitation. The ground level is an indicator of ground water availability. Ground water is an important resource of irrigation of India. It contributes to enhance agricultural production was better realize during green revolution and miss management has result in several problem likes fluctuation in water table and increasing in depth of wall. In last 10 year out of total monitoring wells 60% showed depletion in water table depth during per monsoon dry session. This leads to associated problem off lowering tube well depth and drying of open dug wells in the areas. Few areas with associated problem of lowering tube well depth and drying of open dug wells has becomes the major issues. This also indicates the decreasing trend of ground water table depth over a period of time. The fluctuation of water table is mainly depending upon the precipitation received in the area. Being insufficient annual rainfall and which is not sufficient to crop production, it is become essential to have the use of ground water. For irrigation purpose the ground water is utilized through tube well, pumping etc. For installation of the tube well is necessary to know the base the depth of table.

The present investigation entitled to "develop the model for the prediction and relationship between rainfall and ground water fluctuation of Ambedkar Nagar District" was carried out with objective to establish correlation between rainfall and ground water fluctuation.

A B S T R A C T

Sugarcane is multipurpose crop that serves as source of sugar, juices, jaggery and various products for man and raw materials for industry. But prior to the process of machining process, some processing is required to remove the solid particles, spots and sludge on the cane. The processing of sugarcane strip for industrial or human use involves different operations of which peeling is a major one and cannot be neglected. Of all the unit operations involved in cane processing, several processes have been mechanized successfully. This study presents the features, prospects, performance evaluations and limitations of some sugarcane peeling machines in world like the fixed outer drum peeler, automated cane peeler, knife-edge type self-fed peeler, etc. Their peculiar advantages and operational parameters such as machine speed, output capacity, peeling efficiency and cane losses were evaluated. Aside from the manual ones, the ranges of the peeling efficiency and cane loss were recoded in range of 59.9 – 91.4 % and 2–4% respectively. As machine speed increased, the output capacity and cane loss increased while peeling efficiency decreased. Mechanization of this peeling process has the potential of encouraging growth in cultivation, cane utilization and improving the product quality of value-added products. The product quality, processing efficiency, minimum loss of cane and increased processing rate will be affected by improved sugarcane peeling process.

Introduction

The sugar cane family is made up of over 30 sugar cane varieties. Sugar cane is a perennial grass that thrives in hot, humid locations like Brazil and India. The sugar derived from sugar cane is used in syrups, juices, and molasses, but the rest of the plant can also be used in the production of environmentally friendly paper products.

The juice from the sugar cane's stalk is highly prized and is the source of 70% of the world's sugar. It also has the highest number of calories per unit area of any plant. Fresh sugarcane juice is a popular beverage in many countries particularly in Asian region such as China, India, Malaysia and Thailand due to its taste and cheap price. Flavonoids that can be found in sugarcane juice have the abilities to protect cells from degenerative processes and to reduce the development of health problems

Highlights

- Design and synthesis of base-metal nickel(II) based catalysts.
- Molecular structures were determined by single crystal X-ray diffraction.
- Nearly selective formation of 1-butene from ethylene.
- Productivity up to 17.50 [kg (product/gm catalyst)] h^{-1} bar^{-1}.
- Probable reaction pathway.

Abstract

A new family of base-metal nickel complexes [Ni(L^{1-10})$_2$] (**1-10**) were synthesized from tridentate meridional ligands L^1H to L^{10}H (where H stands for dissociable proton). Different spectroscopic studies were utilized for the characterization of these complexes [Ni(L^{1-10})$_2$] (**1-10**). Molecular structures of complexes [Ni(L^1)$_2$] (**1**), [Ni(L^3)$_2$] (**3**) and [Ni(L^8)$_2$] (**8**) were determined by X-ray crystallography. Electronic properties of complexes [Ni(L^1)$_2$] (**1**) [Ni(L^3)$_2$] (**3**) and [Ni(L^8)$_2$] (**8**) were elucidated with the help of DFT and TD-DFT calculations. Complexes

Abstract

. Bis(imino)pyridine (NNN)-type ligand [(PyPhime-Cina) = 2,6-bis((E)-1-phenyl-2-((E)-3-phenylallylidene)hydrazinyl)pyridine] was synthesized, and a new family of metal complexes [Mn(PyPhime-Cina)Cl2] (**1**), [Fe(PyPhime-Cina)Cl2] (**2**), [Co(PyPhime-Cina)Cl2] (**3**), [Ni(PyPhime-Cina)Cl2] (**4**), and [Cu(PyPhime-Cina)Cl2] (**5**), derived from the ligand, have been synthesized and characterized. Molecular structures of the ligand and complexes **1-5** were determined using X-ray crystallography. Electronic properties and frontier molecular orbitals of the complexes were investigated by DFT and TD-DFT calculations. DNA interaction studies were evaluated by UV-visible absorption, fluorescence and circular dichroism spectral studies which indicated noncovalent binding of complexes with CT-DNA. Hirshfeld surface analysis of all the complexes was studied to know the weak interaction present in the molecules.

Abstract

The tridentate ligands ^{H}PhimpH, ^{OCH3}PhimpH, ^{CH3}PhimpH, ^{tBu}PhimpH, and ^{NO2}PhimpH have been synthesized and characterized. These tridentate ligands having non-innocent phenolato function, N_{py} and N_{im} donors upon deprotonation bind to iron(III) center resulting in a series of novel iron complexes, namely, [Fe(^{H}Phimp)$_2$](ClO$_4$) (**1**), [Fe(^{OCH3}Phimp)$_2$](ClO$_4$) (**2**), [Fe(^{CH3}Phimp)$_2$](ClO$_4$) (**3**), [Fe(^{tBu}Phimp)$_2$](ClO$_4$) (**4**), and [Fe(^{NO2}Phimp)$_2$](ClO$_4$) (**5**). Complexes were characterized by elemental analysis, IR, and UV–visible, and electrospray ionization mass spectral (ESI–MS) studies. Molecular structure of complex **2** was determined by single-crystal X-ray diffraction study. Electrochemical studies depicted Fe(III)/Fe(II) couple in the range of −0.50 to −0.65 V versus Ag/AgCl. Theoretical calculation using density functional theory (DFT) was also performed to optimize the geometrical and structural parameters. Time-dependent DFT (TD-DFT) was also optimized to observe the electronic properties, and data obtained were found to be consistent with experimentally observed values. Representative complex **4** exhibited nuclease and protease activities in the absence of external agents. Complex **4** was found to cleave the DNA and protein via self-activated mechanism. Complexes **1**–**5** were utilized to optimize oxidation of *o*-aminophenol in methanol. Complexes were found to be efficient in the oxidation of *o*-aminophenol. Kinetic experiments were also explored to gain better insight into the oxidation process.

Abstract: ***Background***: Wireless Sensor Network (WSN) is an arising field for research and development. It has various applications ranging from environmental monitoring to battlefield surveillance and more. WSN is a collection of multiple sensor nodes used for sensing the environment. But these sensing nodes are deployed in such areas where it is not that easy to reach, therefore, the battery used in these nodes becomes quite impossible to change, hence there is a need to utilize this energy to get the maximum sensing for a long time.

Objective: To use the Fuzzy approach in the clustering algorithm. Clustering is a key approach to prolong the network lifetime with minimum energy utilization. In this paper, the focus is on the Cluster Head (CH) selection. So, we are proposing a clustering algorithm which is based on some of the attributes, including Average Residual Energy of CHs, Average Distance from nodes to CHs, Standard Deviation of member nodes, and Average Distance from CH to Base Station(BS).

Methods: Initially, some of the nodes are found to have greater residual energy than the average network energy, and fifteen populations are made, each having an optimum number of CHs. The final and best CHs set is chosen by determining the maximum fitness value using a fuzzy approach.

Result: The result positively supports the energy-efficient utilization with lifetime maximization, which is compared with the Base algorithm [1] and LEACH [2] protocol based on residual energy and the number of nodes that die after performing some rounds.

Conclusion: The proposed algorithm determines a fuzzy-based fitness value, provides load-balancing among all the networking nodes, and performs a selection of best Cluster Heads, resulting in prolonged network lifetime and maximized efficiency.

Keywords: Index Terms - Sensor Nodes, Wireless Sensor Network (WSN), Clustering, Network lifetime, Cluster Head (CH), Fitness Value, Fuzzy Logic, Base Station (BS).

1. INTRODUCTION

Wireless Sensor Network is a large collection of autonomously distributed, cost-effective, multiple sensors that have the capability to sense the surrounding fields [1-3] to perceive the data and to process it further to forward it to the Base Station(BS), as shown in Fig. (**1**). Nowadays, WSNs are applied to various fields like health-care, motion, activity, and target tracking [4], border and military [5] surveillance, industries, weather forecasting, etc. The major problems emerging in WSNs are the limited battery life of sensors and the inefficient use of energy and hence the limited network lifetime. Data communication between sensor nodes can be wired or wireless; sensors can have rechargeable or non-rechargeable batteries, but it becomes more efficient to use wireless communication and hence non-rechargeable batteries in case of remote areas; so here comes the need of better energy-efficient algorithm.

Initially, data was transferred directly to the base station, and then comes the multi-hop [6] transmission, which decreases energy utilization. To fix this problem of limited battery and energy constraint, Clustering [5], [7] becomes the best and efficient solution that divides the nodes into some clusters. Clustering is a technique in which the whole sensing area is divided into multiple clusters. Every cluster consists of a Cluster Head (CH) and some of the member nodes. CH in each cluster holds the responsibility to collect and aggregate the data from all the member nodes of its cluster and transmit it to the Base Station (BS) as represented in Fig. (**2**). Member nodes are the remaining nodes other than

A study on Proxy Re-Encryption Schemes

Shashank Shekhar Tiwari[1], Hemant Kumar Baranwal[1], Shweta Tiwari[1], Ritika Yaduvanshi[2]

Department of Information Technology, Rajkiya Engineering College Ambedkar Nagar (U.P), India[1]

Department of Computer Science and Engineering, Mahamaya College of Agricultural Engineering and Technology, Akbarpur, Ambedkar Nagar (U.P), India[2]

Abstract: Proxy Re-Encryption (PRE) is now a primitive encryption used to assign decryption privileges. It was introduced by Blaze, Bleumer and Strauss. With the use of a proxy agent, PRE enables re-encryption of a ciphertext intended for one party to a ciphertext for another party. The underlying message and the sender's private key cannot be read by the proxy agent. The properties of proxy re-encryption systems with different classifications of proxy re-encryption schemes are discussed in this paper.

Keywords: Directionality, Distributed System, Encryption, Proxy re-encryption, Transitivity

I. INTRODUCTION

Encryption is a way to secure our data from unauthorized person. Proxy re-encryption helps in file security and distributed storage. The purpose of this technique is allowing re-encryption of one cipher text to another ciphertext. The encryption is done using private or public key for securing data and perform authentication via sharing security key. In situation where one user wants for another user to decrypt the message by using its own key or a new secret key instead of first user's secret key. An easily implemented re-encryption scheme is one of the proxy in which proxy given control of both User's key so the message will converted into plaintext and re-encrypted for another user or second user. User1's secret key used to decrypt the message from cipher-text into plaintext whereas User2's secret key used to encrypt it.

However, this is the rebelling against the primary goal of security; the goal of the proxy re-encryption is to prevent the disclosure of keys that involves in re-encryption and the plaintext that needs to be re-encrypted to the proxy. In this context, the above method mentioned is not ideal. So for a scenario where belief cannot be held in a proxy. The requirement here is to convert messages encrypted on behalf of User1's public key to messages encrypted on behalf of User2's public key without the proxy being free to decrypt the message. The scheme that ensure this action known as proxy Re-encryption. After all proxy re-encryption scheme is generally, a version of existing encryption scheme found to choose text, generation of keys, transmitting the keys between the concerns parties, conversion from plaintext to cipher-text on one side and conversion from ciphertext into plaintext on another side, the difference appears with the introduction or foundation of two more properties given bellow [1, 2,14]:

A. *Directionality*

Re-encryption scheme categorized as bi-directional and uni-directional scheme. If the re-encryption scheme is reversible then the same re-encryption key is used to convert the messages from User1 to User2 and vice-versa, this scheme is categorized as bi-directional scheme. In which if user sends the message to another, it automatically provides rights to communicate with the sender. In this case, the re-encryption keys are generated with the keys of both sender as well as receiver with their mutual trust and agreements.

A uni-directional scheme is defined as one way scheme in this scenario, giving a higher level of security and make it feasible in non-trusted setups where message transmission is important but not to an extent where receiver should be given authority to respond to it. So if a message is re-encrypted from User1 to User2 with a key and that is not possible the same message is used for re-encryption from User2 to User1. Uni-directional scheme are more useful and can be converted into bi-directional scheme at any time as easily by running in both directions [12].

B. *Transitivity*

Transitivity is defined as the number of re-encryptions allowed by an algorithm in proxy re-encryption scheme (PRE). A transitive PRE would allow a cipher text to be re-encrypted from User1 to User2 and again User2 to User3 and keeps on. While a non-transitive PRE do not allow to a cipher text to be re-encrypted more than one time but only once (or pre-defined limited times). This means in non-transitive scheme proxy does not have authority to appoint deputation rights to others besides the pair of communicating users. Besides the previous mentioned properties, some more of the security properties proved by existing proxy re-encryption scheme are the disability of proxy to see plaintext apart from the scheme. The secret key generated at the end of the owner, and proxy in no way can determine the secret key of sender and receiver from the re-encryption key.

Abstract: A new family of phosphine free organometallic ruthenium(II) catalysts **(Ru1-Ru4)** supported by bidentate NN Schiff base ligands (L^1-L^4 where L^1= N,N-dimethyl-4-((2-phenyl-2-(pyridin-2-ylmethyl)hydrazineylidene)methyl) aniline, L^2= N,N-diethyl-4-((2-phenyl-2-(pyridin-2-ylmethyl)hydrazineylidene)methyl)aniline, L^3= N,N-dimethyl-4-((2-phenyl-2-(pyridin-2-yl)hydrazineylidene)methyl)-aniline and L^4= N,N-diethyl-4-((2-phenyl-2-(pyridin-2-yl)hydrazineylidene)methyl)aniline) were prepared and characterized. These half-sandwich complexes acted as catalysts for C-C bond formation and exhibited excellent performance in the dehydrogenative coupling of ketones and amides. In the synthesis of C–C bonds alcohols were utilized as the alkylating agent. A broad range of substrates, including sterically hindered ketones and alcohols, were well tolerated under the optimized conditions (TON up to 47000 and TOF up to 11750 h^{-1}). This ruthenium (II) catalysts were also active towards the dehydrogenative cyclization of o-amino benzyl alcohol for the formation of quinolines derivatives. Various polysubstituted quinolines were synthesized in moderate to excellent yields (TON up to 71000 and TOF up to 11830 h^{-1}). Control experiments were carried out and ruthenium hydride intermediate was characterized to support the reaction mechanism and probable reaction pathway of dehydrogenative coupling for the C-C bond formation has been proposed.

Introduction

The development of atom economical, eco-friendly and efficient methods for the synthesis α-alkylation of carbonyl compounds is a useful approach for the formation of carbon-carbon bonds.[1] Traditionally, alkylation process executed with alkyl halide as an alkylating source in the presence of a stoichiometric amount of base that leads to the desired product with the formation of toxic waste limiting its sustainable importance. Alkylation of carbonyl *via* borrowing hydrogen (BH) has emerged as an efficient and green choice for the formation of C–C bonds. The main advantage for such reactions would be the utilization of readily available and easy-to-handle ketones and amide as substrates and primary as well as secondary alcohols could act as an alkylating agent and water as by-product. Direct α-alkylation of ketones with primary alcohols has been functionalized under ruthenium,[2] iron,[3] iridium,[4] palladium,[5] copper,[6] manganese,[7] and cobalt[8] based catalysts or under transition metal-free conditions.[9] Similarly, various catalysts were also applicable for β-alkylation of secondary alcohols with primary alcohols.[10] Following the same strategy, alkylation of amides was also done *via* hydrogen transfer method with ruthenium,[11] manganese[12] and cobalt[13] based catalysts. However, alkylations of these substrates are found to be challenging with low catalyst loading. Amides have a comparably low CH-acidic nature due to resonance stabilization.

This type of acceptorless dehydrogenative C–C coupling can be applied for the synthesis of aromatic N-heterocyclic compounds such as quinolines, pyrimidines, pyrroles, and others. The annulation reactions of γ-amino- and 2-amino benzyl alcohols with ketones or alcohols currently require expensive iridium and ruthenium catalysts.[14]

α-alkylated carbonyl scaffolds were known to be biologically active due to their potential applications in anti-bacterial, anti-spasmodic, anti-inflammatory, analgesic, anti-diabetic, and anti-tumor activities[15] (Scheme 1). On the other hand, N-heterocycles have drawn wide attention, as their motifs are applied in functional materials, pharmaceuticals and dyes.[16]

Metal-ligand supportive catalysis can dramatically improve the catalytic performance of acceptorless dehydrogenative coupling reactions using pincer ligands bearing NH, OH or CH_2

Base-metal copper(II) complexes derived from unsymmetrical salen-type ligands were s synthesized using ligands L^1H to L^4H in moderate yield. The synthesized unsymmetrical li L^4H and the corresponding copper complexes (**1–4**) were characterized by UV-visible, IF spectroscopic studies. Molecular structures of complexes **1**, **2** and **4** were determin crystallography. Copper complexes **1–4** were employed as catalysts for [3+2] cycloaddition an reactions. The mutual approach of salen-type ligands and metals *via* active participation of lig achieve the catalytic reactions. Reaction pathways were proposed and possible intermediate s the catalytic cycle were successfully characterized by ESI-MS spectroscopic studies.

Introduction

Transition metal complexes supported by Schiff base ligands have been extensively studied because of their prospective use as catalysts in a wide range of C–C and C–N bond formation reactions such as cyclopropanation, aziridination, [3+2] cycloaddition reactions, A^3-coupling, *etc.*[1] The [3+2] cycloaddition reaction is a reaction where two organic compounds, a dipolarophile and an ylide (1,3 dipole), combine to form a five membered heterocycle.[2] For example, tetrazoles could be synthesized by [3+2] cycloaddition of nitriles and azides.[3] Tetrazoles are a very important class of heterocyclic compounds which are also found in natural products. These compounds exhibit interesting biological activities and in several cases are exploited in medicinal chemistry.[4–9] Tetrazoles have been used as antibacterial, antiviral, antifungal, and antihypertensive drugs. Moreover, thiotetrazolyl acetanilide derivatives are utilized as inhibitors for HIV-1 reverse transcriptase. Tetrazoles are also utilized as ligands in coordination chemistry for the synthesis of coordination complexes having important biological functions (shown in Scheme 1).[10–14]

A^3-coupling reaction is a multicomponent reaction where three or more starting materials react to form a single product.[15–17] A^3-Coupling reaction of amines, alkynes and al attracted much attention because of its appropriate ap friendly and atom economy reaction conditions.[18] I propargylamines, which could be synthesized by reaction, were utilized as the precursor for the various nitrogen containing heterocyclic compound heterocyclic compounds are extremely significant for of biologically active molecules.[23–28] Further, deriv pargylamines have found direct application in the neurodegenerative diseases such as Alzheimer's and disease.[29,30] Some of the therapeutic molecules, *e.g.* TV-3326,[32] rasagiline[33] and PF960IN,[34] are syn A^3-coupling reaction and are depicted in Scheme 2

In the recent literature, the research tendency metal catalysts, earth abundant catalysts, low cost met and their catalytic activity.[35–39] We have been working complexes and have reported a few catalytic activities In fact a few important recent publications drew our a Sardian and co-workers utilized copper complexes s ligands having N_2O_2 donors for tetrazole synthesis.[42] co-workers reported copper based catalysts for A^3-coupl and co-workers utilized salen-type NO_2 donors Cu(II) complexes as catalysts for tetrazole synthesi A^3 coupling.[44]

A closer look at the copper-based catalysts desc clearly depicts that the copper complexes were d salen-type of ligands. Interestingly, the design and these copper-based complexes are very simple, easy This prompted us to design and synthesize new c complexes for the study of [3+2] cycloaddition

Abstract: Proxy Re-Encryption (PRE) is now a primitive encryption used to assign decryption privileges. It was introduced by Blaze, Bleumer and Strauss. With the use of a proxy agent, PRE enables re-encryption of a ciphertext intended for one party to a ciphertext for another party. The underlying message and the sender's private key cannot be read by the proxy agent. The properties of proxy re-encryption systems with different classifications of proxy re-encryption schemes are discussed in this paper.

Keywords: Directionality, Distributed System, Encryption, Proxy re-encryption, Transitivity

I. INTRODUCTION

Encryption is a way to secure our data from unauthorized person. Proxy re-encryption helps in file security and distributed storage. The purpose of this technique is allowing re-encryption of one cipher text to another ciphertext. The encryption is done using private or public key for securing data and perform authentication via sharing security key. In situation where one user wants for another user to decrypt the message by using its own key or a new secret key instead of first user's secret key. An easily implemented re-encryption scheme is one of the proxy in which proxy given control of both User's key so the message will converted into plaintext and re-encrypted for another user or second user. User1's secret key used to decrypt the message from cipher-text into plaintext whereas User2's secret key used to encrypt it.

However, this is the rebelling against the primary goal of security; the goal of the proxy re-encryption is to prevent the disclosure of keys that involves in re-encryption and the plaintext that needs to be re-encrypted to the proxy. In this context, the above method mentioned is not ideal. So for a scenario where belief cannot be held in a proxy. The requirement here is to convert messages encrypted on behalf of User1's public key to messages encrypted on behalf of User2's public key without the proxy being free to decrypt the message. The scheme that ensure this action known as proxy Re-encryption. After all proxy re-encryption scheme is generally, a version of existing encryption scheme found to choose text, generation of keys, transmitting the keys between the concerns parties, conversion from plaintext to cipher-text on one side and conversion from ciphertext into plaintext on another side, the difference appears with the introduction or foundation of two more properties given bellow [1, 2,14]:

A. *Directionality*

Re-encryption scheme categorized as bi-directional and uni-directional scheme. If the re-encryption scheme is reversible then the same re-encryption key is used to convert the messages from User1 to User2 and vice-versa, this scheme is categorized as bi-directional scheme. In which if user sends the message to another, it automatically provides rights to communicate with the sender. In this case, the re-encryption keys are generated with the keys of both sender as well as receiver with their mutual trust and agreements.

A uni-directional scheme is defined as one way scheme in this scenario, giving a higher level of security and make it feasible in non-trusted setups where message transmission is important but not to an extent where receiver should be given authority to respond to it. So if a message is re-encrypted from User1 to User2 with a key and that is not possible the same message is used for re-encryption from User2 to User1. Uni-directional scheme are more useful and can be converted into bi-directional scheme at any time as easily by running in both directions [12].

B. *Transitivity*

Transitivity is defined as the number of re-encryptions allowed by an algorithm in proxy re-encryption scheme (PRE). A transitive PRE would allow a cipher text to be re-encrypted from User1 to User2 and again User2 to User3 and keeps on. While a non-transitive PRE do not allow to a cipher text to be re-encrypted more than one time but only once (or pre-defined limited times). This means in non-transitive scheme proxy does not have authority to appoint deputation rights to others besides the pair of communicating users. Besides the previous mentioned properties, some more of the security properties proved by existing proxy re-encryption scheme are the disability of proxy to see plaintext apart from the scheme. The secret key generated at the end of the owner, and proxy in no way can determine the secret key of sender and receiver from the re-encryption key.

Modelling of Barriers to Innovation for SMEs of Developing Countries Using ISM Approach

Er. Vijay Kumar Yadav[1], Er. Ashish Gupta[2]

Corresponding Author, Mahamaya College of Agricultural Engineering & Technology, Akbarpur, Ambedkarnagar, UP[1]

Mahamaya College of Agriculturual Engineering and Technology, Akbarpur Ambedkarnagar UP[2]

Abstract: For the growth of the country it is important to identify the factor which is responsible. In our study on innovation we found out eight barriers of innovation for SMEs which are modelled using ISM approach. In our result customer response and corruption was top rated barrier. While Taxation was bottom rated barrier further these factors were classified on their driving power and dependency power.

Keywords: Innovation, barriers, ISM, Modeling, SMEs etc.

I. INTRODUCTION

Small and Medium Enterprises (SMEs) are regarded as the main source of entrepreneurship and innovation. These enterprises provide employment to large number of people and contribute significantly to growth and GDP of an economy. In the world economy, knowledge as a determinant of competitive advantage is gradually replacing traditional factors of production like labour and capital. In order to survive and compete in the globalized market, small and medium enterprises need to use knowledge to innovate. In India, small and medium enterprises contribute about 45 percent of the gross turnover in the manufacturing sector and 40 percent of total exports **(Nomita Sharma, 2017).** According to **(O'Bran, 2013)** in America innovation is a very important in our field to achieve their mission vision, and objectives statement. The politician and chief innovation officer are regularly mention the term innovation, **(Kurtao, 2014)** have find out important barrier of innovation which are given as Product Innovation, Process Innovation, Marketing Innovation, Business model Innovation, Supply chain Innovation and Organizational Innovation.

Indian industry has a history of scarce, and hence too expensive, capital; as a result, banks and other sources of capital continue to be conservative. Organisational barriers start from the top and include lack of goals and disinclination to risk, which is particularly high in knowledge creation and innovation activities; a preference for emerging improvements over revolutionary transformation; and failure to evolve unique, competitive business models **(Krishnan, 2006).**

Managerial positions in India are for away from technical work. This creates barriers to innovation including: stiffness with technology and a perception of loss of control among managers and owners; failure to create durable R&D departments and board-level representation for the R&D function; insufficient investment in plant and machinery, old fashioned production tools and inadequate use of computers on the shop floor; the lack of a process positioning; belittle of commercialisation costs, poor quality product development skills, long development cycles and shifting priorities. Companies also fail to invest in training and development of skills in-house, team building, implant innovation systems, insufficient knowledge management systems and creative performance management systems. Public research firms and academic institutions also lack goal orientation and a strong research culture.

Nakane and Hall 2007 presented that some of the producers were undergoing a paradigm shift in the way they look at manufacturing operations there days. As of today, Indian firms have not fared well against the belligerent competitive master plan adopted by their international participants. **AHaleem et al 2012** has been identified distinguish some critical CSFs that are reason for growth of manufacturing sector. The attraction of enablers of innovation of SMEs are study and modelling approximate is used to customize the position of enablers. ISM is applied to comprehend the contextual relationship among the enablers and find out the critical elements of SMEs. **Gorodnichenko, Svejnar and Terrall 2015** have find that opening of border to trade and foreign investment, globalization brings golden time and pressures for domestic firms in upcoming market economy to innovate and improve their competitive positions. Many of these pressures and outcomes operate through increased competitions from and linkage with foreign companies.

This paper is presented in the following order. Section two presents the literature review and previous related work, along with the establishment of barrier. Third section shows the ISM model. Fourth section explains the results obtained. And finally, on fifth section the main conclusions and discussions are provided.

Experimental Investigation for photo-voltaic power generation using the concept of solar tree

AD Gupta[1*], Avinash Mishra[2], RK Mehta[3], Yashi Gupta[4], SK Pandey[5]
Acharya Narendra Deva University of Agriculture and Technology, Ayodhya, Uttar Pradesh, India

Abstract
Solar energy is abundant in quantity and free of cost. Solar PV technology converts incoming radiation from Sun directly into electricity, which makes it one of the most promising renewable technologies available for sustainable development. However, it consumes a large amount of land, which can be used for other human activities. Solar PV tree is a novel technique used for Sunlight capture. It consists of PV panels fixed as leaves on a tree-like structure, and it reduces the land footprint of the PV system.

In this study, the daily energy output of a 36 Watt solar system is maximized. For that, the flexible tree structure is designed. Energy output is maximized by varying the branch angle of the tree structure. Also, comparison of energy output for the standard layout and solar tree of 18 watt is done. The study showed that Solar Tree is a good alternative for the solar power generation instead of conventional layout of photovoltaic generation. Using Solar Tree we can reduce the land footprint area of solar power generation which can save land for other applications. The daily energy output from the Solar Tree can be increased as compared to the standard PV layout. Configuration I, defined in the study is found as optimum at which the energy output increased up to 59.11%.

Keywords: solar, abundant, experimental, generation, investigation

1. Introduction

The proliferating energy demand of the 21st-century modern society is putting immense pressure on the depleting fossil fuel based energy sources of the world. Renewable energy sources are vital to meet the energy demand of the future. Renewable energy based sustainable development have become the main agenda for a clean and green future of the earth. Among all the renewable energy based technologies available commercially, solar PV technology is considered to be mature, stable, and easy to implement and maintain, it is capable of meeting the energy demands with minimal impact on the environment. It involves a photoelectric conversion of incoming photons from the Sun into electricity via a PN junction, usually made with silicon wafers. The PV cell manufacturing process is being heavily researched upon to improve the cell conversion efficiency, reduce the cost of manufacturing and to decrease the energy utilization in the process. Favourable government policies, the uncertainty of grid supply and environmental concerns have contributed towards the rapid development of PV based energy systems around the world in recent years. Solar photovoltaic technology has been noted to be highly beneficial in off-grid rural areas, island nations, and household applications. However despite all the merits, one of the major drawbacks of solar PV is its area requirement; with land being an indispensable necessity for agriculture, transport, industry, and housing, the area requirement of PV systems is to be reduced to enhance its implementation. Rooftop solar PV systems reduce the burden of land required for solar PV systems by installing PV panels on the rooftops of the buildings and houses as well as their facades and walls [1]. Discussed a detailed design and cost analysis for a stand-alone rooftop PV system in India and [2] evaluated the economic viability of rooftop solar for the climate of Iran [3]. Suggested the use of floating solar power plants in their article to reduce the land burden of solar PV systems. Apart from floating solar power plants, recent years have seen an increase in the implementation of building integrated solar PV systems (BIPV) to reduce the land requirement of PV systems. The use of three-dimensional PV structures can also enhance the energy production while consuming less land. The land-based PV systems are usually fixed at a particular set of angles to optimize production during peak Sunshine hours. However, this two-dimensional design of the PV array hampers their effectiveness in Sunlight capture throughout the day and around the year [4]. Pointed out that trees are more effective than PV panels in capturing Sunlight due to the random orientation of its leaves (as some leaves would always encounter normal angles of incidence, although others would encounter grazing angles of incidence) and its three-dimensional structure. One of the routes to solve this issue is the novel concept of a solar PV tree; which is an artistic imitation of natural trees with photo-voltaic panels replacing the leaves and a metal frame taking the place of the branches and trunk. It can generate more power per unit area and capture Sunlight throughout the day owing to its panels being oriented at different angles as discussed by [4] in their simulation study. Various working models of solar PV tree have been demonstrated around the world, some of which are compiled in this thesis further.A solar tree can also be a decorative means of producing renewable electricity. "TREE stands for T = Tree generating R = Renewable E = Energy and E = Electricity". The objectives of a solar tree concept are:-

- To enhance the efficiency of solar PV systems using a three-dimensional structure replicating a natural tree.
- To reduce the land required to harness solar energy.

DOI: 10.1039/c9dt03465j

rsc.li/dalton

A new family of ferrocenyl-palladacycle complexes Pd(L^1)Cl (**Pd1**) and Pd(L^2)Cl (**Pd2**) were synthesized and characterized by UV-visible, IR, ESI-MS, and NMR spectral studies. The molecular structures of **Pd1** and **Pd2** were determined by X-ray crystallographic studies. Palladacycle catalyzed Suzuki–Miyaura cross-coupling reactions were investigated utilizing the derivatives of phenylboronic acids and substituted chlorobenzenes. Mechanistic investigation authenticated the generation of Pd(0) nanoparticles during the catalytic cycle and the nanoparticles were characterized by XPS, SEM and TEM analysis. Direct C–H arylation of thiazole and isoxazole derivatives employing these ferrocenyl-palladacycle complexes was examined. The reaction model for the arylation reaction implicating the *in situ* generation of Pd(0) nanoparticles was proposed.

Introduction

Over the past few decades, ferrocene has been the most employed metallocene due to its unique electrochemical properties and its applications in medicinal chemistry.[1] On the other hand, ferrocene-based co-ordination complexes have been utilized for molecular recognition and as cytotoxic agents.[2] Cyclometalated organometallic complexes based on 6-phenyl-2,2′-bipyridine (NNC) have been widely utilized for their catalytic and luminescence properties.[3] Reports on ferrocenyl based NNC ligands and their metal complexes are scarce in the literature; however, ferrocene based ligands having a combination of phosphorus, nitrogen and sulfur are known.[4] The presence of a Pd–C σ-bond as the central or exterior donor site plays a significant role in thermal stability, potential hemilability and catalytic activity.[5] Along the same lines, the use of the palladacycles of ligands having (N,N) donor groups present in an arm of ferrocene is limited and, to the best of our knowledge, their catalytic applications have not been reported in the literature.[6]

In fact, this class of ligands were utilized for the chelation assisted C–H bond functionalization of the C2 position of ferrocene derivatives.[7] Several transition metals like Ir, Rh, and Pd have been used for the activation of the C2–H of the ferrocene moiety and for the synthesis of ferrocene derivatives.[8]

The Suzuki–Miyaura cross-coupling (SMC) reaction is the traditional method for C–C bond formation. Palladium complexes derived from phosphine-based ligands are the conventional ligands for the SMC coupling reaction.[9] At present organometallic pincer type (NNC or NCN) palladium(II) complexes with different types of donor atoms are widely employed as catalysts for coupling reactions.[10] The use of ferrocene based organometallic complexes in such cross-coupling reactions is less explored yet.[11] Though the SMC reactions of aryl bromides and iodides are available, reports on aryl chlorides are not abundant due to the difficulty in the activation of C–Cl bonds compared to C–Br or C–I bonds with low catalyst loading (0.0001 mol%).[12]

Compared to well-recognized traditional cross-coupling reactions, the palladium-catalyzed direct arylation *via* C–H

Hexacoordinated non-heme iron complexes $[Fe^{II}(L^1)_2](ClO_4)_2$ (1) and $[Fe^{II}(L^2)_2](PF_6)_2$ (2) have been synthesized using ligands L^1 = (E)-2-chloro-6-(2-(pyridin-2ylmethylene) hydrazinyl)pyridine and L^2 = (E)-2-chloro-6-(2-(1-(pyridin-2-yl)ethylidene)hydrazinyl) pyridine]. These complexes are highly active non-heme iron catalysts to catalyze the C (sp^3)–H bonds of alkanes. These iron complexes have been characterized using ESI–MS analysis and molecular structures were determined by X-ray crystallography. ESI – MS analysis also helped to understand the generation of intermediate species like Fe^{III}–OOH and Fe^{IV}=O. DFT and TD–DFT calculations revealed that the oxidation reactions were performed through high-valent iron center and a probable reaction mechanism was proposed. These complexes were also utilized for the degradation of orange II and methylene blue dyes.

KEYWORDS
C-H bond activation, iron oxo (Fe^{IV}=O) intermediate, organic dyes degradation eration gen, reactive HO• radical

1 | INTRODUCTION

The oxygenation of non-activated alkyl C-H bonds is a challenging area of research owing to their chemical inertness towards chemical oxidation. Consequently, highly reactive species, generated by a suitable catalyst, are necessary to perform such chemistry.[1] In the chemical industries, such catalytic oxidation and during the oxidation process, desired selectivity of the organic molecules produced, was extremely important.[2] It is well known that alkanes are thermodynamically stable and difficult to oxidize in a controlled and selective fashion. Chromate and permanganate have already been used as conventional oxidants however these oxidants are rather inefficient and barely selective,[3] thus enhancement in the efficiency and selectivity of the hydrocarbon oxidation became the goal of industrial as well as academic research. Nature has developed several metalloenzymes (heme as well as non-heme) which selectively catalyze the oxidation of hydrocarbon.[4–7] Iron containing metalloenzymes play an important role in these biological processes. For example, cytochrome P450 selectively oxidizes the aliphatic side chain of cholesterol, and the same metalloprotein is involved in biosynthesis of the female hormone progesterone.[8] Iron-dependent cytosolic protein, soluble methane monooxygenase (sMMO) activates C-H bond and converts methane to methanol[9] Fe^{III}-OOH species has been observed and was implicated in the catalytic cycle of C-H bond oxidation. Anticancer drug bleomycin, naphthalene dioxygenase, and Rieske

VANET: Attacks and Privacy Preserving Protocols

Ritika Yaduvanshi[1], Shashank Shekhar Tiwari[2], Kumkum Dubey[2], Prince Rajpoot[2], Shivendu Mishra[2]

Department of Computer Science and Engineering, Mahamaya College of Agricultural Engineering and Technology, Akbarpur, Ambedkar Nagar (U.P), India[1]

Department of Information Technology, Rajkiya Engineering College Ambedkar Nagar (U.P), India[2]

Abstract: Now days, it is seen that VANET are widely spread in the world of vehicular transportation. It is different from the other networks because of its features and working. Main function of Vehicular Ad-hoc Network is to provide safety, increases driving experiences, and good management of the traffic. Further, VANET focuses on private data transferring from one vehicle to other with threat less data management. In this paper, we will discuss about the various features of VANET's with possible attacks, and security requirements in VANET. Moreover, some of the privacy preserving protocols are also describe with their advantages and disadvantages.

Keywords: Vehicular Ad-hoc Network (VANET), Trusted Authorities (TA), Security, Privacy, Message Authentication Code (MAC).

I. INTRODUCTION

Vehicular ad-hoc network is the combination of dynamic and mobile nodes for unstable networks without any help of fixed infrastucture. Mobile ad-hoc networks' principles are the basis for vehicular ad-hoc network. It is based on wireless network technology for exchanging data from vehicle to vehicle within the domain of vehicles.VANET have three most important elementsie. Roadside Units (RSUs), Trusted Authority (TA), and a vehicle with embedded On-Board Units (OBUs). Trusted authority (TA) is responsible for maintenance and storage capabilty of the whole system TA is used to register each RSUs at the road side and OBUs attached with vehicle.RSUs are storage database they have storing information coming from TA and OBUs. RSUs works between TA and OBUs, RSUs also helps to track the harmful vehicle[2].OBUs are used to collect, share traffic information, andto communicate with other vehicles, and increases careful driving environment.There are three kinds of communication exists in VANETs i.e. Vehicle to Vehicle Communication (V2V), Vehicle to Infrastructure Communication (V2I), and Infrastructure to Vehicle communication (I2V)[1].

A. *Features of VANET*

VANET has defferent features which are following-:

- **High Mobilty:** In VANETs nodes which are basically the vehicles generally move at high speed. Thus it is difficult to find the position of nodes hence making security and privacy of node.
- **Dynamic Topology:** Because of the dynamic infrastucture of nodes,It is very difficult to calculate all the nodes position. Thus networks topology in Vehicular ad-hoc netwoks changes on a frequent interval. Further More, The link connections between the vehicles in VANETs has regularly not stable connection due to dynamically nodes position in the environment.
- **Wireless Communication:**Nodescommunication are wireless in VANETs hence security measures must have been taken while communication.
- **Unbounded network size:**In VANETs the size of Network is geographically unbounded. Therefore, VANETs can be implemented at any place i.e. for any city, country and other geaographical areas.
- **Time Critical:**The sending and the receiving of the information to the nodes in VANETs must have been within time interval. So all nodes in VANETs are updating regularly and exchange informaton very fast to each other, critical medical emergency messages must have been delivered on time so save human lives.
- **No Power limitation:**As in MANET there is concerned energy and computation resaurces, the VANET doesn't have the same. That can be further utilized in efficient processing of complex and computational hungry routing and security mechanism.

Effect of Social Distancing on Coronavirus Disease Spread Controlling: A Mathematical Modeling

Ritika Yaduvanshi[1], Nimisha Yadav[2], Prince Rajpoot[3], Shivendu Mishra[3]

Abstract

Coronavirus disease 2019 (COVID19), the outbreak of the novel coronavirus, has posed an unprecedented public h many other countries in the world at present, with a significant effect on health and public health systems, individ world economic. COVID-19 has been declared by the WHO as a pandemic. The structures of public contact signific this infection and, in the absence of vaccines, the control of these structures through extensive social distancing to be the most effective means of mitigation. In this paper, to examine the impact of social distancing in COVID 19 mathematical model using direct correlation between social exposure and reproduction number. We show that distance is an efficient way of monitoring the spread of COVID-19 in the absence of vaccines. In India, we have also reproduction number is 2.5.

Introduction

A large family of viruses known as coronaviruses may cause in humans, several coronaviruses ranging from the common cold to more brutal diseases such as Middle East respiratory syndrome and severe acute respiratory syndrome are known the basis of respiratory infections. The most newly revealed coronavirus causes coronavirus disease (COVID-19). COVID-19 was first reported in month of the December 2019, in the Wuhan city of China. COVID-19 has further spread from Wuhan city to other cities of China and various other countries in the world. COVID19 has wide and rapid spread in the community of most of the countries due to which WHO declared COVID-19 disease as a public health emergency of international concern in January 30, 2020. The global confirmed cases by April 28, 2020, have reached 3,132,312, with a death case of 221,436 and recovered cases of 953,309. COVID-19 epidemic is great harm to people's daily life and country's economic development. COVID-19 has experienced four stages since its reporting: Initial stage, local eruption, community spread, and widespread transmission. China witnessed the fourth stage of transmission earlier in February 2020 while countries such as Italy and the USA are in fact currently in the fourth stage.[1-3]

As per Indian Council of Medical Research, world second population country India is currently in Stage-2 of transmission. This is because of Indian government's sudden and strict enforcement of 21 days national lockdown from March 25, 2020, with further extended until May 3, 2020. In India, the initial case of COVID-19 was reported on January 30, 2020, originating from China. Further, India has reported 31,324 confirmed cases with a death case of 1008, and 7, 747 recovered cases as on April 28, 2020.[2,4] COVID-19 symptoms are very similar to flu such as cough, cold, fever, tiredness, nasal congestion, runny nose, sore throat, diarrhea, and breathing problem. COVID-19 infection increasing rapidly and until now there is no vaccine is announced or available.

TO STUDY THE HALL EFFECT ON MHD FLOW IN A ROTATING SYSTEM

NIMISHA YADAV, P C YADAV ,RITIKA YADUVANSHI

Abstract: In this paper, we have proposed to study the free convection flow caused by buoyancy force when the semi-infinite span of fluid bounded by an infinite vertical porous plate rotates in unison about an axis perpendicular to the plate. The effect of Hall and rotation parameters on the drag experienced by the fluid particles at the plate has been discussed for constant and variable suction cases. The effect of small and large frequencies on flow parameter is discussed with the help of tables. An attempt is made to analyse the unsteady free convection MHD flow in a rotating frame of reference

Key Words: MHD oscillatory flow, Navier-Stokes equations , Hall parameter, Prandtl number, Grashof number, frequency parameter etc.

1 .Introduction:

The flow in the rotating frame of reference has attracted the attention of a number of scholars in geophysical engineering. There appeared a number of studies in literature viz. Vidyanidhy and Nigam [1], Gupta [2] and Jana and Datta [3]. The effect of uniform transverse magnetic field with or without suction was investigated by Gupta [8], Soundalgekar and Pop [1,2,3,4] and Mazumdar et al. [5]. The similarity solutions of the unsteady Navier-Stokes equations in a rotating frame of reference has been obtained by Gupta [6] Chandran et al. [7] and Singh et al. [8] studied the unsteady, MHD Couette flow of electrically conducting fluid in a rotating system. Bergstorm et al. [9,10] studied the flow in a rotating system.

The flow problem in a rotating system has been studied by several authors. It is well known that in a rotating fluid near the flat plate. Ekman layer exists, where the viscous and coriolis forces are of the same order of magnitude. Raptis et al. [11] have discussed the effects of mass transfer and free convection current on the flow past an infinite vertical porous plate with constant heat flux in a rotating fluid. An analysis of Hall and ion-slip current affects on the unsteady MHD free convection flow of a partially ionized fluid past an infinite vertical porous plate in a rotating system subject to a strong transverse magnetic field and fluctuating plate temperature with time about a constant non-zero mean is carried out by Ram [1,3]. Sacheti et al. [12,5] studied the effect of free convection in a vertical channel of rotating porous medium. Sharma et al. [16,17] studied the effect of unsteady flow and heat transfer through a porous medium in the presence of heat source and variable free streams.

Barcilon and Pedlosky [18] studied the linear theory of temperature dependent rotating stratified fluid motion. Recently the study of flow under strong magnetic field when the whole system is rotating with angular velocity about a fixed point in the frame of reference has provided a new impetus specially to practical engineers who are interested in MHD power generator and cooling turbine blades. Ingham
[4,5] have studied hydro magnetic flow in a rotating frame of reference. Forced and natural flows were discussed by Schlitching [1,6], Eckert and Drake [6] and Bansal [1].

1.1 Basic equations:

Consider an unsteady incompressible flow of electrically conducting fluid past an infinite vertical flat plate placed in x^*, z^* plane, y^* axis is taken normal to the plate. A uniform magnetic field of strength B_0^* is acting along y^* axis. The entire system of the fluid and the plate is in a state of uniform rotation about y^* axis. Since the length of the plate is large, therefore, all the physical variables depend on y^* only. The interaction of coriolis force with the hydro magnetic free convection sets up a secondary flow in addition to primary flow and hence the flow becomes to be three-dimensional. Since the plate is of infinite extent along x^* and z^* directions, all the physical variables (except pressure) are the functions of y^* and t^*

To Study The Effect Of Convection And Electric Field Load Parameter On Mhd Couette Flow Past A Channel With Highly Permeable Bed.

Abstract: In the present investigation, the MHD couette flow of an electrically conducting fluid through a channel with highly permeable bed, has been considered in the presence of buoyancy and magneto-electric forces. The effect of the buoyancy force, permeability of porous medium, load parameter, magnetic field, on the velocity distribution, temperature field, skin-friction, flux and rate of heat transfer are discussed.

IndexTerms - MHD oscillatory flow, Temperature field, Skin friction, Load parameter, Porous medium etc.

I. INTRODUCTION:

Flow through porous media are very much prevalent in nature and therefore the study of flows through porous media has become of principal interest in many scientific and engineering applications e.g. in the field of agricultural engineering to study the underground water resources, seepage of water in riverbeds. The effect of magnetic field on the flow of a electrically conducting viscous fluid has received considerable attention due to its wide range of engineering, geophysical, astrophysical applictions. MHD channel flows have been studied extensively, including their heat transfer aspect. An excellent review of existing theoretical and experimental work on these subjects can be found in the recent books and monographs by Bejan[1], Cebeci[3], Chauhan and Vyas[4], Ingham and Pop[8], Jothimani and Anjalidevi[9], Kaviany[10], Nield and Bejan[14], Pop and Ingham[15] and Singh and Gholami[16].

Buoyancy driven convective heat transfer is of interest in relation to the underground spread of pollutants, solar power collectors, geothermal energy systems and others. In past, most of investigations have not been taken into account the effect of buoyance forces since the problems were on horizontal flows.

It was assumed that the buoyancy forces are almost negligible in horizontal flows, but some authors have shown that in the case of horizontal flow of liquids with low Prandtl number (Pr), the buoyancy forces cannot be neglected as they significantly affect the flow field. The buoyancy layer flows for such fluids have been discussed by Bejan and Khair [2]. Gholami and Singh [7] analysed the problem of simultaneous heat and mass transfer with the entire range of buoyancy ratio for most practical chemical species in dilute solutions and aqueous solutions. Yan and Chang [17] have investigated numerically the laminar mixed convective flow in the channel and simultaneous influence of the combined buoyancy effects of the thermal and mass diffusion for an air-water system. Garander *et al.*[6] proposed an analytic solution to the governing equation of MHD to be used model the effect of a transverse magnetic field on natural convection. When the fluid is electrically conduction and exposed to a magnetic field the Lorentz force is also active and interacts with the buoyancy force in governing the flow and temperature fields. Employment of an external magnetic field has increasing application in material manufacturing industry as a control mechanism since the Lorentz force suppresses the convection currents by reducing the velocities. Study and through understanding of the momentum and heat transfer in such a process is important for the better control and quality of the manufactured products. The MHD heat transfer in two phase flow with fluid in one phase being electrically conducting was studied by Lohrasbi and Sahai [12]. The problem of MHD heat transfer for short circuit case in a two-phase flow have discussed by Malashetty and Leena [13]. Firat *et al.* [5] observed the Lateral load estimation from visco-plastic mud flow.

ABSTRACT

Vehicular ad hoc Network or VANET is a sub form of Mobile ad hoc Network or MANET that provides us communication between vehicles and also between vehicles and road side base stations. Since we know vehicles generally proceed at a high speed, hence the network topology also changes quickly. It's an important and bright application of the Intelligent Transport System or ITS. In order to achieve safety and security in Vehicular Transportation, we can implement VANET as there happens an Inter Vehicular Communication. Also, there are many challenges when it comes about implementing VANET. This Survey Paper's goal is to provide an overview on VANETs, its Measures, Security Issues, Applications and existent VANET routing protocols.

INTRODUCTION

In today's life the large volume of traffic tends to affect the safety and effectivity of the whole traffic surroundings. A huge number of people died in road accidents all around the globe every year. It has always been a challenge to stop and avoid all such accidents and provide people's safety. Safety applications are very important in nature since these are directly associated to the users and their lives. One of the promising ways is providing the traffic situations to the vehicles around so that it can be used to analyze the traffic conditions of the vehicles all around which can be detected by sharing of information between them. With enhancement in the technology of microelectronics, it has now become possible to integrate nodes and network devices into a single unit and wireless interconnections [1]. VANET is one of the important applications of Mobile ad-hoc Networks (MANETs). VANET is that technology which delivers naturalistic vehicle to vehicle (V2V) and vehicle to roadside infrastructure (V2I) communications. VANET is a self-formed system in which vehicle works as node and to form these networks WIFI technologies are used. VANET is used for making an intelligent transportation system (ITS) that makes roads safer, provides traveler welfare and traffic efficiency. Achievement in VANET relies upon the essential elements like statistics routing in between nodes and the entrance to the internet. Vehicular ad hoc Networks (VANETs) lead to the foundation of Intelligent Transportation System (ITS) which is done by making vehicles able to communicate to each other through Inter-Vehicle Communication (IVC) also with safer and more efficacious roads by giving appropriate information to the drivers and interested authorities.

Simulating study area on Vehicular Network can only be done where we can bring the ad hoc system to its entire potency. When this statistical data got exchanged repeatedly on frequent times then it clearly points out towards the role of security. In order to communicate securely it is very important that the statistical data should be transmitted accurately from source to destination for the safety program. Therefore, security is such a vital issue that cannot be ignored in a case. Attackers may generate difficulties by accessing the system fully hence any kind of malicious attack can result in loss of lives and loss of money as well. Therefore, information's and data's protection are very critical in VANET system [2].

ABSTRACT

Software Development Life Cycle Models (SDLC) are systematic and well defined approach for problem solving; it is a series of identifiable stages that software goes during its lifetime. It practiced for developing high quality and reliable software system. In the early years, software was cheaper then hardware. In digital era, hardware is cheaper and software is expensive. So the costs of hardware and software have been reversed due to increased demand of well engineered software products so we have to develop software products due to increasing demand of software in market so for developing a software product we have to follow the models that deliver a quality software product There are many SDLC models available, but in this paper we make our attention in four SDLC models namely; Waterfall model, V shaped model, Spiral model, and Prototype model, there uses, advantages and disadvantages.

Copyright © Shashi Prabha Anan *et al*, 2019, this is an open-access article distributed under the terms of the Creative Commons Attribution License, which permits unrestricted use, distribution and reproduction in any medium, provided the original work is properly cited.

INTRODUCTION

Every work is done with the help of a computer in real life, so we need to develop a software system that meets all user needs and is easy to use. Thus SDLC systematically and disciplined develops the project. It defines entry and exit criteria for each phase, a phase can only begin if the entry and exit criteria are met so that it becomes very difficult without using SDLC models.

A software design strategy relates to the structure used to plan, manage and control the method of creating a software system [1]. Formally, the methodology of software development is known as the SDLC abbreviate as the Software Development Life Cycle and is used in many areas, for example, engineering of software, system engineering, computation and other industrial applications.

For example, software engineering, system engineering, inform atics engineering, mechanical engineering and applied engineer ing [2].

Software was inexpensive in the early days and equipment was expensive. But now day software is costly and hardware is cheap. So the software and equipment expenses have been inverted owing to growing demand for well-designed goods.

Motivation of SDLC Models

- Encourage computer developers to use multiple SDLC designs for well-maintained initiatives.
- Encourage consciousness of software performance.
- To research the facts that influence software performance.

Phases of Software Development Life Cycle Models

Series of identifiable stages that software goes during its life cycle are:

1. Feasibility study
2. Requirement analysis
3. Design
4. Coding
5. Testing
6. Maintenance

Feasibility study: It works out on overall understanding of problem, formulates different solution and strategies, performs a cost benefit analysis, may also find none of solution is feasible due to high cost, resource constrains, technical reason.

Requirement analysis: Aim of this phase to understand the exact requirement of customer then document them properly.

Tool Steel D3, Heat treatment, Machining.

ABSTRACT

Investigation of my project is to evaluate the effects of heat treatment process on mechanical properties machinability of material. Material used for this project is Tool steel D3 and CBN insert tool is chosen for performing machining operations on CNC. Comparison of roughness has been done for before and after conventional heat treatment process. Similarly tool wear and chip morphology before and after conventional heat treatment process are also established in detail. Working conditions like cutting speed, depth of cut & feed rate are varied for different values. Mitutoyo surface roughness tester is used for before and after result comparisons. Optimisation is done using Response surface method technique. Resultant machining properties show improvement after heat treatment.

INTRODUCTION

Tool steels are the alloys which are used to manufacture the dies tools and mold, and cut other materials, including ferrous and nonferrous materials and plastics etc[1-3]. Properties of tool steel depend upon the composition of alloys therefore we can say that when we change the composition of tool steel then properties of tool steel will also change and therefore by changing the composition of tool steel we can obtain the desire properties[4-5]. Properties of tool steel also depend on the crystal structure of tool steel so we can also change the properties of tool steel by using the different type of heat treatment process because heat treatment process change the crystal structure of material such as crystal structure of steel in iron carbon diagram change from face center cubic (FCC) to body center cubic (BCC) during cooling of y-austenite ateutectoid point in iron carbon diagram [6].

Tool steel is also classified on the basic of American iron and steel institute (AISI) such as water hardening tool steel, hot work tool steel , tungsten high speed tool steel, chromium based tool steel etc. Tool Steel D3 is classified by AISI system which is chromium hot work tool steel, UNS (unified numbering system) number of tool steel D3 is T20813 which has 0.35%C, 5%Cr, 1%V, 1.5%Mo [7].

An overview of important heat treatment process Heat treatment process are used to improve the mechanical properties of material by changing the crystal structure (such as change the FCC to BCC etc.) or we can say that we can obtain desire properties of material by use of heat treatment process. Heat treatment process consist full annealing process, recrystallization annealing, stress relief annealing, spherodisation annealing, cooling process, surface hardening, case hardening, work hardening process, tempering, normalizing etc.[8-9], and heat treatment process can affect the entire work piece or only Surface or some region in material depends upon the heat treatment process and parameter used in heat treatment process. Different types of heat treatment process are almost same because all heat treatment process requires the heating and cooling process. But difference is distinguished by rate of heating and cooling. Heat treatment process is mainly three step process.

Stage 1 – heat the metal (sample) to the desire temperature and ensure the uniformtemperature
Stage 2 – hold the metal at high temperature for sufficient time period according torequirement
Stage 3 – cool the metal to room temperature

Types of Heat Treatment Process

Annealing- Annealing is used to relieve the internal stress of material and soften the material then make it more ductile and refine the structure of grains.

Normalizing: Normalizing is the heat treatment process for ferrous metals only. Normalizing less differs from annealing. In normalizing, we heat the metal to high temperature in furnace

Rotating shaft, MATLAB, ANSYS & Vibration analysis.

ABSTRACT

The problem of misalignment encountered in rotating machinery is of great concern to designers and maintenance engineers. On several occasions stability conditions can change the shaft alignment between the driver and driven machines. Owing to high speed of rotating machinery, a good understanding of the phenomena of misalignment is becoming necessary for maintenance engineers for troubleshooting. Mostly, rotating equipment consists of a driver and a driven machine. Coupled through a mechanical coupling. Rigid mechanical coupling are widely used in rotating machinery to transmit torque from the driver to the driven machine. When two connected machines are under misalignment, they produce higher vibrations to the machine assembly. In this study an analysis of rigid flange coupling is done. The two dimensional analysis of whole system having flanged coupling was performed numerically using MATLAB programming in order to detect faults from unbalanced and misaligned parts. The results are compared with the experimental results obtained from literature and were in good agreement. Moreover a frequency plot obtained from MATLAB of aligned and misaligned shaft was compared to detect faults in the design. Thus after detection of fault using MATLAB, rpm of shaft is varied and its effects on whole coupling system are noted. While the three dimensional rigid coupling model was analyzed in ANSYS in order to determine stress and model frequencies under normal and misaligned condition. The results were in good agreement with literature study. The healthy system in ANSYS was considered to be of bonded nuts and bolts while in misaligned Flange model nuts and bolts were given frictional contacts.

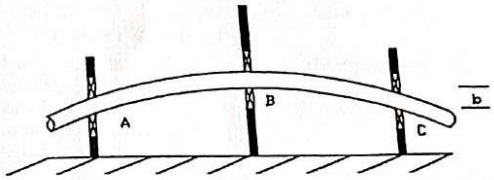
INTRODUCTION

Misalignment is an important cause of vibration problems in rotating machinery. Misalignment in the context of this thesis includes any deviation from the ideal case in which a straight shaft rotates in perfectly aligned bearings [1-3]. Thisstudy performs a survey on the various types of misalignments often encountered in rotating machinery and the vibrational characteristics which arise due to these misalignments are examined. In particular lateral, axial and angular coupling misalignments will be studied as a function of flexible coupling vibrational behavior [3-4].

A single uncoupled rotor may exhibit vibration problems for a variety of reasons. Sources of these vibrations may include shaft bearing misalignments, bowed rotors and mass unbalance. Bearing-shaft misalignments may from the vibrational analysis point of view be the hardest to detect. A shaft-bearing misalignment occurs when the bearing Journal placements are not axially concentric and a straight shaft is forcefully fitted into the bearings. An extreme case of a shaft distorted by bearings not axially aligned. The forces exerted by each of the bearing foundations cause the shaft to bend. As this forcefully bent shaft rotates, the forces exerted by the foundations remain constant as the shaft rotates at its operating angular velocity.



Shaft Alignment

Shaft alignment is a process where two or more shafts are aligned within permissible margin when the shafts are connected with the help of suitable coupling. It is mandatory to align the shafts within this permissible margin before the machinery is put in service.

PID Controller; Tuning methods; Internal Model Control (IMC); Direct Synthesis (DS); First order filter.

ABSTRACT

This study presents the analysis of control techniques of PID tuning parameters for load frequency control (LFC) of power system in order to maintain the frequency regulation. There are five tuning techniques is used to cognize the problem of load frequency control such as Ziegler-Nichols (ZN), Honeywell Tuning, Internal Model Control (IMC) based PID Controller Direct Synthesis (DS) and IMC based PID controller with first order filter. The primary attention of this paper is to collate these tuning techniques for single input and single output (SISO) system using MATLAB SIMULINK and using the model order reduction techniques with the help of ROUTH approximation, SKOGESTAD method and TAYLOR approximation method. third order system's LFC abolished into second order model, second order plus dead time (SOPDT) model and first order plus dead time (FOPDT) model by using this three MOR techniques. This paper identified the comparative dissection of execution diagnosis of isolated response entire in the indication of time and frequency response specification. It is accomplished that Inter Model Control based PID Controller with first order filter demonstrate the better performance comparatively.

ABSTRACT

Load frequency control (LFC) play a vital role in order to maintain the frequency regulation in power system. This study shows a comparative analysis of PID controller tuning methods for load frequency control in power system. Six tuning methods namely Ziegler-Nichols Method (Z-N), Tyreus-Luyben Method, Internal Model Control (IMC), Direct Synthesis Method (DS), Robust PID Controller and Optimum PID tuning for set point changes and Disturbance Rejection is adapted to evaluate their performance and used to solve the problem of load frequency control. In this paper higher order single input and single output (SISO) system is carried out with the help of Routh Approximation Method (- expansion) and Pade Approximation Method to reduce second order model model. The performance analysis is compared to time response specification such as maximum peak overshoot, settling time, rise time and peak time and it is observed that Inter Model Control based PID Controller with first order filter exhibit better performance comparatively.

INTRODUCTION

The Power system has a long history of the trouble with the Automatic Generation Control (AGC) or Load Frequency Control (LFC) and is one of the sincerely fundamental two of researches with methodical exploration and perusal of objects and sources in order to install facts and approach new inferences of interconnected power systems. As an auxiliary service in a power system, load frequency control plays an important and fundamental role in maintaining the reliability of the power system at a reasonable level. It has been gained importance with the change in the structured of the electrical power system and growth of size and complexity of interconnected systems [1-5]. For comprehensively electrical power system, the unified and interrelated control areas are composed to load frequency. It is crucial to hold the frequency and distinction surface tie power with calculated significance power. Input mechanical power has been employed to control the frequency of the generator, variation and transformation in frequency and tie-line power, which is a measure to shift and variation in the rotor angle. A well-prepared power system should be able to provide an acceptable level of power to maintain the magnitude of the frequency and voltage within satisfactory boundaries. Some changes in the electrical power system, load especially affected the system frequency, while the reactive power is shorted susceptive to change in the frequency and is mainly subordinate on the motility of the voltage magnitude. Therefore, the control of active and reactive power in the electrical power system is trade separately. So weight frequency control is mainly related to system frequency and actual power control, while the automatic voltage regulator loop controls is used to change in the reactive power and voltage appearance and magnitude. Load Frequency control is an elevated level of many promotions and advanced concepts, which governs the dimensions of the electrical power system. Load Frequency Control (LFC) has a basic control structure or arrangement, of parts of the machine and similar devices in term of power system operation and control. Load Frequency Control use to keep the uniform frequency during changing load. When system frequency is changed, the main problem is that the system output of generating units cannot be controlled with in specified limit is called load frequency control (LFC) [6-8]. The speed depends on the frequency of the alternative current power supply. These are the main situation when speed permanence is required to be higher order. Electrical chronometers are operated by synchronous motors. The precision of the chronometer do not depend only on the frequency but the integral part of the frequency error. If the normal frequency of any network is 50 hertz, and the network frequency falls below 48.5 hertz, and goes to high level 51.5

ABSTRACT

A PID tuning method for load frequency control (LFC) of Power system discuss in this paper. The tuning method is based on the Ziegler-Nichols (ZN), Tyreus-Luyben(TL), Internal Model Control (IMC) and Direct Synthesis(DS) method. Our purpose in this study is comparison of these tuning methods for single input and single output (SISO) system using Matlab simulink and comparatively analysis of performance evaluation of different controller. Such as percentage of Maximum overshoot, Settling time, Rise time, Peak time has been used as the criterion for comparison of SISO system and these tuning methods have been implemented for FOPDT(First-order-plus-dead-time) model, SOPDT(second-order-plus-dead-time) model and higher order system.

solar collector, rounded tip V-grooved collector, packed bed

ABSTRACT

The thermal efficiency of conventional solar air collectors is found to have low thermal efficiency mainly due to higher top losses and low heat transfer rate from absorber plate to flowing air due to low specific heat of air. Use of packed bed solar collector helps in reducing the top layer temperature by absorption of heat energy in depth, thus minimizing the top losses. Also, heat transfer coefficient between the packing element and flowing air is increased as a result of air flows through the tortuous path. Heat transfer area is also increased in packed bed air heaters. Overall effect is the enhanced thermal efficiency of the collector along with increased pressure drop. Rounded V-grooved absorber plate have also been used for increasing the thermal efficiency of conventional smooth collectors taking advantage of large amount of intercepted radiation on the absorber plate, without any increase in the pressure drop. Use of rounded V-grooved absorber plate is made in packed bed air heaters in the present investigation which is found to further increase thermal efficiency of a packed bed collector, without additional pressure drop penalty in packed bed.

Experiments are conducted on a solar collector under simulated conditions using wire screen matrices in its air flow duct for varying operating parameters. It has been observed that the maximum thermal efficiency of 85.2% with outlet temperature of 56.1 oC is obtained at a mass flow rate of 0.035 kg/s.m2 and a fixed insolation of 1100 W/m2. These results in thermal efficiency enhancement by approximately 65% compared to the conventional smooth collector. For a mass flow rate of 0.015 kg/s.m2, the increase in efficiency has been found to be 46% higher compared to conventional collector for same value of insolation with air outlet temperature of 68.9 oC

It is seen that the efficiency of the collector increases with increase in mass flow rate and insolation. It has been found that geometry of absorber plate significantly affects the performance of the collector.

INTRODUCTION

The fast depleting conventional energy resources and problems regarding pollution and global warming have made it inevitable to think about cleaner and sustainable form of energy. One such form of energy is solar energy, which has got great potential especially for countries like India because of abundant insolation available due to their geographical location. The utilization of this form of energy can easily be achieved for low temperature applications using flat plate solar collectors, which have a wide range of applications viz. domestic and industrial water heating, drying of agricultural products such as fruits and grains, green house chambers, space heating, solar refrigeration and air conditioning etc. Conventional solar air collectors have inherent disadvantages viz low thermal efficiency due to low value of specific heat of air. In order to increase the thermal efficiency of conventional collectors different techniques have been proposed for thermal performance improvement [1-6]. These techniques include enhancement of heat transfer coefficient between absorber plate to working fluid and reduction of top losses etc.

The enhancement of heat transfer coefficient can be achieved in several ways, such as the use of artificial roughness which disturbs the viscous boundary layer of the flowing fluid and thus augmenting the heat transfer rates. Use of finned plate absorber surface causes an increase in the turbulence of air flowing through the duct, increasing the thermal performance with limited increase in pressure drop. Use of rounded tip V-grooved absorber plate proves to be beneficial in increasing the effective absorbing area as compared to the conventional collectors. This effectively increases the absorbing area and the amount of incident solar radiations collected by the absorber plate. Use of packed bed solar air heaters is another approach to

Abstract

The present work is focused on the methodology for production of alternative fuel for automobile engines along with waste material management. This is done using pyralysis, which is a technique used to produce liquid fuel from solid waste material using a reactor unit. In the present investigation, an electrically operated pyrolysis reactor unit with thermostat (a temperature control device) with water-cooled condenser is used for the pyrolysis process. An attempt is made to obtain the pyrolysis oil from the waste plastic bottles disposed of after use. Used plastic bottles are collected from various places like railway station, restaurants and other places where disposable water bottles and other plastic containers are thrown away. These plastic bottles and containers are initially washed for removing impurities and then dried in the open air for about two days. In the experimental process, 2.5 kg of crushed bottles are taken and using pyrolysis reactor unit these are converted into oil. Brown colored oil produces after the process is collected. Various ignition properties of the pyrolysis oil obtained are evaluated and analyzed. Important characteristics of the fuel obtained from the pyrolysis process are compared with the high-speed diesel. It is observed that the obtained pyrolysis oil has properties similar to the high-speed diesel. Experimental investigation reveal that ignition properties of the pyrolysis oil are suitable for use in diesels engine with minor design modifications.

1. Introduction

The demand of the petroleum product is increasing day by day. The natural resources of petroleum fuel are limited and going on depleting very fast. So, it's need of the hour to find the new alternates of these fuels. These finite resources of petroleum are highly concentrated in certain regions of the world have given rise to uncertainty in its supply and price and are impacting growing economies of countries like India, where imports approximately 70% of the total demand for crude. Table1 clearly indicates that India's petroleum product consumption has increased from 1×10^9 tons in 2001-02 to 1.3×10^9 t in 2008-09 at a CAGR of 4.1% and is likely to increase up to 2.2×10^9 t by 2020- 21 and 3.3×10^9 t by 2030-31, resulting in the steep rise of under-recoveries of oil marketing companies at current levels of crude prices. This makes it difficult for the government to subsidize petroleum products in the future. Around the world, there are initiatives to replace gasoline and

Randomness in Circular - Complex Extreme Learning Machine Vs Voting Based Extreme Learning Machine with Accuracy Based Ensemble Pruning: A Review

Ashish Gupta

Department of Computer Science and Engineering,

Mahamaya College of Agricultural Engineering and Technology, Ambedkar Nagar, Uttar Pradesh, India

Abstract: Extreme Learning Machine is a fast single layer feed forward neural network for real valued classification. It suffers from the problem of instability and over fitting. Extreme Learning Machine (ELM) has recently emerged as a fast classifier giving good performance. Voting based Extreme Learning Machine; VELM reduces this performance variation in Extreme Learning Machine by employing majority voting based ensembling technique. Circular–Complex Extreme Learning Machine (CC-ELM) is recently proposed complex variant of ELM which has fully complex activation function. It has been shown that CC-ELM outperforms real valued and other complex valued classifiers. In both CCELM & ELM parameters between input and hidden layer are initialized randomly and the weights between hidden and output layer are obtained analytically. Due to this randomization, the performance of both ELM & CC-ELM fluctuates. In this paper, performance fluctuation due to random parameter of CC-ELM and the circular transformation function have been analyzed first, then by using an Ensemble approach namely Bagging, a variants Bagging.C1 is proposed to bring the stability in the performance of CC-ELM. In Bagging.C1 various data samples are generated by using random parameters of circular transformation function. This work further proposes and evaluates Voting based Extreme Learning Machine with Accuracy based ensemble Pruning, VELM_AP. VELM_AP generates component classifier in the same way as VELM. Performance of proposed classifier ensemble is evaluated using a set of benchmark real-valued classification problems from the University of California, Irvine machine learning repository.

Keywords: Classification, Complex-Valued Neural Networks, Extreme Learning Machine, Ensemble Pruning

I. INTRODUCTION

Extreme learning machine is a fast classifier with a good prediction ability which was recently proposed by Huang et al [1]. It is a single layer feed-forward neural network in which the input weights and hidden layer biases are initialized randomly and the weights between hidden layer and output layer are determined analytically using Moore-Penrose generalized inverse H† of the output matrix of hidden layer. Unlike other traditional gradient descent learning algorithm such a back propagation ELM does not require tuning of the parameters like learning rate, learning epoch etc and can provide better performance in terms of learning speed, reliability and generalization Tian et. al [2]. It does not have to encounter problems like stopping criteria and local minima Wang et. al. [3].

With the evolution of technologies that include the processing of complex-valued signals like, signal processing, adaptive array processing [4], image processing [5] it has been a necessity to create and develop complex-valued neural networks. R.Savitha et. al [6] proposed a Fast learning circular complex valued extreme learning machine (CC-ELM) for the classification of real valued data sets in complex domain.CC-ELM uses sin(z) as circular transformation function and sech() as fully complex Gaussian type activation function. Circular transformation function, an orthogonal decision boundary of CC-ELM at hidden layer and output layer shows better performance and prediction ability of real valued data than ELM and various complex valued classifiers [7]. Various variants of ELM also have been proposed in literature to enhance the performance like OS-ELM [8], I-ELM [9], W-ELM [10], C-ELM [11] etc. However these variants could not address some drawbacks of ELM [12] which are mentioned below:

1. The ELM and its variants randomly select the input weights and the hidden layer bias. This causes instability in the predictions of ELM.
2. The ELMs suffer from the over fitting problem. This is due to more number of hidden nodes on larger datasets and the complexity of the input instances distribution.
3. With the size of the dataset increases the order of the matrix H also increases. This implies that when larger datasets are used large memory is required to calculate the Moore-Penrose inverse.

ABSTRACT

Fusarium wilt is one of the major diseases in lentil crop which causes a significant yield loss. The present study aimed to manage the *Fusarium wilt* of lentil through seed treatment with fungicide, botanicals and bio-agents alone or in combination which is carried out at Student Instructional Farm of ANDUAT, Kumarganj, Ayodhya. It was observed that Minimum disease incidence was found in T_8 Metalaxyl 8% + Mancozeb 64% + Neem leaf extract (10%) + *T. viride* (14.13 %) with per cent disease control (82.76) followed by T_3 Metalaxyl 8 % + Mancozeb 64 % + *Trichoderma viride* (15.85 %) having PDC (80.67), T_2 Metalaxyl 8 % + Mancozeb 64 % + *Trichoderma harzianum* (22.37%) having PDC (72.71), T_7 Metalaxyl 8% + Mancozeb 64% + Neem leaf extract (10%) (28.84%) having PDC (64.82).

Introduction

Lentil (*Lens culinaris* Medik) commonly known as Masur was among the first crop domesticates and has become an important pulse crop in the farming and food system of many countries globally (Sarker and Erskine, 2006). Lentil also known as 'Poor man's meat' as it is rich in nutrients, include 60-67% carbohydrates, 20-36% protein, <4% lipid, and 2-3% ash on dry weight basis (Bhatty, 1988). Major lentil growing states in India are Madhya Pradesh (42.50%), Uttar Pradesh (31.25%), West Bengal (9.38%) and Bihar (8.75%). In India, lentil was grown in 1.49 mha with production of 1.61 mt with an average production of 1006 kg/ha (Anonymous, 2018).

Among biotic factors disease are major constraint in lentil production. Among the fungal diseases, Fusarium wilt of lentil caused by *Fusarium oxysporum* f.sp. *lentil* is a major threat in lentil production worldwide (Bhalla *et al.*, 1992). In India, this disease causes significant yield losses in various states of India where lentil is grown. The fungus is soil and seed borne and also

Lentil (*Lens culinaris* Medik L.) is one of the most important pulse crop in India and mostly grown in north east plain zone and central part. It is a diploid and self-pollinated crop which is grown in winter season. Lentil suffers from attack of a number of diseases such as vascular wilt; collar rots, root rot, stem rot, rust, powdery mildew downy mildew and fusarium wilt which are caused by

Evaluation of Pigeon pea genotypes for resistance to *Fusarium* Wilt

Subhash Chandra, Neeraj Kumar Rajvanshi, Ajay Kumar, Kumari Punam* and Ramesh Chand**

*Department of Plant Pathology, Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya – 224 229 (U.P.), *Department of Botany, J. P. University Chhapra (Bihar)*
***Department of Nematology, ND.U.A.&T., Kumarganj, Ayodhya – 224 229(U.P.), India*
<chandrasubhash75@yahoo.in>

Pigeon pea (*Cajanus cajan* L.) is widely adaptable to wide variety of climate and is one of the important legume crops of tropics and subtropics. It played a major role in nutritional security for the people taking cereal based diet. Beside their dietary value and nitrogen fixing ability, pulses also play an important role in sustaining intensive agriculture by improving physical, chemical and biological properties of soil and are considered excellent crop for diversification of cereal based cropping system.

Wilt disease caused by *Fusarium udum* Butler, is the most destructive soil and seed born disease of pigeon pea in India leading to heavy production losses. The *F. udum* is host specific to pigeon pea (Patel *et al*., 2011) and can survive in soil under wilted plant stubble for a long period. The best way of wilt management is by growing resistant varieties. For developing resistant varieties, resistant source are the basic requirement. Therefore, the present investigation was undertaken.

Seeds of 58 germplasm of Pigeon pea were obtained from the Department of Genetics and Plant Breeding, N.D.U.A.&T., Ayodhya and ICAR-IIPR, Kanpur. The germplasms were screened under sick plot technique. The plots (sick soil) showed over 90% wilt incidence in susceptible cultivar Bahar of Pigeon pea was used as test variety. After germination, observations were recorded regularly up to 60 days for the appearance of wilt symptoms and severity. The disease was recorded using 1-9 scale for the wilt disease.

Fifty eight germplasms of Pigeon pea were screened for their reaction to *Fusarium udum* in sick plot. It is evident (Table 1) that out of 58, 6 germplasms *viz*.; AKT 201030, IPA 96, IPAF, IPA 204, JSA 59 and WRGE 18 were found resistant, attributing to the higher concentration of phenol as observed by Haldar and Srinivasan (2007), 5 moderately resistant, 10 tolerant, 16 moderately susceptible and 21 germplasm were highly

Table 1. Performance of Pigeon pea genotypes against *Fusarium udum* under field condition (Sick plot technique)

Reaction (Rating scale)	Name of the genotypes
Resistant (1)	AKT201030, IPA96, IPAF, IPA204, JSA59, WRGE18.
Moderately resistant (3)	IPA9F, IPA204, ICP8863, WRGE18, BDN2.
Tolerant (5)	IPA13F, AL1573, H2001-4, HDM04-1, UPAS120, GRG206, JKM197, PT02-9, IPA2F, IPA4F.

Studies on the life cycle of *Meloidogyne graminicola* on rice and wheat crop

Ramesh Chand, Manish Kumar, Vipin Kumar Verma, Shyam Babu Gautam and Vinay Kumar Verma

Abstract
The experiment work was carried out at Narendra Deva University of agriculture and technology, Narendra Nagar (Kumarganj), Ayodhya (U.P.) during the year 2016-2017. Studies on the management of rice root-knot nematode, *Meloidogyne graminicola* revealed that the larvae of *M. graminicola* complete their life cycle within 20 days on rice plant var. Jaya and take 23 days on wheat variety PBW-154, further is also revealed that wheat varieties support less number of nematode populations as compared to the rice varieties under Studies.

Keywords: rice, wheat, *Meliodogyne graminicola*, life-cycle

Introduction
Rice (*Oryza sativa* L.) is the staple food of a vast majority of the population in the East and South East Asian, African and South American countries. In addition to its direct food value, rice grain is used in manufacturing of several industrial and commercial products. The paddy is most important cereal crop in India occupying 44.48 million hectares of area with an annual production of 112.91 million tones with the productivity of 19.56 quintals per hectare during 2017-18. Rice is grown in diverse environment either as a sole crop (rainfed, irrigated or deep water) or as major component in various cropping systems. Cropping systems, involving different year specific crop sequences or fallow in a given area, create conditions of varying favorability for microbes and weeds and thus affect the flora and fauna. Since, rice cultivation cover large area in India, even a smallest pest problem would have great impact on yield and farmers' income. Soil borne diseases are becoming increasingly important in the rice-based cropping systems. One of the most important soil born pests is plant parasitic nematode in rice crop. About 300 nematode species belonging to 35 genera have been reported infesting rice. Among them, *Meloidogyne graminicola* (Golden and Birchfield) is considered as most important constraint in rice production. *Meloidogyne graminicola* reduce rice yield by more than 17% in a greenhouse experiment and the yield losses might go as high as 98% (Bridge & Plowright 1990) [2] in pot experiment under favorable conditions. To prevent further yield losses and improve productivity, it is necessary to find out the effective sustainable management strategy. Many species of *Meloidogyne* have been reported by various scientists throughout world. *M. graminicola* is reported as an important nematode pest of rice from countries like South East Asia, Burma, Bangladesh, Laos, Thailand, Vietnam, India, China, Philippines, Nepal and USA. *Meloidogyne oryzae* an another species of this genus is also reported on irrigated rice from Surinam and *M. incognita* is reported from Costa Rica, Cuba, Egypt, Ivory Coast, Nigeria, South Africa and Japan, *M. javanica* in Brazil, Egypt, Comoro Islands, Nigeria and Ivory Coast. Apart from this *M. arenaria is reported from* Nigeria, Egypt and South Africa and *M. salasi* in Costa Rica and Panama on upland rice.
The root-knot nematode is making its importance felt in almost all the rice growing areas. *M. triticoryzae* infecting rice including some monocot weeds is also reported from India Upadhyay V., (2014) [8] and its occurrence is restricted to a few areas. In India, *M. graminicola* is the dominant species infecting rice. *M. graminicola* has been found infecting rice in different parts of India namely, Assam, Andhra Pradesh, Karnataka, West Bengal, Orissa, Kerala, Tripura and Madhya Pradesh. *M. graminicola* is a serious pest of upland rice Panwar & Rao (1998) [5, 10] and nurseries world over in well drained soils. The nematode was reported on irrigated rice in Andhra Pradesh and Karnataka. The nematode can infect and multiply on semi-deep or deepwater rice also. *Meloidogyne graminicola* described by Golden and

USE OF DIFFERENT DOSES OF SYSTEMIC FUNGICIDE (PROPICONAZOL) FOR MANAGEMENT OF FOLIAR BLIGHT DISEASES OF BARLEY

SANTOSH KUMAR, S.P.SINGH, SUBHASH CHANDRA, ASHOK KUMAR AND RAMESH CHAND*
Department of Plant Pathology, Department of Nematology*, Narendra Deva University of Agriculture & Technology Kumarganj, Ayodhya, U.P. 224229.

Abstract

Barley crop suffers from a number of fungal foliar diseases which cause heavy yield loss. Investigations were therefore, conducted to record the disease severity and avoidable yield loss caused by different foliar blight pathogens and fungicidal management against these diseases. Field trial conducted and established 2 sprays of propiconazole (Tilt 25 EC) @ 1.0, 0.75 and 0.50 l/ha each at boot leaf and soft dough stages as most effective for managing foliar blight of highly susceptible barley variety RD 2503. It resulted in 40.55, 48.77 and 59.30 per cent disease severity, 37.13, 36.96 and 32.75q/ha yield and 33.32, 33.03 and 24.42 per cent avoidable yield loss. It was significantly followed by treatments having single spray of propiconazole @ 1.0, 0.75 and 0.50 l/ha at boot leaf stage with disease intensity 56.94, 63.60, 69.99 per cent, yield 34.56, 32.43, 26.13 q/ha and 28.38, 23.70, 0.282 per cent avoidable yield loss.

Keywords: Foliar blight, fungicidal management, propiconazole

Introduction

Barley (*Hordeum vulgare* L.) is one of the important crops of present era due to its superior nutritional qualities and satisfactory yield in problematic soil. It is grown under a wide range of environmental conditions, cooler climates, during the growing seasons, and well drained light to heavy loam soil being most suitable. Barley is a crop of international importance and serve mainly as staple food, feed to livestock and poultry, as malt for manufacture of bear and other liquors like whisky, brandy etc. Foliar blight causing pathogens viz., *Bipolaris sorokiniana*, *Alternaria alternata*, *Drechslera graminea* and *Drechslera teres* are most destructive pathogens of barley and cause severe yield loss. The management of foliar blight pathogens is more effective by using different doses of propiconazole (Tilt 25 EC) sprayed at different crop growth stages. The chemical control of these pathogens therefore, is alternative possibility. Propiconazole as a effective chemical against foliar blight diseases after six to some years.

Materials and Methods

The experiment having following details, were conducted with view to work out an effective fungicidal management schedule for the disease. Two sprays of propiconazole (Tilt 25 EC) @ 1.0 l/ha, each at boot leaf and soft dough stages. One spray of propiconazole (Tilt 25 EC) @ 1.0 l/ha, at boot leaf stage. Two sprays of propiconazole (Tilt 25 EC) @ 0.75 l/ha, each at boot leaf and soft dough stages. One spray of propiconazole (Tilt 25 EC) @0.75 l/ha, at boot leaf stage. Two spray of propiconazole (Tilt 25 EC) @ 0.50 l/ha, each at boot leaf and soft dough stages. One spray of propiconazole (Tilt 25 EC) @ 0.50 l/ha, at boot leaf stage. Two spray of water @ 1000 l/ha, each at boot leaf and soft dough stages and untreated (check). Initiation of the disease, disease intensity after 15 and 30 days spray of Tilt following Kumar *et al.*, 1998, double digit scale, 1000-grain weight (test weight) and yield (q/ha).

Comparison between all the 8 treatments was made based on means of relevant parameters. Severity recorded on double digit scale, rating was averaged for leaf and next lower leaf as per (Dubin *et al.*, 1998) formula, which served as means of observation. Avoidable yield losses will be calculated by the formula given below:

$$AYL = \frac{YP - YU}{YP} \times 100$$

Where,
YP = Yield under protected condition
YU = Yield under unprotected condition

Per cent disease intensity (PDI) was calculated by employing the formula:

$$PDI = \frac{\text{Sum of total numerical rating}}{\text{Total number of leaves examined} \times \text{highest rating}} \times 100$$

Results and Discussion

Foliar blight of barley caused by *Bipolaris sorokiniana*, *Alternaria alternata*, *Drechslera graminea* & *Drechslera teres* was managed by using different doses of propiconazole (Tilt 25 EC) sprayed at different crop growth stages. Disease severity, thousand grain weight, yield quintal per hectare and avoidable yield loss was recorded in each treatment separately. All the treatments except water spray were found significantly effective in reducing the disease severity over untreated check. The propiconazole, with disease intensity of 40.55 per cent proved most effective when sprayed @ 1.0 l/ha, both at boot leaf and soft dough stages. Similar sprays @ 0.75 l/ha with a disease intensity of 48.77 per cent were next to follow. It was significantly followed by treatments having single spray of propiconazole @ 1.0 l/ha, at boot leaf stage and two sprays of 0.50 l/ha, each at boot leaf and soft dough stages (Table 1).

The treatments have their significant impact on the yield of barley grains over untreated check and water spray. The treatment, two sprays of propiconazole @ 1.0 l/ha, each at boot leaf and soft dough stages, with 37.12 q/ha grain yield gave significantly higher yields over rest of the treatments followed by two sprays of propiconazole @ 0.75 l/ha, each at boot leaf and soft dough stages with 36.12 q/ha grain yield, but both were at par. These were followed by single spray of propiconazole @ 1.0 l/ha, at boot leaf stage, two sprays @ 0.50 l/ha, each at boot leaf and soft dough stages, and single spray @ 0.75 l/ha at boot leaf stage with grain yield of 34.56, 32.75 and 32.43 q/ha respectively. Single spray @ 0.50 l/ha at boot leaf stage with a yield of 26.13 q/ha were recorded least effective amongst all the treatments and also at par with untreated check and water sprayed.

Data gathered on account of test weight of barley grains. Approximately similar results were also recorded in case of test weight. Two sprays of propiconazole @ 1.0 l/ha, each at boot leaf and soft dough stages gave significantly best performance (40.52 g) over all the treatments and untreated check followed by two sprays of propiconazole @ 0.75 l/ha, each at boot leaf and soft dough stages but both were at par. Single spray of propiconazole @ 1.0 l/ha, at boot leaf stage, single spray @ 0.75 l/ha and two sprays of propiconazole @ 0.50 l/ha, each at boot leaf and soft dough stage were the second performer which gave 37.91 g, 37.10 and 37.46 g test weight respectively and all were statistically at par. All the treatments of propiconazole were significantly superior over untreated check and water sprays. Maximum loss of 33.32 per cent in grain could be avoided with two sprays of propiconazole @ 1.0 l/ha, each at boot leaf and soft dough stages, followed by two sprays of propiconazole @ 0.75 l/ha, each at boot leaf and soft dough stages which avoided a loss of 33.03 per cent in grains. Minimum avoidance of loss of grains (0.28 per cent) was recorded with single spray of propiconazole @ 0.50 l/ha, at boot leaf stage. All the treatments propiconazole found significantly effective in reducing the disease severity. Propiconazole at concentration of 1.0 l/ha sprayed at boot leaf and soft dough stages, proved significantly superior in managing leaf blight intensity over check and all other treatments. The propiconazole, with disease intensity of 40.55 per cent proved most effective when sprayed @ 1.0 l/ha, both at boot leaf and soft dough stages. Similar sprays @ 0.75 l/ha with disease intensity of 48.77 per cent were next to follow. It was

Effect of Neem plant parts and its products on egg hatching and larval penetration of *Meloidogyne incognita* on Tomato

Shyam Babu Gautam, Ramesh Chand, Vipin Kumar Verma, Manish Kumar and Ram Veer

Department of Nematology, N.D. University of Agriculture and Technology, Kumarganj, Ayodhya - 224 229 (U.P.)
<kardam.nda@rediffmail.com>

Date of Receipt: 20.02.2019; Accepted: 07.03.2019

ABSTRACT

The data showed the significant reduction in egg hatching and larval penetration in all the cases with increase in exposure period. The observation indicated highest reduction in hatching (220.25) in neem ethanol leaf extract @ 5.0% treatment followed by leaf extract @ 5.0%, 2.0%, achook @ 7.5%, 5.0%, leaf compost @ 7.5%, 5.0% and neem cake @ 7.5%, 5.0% i.e. 233.00, 236.50, 268.25, 275.25, 291.75, 436.50, 441.75, 445.50 and 454.50, respectively in descending order over control at 12 hrs exposure period. After 24 hrs of incubation period the hatching was observed 270.00, 233.00, 236.50, 268.25, 275.25, 291.75, 436.50, 441.75, 445.50 and 454.50 after 48 hrs of incubation period was hatching was observed 330.50, 349.25, 351.25, 378.00, 385.00, 396.25, 315.75, 328.00, 336.00 and 347.50 after 72 hrs of incubation period was hatching was observed 391.75, 397.50, 406.00, 419.75, 424.75, 431.50, 280.25, 294.25, 301.25 and 312.75 in ethanol leaf extract @ 5.0%, 2.0%, leaf extract @ 5.0%, 2.0%, achook @ 7.5%, 5.0%, leaf compost @ 7.5%, 5.0%, neem cake @ 7.5% and 5.0% treatment, respectively. At all the four incubation period i.e.12, 24, 48 and 72 hrs the hatching inhibiting was of greater instarce which recorded as the period was increased. Similar trends were also observed larval penetration in all the treatments at all exposure periods.

Key words: *Azadiracta indica*, Hatching, Penetration, *Solanum lycopersicum*.

Tomato (*Solanum lycopersicum* Mill.) is an important food and cash crop of the formers and is widely cultivated throughout the country. Root-knot nematodes (*Meloidogyne* spp.) are among the major pathogens of vegetables especially in tomato and eggplant throughout the world. It severely restrict all the vital functions of plant roots including the absorption and transportation of water and nutrient. Besides, they provide easy entrance to micro-organism which creates secondary infection in root system (Romy & Robert, 2008). Therefore, to avoid damage due to root-knot nematode, appropriate management options should be applied timely. Thus, the present study was planned to test the efficacy on neem biopesticides on hatching and penetration to tomato.

Materials and Methods

Experiment was conducted under natural pot condition at experimental field of Department of Nematology, NDUAT, Faizabad. The effect of neem plant products *viz*. neem cake, Achook, leaf compost, Leaf extract (ethanol), leaf extract (water), on egg hatching of *Meloidogyne incognita* was studies. A total eleven treatments i.e. Ethanol leaf extract @ 5.0% (T_1), ethanol leaf extract @ 2.0% (T_2), leaf extract @ 5.0% (T_3), leaf extract @ 2.0% (T_4), leaf compost @ 7.5% (T_5), leaf

Survey on alternate weed host of rice root-knot nematode, *Meloidogyne graminicola* in kharif Session

Manish Kumar, Ramesh Chand, Vipin Kumar Verma, Shyam Babu Gautam and Himanshu Verma

Abstract
The survey conducted to know the alternate weed host of rice root-knot nematode showed that out of 465 sample collected from both rice and wheat field of metrology farm, GPB field and the Jorium 50 samples collected from rice crop and 80 sample wheat field were found free from any nematode sample while 210 and 79 samples was observed to be infected with the larvae and galls were recorded ransing from 3-19 on the root of rice plant and 1-3 gallls per plant on wheat the decomposed plant leaves of wheat botanicals was used @5, 10 and 15g/kg soil in nematode infecting soil containing 3 larvae/ g soil.

Keywords: Rice, wheat, survey, *Meliodogyne graminicola*

Introduction
Rice (*Oryza sativa* L.) is the staple food of a vast majority of the population in the East and South East Asian, African and South American countries. In addition to its direct food value, rice grain is used in manufacturing of several industrial and commercial products. The paddy is most important cereal crop in India occupying 44.48 million hectares of area with an annual production of 112.91 million tones with the productivity of 19.56 quintals per hectare during 2017-18. Rice is grown in diverse environment either as a sole crop (rainfed, irrigated or deepwater) or as major component in various cropping systems. Cropping systems, involving different year specific crop sequences or fallow in a given area, create conditions of varying favorability for microbes and weeds and thus affect the flora and fauna. Since, rice cultivation cover large area in India, even a smallest pest problem would have great impact on yield and farmers' income. Soil borne diseases are becoming increasingly important in the rice-based cropping systems. One of the most important soil born pests is plant parasitic nematode in rice crop. About 300 nematode species belonging to 35 genera have been reported infesting rice. Among them, *Meloidogyne graminicola* (Golden and Birchfield) is considered as most important constraint in rice production. *Meloidogyne graminicola* reduce rice yield by more than 17% in a greenhouse experiment and the yield losses might go as high as 98% (Bridge & Plowright 1990) [1] in pot experiment under favorable conditions. To prevent further yield losses and improve productivity, it is necessary to find out the effective sustainable management strategy. Many species of *Meloidogyne* have been reported by various scientists throughout world. *M. graminicola* is reported as an important nematode pest of rice from countries like South East Asia, Burma, Bangladesh, Laos, Thailand, Vietnam, India, China, Philippines, Nepal and USA. *Meloidogyne oryzae* an another species of this genus is also reported on irrigated rice from Surinam and *M. incognita* is reported from Costa Rica, Cuba, Egypt, Ivory Coast, Nigeria, South Africa and Japan, *M. javanica* in Brazil, Egypt, Comoro Islands, Nigeria and Ivory Coast. Apart from this *M. arenaria is reported from* Nigeria, Egypt and South Africa and *M. salasi* in Costa Rica and Panama on upland rice.
Considering the fact that *M. graminicola* is serious nematode pest of rice of eastern Uttar Pradesh where it is predominantly used by the farmers, investigation was planned to generate information on its distribution and host range with host reaction on some rice and wheat varieties. Broad host range of nematode is beneficial to maintain population in absence of main host, many scientist have reported that rice root knot nematode *M graminicola* maintain the population on various weed host and maintain population on weeds for next season (Rich, *et al.*, 2009) [3]. Moreover rice root nematode complete life cycle is a very fast span, within 15 days at 27-37 °C (Jaiswal and singh, 2010) [7].

Effect of *Parthenium hysterophorus* plant parts products on hatching and larval penetration of root-knot nematode, *Meloidogyne incognita*

Vipin Kumar Verma, Ramesh Chand, Shyam Babu Gautam, Manish Kumar and Richa Singh

Abstract
An experiment was conducted on the effect of *Parthenium hysterophorus* on hatching of *Meloidogyne incognita* eggs under pot condition during 2017-18. The observations reveal that all the treatment were found significantly different from each other over control except to that of leaf compost @ 2.0 % with leaf powder @ 2.0 %; leaf compost @ 5.0 % with leaf powder @ 5.0 % and 7.5 %; ethanol leaf extract @ 2.0 % with 5.0 % with leaf extract 5.0 % were found at par to each other. The egg hatching recorded highest (609.75, 692.25, 702.00 and 725.50) was observed at 12, 24, 48 and 72 hours in control treatment where soil is not amended, however the minimum hatching was seen ethanol leaf extract treatment followed by leaf powder, leaf compost, leaf extract and ethanol leaf extract. The impact of *Parthenium hysterophorus* on larval penetration of *Meloidogyne incognita* shows that the penetration of second stage juvenile in the root system decreased in all the treatments as compared to untreated check. Maximum penetration was observed in untreated check i.e. 510.50, 565.25, 614.00, 692.75 and minimum penetration observed in the treatment in ethanol leaf extract @ 5% i.e. 204.00, 245.75, 325.25, 346.50 after incubation period 12, 24, 48 and 72 hours respectively.

Keywords: Tomato, *Parthenium hysterophorus*, *Meloidogyne incognita*, egg hatching and larval penetration

Introduction
Tomato (*Lycopersicon esculentum* Mill.) is an important cash crop grown by both sustainable and commercial growers in India. It is grown in both rainy and dry season. It is perhaps the most profitable crop for small- scale farmers. Genus *Lycopersicon* has several species, but only two of them are edible i.e. L. *esculentum* Mill. and L. *pimpinenellifolium* Muller, are the only cultivated tomato. The tomato is an important vegetable crop which is cultivated throughout the year. In India, tomato is cultivated in 8.09 lack ha. With a total production of 19.69 corer tonnes with the productivity of 24.40 tonnes/ha. (NHB, 2016-17) [10]. The total area under tomato cultivation in Utter Pradesh is 2.08 lakh ha. With total production of 82.63 lakh tonnes and the productivity is 39.57 tonnes/ha. (NHB 2016-17) [10]. The ability of this crop to grow throughout the year, except in extreme climatic condition, makes it a very valuable to the growers and is an additional source of earning profit even during off season and tomatoes are being cultivated as food (Boswell, 1949) [3]. It can be used as a vegetable, soup, salad, pickles, ketchup, sauce and in many other ways. It is the most important "Protective food" because of it special nutritive value and also of its widespread production. Tomato is an important component in the diets of majority of Indians. The tomato fruit has been found to have considerable health benefits.

In spite of development of various plant protection measures, the crop unfortunately suffers severely from several diseases caused by bacteria, fungi, virus, nematode or by adverse environmental condition. Among nematodes, root-knot nematode, *Meliodogyne incognita* (Alam *et al*, 1975) [1], *M. javanica* (Rao and Prasad, 1969) [8], attack tomato crop but the root-knot nematode is the most common. Due to the wide distribution of root-knot nematode, it has gained countries. However, in Rajasthan, in was first noticed by Arya, 1957 [2] and found its infestation on tomato and later Yadav and Naik, 1966 [13], found *Meliodogyne spp*. Widely distributed in the soils of Udaipur, infecting vegetable and many other economically important crops.

Abstract

Oat is one of the most important cereal fodder crops of Rabi season. It provides soft and palatable fodder. Its fodder, on dry matter basis contains 10.0 -11.5 % crude protein, 55-63 % neutral detergent fiber, 30-32 % acid detergent fiber, 22.0-23.5 % cellulose and 17-20 % hemicelluloses when harvested at 50 % flowering stage of crop. Oat is also used as straw, hay or silage. Total world area under oats is approximately 13.9 million hectares. The production of oat is not being fully exploited because of the lack of proper information on its optimum fertilizer requirement. Among the different production factors, fertilizer application is one of the most important factors in limiting the production of oat crop.

Introduction

Phosphogypsum is a byproduct of all diammonium phosphate plants. Every matric tons (MT) of phosphoric acid manufactured generates 5 MT of phosphogypsum. There is now an estimated stock of about 125 lakh MT of byproduct phosphogypsum in the country. Its agricultural use started only very recently with the onset of calcium and sulphur deficiency in oat grown mostly in light textured soil. Its utilization is however very much restricted because of lack of knowledge on its use, appreciation of benefit in different crops and anticipated environmental problem associated with its use. Phosphogypsum contains 16% S, 22% Ca and 0.71% P_2O_5. Pure gypsum ($CaSO_4$) contains 18.6% S and 21% Ca, while commercial agricultural grade gypsum of 70-80% purity contains 13-15% S and 40% CaO. Sulphur is now recognized as the fourth major plant nutrient after nitrogen, phosphorus and potassium. Crops in general require as much sulphur as they need phosphorus. Sulphur deficiencies have been reported in soil from several state of India and importance of sulphur fertilization in increasing crop yield and product quality is being increasingly recognized. It performs many important functions in the plants. It is best known for its role on the synthesis of protein and vitamins. It is constituent of amino acids and thus vital for production. Sulphur is associated with the production of crop of superior nutritional quality. Since the quality of forage crop is important for their utilization by live stock, hence sulphur fertilizer is of much important in forage production. It enhances the effects of other nutrients also. The effect of sulphur on yield and crop quality is further enhanced where it interacts positively with other nutrients. Reports on the sulphur phosphorus interaction have been conflicting since both positive and negative interactions have been observed (Kanwar and Mudahar, 1985). The sulphur application can ensure the high production of oat. Keeping facts in view an effort has been made to assess the phosphogypsum level which is a byproduct of phosphoric acid plant and on various cultivar of Oat fodder crop.

Material and Methods

The field experiment was conducted to evaluate the effect of phosphogypsum levels to various cultivar of fodder oat crop at Genetics and Plant Breeding Farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad, Uttar Pradesh, India during *Rabi* season 2015-2016 under the project of All India Coordinated Research Project (AICRP) on forage crops. The experimental soil having silty loam in texture, pH (1:2.5) 8.59, EC 0.38 dSm^{-1}, Organic carbon 3.1 gkg^{-1}, available nitrogen 173.4, phosphorus 14.80 and potassium 195.10 $kgha^{-1}$. The twelve treatment were comprised of one time application of four levels of phosphogypsum on basis of sulphur content (0, 125, 250 and 375 $kgha^{-1}$) with three cultivar viz. NDO-1, NDO-2 and NDO-711 in randomized block design replication each treatment thrice. The plant spacing was row to row 25cm and plant to plant 5cm. The phosphogypsum was applied through broadcast and surface incorporation. The half dose of nitrogen @ 100 kg N ha^{-1} though urea, and full dose phosphorus @ 40 kg P_2O_5 ha^{-1} through Diammonium phosphate applied at the time of sowing of the crop. The remaining half dose of nitrogen was top dressed in standing crop at 25 DAS just after first irrigation of the crop. Representative soil samples at initial and after harvest of the crop (0-15cm) of investigation were drawn from individual treatment plot and analyzed with methods described in *Jackson*, 1973. The cutting was done with the help of sickle at 50% flowering stage at 105 DAS. The chlorophyll contents was estimated following the methods of Arnon and Stout (1949) and expressed as mgg^{-1} fresh leaves. The nutrient uptake was calculated with multiplication of dry matter yield by nutrient content in percentage.

Results and Discussion

Growth and fodder yield

Data pertaining to growth and fodder yield are presented in Table-1. Inherent genetic variability in plant was notice among entries. Among the entries of fodder oat crop, the maximum plant height with NDO-711(113.5cm), tillers m^{-2} (397), dry matter accumulation (1273.27 gm^{-2}), green forage yield (515.28 qha^{-1}), dry matter yield (124.33 qha^{-1}), crude protein yield (13.83 qha^{-1}) and chlorophyll content (1.70 mgg^{-1}) which was found significantly superior in respect of plant height, dry matter accumulation, green forage yield, dry matter yield, crude protein yield and chlorophyll content over rest of the cultivars. Among the phosphogypsum levels the maximum plant height (117.9 cm), tillers (391 m^{-2}), dry matter accumulation (1241.78 gm^{-2}), green forage yield (515.2 qha^{-1}), dry matter yield (124.2 qha^{-1}), crude protein yield (14.2 qha^{-1}) and chlorophyll content (1.78 mgg^{-1}) were received with the application of phosphogypsum 375 $kgha^{-1}$ (60kg S ha^{-1}) which was found significantly superior in respect of plant height, dry matter accumulation, green forage yield, dry matter yield, crude protein yield and chlorophyll content with 125 $kgha^{-1}$ and found statistically at par the level of 250 kg ha^{-1} phosphogypsum. Better growth and development of oat plants due to higher levels of phosphogypsum (sulphur) doses would have been due to multiple role of S in protein and carbohydrate metabolism of plants by activating a number of enzymes which participate in dark reaction of photosynthesis hence increases the plant height and dry matter was observed with increased doses of phosphogypsum (sulphur). Similar finding were also reported by Choudhary *et al.* (2013), Varshney *et al.* (2008) and Tanveer *et al.* (2013) Sulphur play an important role in plant metabolism by virtue of being essential constituent of various metabolically active compounds like amino acid, proteins, nucleic acid, porphyrins (chlorophyll), enzyme and co-enzyme. Constituent of chlorophyll it is important for photosynthesis. It influences the rate of cell division and their enlargement and hence tends to rapid growth of meristemetic tissue. Similar finding were also reported by Shukla and Menhi (2004).

Nutrient uptake

The data with respect to nutrient uptake by oat fodder presented in Table-2 which revealed that among the entries of fodder oat crop, the maximum nutrients uptake (N 22.78, P 25.98, K 213.37 and S 22.60 kg ha^{-1}) were received with the cultivar NDO-711 which was significantly superior over rest of the entries (NDO-2 and NDO-1). This might be due to the genetic characteristics of variety, resulting

Studies on the bio-efficacy of *Dactylaria brochopaga* against root-knot nematode *Meloidogyne incognita* on brinjal

Ramesh Chand and Pintoo Kumar

Abstract
The *In vivo* efficacy of *Dactylaria brochopaga* against root-knot nematode, *Meloidogyne incognita* on brinjal was studied. The observations on predacity test of *D. brochopaga* against J_2 of *Meloidogyne incognita* showed that J_2 trapping increased with the increase in J_2 population and the exposure time allowed for trapping in culture being maximum at 96 hours of exposure period. while studying the effect of *D. brochopaga* in combination with various organic manures, the observations on plant height and root length showed increase in length significantly in all the treatments in comparison to the inoculated, uninoculated and treated check with minimum in inoculated check, 16.00 and 3.62 followed by treated check 18.50 and 7.50, 18.00 and 6.00 in T_3, 17.75 and 7.00 in T_1, 17.62 and 6.87 in T_2, 17.25 and 6.50 in T_4, 17.00 and 6.87 in T_5 respectively in descending order. The reproduction parameters of *Meloidogyne incognita* on brinjal i.e. Nematode population in root and soil, eggs/ plant, total nematode population and multiplication factor significant decreased in all the treatments over the inoculated check where as significant increase was observed over the treated check. The nematode population in root and soil, egg / plant, total nematode population and nematode multiplication factor was highest (121.75, 1198.00, 8642.50, 9962.25, and 6.64) in inoculated check followed by 52.25, 188.25, 3182.00, 3422.50 and 2.28 in T_5, 41.25, 182.75, 1639.50, 2163.00 and 1.44 in T_2 46.75, 162.00, 1879.00, 2087.75 and 1.39 in T_4, 48.50, 156.75, 1836.75, 2042.00 and 1.36 in T_3, 42.50, 183.25, 1774.25, 2000.00 and 1.33 in T_1 with the minimum 26.50, 122.00, 1345.50, 1494.00 and 0.99 in treated check (T_8) respectively in descending order.

Keywords: Root-knot nematode, Nematode trapping fungi, Bio-efficacy, Bio-control of nematode, Nematode management

1. Introduction
Among plant parasitic nematodes, root-knot nematode, *Meloidogyne spp.* have been identified as one of the noxious nematode problem in India as well as in world over, causing enormous yield loss in brinjal crop along with more than 2000 plant species of vegetable, fruit, spices and causing average yield loss of 5% globally. (Hussy and Janssen, 2002) [7]. The avoidable yield loss in vegetable crops due to *Meloidogyne spp.* ranges between 28.3 to 47.5 in tomato, 26.5 to 50.0 in brinjal, 19.7 to 33.3 in chilli and 60.0 to 90.0 per cent in bitter gourd under Indian condition (AICRP, 1992). Among various approaches known so far for the management of root-knot nematode, culture practices are not generally preferred because of several inherent difficulties (Jatala 1985) [9]. Although nematicidal applications manage root-knot nematode population effectively but due to high cost, non-availability, mammalian toxicity, environmental pollution and resurgence of new nematode pests, biological control of root-knot nematode through nematode trapping and antagonistic fungi is observed to be the one of the potential approaches having ability to be the environmentally safe and effective as alone and in combination as an integral part of the integrated nematode management strategy. *Arthrobotrys oligospora* having proven its nematode controlling potential (Mankar, 1962; Kerry, 1987; Cooke, 1962) [15, 5, 10]. The sophisticated larval capturing mechanism and higher nematode predacity indicate the bio-control potential of *D. brochopaga*. (Singh *et al.*, 2007) [20]. Accordingly studies on the bio-efficacy of *D. brochopaga* against root-knot nematode, *Meloidogyne incognita* on brinjal was studied.

Materials and Methods
In vitro Studies on nematode capturing ability of *Dactylaria brochopaga* was tested against J_2 of root-knot nematode, *M. incognita* using the method as described by Belder and Jansen (1994) [4]. 2.00 mm fungal disc of *D. brochopaga* was taken from the periphery of 10-12 day old culture and inoculated into the 50 mm diameter petri dishes containing 1:10 maize meal agar

(Received: April 14, 2016; Revised received: November 09, 2016; Accepted: November 16, 2016)

Chilli (Capsicum annuum L.) is an economically important spice of India, which suffers many fungal and viral diseases, among them Chilli leaf virus is one of the most destructive pathogen causing heavy yield loss in major chilli growing area. The experiment was conducted during February to May in 2014 and 2015 to evaluate the chilli cultivars against chilli leaf curl virus. Out of 36 cultivars, none was found the immune, three cultivars viz Pusa Jwala, Japani long and Pusa Jwala was showed highly resistant, where as ten cultivars viz., Agni,Arkalohit, Faizabad kala, Super (Local), Ajeet-1 Pusa Sadabhar, Suhawak-17, HC-44, DCH-2 and PBC-473 was showed resistant, Moderately resistant cultivars were BC 14-2, Faizabad long, PDC-54, Pant C-1, IC 119348 and Pusa sadabhar. Rest of eight cultivars was showed moderately susceptible and nine cultivars were found highly susceptible against chilli leaf curl viral disease. These resistant and moderate resistant cultivars could be used by farmers in cultivation under integrated production systems and by breeders in developing new chilli hybrid resistant cultivars against leaf curl disease.

Key words: Chilli cultivars, Chilli leaf curl, Viral disease, Field condition

Introduction

Chilli (*Capsicum annuum* L.) is one of the most valuable crops and widely cultivated worldwide for its pungency. Chilli is grown almost all state of India for commercial use such as vegetables, spices, and industrial (oleoresin and capsaicin extraction) purpose (Kumar and Rai 2005). India produced about 1260.1thousands metric tons of chilli from an area of 792.1 thousands hectare, (Anonymous, 2012). Andhra Pradesh is the largest producer states of chilli in India. The crop is attacked by a large number of fungi, bacteria and viruses among of them viral diseases which are characterized by yellow mosaic, mosaic mottle, leaf curl, leaf roll and necrosis has been reported to caused heavy yield losses (Yadav et al., 2013; Talukdar et al., 2015). The occurrence of chilli leaf curl disease caused by whitefly (Bemisia tabaci) transmitted geminivirus of almost concern to chilli growers for its sever incidence and complete crop failure (Kumar et al., 2009). The partial control of viruses may be achieved with the application of pesticides by the controlling the vector population but complete safer protection from the virus through host plant resistance is more preferred and effective option, leaf curl resistant genotypes under open field condition have been reported by Sharma and Singh (1985), Memane et al., (1987), and Kumar (2008). The resistance cultivars are the only way to produce disease free material, but their long term stability virtue of true resistance are need for their confirmation under field condition has been also infested (Ashfak et al., 2014). Present research work has been directed to identify resistance sources under field condition with continuing screening process of available genotypes against chilli leaf curl virus.

Material and Methods

The experiment was carried out during the month of February to May in 2014 and 2015 at student's instructional farms of N.D. University of Agriculture and technology, Kumarganj, Faizabad. Thirty days old seedlings were transplanted in first week of February at the spacing of 60x45 cm in augmented design under field condition for evaluation of their resistance against leaf curl virus. Total 36 chilli germplasm cultivars were collected from Vegetable Farm, N. D. University of Agriculture and Technology, Kumarganj, Faizabad and Indian institute of vegetable research, Varanasi, U.P. Seeds of all the cultivars were sown in single lines 2.0x2.5 cm deep furrow for nursery. Two rows of chilli leaf curl susceptible (check) cultivar (IC 119797) were transplanted all around the field to create epiphytotic conditions. Recommended package & cultural practices were followed to raise the crop and to promote natural infection. Periodical fungicidal sprays were given to avoid fungal diseases. Ten plants in each plots were randomly selected and tagged for visual observations on symptoms appearance at 30, 45, 60, 75 and 90 days after transplanting. The leaf curl disease intensity noted on each cultivars and was rated following a intensity scale 0 - 5 (Banerjee and Kallo, 1987). Percent disease intensity

ABSTRACT

Aim: *Stem gall diseases have become major economic significance. The disease manifests itself in the form of galls on stem, branches, leaves, petioles and fruits, causes 15-20 per cent yield loss and deteriorates quality of seeds. Quantitative biochemical changes are required to determine for development of resistant variety against stem gall*

Methodology: *Stem gall symptoms were regularly observed during whole crop growth stage from appearance of symptom on different parts of the coriander plants. The leaves, stems, inflorescence, petioles and fruits showing characteristic symptoms were separately collected and kept in rough dry envelopes and marked clearly mentioning location, infected parts, variety reaction types, date of collection etc. and brought to the laboratory for identification of the pathogen and used for the study of biochemical changes such as total phenol, tannins, flavonoids and Saponins*

Results: *The stem gall symptoms were observed as small tumour-like swellings on all herbaceous parts of the affected plants, namely, stems, petioles, flower stalks and leaves. The mycelium of Protomyces macrosporus was septate, hyaline, irregular, branched, 2 to 5 µm thick, 36.50 µm length and 35.00 µm width. Intercellular and multinucleate mycelium's are formed Chlamydospores, which are globose to ellipsoid, thick-walled, three-layered membrane and smooth with brownish colour. Mature Chlamydospores were multinucleate and measured 60-70 µm x 50-60 µm in diameter. Severely infected plant parts have synthesized low amount of phenol, tannin, flavonoid and saponin content, whereas comparatively high amount of these compounds are found in less infected plant parts or healthy one*

Interpretation: *Stem gall infected plant parts were immediately accumulate total phenol, tannin, saponin and flavonoids following the pathogenic attack in resistant varieties, whereas susceptible varieties did not accumulate significantly higher amount of these substances.*

Key words: *Stem gall, Coriander, Symptoms, Chlamydospore, Spread, Bio-chemical*

Abstract

Chilli (*Capsicum annum* L.) is an important spice crop grown all over the world. The importance of chilli leaf curl, a disease has been recognized for many years, wherever chilli crop is grown. An experiment was designed to evalua efficacy of a few botanical pesticides against leaf curl viral disease in chilli. Minimum disease incidence (34.63-37.88% recorded in plots, which received seedlings treated with *Clerdendrum aculeatum* (leaf extract) followed by three foliar s of *Terminalia arjuna* (bark extract). Whereas, seedling treatment with *Clerdendrum aculeatum* (leaf extract) follow three foliar sprays of *Terminalia arjuna* (bark extract) were observed maximum per cent disease control (60.72-57.70%) with fresh fruit yield (2.35-2.07 kg plot^{-1}) and an increase in fresh fruit yield (58.75-58.24%). Maximum plant height (55.83- cm), maximum plant canopy (72.31-67.55 cm), days of 50 per cent flowering (85.04-85.79DAT), maximum fruit weight (2.23g), maximum total number of fruit plant^{-1} (72.29-70.63) and maximum number of seed fruit^{-1} (58.35-57.70).

Key words : Ecofriendly, antiviral agents, leaf curl disease, chilli.

Introduction

Chilli (*Capsicum annuum* L.) is an important spice crop cultivated in many countries throughout the world. India produces approximately 12.60 thousand metric ton from an area of 792.1 thousand hectares (Annon., 2012-13). Uttar Pradesh occupies an area of 13.47 thousand hectares with production of 10.30 metric tonns (Annon., 2012-13). India is rich in diversity of chilli varieties with different nutritional quality. Besides traditional use of chilli such as vegetables, spices, condiments, sauces and pickles; it is being used in pharmaceutics, cosmetics and beverages (Tiwari *et al*., 2005). The average productivity of chilli is very low in India comparison to other countries because the crop is infested with many insects and diseases. It is because most of chilli verities are susceptible to various pathogens; which cause heavy yield losses. Viruses are considered as one of the important limiting factor (Villalon, 1981). Among them, chilli leaf curl virus (Geminivirus) is most destructive viral pathogen in many parts of India, which is affecting chilli cultivation

human health hazards, destruction of ben microorganisms and environmental pollution. The emphasis is on the development of non-chem ecofriendly method for the management of this which has provided impetus to more extensive expl of natural resources and to identity effective extracts/botanical bio-pesticides for the managem chilli leaf curl virus by reducing vector population field.

Materials and Methods

The experiment was conducted at Stu Instructional Farm, N. D. University of Agricult Technology, Kumarganj, Faizabad. Seeds were c from the Department of Vegetable Science University of Agriculture and Technology, Kum Faizabad. The experiment was conducted duri consecutive years (2014 and 2015) consisting treatment combinations *viz* T_1- root treatme *Tinospora cordifolia*

Keywords: Turmeric.*Colletotrichumcapsici*, cow's urine, leaf spot, management

Turmeric (*Curcuma longa* L.)is highly prone to several fungal diseases, among them major fungal disease is leaf spot incited by *Colletotrichumcapsici* (Syd.) Butler &Bisby causing fresh rhizome yield loss to the tune of 15-60% (Pruthi, 1998) and dry rhizome yield 62% approximately. The disease was first reported from Coimbatore district by Mc Rae in 1917 (Ramakrishnan, 1954). It is more severe in southern states (Gomathi, 2001) but caused heavy yield loss in Uttar Pradesh (Mishra and Pandey, 2014).The application of chemical fungicides are producing hazardous consequences in term of soil pollution, reducing the quality of arable land and ground water (Bezbaruah, 2000) and bio-pesticides are usually inherently less toxic than conventional pesticides (Singh, 1999). They generally affect only the target pathogenic organism, in contrast to broad spectrum fungicides. Fresh plant extracts from different plant parts are becoming valuable for management of the pathogens, which can be easily prepared by farmers. Cow's urine is an important constituent of Panchgavya and is used in several Panchgavya formulations (Okigbo and Nameka,2005). Cow's urine based Nigerian herbal formulation were prepared with the use of several herbs like tobacco, garlic, lemon juice and bulbs of onion. These herbal formulations have been described for the use in medicinal and agricultural applications. (Fulzele*et al*, 2001). Keeping in view, fieldstudies were carried out to select suitable management practices for reducing the leaf

alluvial soil with having low organic matter and high pH 8.5. *Colletotrichum* Leaf Spot disease susceptible variety NDH-1 was selected for trial in Randomized Block Design with 20 treatments and three replications. Botanical-formulations were prepared with mixture of fresh neem leaves –500g, fresh madar leaves – 500g, fresh datura leaves – 500g, bulb of onion- 500g, bulb of garlic-500g. Each plant parts were grinded with the help of mixture and grinder. The grinded materials were mixed and dissolve in 5 liters of cow urine, acetone and distilled water (1:2 ratios) separately. These solutions were kept 30 days in earthen pot for fermentation. The fermented solutions were filtered through muslin cloth and use as standard solution 100 percent concentration. The rhizomes were planted on raised beds 3x1 meter size at spacing 30x25 cm in the first fortnight of July. Foliar spray @20% concentration was done at 60, 75, 90 and 120 days after planting. A sticker, ASPA 80 @ 0.1% was mixed in spray fluid for stickiness. Only water was sprayed in control for comparison. Randomly six plants of each plot were selected for recording the disease intensity at 120 days after planting. All the leaves of selected plants were individually scored based on 0-6 scale. Where 0 = No infection, 1 = 0.1 to 10 percent area infected, 2=10.1to20 percent area infected, 3 = 20.1 to 30 percent area infected, 4 = 30.1 to 40 percent area infected, 5 = 40.1 to 50 percent area infected,6 = more than 50 percent area infected. The Plant Disease Intensity (PDI) was calculated according to the formula

Abstract

Coriander faces severe management issues from fungal diseases such as stem gall, wilt, blight and powdery mildew. A broad array of fungicides is used to control fungal diseases by the growers. These control agents are used injudiciously, Coriander is being of export commodity fungicides residue are very much conscious. Keeping this issues, experiment on solar heating of soil by polythene were conducted from 2014-15 to 2016-17 for the management of stem gall disease and yield of coriander. The minimum disease severity (4.6 to 21.3%) was recorded in Soil solarization + Plastic mulching+ seed treatment and foliar spray of 1% neem oil followed by Seed treatment with propiconazole (6.3-22.5%), plastic mulching + seed treatment and foliar spray of neem oil (4.9-24.2%), Soil solarization + Plastic mulching (9.0-22.8%) and Soil solarization (5.3-23.3%). The highest seed yield of coriander was also recorded in Soil solarization + Plastic mulching+ seed treatment and foliar spray of neem oil (11.17q/ha).

Key words: soil solarization, plastic mulching, stem gall, yield, coriander

Introduction

Seed spices play a significant role in our national economy because of its large domestic consumption and growing demand for export. Presently 16.53 lakh ha of area is under seed spices cultivation with production of 11.75 lakh tonnes annually (Anon, 2016). Seed spices are mainly cultivated in Rajasthan and Gujarat and have sizeable area in Madhya Pradesh, Haryana, Punjab, Uttar Pradesh, Andhra Pradesh and Karnataka. 17 seed spices are grown in the country among them coriander is pillars of economic importance because it is the highest export earner next to cumin. Coriander production was 313.6 thousand tonnes from an area of 447.1 thousand ha with 701.4 kg/ha productivity during 2013-14 (Anandaraj, 2016). In spite of several technologies were developed for the boosting of coriander production *viz.* cultivation practices, high yielding varieties for different qualities and traits, management of pest and diseases, harvesting and post harvesting processing, quality of yield production is still less in comparison to other country, it is due to lac of stem gall resistance variety and climate change whic enhanced biotic and abiotic stress. This would need hig prioritized research to convert negative effect of increas temperature into positive opportunity. Therefore, prese experiment was designed to harvest solar energy f management of stem gall disease through soil solarizati and plastic mulching.

Materials and method

The present research was carried out at Vegeta Form, N.D. University of Agriculture and Technolo Kumarganj, Faizabad, UP, India during *Rabi* 2014-15 2016-17. The seeds of coriander variety NDcar-2 w shown in field at 40cm × 10cm spacing with th replication and nine treatments *viz.* T_1= Soil solariza by polythene sheet (60 days), T_2= Plastic mulching (F sowing to harvest), T_3= Seed treatment and three fo spray at 45, 60 and 90 days with 1.0% neem oil, T_4= solarization by polythene sheet (60 days) + Pla

EVALUATION OF FENUGREEK GENOTYPES FOR SEED YIELD AND DOWNY MILDEW RESISTANCE

R. S. Mishra

Department of Vegetable Science

N. D. University of Agril. & Technology, Kumarganj, -224229, Faizabad, UP, India

Key words: Fenugreek, Screening, Downy mildew, *Peronospora trigonella*, Seed yield

Fenugreek (*Trigonella foenum graecum* L.) is affected by many diseases; downy mildew caused by *Peronospora trigonella* Gaum is considered one of the most destructive and wide spread diseases of the crop, which is commonly occurring February and March (Thind, 1942, Gupta *et al.*, 2015). The infected leaves are easily detected by the presence of yellow patches on the upper surface and cottony grayish- violet mycelial growth on the lower surface of the leaves. The disease is also reported from Algeria, Pakistan, United Kingdom and India (Acharya, 2014). The common methods of disease managements are use of chemical and disease resistant variety. However continuous use of chemicals to control plant diseases is neither environmentally sound nor economically cheap (Iqbal *et al.*, 2011). The literature on downy mildew resistant germplasm of fenugreek is scanty. Therefore identification of downy mildew resistant / tolerant genotypes of the self pollinated crop will be useful for development of resistant cultivars where the disease is prevalent and causing heavy yield loss.

The field experiment was conducted at vegetable farm of N.D.University of Agriculture and Technology, Kumarganj, Faizabad and AICRP on spices centre of Jobner from 2012-13 to 2014-15. The seed materials of fenugreek genotypes were obtained from AICRP on spices IISR, Kozhikode Kerala, India. The experiment was laid out in randomized block design with three replications. Sixteen genotypes were sown in 2.0 x 2.4 m^2 area with 30 cm row to row and 10 cm plant to plant spacing. The seed was sown at 3rd week of October under natural downy mildew infected area. The percent disease intensity of downy mildew was recorded at second week of March using 0-4 scale given by earlier workers (Fallon *et al.*, 1995). The tested entries were graded 0- No disease symptoms, 1- Resistant, 2- Moderate resistant, 3- Susceptible, 4- Highly susceptible. The yield data were recorded after the harvest.

Out of 16 genotypes five were resistant, nine moderately resistant and two susceptible at both Kumarganj and Jobner test centre. None of the genotype was found immune and highly susceptible against downy mildew. However AFg-5, LFC-98, Um-202, NDM-69 and RMt-361 (Check) were found resistant with percent disease intensity of 18.99, 18.52, 19.69, 14.31 and 18.19, respectively. The genotypes JFg-245, JFg-266, AFg-6, LFC-93, Hm-280-1, NDM-72, Rm-188, Rmm-194 and Hissar Sonali were moderately resistant with ranging 24.48 to 36.97 PDI. The susceptible genotypes Hm-259 and Um-354 showed 53.20 and 42.54 percent disease intensity at Kumarganj. Whereas, at Jobner, AFg-5, Um-202, NDM-69, Rm-188 and RMt-361 showed resistant reaction with 15.83, 6.66, 16.66, 10.83 and 13.33 percent disease intensity, respectively. The genotypes JFg-266 (23.33PDI), AFg-6 (39.19 PDI), LFC-98 (35.0PDI), Hm-280-1(38.33PDI), Um-354 (36.99PDI), NDM-72(28.33 PDI) and Hissar Sonali(28.33PDI) were categorized moderately resistant, while rest of the genotypes were susceptible to downy mildew at Jobner. The findings are supported with earlier workers (Thind, 1942; Prakash and Saharan, 2001; Gupta *et al.*, 2015). Yield data of 16 genotypes (Table-1) revealed that highest grain yield was recorded in JFg-245 (1402Kg/ha) and lowest in Hissar sonali (1231Kg/ha) at Kumarganj. Rm-188 (1489.35Kg/ha), NDM-69 (2276.39Kg/ha) and Um-202 (2186.73 Kg/ha) produces highest seed yield at Jobner. Average yield of fenugreek was reported from 150-2800 Kg/ha by growers under dry land conditions and

ABSTRACT

Coriander (*Coriandrum sativum* L.) is an important spices crop, grown in a wide range of weather conditions. Coriander suffers from various abiotic and biotic diseases. Among the biotic diseases, stem gall caused by *Protomyces macrosporus* is a major disease, which causes yield loss up to 33-36%. The experiments were conducted during 2016-17 at Vegetable Farm, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) with eleven treatments *viz*., cow urine, cow dung slurry @ 10, 20 and 30% concentration of panchgavya, thiram @ 0.25%, carbendazim @ 2%, propiconazole @ 0.2% concentration and control. The effectiveness of organic treatments @ 30% concentration was significantly reducing the disease intensity. The maximum reduction was found 49.60% and 49.57% in panchgavya @ 30% concentration and minimum 17.61%, 26.88% in cow dung slurry @ 10% concentration during flowering and maturity stage respectively. In case of fungicides, the maximum disease control was recorded 51.70% at flowering stage and 49.71% at maturity stage treated with propiconazole @ 0.2% concentration. The maximum average numbers of chlamydospores were found at soil surface (198.80 g soil^{-1}) and minimum in 2 inch depth (42.20 g soil^{-1}) around the plant. The highest plant height (111.14 cm), no. of branch's/plant (7.26), number of umbel/plant (100.6), nuber of umblet/plant (6.13), seed weight/plant (9.82 g), straw weight (14.52 g) were obtained in seed treatment + soil drenching of panchgavya @ 30% concentration. The lowest plant height (101.13 cm), no. of branch's/plant (6.60), number of umbel/plant (84.93), number of umblet/plant (5.33), seed weight/plant (7.78 g) and straw weight (9.58 g) were obtained in seed treatment + soil drenching with cow dung slurry @ 10% concentration respectively.

Chilli Leaf Curl Virus and its Management

RS Mishra* and AN Chauvey

Department of Plant Pathology, Narendra Deva University of Agriculture and Technology, Faizabad, Uttar Pradesh, India

*Corresponding Author: RS Mishra, Department of Plant Pathology, Narendra Deva University of Agriculture and Technology, Faizabad, Uttar Pradesh, India.

Received: December 20, 2017; **Published:** February 07, 2018

Abstract

Chilli (*Capsicum annuum L.*) is an economically important and widely cultivated crop of India. Chilli leaf curl virus is one of the major limiting factors in chilli production, which is drastically decreases yield. The significant symptoms of chilli leaf curl are curling of leaf margin, reduction in leaf size, vein clearing accompanied by puckering, thickening and swelling of the veins. The maximum leaf curl disease was observed in 19th standard week when the white fly population was highest in the field. The increase or decrease of leaf curl virus disease of chilli was found directly correlated with vector population and vector population was determined by environmental factors. Three cultivars of chilli viz., Surajmukhi, Japani long and Pusa Jwala were showed highly resistant against leaf curl disease. Seed treatment with raw cow milk and *Trichoderma viridae* showed the reducing trends of chilli leaf curl disease incidence. Whereas seed treatment with imidacloprid 70 WS (5 gm/kg) along with two sprays of imidacloprid 17.8 SL (0.24 ml/lit) at 45 and 60 days after planting recorded least number of whiteflies and leaf curl virus per plant with significant increase of growth and yield.

Keywords: Chilli Leaf Curl; *Capsicum annuum L.*

Introduction

Chilli leaf curl locally known as murda is a most destructive disease of chilli in India. It is transmitted by mites (*Polyphagotarsonemus latus* Banks) (Kulkarni, 1924) and thrips (*Scirtothrips dorsalis* Hood). The natural occurrence of tobacco leaf curl virus was observed on chilli in India by Pal and Tandon (1937) and Seth and Dhanraj (1972). Chilli is known to be affected by forty two viruses, twenty two of them reported to occur naturally and twenty viruses infect to chilli through artificial inoculation. Among the twenty two viruses occur naturally on chilli, eleven viruses have been reported from India, viz., cucumber mosaic virus [1], tobacco leaf curl virus [2], Indian chilli mosaic virus [3] potato virus Y [4-6] and Potato virus X [7,8]. Prasada Rao [9] reported tobacco ring spot virus, pepper veinal mottle virus and pepper vein banding virus, Chilli leaf curl virus [10] and Tomato leaf curl New Delhi virus [11,12].

Importance of chilli leaf curl complex disease

Sastry and Singh [13] reported that TLCV infected plants produced very few fruits when infected within 20 days after planting and resulting up to 92.3 per cent yield loss. Plants infected 35 and 50 days after transplanting resulted in 74 and 22.9 per cent yield loss, respectively. The premature death of seedlings was observed when infection was occurred at 2nd and 4th leaf stages, while a considerable reduction in plant height (70.9 cm) and internodal length (5.7 cm) was observed in comparison to healthy plants (127.0 cm and 12.2 cm). The yield reduction at 5th leaf stage was found 94.9 per cent, while it was 65.8 per cent at 10 - 11th leaf stage infection.

Symptomology

Leaf crinkle or leaf curl complex was observed on chillies by Hussain [2]. The vein clearing and leaf malformation was reported by Fernando and Pieries (1967). Curling of leaf margin, reduction in leaf size, vein clearing were observed in India, Sri Lanka and USA [14]. Abaxial curling of the leaves accompanied by puckering, thickening and swelling of the veins were observed by Mishra., *et al.* [15] and Muniyappa and Veeresh [16]. Appearance of most prominent symptoms such as vein clearing followed by veinal distortion, swelling of veins and vein lets on dorsal side were reported by Muniyappa [17] and Ravi [18].

Survey of chilli leaf curl viral complex on chilli in some districts of Uttar Pradesh

Some perennial types with small pungent fruits in Tarai region of Uttar Pradesh were shown to immune against viruses. Selection from crosses between the perennial local types and NP - 46 A was released under the name Pant C - 1, and Pant - 2, which were known to be resistant for leaf curl virus [19]. Wet and dry season are favourable for infection of chilli leaf curl virus on chilli (*Capsicum frutescens* and *C. annuum*), mung bean yellow mosaic virus on mung bean (*Vigna radiata*) and okra yellow vein mosaic virus on okra, all were transmitted by *Bemisia tabaci* (Gennadius) Shivanathan., *et al* (1983). Leaf curl disease of chilli was emerged as a serious problem in Jodhpur district, the major chilli growing area of Rajasthan state. During december, very high disease incidence up to 100% observed in farmer's fields in Narwa and Tinwari villages

Key words: Turmeric, foliar disease, tolerant, yield and quality
Received: 09-05-2018 Accepted: 20-05-2018

Turmeric (*Curcuma longa*) is a tropical crop grown in India, occupies the third position in its importance among spice crops and native to tropical South East Asia. The economic importance of turmeric is the dried rhizome. India has a 232.6 thousands ha area under turmeric cultivation with total production of 1189.90 thousand tons and productivity is 51.15q/ha (Anonymous (2014)). Turmeric crop is highly prone to several fungal diseases (Purthi, 2000). The serious foliar diseases reported in Uttar Pradesh are leaf spot caused by *Colletotrichum capsici* (Syd.) Butler & Bisby, and leaf blotch caused by *Taphrina maculans*, Butler. Despite the importance of the crop farmers fail to realize maximum potential yields because of several limiting factors, among them low yielding with foliar disease susceptible variety are one of the main region. Therefore aims of present work are evaluation and identification of genotypes for foliar disease resistance and quality yield of turmeric.

The field experiments were conducted at Vegetable farm, N.D. University of Agriculture and Technology Kumarganj, Faizabad (UP),India during 2013 -14 to 2015-16 in alluvial soil for three years. The fifteen turmeric genotypes used in present study were collected from IISR, Kozhikode, Kerala. The experiment was laid out in randomized block deign with three replications. The rhizomes were planted in beds of 3.0 x 1.0 m^2 size at a spacing 30 x 20 cm in the first week of July every year. Fertilizers N: P: K were applied @ 120 kg, 80 kg and 80 kg per ha in the form of urea, DAP and muriate of potash respectively. Other standard agronomical practices were carried out as and when required. Observations of disease severity were recorded at 110 days after planting on 10 randomly selected plants in each replication for disease scoring. All the leaves of selected plants were individually scored based on 0 – 6 point scale as suggested by Palarpawar and Ghurde, (1989). The percent disease severity (PDS) was calculated. The yield of fresh rhizome in each treatment was recorded after harvest and data of quality attributes were recorded at AICRP on spices, Solan, HP.

Promising genotypes of the India were tested three year continuously and observations are presented in table -1. Data revealed that NDH-128 was resistant against leaf spot disease with 7.87 PDS followed by moderate resistant TCP- 129 (13.94 PDS), TCP- 14 (14.12 PDS), NDH-10 (15.75 PDS) and CL-34 (20.40PDS). Rests of the entries were found moderately susceptible with 26.08 PDS to 38.77 PDS. None of genotypes were found susceptible and highly susceptible. Kar and Mahapatra (1981) reported the occurrence of different species of *Colletotrichum* on the leaves of various host plants including turmeric plant in West Bengal. Palarpawar and Ghrude (1989) reported the saprophytic colonization of *C. capsici* on turmeric leaf. *C. capsici* and *C. curcumae* competed with each other and established their colony in the susceptible dead leaf sheath of turmeric saprophytically. Nageshwar Rao *et al.* (1993) recorded the leaf spot disease incidence of 49% in the field surveyed. Palarpawar and Ghurde (1997) reported heavy losses in the yield of turmeric rhizome due to leaf spot disease incited by *C. capsici* and *C. curcumae* in Maharashtra state.

The performance of CL-34 (20.89 PDS), NDH-128 (26.47 PDS), CL- 32(27.80 PDS) and TCP-16 (28.22 PDS) were significantly tolerant against leaf blotch of turmeric in comparison to ruling variety NDH-1 (44.12 PDS). The percent disease severity of TCP-14, TCP-129, NDH-40 and NDH-10 was significantly lower than NDH-1, RH-406, RH-410, CL-59 and CL-52. Sangamaheswara Sharma and Krishnamurthy (1962) screened four short duration *Curcuma longa* and 7 long duration types of *Curcuma longa* for varietal resistance of turmeric crop against leaf spot and leaf blotch diseases and found there was considerable variability in the cultivars in the degree of tolerance to both the leaf diseases. Generally the long duration types of *C. longa* were susceptible to leaf spot

Key words: Turmeric, soil borne disease, crop rotation and yield
Received: 21-03-2018 Accepted: 30-06-2018

Turmeric (*Curcuma longa*) is a tropical crop grown in India, occupies the third position in its importance among spice crops and native to tropical South East Asia. The economic importance of turmeric is the dried rhizome. India has a 232.6 thousands ha area under turmeric cultivation with total production of 1189.90 thousand tons and productivity is 51.15q/ha (Anonymous 2014)). Turmeric crop is highly prone to several fungal diseases (Parthi, 2000). The serious foliar diseases reported in Uttar Pradesh are leaf spot caused by *Colletotrichum capsici* (Syd.) Butler & Bisby, and leaf blotch caused by *Taphrina maculans*, Butler. Crop rotation implies repeated sowing of the same crop in the cycle at periodical intervals because monoculture are not economically profitable to the farmers, it is due to same crop grown continuously in the same land becomes sick and unsuitable for cultivation. To overcome these problems, the work was planned to study the effect of crop rotation on management of soil borne diseases, growth and yield of turmeric.

The field experiment was conducted at Vegetable Farm, N.D. University of Agriculture and Technology, Kumarganj, Faizabad (UP),India during 2012-13 to 2015-16 in alluvial soil with six treatment *viz*; T-1: Monoculture of turmeric, T2: two year old crop without harvest, T3: Three year old crop without harvest, T4: Crop rotation turmeric- coriander- turmeric, T5: Crop rotation Turmeric – fenugreek – turmeric, T6: crop rotation turmeric - coriander – fenugreek – turmeric and three replication in randomized block design. The plot size was maintained 3.0 x 1.0 M size and spacing of turmeric was 30 x 20 cm. Other standard agronomical practices of crops were adopted during the experiment from sowing to harvest. Observations of turmeric diseases were recorded by using 0 -6 point scale (Palarpawar and Ghurde, 1989) from 25 October to 10 November every year. The disease severity was calculated using the formula suggested by Datar and Mayee (1981). Plant height and leaf length were measured from 15 December to 30 December. Fresh rhizome yield was recorded at the time of harvest and yield data was calculated q/ha.

The disease severity of colletotrichum leaf spot was maximum in three year old crop without harvest (56.8%) and minimum in crop rotation turmeric – coriander – fenugreek – turmeric (9.3%). The lowest percent disease severity of Taphrina leaf blotch was also in crop rotation turmeric – coriander – fenugreek –turmeric (9.33%) followed by turmeric – fenugreek – turmeric (12.46%), turmeric – coriander – turmeric(25.20%) and monoculture (34.26%). *Colletotrichum* leaf spot and *Taphrina* leaf blotch severity were significantly lowest in crop rotation and highest in three year old crop without harvest. Crop rotation minimised the survival ability of the pathogen due to lack of susceptible host in the soil. Results of present study revealed that continuous ratooning of turmeric crop enhanced the survival ability of pathogen due to presence of their regular living host that have increased the inoculums density Finding is supported with Shipton (1979). The maximum plant height was observed in three year old crop (112.73 cm) and minimum in monoculture of turmeric (76.56 cm). In case of leaf length, largest was recorded in crop rotation, turmeric – fenugreek – turmeric (49.96 cm) and smallest in monoculture (42.43 cm). The fresh rhizome yield was recorded maximum in crop rotation followed by three year old crop and monoculture crop. Monoculture crop provide the suitable environment for survival and spread of the disease inoculums which have been suppressed the growth and yield of turmeric (Curl,. 1963). Other hands crop rotation has increased antagonistic microorganism in the biotic environment because of rotational crop released different chemical residues on the decomposition substances that have favoured to plant growth with better nutritional availability.

It is concluded that four year crop rotation *viz*; turmeric – coriander – fenugreek – turmeric was found best cultural practice for management of diseases as well as higher growth and yield of turmeric. Because of

Key words: Cow products, Botanicals, management, Cercospora leaf spot, fenugreek

Received : 06-12-2017

Accepted : 27-12-2017

ABSTRACT

Cercospora leaf spot incited by *Cercospora traversiana* reported as the most destructive disease under suitable environmental conditions can cause 80 per cent reduction in yield. Seed treatment and foliar spray of cow urine, cow dung slurry, panchgavya and vanaspativash significantly decreased the percent disease intensity of Cercospora leaf spot. Percent disease intensity was recorded in seed treatment with cow Urine (13.43-33.31), cow dung slurry (13.46-35.24), Panchgavya (14.15-39.33), Vanaspativash (13.96-38.97) and Vanaspativash + cow urine+ cow dung slurry (15.51-40.29), in comparison to control (17.88- 41.34).). Foliar spray of organic treatment minimized the disease intensity from 20.08 – 21.73% in cow urine, 14.20- 22.22% in cow dung slurry, 15.55 to 22.02% in panchgavya and 14.90 – 19.50% in Vanaspativash over the control. Seed treatments and foliar spray of the organic treatments significantly increased the growth and yield of fenugreek viz. Plant height, primary branching, secondary branching and number of pods per plants and number of grain per pods. The organic treatment induced higher number of grain per pods (5.07 – 17.28%) and test weight of seed (5.46 – 13.72%) that have improve total grain yield of fenugreek (6.67- 42.62%).

The genus *Cercospora* is causing diseases in many plant species, some are economically important such as *Cercospora* leaf spot of palak caused by *Cercospora beticola* Sacc, leaf spot of peanut caused by *Cercospora arachidicola*, leaf spot of maize caused by *Cercospora zea - maydis* and *Cercospora* leaf spot of fenugreek (Zimmer, 1984). *Cercospora* leaf spots of fenugreek occurred at all the stage of plants and caused serious defoliation. Hence, considered as one of the destructive and wide spread disease of fenugreek (Acharya *et al.*, 2010). Panchgavya is an organic product for the potential source of nutrients to play important role for promoting growth and providing immunity in plant system (Pagar *et al.*, 2015). Biochemical properties of panchgavya revealed that it consist major plant nutrient like nitrogen, phosphorus, potassium and micronutrients necessary for plant growth. Thus panchgavya has been used for improving health and quality of fruit and vegetable, used as a foliar spray, soil treatment with irrigation and seed treatment (Natarajan, 2002). Cow product separately and collectively used as seed treatment and foliar spray could manage the *Cercospora* leaf spot and enhanced the growth and yield of fenugreek (Singla and Satwinder Kaur, 2016). Cow product has greatly checked the spread and spore germination of pathogen. Testing under controlled environmental conditions was done in detail, however in field condition, very few literature are available. Therefore study was carried out for management of *Cercospora* leaf spot of fenugreek with alternate management practices of cow products to enhance the yield.

MATERIAL AND METHODS

The trial was conducted in a Randomized Block Design with three replications and 11 treatments including check during *Rabi* season, 2016-17. The plot size was 2.0 X 2.4 m^2 accommodating six rows with row to row 20 cm and plant to plant distance 10 cm. Fresh cow urine and cow dung were collected in a sterile container from a local variety of cow, College of Veterinary and Animal Husbandry at Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad, Uttar Pradesh. The urine was filtered through Whatman No. 1 filter paper (to get rid of debris and precipitated material) and was stored in airtight container at 4°C temperature before use. Cow dung slurry was prepared with adding equal amount of water (w/v). Fresh five products *viz.* cow dung (3kg), cow urine (3L),

INTRODUCTION

Potato is an annual, herbaceous plant belonging to the family Solanaceae. It contains about 79% water, 18% starch, 2% protein, 1% vitamins, minerals and many trace elements. Potato is the world's leading vegetable crop. It is grown in about one hundred and forty countries (Haase, 2008). Cultivation of potato is influenced by the abiotic and biotic (mesobiotic) stresses including viruses. Number of viral diseases has been reported on this crop by several workers in the world, which produced various Robert *et al.* (2000) used some epidemiological approaches to the control of aphid borne viral diseases i.e. PVY (Poty virus Y) and PLRV (Potato Leaf Roll Virus) in seed potato crops in northern Europe. PVX causes mild mosaic, interveinal chlorosis and rugosity and sometimes top necrosis. Infected plants produce few tubers which are smaller and under sized. PVX is a latent virus, therefore, sometimes unable to identify on symptom basis. About twenty viruses are known to infect potato. While most important are PVX, PVY and PLRV which cause severe damage to potato crop in Pakistan. In Pakistan, potato crop losses were reported up to 83% due to viruses (Mughal and Khalid, 1985). Severe infection can reduce yield by 40 – 70% (Purcifull and Edwardson, 1981). Potato virus X (PVX) infects more than 200 plant species, majority of which belongs to family Solanaceae (Wustman, 1978). Losses due to PVY lie between 58-83% in Pakistan (Khalid et al., 2000). It induces severe mosaic, rugosity, crinkling, necrosis and affected plants produce small size tubers. Khan (2001) studied the major potato viruses (PVX, PVY

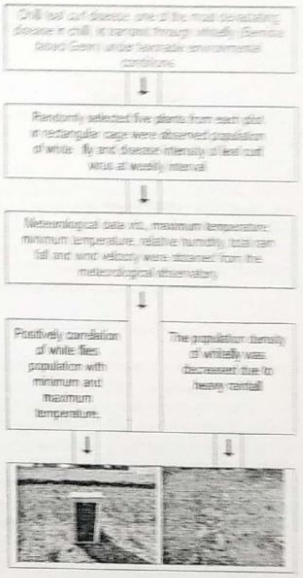
Abstract

Aim : Chilli (Capsicum annum) is an important spice crop cultivated all over the world. The importance of chilli leaf curl disease has been recognized for many years because it is one of the most devastating disease in chilli growing area and transmitted through the vector whitefly (Bemisia tabaci Genn) under favorable environmental conditions. The present study was conducted to study the effect of meteorological factors on whitefly population and incidence of chilli leaf curl virus disease.

Methodology : A rectangular cage was formed by ply wood and fiber glass. The ply wood plate was cut according to required size and made in rectangular form. Randomly selected five plants of each plot in rectangular cage were observed population of white fly and disease intensity of leaf curl virus at weekly interval starting from 20 days after transplanting at the morning hours (6-7 a.m.) on the defined day. Meteorological data viz., maximum temperature, minimum temperature, relative humidity, total rain fall and wind velocity were obtained from the meteorological observatory, Narendra Dev University of Agriculture and Technology, Faizabad.



Results : The first appearance of white fly was recorded on 10th standard week and rapid progress of white fly population was recorded from 11th standard week to 17th standard weeks in 2014 and 18th week in 2015. The increase in white fly population was positively correlated with minimum and maximum temperature. Disease incidence of chilli leaf curl virus was significant and positively correlated with white fly population (r=0.93 in 2014 and r=0.89 in 2015). The maximum percent leaf curl increase was observed on 19th standard week when white fly population was highest in the field.

Interpretation : The increase or decrease of leaf curl virus disease of chilli was directly correlated with vector population and vector population was determined by environmental factors. It is concluded that whitefly population and leaf curl incidence increased with increasing the temperature, as well as relative humidity and decreased with the occurrence of rainfall.

EFFICACY OF PLANT EXTRACTS WITH DIFFERENT SOLVENTS AGAINST *TAPHRINA* LEAF SPOT OF TURMERIC

R. S. Mishra

College of Agriculture, Azamgarh N.D. University of Agriculture & Technology, Kumarganj, Faizabad-224229 (UP)

Abstract

Taphrina leaf spot is widely distributed in the genetic plains of Uttar Pradesh and Bihar. The foliar destruction due to leaf spot reduces the yield considerably when the disease starts in its early stages of crop growth. The herbal formulations have been described for the use in medicinal and agricultural applications. Hence field studies were carried out to select plant extracts with suitable solvent for reducing the leaf spot disease of turmeric. Plant extract with cow urine was resulted lowest disease intensity in neem (47.5%), garlic (48.4%) and onion (50.7%) followed by water based extract of neem (48.1%), onion (44.9%) and garlic (54.1%) where as highest in acetone based extract of neem (49.3%), onion (50.0%) and garlic (53.4%). The plant growth and yield of turmeric were found highest in cow urine based plant extract as compared with acetone and distilled water based plant extract.

Key words: Turmeric, *Taphrina*, leaf spot disease, cow urine, plant extracts and yield

Introduction

Turmeric (*Curcuma longa*) is a tropical crop grown in India, occupies the third position in its importance among spice crops and native to tropical South East Asia. The economic importance of turmeric is dried rhizome. India has a 232.6 thousands ha area under turmeric cultivation with total production of 1189.90 thousand tons and productivity is 51.15q/ha (Anonymous, 2014). Turmeric crop is highly prone to several fungal diseases (Purthi, 2000). The serious foliar diseases reported in Uttar Pradesh are leaf spot caused by *Colletotrichum capsici* (Syd.) Butler & Bisby, and leaf spot caused by *Taphrina maculans*, Butler. *Taphrina* leaf spot was known to report from Gujarat, Saharanpur (UP) and Rangapur in 1911. It is widely distributed in the gangetic plains of Uttar Pradesh and Bihar. The foliar destruction due to leaf spot reduces the yield considerably when the disease starts in its early stages of crop growth. The farmers are growing local clones for their desirable aroma, colour and palatability. These clones are susceptible to the disease leaf spot diseases.

The application of chemical fungicides are producing hazardous consequences in term of soil pollution, reducing the quality of arable land and ground water (Bezbaruah, 2000) and bio-pesticides are usually inherently less toxic than conventional pesticides (Singh, 1999). They generally affect only the target pathogenic organism, in contrast to broad spectrum fungicides. Fresh plant extracts from different plant parts are becoming valuable for management of the pathogens, which can be easily prepared by farmers. Cow's urine is an important constituent of Panchgavya and is used in several Panchgavya formulations (Okigbo and Nameka, 2005). Cow's urine based Nigerian herbal formulation was prepared with the use of several herbs like tobacco, garlic, lemon juice and bulbs of onion. These herbal formulations have been described for the use in medicinal and agricultural applications. (Fulzele *et al.*, 2001). Keeping in view, field studies were carried out to select suitable management practices for reducing the leaf spot disease of turmeric.

Abstract

Turmeric (*Curcuma longa*) is a tropical crop grown in India, occupies the third position in its importance among spice crops. The economic importance of turmeric is the dried rhizome. Turmeric crop is highly prone to several fungal diseases. The serious foliar diseases reported in Uttar Pradesh are leaf spot caused by *Taphrina maculans*, Butler. The foliar destruction due to leaf spot reduces the yield considerably when the disease starts in its early stages of crop growth. The herbal formulations have been described for the use in medicinal and agricultural applications. Hence, field studies were carried out to select plant extracts with suitable solvent for reducing the leaf spot disease of turmeric. The present study showed that all treatments were significantly superior over control for management of *Taphrina* leaf spot of turmeric in field condition. Among the treatment cow urine based botanical formulation was most effective at 90 days (44.04%) in comparison to acetone based botanical formulation (37.22%) and distilled water based botanical formulation (45.61%).

Key words : *Taphrina maculans*, leaf spot, turmeric, plant extracts, cow urine, growth, yield.

Introduction

Turmeric is very important spice in India, which produces nearly entire whole world crop and consumed 80% of it. India is by far the largest producer and exporter of turmeric in world. It has versatile uses in flavoring, dye making, drug preparation, cosmetics and medicine. Around 100 active constituents have been recorded from turmeric. This herbal plant is highly prone to several fungal diseases; one of them is Taphrina Leaf spot disease, caused by *Taphrina maculans*. The disease manifests whole leaves and reduces heavy yield loss. Managing the disease solely through the use of chemical pesticides being undesirable because of the associated risks of environmental pollution and human health, there is an all-round compulsion to go in for bio-rational alternatives. Eco-friendly disease management holds substantial importance in spice crop as most of them consumed as for direct spice purposes. Considering all these points and importance of crop, the present investigation was taken up to generate information regarding the cause of disease and tested various plant extract and mixture of these plant extract with cow urine, acetone and distilled water to find out management sources against the disease.

* *Author for correspondence :* E-mail: drramsumanmishra@gmail.com

Materials and Methods

Plant species Madar (*Calotropis procera*) and Dhatura (*Datura stramnium*) free from any disease were selected on the basis of their antifungal properties reported elsewhere and easy availability round the year in the field. The effectiveness of cow urine, acetone and distilled water based plant extracts were tested against naturally occurring year to year *Taphrina* leaf spot of turmeric in field experiment. Concentration of plant extract was selected on the basis of *in vitro* experiment on *Colletotrichum*. The field experiment was conducted at vegetable farm, Narendra Deva University of Agriculture and Technology Kumarganj Faizabad during 2014 to 2016 in sandy alluvial soil with having low organic matter and high ph 8.5. NDH-1 is susceptible variety to Taphrina leaf Spot and showed disease incidence ranging from 42.8 to 79.3% under natural condition (previous year)

EVALUATION OF TURMERIC GENOTYPES FOR QUALITY, YIELD AND DISEASE RESISTANT

R. S. Mishra

Department of Plant Pathology, N.D. University of Agriculture and Technology, Kumarganj -224229, UP, India

*Corresponding author: drramsumanmishra@gmail.com

ABSTRACT

Turmeric (*Curcuma longa* L.) is one of the important spice crop cultivated in tropical and subtropical countries of the world. India is the world's largest producer of turmeric and accounted 80 percent of the world's production; it occupies 6 percent area under turmeric cultivation. Productivity of this crop is low due to its cultivation on marginal lands with low fertile level, lack of improved varieties, production and protection technology. Among various diseases attacking to turmeric crop, Taphrina leaf blotch (*Taphrina maculans*) and *Colletotrichum* leaf spot (*Colletotrichum capsci*) are the most destructive disease. Out of 37 evaluated genotype three genotypes viz; NDH-136, CL-32 and ACC-79 were found moderately resistant for both *Colletotrichum* leaf spot and *Taphrina* leaf blotch disease. The percent disease intensity of leaf spot was 17.93-21.40, leaf blotch 17.30 - 23.80, curcumin 3.6- 4.8%, essential oil 6.0 – 6.8% and oleoresin 10.09 – 12.72%. Nine genotypes NDH-8, NDH-11, NDH-68, NDH-74, NDH-79, Pratibha, CSTH-9, MEDUKAR, and CL-34 were found moderately resistant for leaf spot with curcumin content 4.1-4.6%, essential oil 6.0 – 6.8% and oleoresin 10.56 - 11.90%.

KEYWARDS: Turmeric, Genotypes, Foliar diseases, Yield, Curcumin, Oleoresin, Essential oil.

INTRODUCTION

Turmeric (*Curcuma longa* L.) is one of the most important spice crops cultivated in India. It is a rhizomatous herbaceous perennial plant of the family Zingiberaceae. Turmeric is used in flavoring, dye making, drug preparation, cosmetics and medicine (Jagtap *et al*., 2013). The annual production of turmeric in India is about 1062.5 thousands metric tonnes on area 199.0 thousands hectare. In Uttar Pradesh, the area covered under turmeric cultivation is 1828 ha with production of 5149 mt tonnes (Anonymous, 2012). This crop is highly prone to several fungal diseases (Naidu, 1988; Purthi, 2000). The serious foliar diseases on turmeric reported in UP are leaf spot caused by *Colletotrichum capsici* (Syd.) Butler & Bisby and leaf blotch caused by *Taphrina maculans* Butler. The foliar destruction due to leaf blotch reduces the yield considerably when the disease starts in its early stages of crop growth. Leaf spot incited by *Colletotrichum capsici* reduces the yield in tune of 15-60% (Pruthi, 1998) and dry rhizome yield 62%. The farmers are growing local clones for their desirable aroma, colour and palatability. These clones are susceptible to the disease. The experiments were conducted to evaluate the promising genotypes of turmeric to find out the effective management tools for overcome of yield losses due to *Taphrina* leaf blotch and *Colletotrichum* leaf spot disease of turmeric. The drug yielding qualitative traits of turmeric were also studied to find out the promising elite genotypes in terms of high curcumin, oleoresin and essential oil content.

MATERIALS AND METHODS

The field experiments were conducted at Vegetable Research Farm, N.D. University of Agriculture & Technology, Kumarganj, Faizabad from 2015-2017 in sandy loam soil with leaf spot disease susceptible NDH-1 variety. The trial was laid out in randomized block design with 37 genotypes and three replications for evaluation against foliar diseases quality and yield. Rhizomes were planted on raised beds of 3 x 1 M size at spacing of 30 x 20cm in the first forty night of June. The other normal agronomical practices were adopted to raise the crop as and when necessary. The observation of leaf spot and leaf blotch intensity were recorded at 105 DAP on 10 randomly selected plants in each replication for disease scoring. The disease rating was recorded by adopting 0-6 scale (Palarpawar and Ghurde, 1989), where 0= No infection (Healthy plants), 1= 0.1 to 10 percent leaf area infected, 2= 10.1 to 20 percent leaf area infected, 3= 20.1 to 30 percent leaf area infected, 4= 30.1 to 40 percent leaf area infected, 5= 40.1 to 50 percent leaf area infected, 5= More than 50 percent leaf area infected. The percent disease intensity (PDI) was calculated according to the formula suggested by Datar and Mayee (1981) given as below:-

$$PDI = \frac{\text{Sum of rating of infected leaves in plant}}{\text{Total no. of leaves observed x maximum disease score}} \times 100$$

Received: August 07, 2019; Revised: August 26, 2019; Accepted: August 27, 2019; Published: August 30, 2019

Abstract: Fenugreek (*Trigonella foenum-graecum*) is self-pollinated crop. It occupies a prime position among various seed spices grown in India. The plant leaves and seeds are widely consumed in Indo-Pak subcontinent. Fenugreek is high influence of environment on the morpho-physiological expression, therefore the aim of this work to develop new high yielding variety to perform uniformed under different environmental condition. High yielding genotype (NDM-69) was identified among the pooled germplasm of N.D. university of Agriculture & Technology Ayodhya by selection methods. The NDM-69 was evaluated for alkalinity and disease tolerance under natural field condition. This genotype has been tested at 13 centres under AICRP on Spices for yield potential. On the basis of data collected from the different centre variety Narendra methi-2 (NDM-69) has been recommended for release in the workshop of AICRP on Spices. Narendra methi-2(NDM-69) has been tested with national check Hisar Sonali and found 14.74 percent high seed yield. The yield was found variable in location to location due to variance of environmental condition .On the basis of pooled seed yield of fenugreek entries tested under the coordinated varietal trial goes 1st rank to UM-354, 2nd to AFg-5 and 3rd to NDM-69.The variety has shown strong genetic stability under different environmental conditions which can face the natural challenges and remain sustainable to produce good seed yield.

Introduction

Fenugreek (*Trigonella foenium graecum* L.) locally known as Methi is an important multipurpose winter season seed spice crop mainly grown in Rajasthan, Gujarat, Madhya Pradesh Maharashtra, Uttar Pradesh, Haryana, Punjab and Bihar. The seed of fenugreek are used as a nardiment and seasoning agent of garnishing and flavourings dishes and it has many medicinal properties like diuretic, tonic, carminative and aphrodisiac [1]. .Its tender leaves are consumed as leafy vegetable, chopped leaves are mixed in flour to prepare Paratha [2]. In India fenugreek is covering an area 93090 ha with an annual production and productivity of 112645 tonnes and 1212.2 kg/ha, respectively in year2012-13 [3]. The production potential of the crop has not been fully exploited due to lack of high yielding variety with resistant to biotic and abiotic factors. It is well known that phenotype is the product of interaction between environment and genotype. A particular genotype may express its full genetic potential only under optimum environmental conditions. Therefore, it has been observed that relative performance in a set of varieties is altered, when comparisons are made over series of environments. Stability in the performance is one of the most desirable characteristics of a genotype to be released as a variety for wide commercial cultivation and that is one of the major objectives in this programme to develop stable variety so that effects of environment on yield can be minimized. Therefore, the present investigation was planned to test newly bred lines of fenugreek for their high yield under different centre across the India.

Materials and Method:

The experimental material for present investigation was comprised sixty diverse elite lines viz:JFg 245, JFg 266,AFg 5,AFg 6, LFC 98, LFC 93 and HM 259 ,HM 280-1, UM 202, UM 354 NDM 69, NDM 72, RM 188, RM 194, Hisar sonali (NC), RMI 361 (NC) of fenugreek.

The seed materials of fenugreek genotypes were obtained from coordinated unit of AICRP on spices IISR, Kozhikode Kerala, India. The crop was sown during *rabi* 2012-13 to 2014-15 under central varietal trial (CVT) in all 13 centers viz. Ajmer, Jobner, Kota, Hisar, Jagudan, Pantnagar, Jabalpur, Dholi, Raigarh, Coimbatore, Guntur, Navsari, Kumarganj. This fenugreek line was evaluated 2.0 x 2.4 m^2 area. Row to row and plant to plant distance was kept 30 cm and 10 cm respectively in randomized block design (RBD) with three replications of each genotype at each centre. All the recommended package and practices were followed to raise the good normal crop. In addition to it, variety Narendra Methi-2 has been tested at Vegetable farm, N. D. University of Agriculture and Technology, Kumarganj, Faizabad from 2007 to 2012in the name of NDM-69.. It was also grown at different KVKs and formers field. The percent disease intensity of downy mildew was recorded at second week of March using 0-4 scale given by earlier workers. The tested entries were graded 0- No disease symptoms, 1- Resistant, 2- Moderate resistant, 3- Susceptible, 4- Highly susceptible. Growth data were recorded at the time of 50% flowering. The yield data were recorded after the harvest.

Alkalinity tolerance

The experiment has been conducted during *rabi* 2006-07 to2008-09 to identify alkalinity tolerance genotypes under greenhouse condition at 10, 20, 30 and 40 ESP level. Ten fenugreek genotypes were sown at each ESP level in three replications. Twenty seeds were sown in each pot at the depth of 2 cm. Standard agronomical practices were followed during the experiment. Yield data per plants were observed at the maturity of the seed

Results and Discussion

Narendra methi-2 has been tested from 2007-08 to 2011-12 with national check Hisar Sonali across 41 location [Table-1] revealed 14.74 percent high seed yield.

EFFICACY OF FUNGICIDES AGAINST POWDERY MILDEW OF CORIANDER

R. S. Mishra*

Department of Plant Pathology, N.D. University of Agriculture and Technology Kumarganj-224229, Faizabad, (U.P.)

*Email: drramsumanmishra@gmail.com

Received : 25.11.2018 Accepted : 11.12.2018

Coriander (*Coriandrum sativum* L.), a native of Mediterrian region is now commercially grown as spice crop in India. India is the biggest producer, consumer and exporter of coriander in the world with producing 482 thousands metric tonnes from the 5305 thousand hectares and productivity of 0.9 metric tonnes per hectare in 2011-12 (Anonymous, 2012). Major coriander growing states are Andhra Pradesh, Karnataka, Rajasthan, Gujarat, Madhya Pradesh, Uttar Pradesh, Bihar and Rajasthan. The aromatic odour and taste of coriander fruits are its essential oil containing 0.03 to 2.6 percent (Nadeem *et al.*, 2013). Coriander seeds are used as culinary herb. Although, the area and production of coriander is increasing year after year but the productivity is stagnant in spite of development of high yielding varieties and improved package of production technology. One of the major reasons behind this fact is the incidence of many diseases. Powdery mildew disease caused by *Erysiphe polygoni* is an important disease in coriander growing area of Madhya Pradesh and adjoining districts of Rajasthan and Uttar Pradesh. The disease is air borne and survives in the form of chlamydospore. The disease symptoms appear in the form of white circular patches on young parts of stems, branches, leaves, petioles and fruits, which causes severe yield losses and also deteriorate the quality of seeds. Powdery mildew disease reduces the plant growth and increased the flower drop which reduced seed formation. Affected field showed 20 -30 percent less seed production. Breeding effort to high yielding varieties with resistant to powdery mildew disease in coriander are very limited, therefore control of powdery mildew is difficult because of its air borne nature and rapid disease development with intensive cultivation of the susceptible host crop and recurrence of the disease in the same field led to explore the possibility of new generation fungicides against powdery mildew.

The experiment was conducted at Vegetable farm of N.D. University of Agriculture and Technology Kumarganj, Faizabad, (UP), India during 2014-15 to 2016-17 with thirteen treatment *viz;* T1= One foliar spray of Tebuconazole (0.1%), T2=One foliar spray of Propineb (0.2%), T3= One foliar spray of Azoxystrobin (0.1%), T4= One foliar spray of Wettable sulphur(0.2%), T5= foliar spray of Hexaconazole(0.1%), T6= One foliar spray of Propiconazole(0.1%), T7= Two foliar spray of Tebuconazole (0.1%), T8= Two foliar spray of Propineb (0.2%), T9= Two foliar spray of Azoxystrobin (0.1%), T10= Two foliar spray of Wettable sulphur(0.2%), T11= Two foliar spray of Hexaconazole(0.1%), T12= Two foliar spray of Propiconazole(0.1%), T13= Control with local powdery mildew susceptible genotype NDcor-5. The trials were laid out in randomized block design with three replications. The crop was grown during *Rabi* every year following recommended package of practices. The first spray of fungicides was given at the time of first disease symptoms appearance and second spraying was done after 15 days of first spray. Data were recorded days to maturity and yield q ha^{-1}. Powdery mildew disease was assessed on a 0-4 scale (0= no disease symptoms and 4= all the plant parts are covered with white powdery mass) as described earlier Kalra *et al.*, (1995). The data of percent disease severity of powdery mildew was recorded 15 days before harvesting.

Spraying of tebuconazole, propineb, azoxystrobin, wettable sulphur, hexaconazole and propiconazole significantly increased the yield of coriander over control and was found superior two foliar sprays over the single spray (Table 1). The minimum mean disease severity of 2014-15 to 2016-17 was recorded 8.27% in two foliar spray of tebuconazole (0.1%) followed by 8.94% in two foliar spray of propineb (0.2%), 10.93% in two foliar spray of wettable sulphur (0.2%) and 11.0% in two foliar spray of azoxystrobin (0.1%) in comparison to single spray of tebuconazole (PDS-57.23), propineb (PDS-48.12), wettable sulphur (PDS-46.91), hexaconazole (PDS-49.78), propiconazole (PDS-51.14) azoxystrobin (PDS-52.41). The yield of coriander was significantly increased in all fungicide spray in comparison to control. The highest mean yield of 2014-15 to 2016-17 was found 11.09 q/ha in two spray of tebuconazole followed by 9.67q/ha in two spray of azoxystrobin,9.66q/ha in two spray of propineb and 9.43q/ha in two spray of wettable sulphur. The yield was significantly higher in all two sprays of fungicides than single spray of fungicides. In 1929-30, powdery mildew caused by *E.polygoni* has been reported to be controlled by timely dusting of sulphur

Abstract: Turmeric is a sacred spices of India is seriously affected by foliar diseases caused by *Taphrina maculans* and *Colletotrichum capsici*. Although the diseases can be kept under check with repeated chemical sprays, but excessive use of fungicides pose a threat due to pollution and health hazards, which thereby attempt have been made to evaluate 15 accession of turmeric against foliar diseases. Among them NDH-128 have been found tolerant against *Colletotrichum* leaf spot (14.2 PDI) and *Taphrina* leaf blotch (25.8 PDI) diseases with good rhizome yield. However NDH-123 was tolerant against Taphrina leaf blotch and NDH-130 for *Colletotrichum* leaf spot. NDH-135 gave higher fresh rhizome yield (40.66 t/ha).

Introduction

Turmeric (*Curcuma longa* L.) is one of the most important spice crops cultivated in India. It is a rhizomatous herbaceous perennial plant of the family Zingiberaceae. Turmeric is used in flavouring, dye making, drug preparation, cosmetics and medicine [1]. The annual production of turmeric in India is about 1062.5 thousand metric tonnes on an area of 199.0 thousand hectares. In Uttar Pradesh, the area covered under turmeric cultivation is 1628 ha with a production of 5149 MT tonnes [2]. This crop is highly prone to several fungal diseases [3,4]. The serious foliar diseases on turmeric reported in UP are leaf spot caused by *Colletotrichum capsici* (Syd.) Butler & Bisby and leaf blotch caused by *Taphrina maculans* Sutler. Among them, leaf spot is the most important disease of turmeric resulting to losses of 25.83 to 62.12% fresh weight and 42.10 to 62.10% dry weight of rhizomes, respectively [5,6]. Keeping in view of economic importance of the crop and disease, efforts were made to evaluate various turmeric accessions for tolerance to foliar diseases.

Materials and Methods

Experiment was conducted at N.D. University of Agriculture & Technology, Kumarganj, Faizabad from 2014-2017 in sandy loam soil with leaf spot disease susceptible the variety NDH-1. The trial was laid out in randomized block design with 15 turmeric accession and three replications. Rhizomes were planted on raised beds of 3 x 1m size at a spacing of 30 x 20 cm in the first fortnight of June. The other normal agronomical practices were adopted to raise the crop as and when necessary. The observation on germination was recorded at 30 DAP, leaf spot intensity was recorded 105 DAP on 10 randomly selected plants in each replication. The disease rating was recorded by adopting 0-5 scale (Pallampawar and Ghurde, 1989), where 0= No infection (healthy plants), 1=0.1 to 10 % leaf area infected, 2=10.1 to 20 percent leaf area infected, 3=20.1 to 30 % leaf area infected, 4=30.1 to 40 percent leaf area infected, 5=40.1 to 50 %leaf area infected, 5= More than 50 % leaf area infected. The percent disease intensity (PDI) was calculated according to the formula suggested by Dalal and Mayee (1981) [7]. The yield of turmeric (fresh rhizome) in each treatment was recorded after harvest. The data obtained in all the experiments were statistically analyzed.

Results and Discussion

Susceptibility of foliar diseases is variable among the accessions as usual characteristics of the turmeric plants. Accession NDH-123 was found tolerant against Taphrina leaf blotch with 25.17 percent disease intensity, NDH-128, NDH-124 and NDH-131 were found comparable with that of a NDH-123 recording 30.40-32.53 percent disease intensity of Taphrina leaf blotch. NDH-128 accession showed tolerant against Colletotrichum leaf spot (14.2 PDI) and Taphrina leaf blotch (25.80 PDI). Other accession NDH-130, NDH-123, NDH-129 and NDH-131 were also found better tolerant against Colletotrichum leaf spot with 25.9 -26.1 PDI. Rest of the accessions were considered as moderate susceptible to susceptible for both foliar diseases. In case of fresh rhizome yield, a considerable variation was existed among the accession because it is collected from different ecological situations. NDH-135 accession produced highest rhizome yield 40.66 t/ha followed by NDH-136 (37.11t/ha), NDH-134 (36.10 t/ha) and NDH-130 (35.55 t/ha). Wide variability existed among the accession were supported by earlier workers [8-10]. Yield of turmeric varies from place to place due to genetic variability and influence of environment [11]. It is concluded that cultivation of tolerant variety (NDH-128) will be beneficial not only for reducing the losses due to foliar diseases but also improves the quality and yield of turmeric.

Conclusion

NDH-128 accession was found tolerant against both foliar diseases which is a major limiting factor for cultivation of turmeric.

Application of research: NDH-128 will be useful for the farmers where foliar diseases occurring year to year and causing huge yield loss.

Effect of organic treatments on total phenol, Saponin and flavonoids in leaf spot infected fenugreek leaves

RS Mishra

Abstract
Fenugreek (*Trigonella foenum graecum* L.) is an important medicinal crops cultivated throughout the world. Increasing demand of medicinal plants for the pharmaceutical industry, is required to boost the production of fenugreek with minimized the infection of diseases which reduces the huge yields. therefore present study was conducted to determine the effect of organic treatments on secondary metabolites. The total phenol in healthy leaves was maximum in seed treatment with cow urine@10 %(12.24µg/g) followed by foliar spray of cow urine (11.47 µg/g) and panchgavya (11.37 µg/g). Flavonoid content was observed highest in cow urine (4.11 µg/g) and lowest in vanaspativash (2.17 µg/g). Whereas saponin content was recorded higher in seed treatment withcow urine (15.33 µg/g) and lower in foliar spray of vanaspativash (13.06 µg/g). Percent disease intensity of Cercospora leaf spot was 33.29% in seed treatment with mixture of vanaspativash, cow urine and cow dung slurry and maximum in control 41.34%.

Keywords: Fenugreek, *Cercospora*, leaf spot, organics, biochemicals

Introduction
Cercospora traversiana is only species of the *Cercospora* that can infect fenugreek (Ryley, 1989) [11]. The disease is uniformly distributed throughout the field grown for seed production. In severely infected plants only a few upper leaves remained survive. The sign of disease symptoms were surrounded by yellowish halo on older leaves stem and pods (Mishra and pandey, 2013) [6]. Fenugreek leaves and seeds have been used extensively to prepare extract and powder for medicinal uses (Basu *et. al.*, 2003). The medicinal value lies in the form of secondary metabolites produced in plants are low molecular weight in natural products. Saponin, flavonoids and total phenolics compound are widely distributed in fenugreek plants that have exerted multiple biological effects including antioxidant, free radical scavenging, anti-inflammatory and anti carcinogenic. The accumulation and oxidation of secondary metabolites are associated with defence mechanisms in plants are also known to increase especially during fungal infections (Gasper *et al.*, 1982) [4]. The activities of phenolics related enzymes and the accumulation of phenolics have been correlated with resistance to biotic stresses (Mohammad and Kazemi, 2002) [7]. Investigation in disease physiology may provide in depth understanding of host pathogen interaction. This study was therefore designed to biochemically analyse with *Cercospora* leaf spot infected fenugreek plants at maturity stage in comparison to healthy ones.

Materials and Methods
The experiment was conducted at main experiment station (MES), Department of Vegetables Science, Narendra Deva University of Agriculture & Technology, Kumarganj Faizabad during 2015-16 to 2016-17. Experimental field was sandy loam, slightly alkaline soil (pH 8.0), low in organic carbon and nitrogen, medium in phosphorus and potassium. The mechanical composition of soil constituted 64.4 per cent sand, 27.8 per cent silt and 11.3 per cent clay. Trial was conducted in a randomized block design with three replication, 11 treatments and fenugreek variety Hisar sonali was sown @ 50 g seed/plot. Seeds were sown in 3.0 X 2.4m plot size on 30 November each year with 20 X 10 cm spacing. The layout of the experiment in detail is T_1: Seed treatment with cow urine @10% concentration,T_2: Foliar spray of cow urine @10% concentration at 60 and 90 days after sowing (DAS),T_3: Seed treatment with cow dung slurry @10% concentration,T_4: Foliar spray of cow dung slurry @10% concentration at 60 and 90 days after sowing (DAS),T_5: Seed treatment with panchgavya@10% concentration,T_6: Foliar spray of panchgavya@10% concentration at 60 and 90 days after sowing (DAS), T_7:

Leaf curl disease of *Capsicum annuum* and its impact on secondary metabolites

AN Chaubey and RS Mishra

Abstract
Leaf curl disease of *Capsicum annuum* has been recognized serious problem, wherever crop is grown. Experiment was designed to observe the leaf curl incidence and biochemical changes in infected and healthy plants of nine cultivars. The lowest leaf curl incidence was recorded 2.27% and highest 85.83%. The chlorophyll content were found highest in healthy leaves (0.684 mg g^{-1}) then infected leaves(0.511 mg g^{-1}).Whereas, total phenol content was significantly lowest in leaf curl infected leaves (5.582 mg g^{-1}) as compared to healthy leaves (7.544 mg g^{-1}). The average total tannin content was observed significantly higher in healthy leaves (4.028 mg g^{-1}) as compared with infected leaves (3.128 mg g^{-1}). Out of nine cultivars total phenol (9.905 mg g^{-1}) and tannin (5.27 mg g^{-1}) contents were found maximum in Gucchedar.

Keywords: *Capsicum annuum*, Leaf curl virus, incidence, chlorophyll, phenol, tannin

Introduction
Chilli (*Capsicum annuum* L.) is an important spices crop belongs to the family solanaceae and is one of the important widely cultivated crops grown for the value of its green and ripe fruits in India. India is rich in maximum diversity of chilli varieties with differing habit, size, shape, colour and pungency of fruit. Besides, traditional use of chilli as vegetables, spices, condiments, souces and pickles, it is also used in pharmaceuticals, casmatics and beverages [24]. India produces approximately 12.60 thousands metric tonns from an area of 792.1 thousands hectare [1]. Uttar Pradesh occupies an area of 13.47 thousand hectares with production of 10.30 metric tonns [1]. The yield of chilli is much lower than potential yield of improved varieties, it is due to several other factors, lack of improved varieties against incidence of different pest and diseases are the main constraints for getting low productivity [8]. Viral diseases of plants cause economic losses to the tune of 15 billion dollars per annum on global basis [25], particularly in tropical and semitropical regions. These provide ideal conditions for the perpetuation and transmissions of viruses through vectors. Natural occurrence of several viruses have been reported on chilli (*Capsicum annuum* L.) by various workers [14], among them leaf curl virus has been reported most destructive for chilli, tomato, potato, okra, cotton and cucumber cultivation in terms of incidence and yield losses [11]. Leaf curl virus affecting chilli in India was first reported from Jodhpur during December, 2004 and emerged as a serious problem in major chilli growing area of Rajasthan with very high disease incidence upto 100 per cent plants infection in farmers' fields [18]. Leaf curl virus is a member of genus *Begomovirus,* family geminiviridae. The genome of *Begomoviruses* have a single or double stranded circular DNA of c. 2.7kb, which is encapsulated in a quasi-isometric geminate particles of C.20-30nm. During the past two decades, agricultural intensification has resulted *Begomoviruses* inciting disease out breaks in tropical and subtropical regions, causing 80 per cent yield losses of many crops [20]. The leaf curl disease was first reported from India on tomato by Vasudeva and Samraj [26]. The virus is transmitted in nature by the white fly (*Bemisia tabaci*) in a semipersistant (Circulative) manner. The minimum acquisition and inoculation feeding periods are 15-30 minutes, the latent period in the vector is more than 20 hours and virus is retained by the vector upto 20 days. Single white fly can carry a finite number of virions in the range of 600 million [27]. The investigation of plant responses to elicitors is one of the most rapidly developing lines of injury in the plant physiology. The elicitors stimulate the contact between plants and phytopathogens and thereby trigger defensive mechanisms that constrain the invasion of pathogenic viruses. The phenol and tannins are more studied biochemical, which regulate the expression of resistance genes and induced its synthesis in plant [23]. These techniques for the detection of chlorophyll, phenol and tannin have provided an opportunity to develop methods for the diagnosis of plant resistance.

Assessment of occupational health hazards among farm workers involved in agricultural activities

Pragya Ojha and Abha Singh

Abstract
Indian Farm workers are highly involved in various agricultural operations. They perform a sequential work through manual efforts. In the present investigation efforts have been made to assess the occupational risk related to various agriculture activities and to compare the physical strength of male and female farm workers, during manual method to perform agricultural operations. For the study, twenty female and twenty male subjects were selected. From this study, it has been recommended that there is dire need to create awareness among the farm workers about the low cost improved technologies related to flower cultivation which can significantly improve the livelihood security and working conditions of farm workers. It will also reduce the level of occupational risk and enhance the physical strength of the workers.

Keywords: Occupational risk, Physical strength, Agricultural Workers, Agricultural Activity

Introduction
In the context of occupational safety and health, the term 'agriculture' is generally used in a broad sense including all activities directly related to cultivating, growing, harvesting and primary processing of agricultural products, animal and livestock breeding including aquaculture, and agroforestry. Agricultural work is dangerous; workers in this industry have among the highest rates of fatalities (BLS, 2014 and Liabman *et al.* 2013). Furthermore, Wang *et al.* (2013) also mentioned that work in agriculture involves exposures to a variety of hazards, including dust, noise, thermal stress, pesticides and other chemicals, and ergonomic risk factors. As a result, agricultural workers have elevated rates of injuries and illnesses. Das *et al.* (2011) also supported that agricultural works are associated with several occupational disorders among the farmers and agriculture farming involves several types of hazardous activities including prolonged and awkward postures. Agriculture workers perform many strenuous activities. These are: spading, carrying seeds, uprooting, transplanting saplings, harvesting or cutting crops, sheafing, carrying crops, threshing, sweeping and winnowing. Therefore, the main aim of this investigation was to know the level of occupational health hazards among agriculture workers and an attempt was made to compare the physical strength of male and female farm workers during the performance of work.

Materials and Method
Selection of subject and field
From Faizabad district of Uttar Pradesh state, India, twenty male and twenty female subjects with normal health, without any major illness or cardio-vascular problems were purposively selected because only without illness or cardio- vascular problems, agricultural workers can perform the activities more efficiently. This study was conducted in the month of February-August in the year of 2016. The age range of the selected subjects was 20-55 years. Care was taken to select the female farm workers who were non pregnant and who can perform the agricultural activities regularly. The agricultural operations were performed for 7:00 A.M to12:30 P.M. and 2:00 P.M. to 5:30 P.M. Agriculture workers performed the continuous agriculture operations for 50 minutes and taking 10 minutes break.

Calibration of subjects: The subjects were calibrated with the Body Mass Index to determine their physical fitness index. The body mass index of subjects was calculated by dividing square of height (m2) to weight (kg).

Quantification of safety and Health Hazards
Semi quantitative observational tool to characterize safety and health hazards developed by Neitzel *et al.* (2014) has been used to quantify the level of safety and health hazards among

ASSESSMENT OF MUSCULO-SKELETAL DISORDER IN FLOWER PLUCKING WOMEN IN FAIZABAD DISTRICT OF UTTAR PRADESH

MANEESHA MISHRA *
Dr. ABHA SINGH **

ABSTRACT

Women play a significant and crucial role in Agriculture development, livestock production and Floriculture as a manager decision maker and skilled farm worker. In this study attempt has been made to study the role performed by farm women engaged in floriculture and to find out the MSD (Musculoskeletal disorder) and OH (Occupational Hazard) among women. The study was conducted in Faizabad District in U.P. 100 samples were taken of women involved in flower management. It was found from the study that majority of respondents (40%) suffered from the Back pain while (20%) women suffered Knee pain. The analysis of the study shows that Poor postures and finger nodes. Stress full work, unawareness of new techniques in the use of equipment and unwariness for safety measures were the reason for musculoskeletal discomforts. 70% women used foot wears due to the awareness of the advantages of it. The preferred activities by women were grading of flower (42%) as first followed by Deeping of flowers (34%), plucking of flower (12%) and storage flower (11%) respectively. The study will be use full in policy making designing women friendly implements for flower plucking and right posture training.

Key word: MSD (Musculo-Skeletal Disorder), Occupational Hazard, Knee pain, Back pain, Musculoskeletal Disorder.

ABSTRACT

The present investigation was carried out at Main Experiment Station, Horticulture, N.D. University of Agriculture and Technology, Narendra Nagar (Kumarganj), Faizabad during 2012-2013. The experiment was laid out in Factorial Randomized Block Design. The seedlings were planted in September, 2012 in pots having sodicity (15, 25, 35 ESP) including control (9. 10 ESP). The mango genotypes were grown for 19 months in a greenhouse before the experiment was terminated. A site with normal soil was marked and top soil upto 15 cm depth was scrapped from the site. The soil was passed through 2 mm sieve and the waste materials were removed. After proper mixing of soil, random sample were taken from the heap of the soil. The samples were analyzed for various physical and chemical constituents. The polyembryonic mango genotypes (cultivars) Bappakai, Chandrakaran, EC95-862, Goa, Kurukkan, Nekkare, Olour, Peach, Sabre, Starch and 13/1 were grown under greenhouse in pots containing soil mixtures of varying ESP namely, 9.10 (control), 15, 25 and 35. Growth of high sodium tolerant cultivars 13/1, Sabre and Olour upto 35 ESP and intermediate tolerant cultivars Bappakai, Nekkare and Kurukkan upto 25 ESP was better than other cultivars and the reduction in their growth was lesser in terms of stem length and diameter, number of leaf, size of leaf and fresh, dry weight of root than other cultivars.

Key words : *Mango, Rootstocks, Polyembryony, Genotypes, Cultivar, Factorial Randomized Block Designand Sodicity.*

The common mango (*Mangiferaindica* L.) is indigenous to north-east India and north Myanmar in the foot-hills of the Himalayas, and is said to have originated in the Indo-Burma region and considered as the fifth most important fruit crop of the world after apple, citrus, banana and grapes *(FAO Yearbook, 2000).* India still dominates the world mango production and ranks first with the total production of 18002.4 thousand MT and productivity 7.2 MT/HA from an area of 2500 thousand ha *(Anonymous, 2013).* In India mango is cultivated in almost all the states. The leading mango producing states in India are Andhra Pradesh (24.5%), Uttar Pradesh (24.4%), Karnataka (10%), Bihar (7.6%), Gujarat (5.6%), and Maharashtra (3.5%). It is cultivated in 28.85 million (M) ha in more than 100 countries speedier 0-36^0 NS of the equator. Mango is a tropical fruit grow equally well under semi- tropical conditions. In India, mango is distributed throughout the length and breadth of the country except in hilly regions above 915 meter from the mean sea level. The mango being a deep rooted tree needs soil profile of at least 2 meter depth. It has been observed that mango is equally well on alluvial as well as lateritic soils but deep black cotton soils of India have generally been considered unsuitable for mango cultivation. For mango growing the water table should be below 180 cm and a pH of 5.5 to 7.5 has been found suitable *(Singh, 1960).* Although a tropical fruit, the mango grows equally well under semi-tropical conditions. The optimum growth temperature for mango is 23.9-26.7 ^{0}C. In India, mango grows equally well both under low and heavy rainfall of 25 to 250 cm annually. The flowering of mango in India takes place as early as November-December in Rayalasema area of Andhra Pradesh, February-March in Northern India and slightly earlier January-February in eastern parts of the country. India has a rich wealth of mango germplasm with more than 1000 varieties grown throughout the country. However, only about 21 of them are commercially cultivated in different regions *(Yadav, 1997)* and few have been found as rootstock for mango growing in saline-alkali soils namely 13/1 *(Kadman et al., 1976).* Other cultivars reported as salt tolerant like Ann and Gomera-1 *(Galan-Sauco, 1997, Galan-Sauco et al., 1989),* Olour and Bappakai *(Anonymous, 1989)* have not been extensively- studied. Although these cultivars have little commercial value due to their poor fruit quality, they have potential to be used as rootstock for saline-alkali soils or places where irrigation water contains high sodium or other water soluble injurious ions for plant because these are polyembryonic cultivars and can be used as clonal rootstocks, like use of 13/1 as clonal rootstock has increased mango productivity many fold in Israel during the last two decades and Israel has become a major mango exporter to European Union recently. Hence present investigation were undertaken to study the growth performance of polyembryonic rootstocks of mango.

ABSTRACT

An experiment was conducted on "Effect of land configuration and moisture regimes on productivity of hybrid maize (*Zea mays* L.) in summer season." during 2018-19 at Agronomy Research Farm, ANDUA and T, Kumarganj, Ayodhya (U.P.). The experiment accomplished of 12 treatment combinations and laid out in split plot design, replicated three times. The Experiment consisted of three land configuration *viz.* flat bed planting (P_1), ridge planting (P_2) and paired row planting on raised bed (P_3) were kept in main plots and four moisture regimes *viz.*0.5 IW/CPE ratio, 0.7 IW/CPE ratios, 0.9 IW/CPE ratios and 1.1 IW/CPE ratios were allotted in sub plots. The experimental results revealed that growth parameters, such as plant height, leaf area index, dry matter accumulation, days to 50 percent ear emergence and days to50 percent maturity and yield were obtained maximum with the paired row planting methods followed by ridge planting and flat bed planting and yield attributes such as number of cobs plant^{-1} , number grains row^{-1}, number of grains cob^{-1}, cob length (cm), cob girth (cm), grains weight cob^{-1}(g), cob weight (g), shelling percentage (%), grain yield (q ha^{-1}), stover yield (q ha^{-1}), and biological yield (q ha^{-1}) were also increased similarity in same treatment. In case of moisture regimes, the same trends were observed maximum when applied irrigation at 1.1 IW/CPE ratios as compared to other moisture regimes.

Abstract
The present study was carried out to evaluate the influence of Moringa oleifera leaf extracts on carcass traits and mortality of broiler chickens. A total of 250-day-old broiler chicks (Vencobb-430) were randomly distributed into five groups with 5 replicates of 10 birds in each. Different dietary treatments were; basal diet with no supplement (NC- negative control) and basal diet supplemented with antibiotics (PC-positive control), aqueous extract of 1.5% Moringa powder (MOAQE), ether extract of 1.5% Moringa powder (MOEE) and alcoholic extract of 1.5% Moringa powder (MOALE). Percent weight of various cut parts, eviscerated weight and drawn yield were evaluated after 35 days of experiment. The results showed significantly higher eviscerated weight and drawn yield percentage in Moringa extracts supplemented groups compared to PC group. PC and MOAQE group recorded significantly (P<0.05) higher drumstick % compared to NC, MOEE and MOALE group. Moringa extracts group recorded significantly (P<0.05) lower mortality than PCand NC group birds. From above results it was concluded that supplementation of Moringa extract of 1.5% Moringa oleifera leaf powder improved the carcass traits and reduced the mortality of birds.

Key words: *Broiler, Extract, Carcass, Mortality and Moringa (words in alphabetical order)*

Introduction

Major cost involved for poultry enterprise is in the form of feed. Various approaches such as feed supplements and additives are being used to obtain more net return and to minimize expenditure on feed (Agasheet *al.*, 2017). *Moringa oleifera* leaf (MOL) has fascinated great attention as a non-traditional feed component because of its unique qualities. Moringa oleiferagrows fast, drought-tolerant tree native belonging to sub-Himalayan tracts of northern India, Pakistan, Bangladesh and Afghanistan. Moringa is currently cultivatedglobally in the tropics and subtropics (Faheyet *al.*, 2001). Crude protein content in Moringa varies from 25% to more than 30% on a dry matter basis (Melesse et al., 2013), with a high proportion of essential amino acids (Lu *et al.*, 2016). Moringa leaves, flowers and Pods are used as good sources of vitamins A, B and C, riboflavin, nicotinic acid, folic acid, pyridoxine, ascorbic acid, beta-carotene, calcium, iron and alpha-tocopherol (Dahot M.U., 1988). Moringa leaves are the preferred part of tree for use in animal diets as leaf meal due to high nutritional and medicinal properties (Abbas, 2013). The meat obtained from broiler chickens is an excellent source of protein, vitamins, mineralsand lower in fat content, so having a great demand among non-vegetarians(Naji *et al.*, 2013).Addition of*Moringa oleifera* leaf meal in broilers diet resulted significant increase in dressed weight, eviscerated weight and dressing percentage (Ayo-Ajasa *et al.* 2016). Dietary supplementation of Moringa leaves would be a potential strategy to improve the meat quality in broilers due to its antioxidant potential. It was further reported that phytosterols could lower malondialdehyde content and increase glutathione concentration in the breast muscle of broiler chickens (Naji *et al.*, 2013).

This study was carried out to evaluate the effect of different extracts (1 5%) of *Moringa oleifera* leaves powder as feed supplement in broiler diets on carcass characteristicsand mortality of broiler birds.

(Please correct red marks)

Materials and Methods

The present experiment was conducted after an approval from "Institutional animal ethical committee (IAEC)" was obtained vide reference number IAEC/CVSc/P-36/2019. A total of 250 one-day old Vencobb-430 strain chicks were randomly allocated into five dietary treatment groups with 5 replicates of 10 chicks in each. The chicks were kept on five dietary treatments which includes a basal diet without any additive in negative control (NC) or that supplemented with antibiotics (Positive control-PC), aqueous extract of 1.5% Moringa powder (MOAQE), ether extract of 1.5% Moringa powder (MOEE) and alcoholic extract of 1.5% Moringa powder (MOALE) in basal diet. Birds were fed *ad libitum* in different phases of experimental trial. The composition of formulated experimental diets as per BIS (2007) has been given in Table 1.

The chicks were kept on deep litter system under uniform standard management conditions with availability of clean, fresh and wholesome drinking water. Mortality was recorded during the entire research period. At the end of trial one bird per replicate (5 birds/treatment) were selected randomly for the carcass evaluation and sacrificed after 12 hours pre-slaughter fast though drinking of water was allowed. After complete bleeding carcass were dipped in hot water (58°C) for 1-2 minutes and feather were removed. Evisceration was done by making a slit from tip of breast bone up to the area around the cloaca. Thorough washing and cleaning were done after evisceration. After that the carcass were kept hanging on the special racks for 5-10 minutes. The visceral organs were removed by supporting the bird with one hand via the incised abdomen. Eviscerated carcasses were weighed and cut parts like thigh, drumstick, breast, wings, back, head, neck and shank were also weighed.The relative weight of dressed, drawn yield and different edible cuts were calculated as percentage of live weight.

The data were analysed under completely randomized (CRD) by employing one way analysis of variance (Snedecor and Cocran, 1994) and means of different dietary treatments were compared with Duncan multiple range test. The P value lower than 0.05 was thought-out significant.

(Please correct red marks)

Results and Discussion

Carcass characteristics:

The data pertaining to the carcass traits of broilers presented in Table 2. The results showed that the dressed weight and thigh weight of different groups was similar and showed no significant (P>0.05) effect of various Moringa extracts. The eviscerated weightof aqueous extract (72.24), ether extract (73.10) and alcoholic extract (73.09) supplemented group broilers were similar to NC (72.05) group, however significantly (P<0.05) higher than PC (70.39). The drawn yield of MOAQE, MOEE, MOALE and NC also significantly (P<0.05) higher than PC group. Leg and drumstick weight % of PC group was significantly (P<0.05) higher than MOEE and MOALE group. However, leg weight was

Abstracts

The present study was conducted to investigate the effect of different litter materials on growth performance of Kadaknath chicks. 300 Kadaknath chicks were raised on three litter treatments viz. Sand, rice hulls and rice hulls plus chopped paddy straw (1:1) co of two replicates in each treatment. The result showed that chicks reared on paddy straw + rice hulls litter had significantly hig weight, lower feed intake and better FCR($P<0.05$). The body weight of chicks raised under sand and rice hull litter did n significantly, however the average daily feed intake of chicks under rice hulls was significantly higher than that of under sand li performance index of the earlier study period was significantly higher in paddy straw+ rice hulls followed by sand and ri respectively.

***Key words:** Kadaknath, feed, body weight, sand, rice hulls, litter materials*

Introduction

Desi fowls are cheaply reared as scavenging flocks by feeding household left over and their meat and egg taste are preferred over those of exotic chickens (Dessie and Ogle, 2001).Wood shaving has been standard choice for poultry litter for many years. Rice hulls appear to be a favourable alternative to wood shavings (Grimes *et al.*, 2007).Various types of litter materials like sand (shields *et al.*, 2005), gypsum (Grimes *et al.*, 2007), rice and wheat straw (Srechari Sharma 2010), ground corn cob and soyabean straw(De Avila *et al.*, 2008) have been utilised as bedding materials for rearing of poultry birds. Sand has shown good potential as an alternate litter for more reuse quality and very less caking.

Pine shavings and saw dust are the most desirable and most widely used litter materials for broiler production in the United States. About 60% of farmers used saw dust as litter materials, 16.7% used wood shaving, 20% used both wood shaving and saw dust while 3.3% of farmers do not use bedding materials. The types of litter used by farmer depend on locality and availability (Kalu E. 2015) . Paddy husk is most commonly used litter material in northern India.Sigroha et al., (2017) used saw dust, wheat straw, rice husk, river bed sand and sandy soil as litter materials and found higher weight of birds at 42 days of age in wheat straw followed by sandy soil, saw dust, river bed sand and rice husk. As far as seen in literature there is no concert conclusion for litter type and thickness for various regions and climates. In view of above a study was undertaken with following objectives-

To investigate the effect of litter material on the growth perf of kadaknath fowls

To study the feed conversion efficiency of kadaknath fow various bedding materials

Materials and Methods:

The present investigation was carried out to study the different litter materials on growth performance, feed gain Kadaknath fowl. The study was carried out at the poultry Teaching Livestock and Poultry farm of the College of V science and Animal Husbandry, N.D.U.A.T. Kumarganj, U.P., situated at a distance of 42 km away from Faizabad cit km away from Jagdishpur Industrial area at an altitude o above sea level and latitude of 26° 47' North and longitude East and it falls in Eastern plain Zone of Middle Gange region of India.

Experimental period and climatic conditions

The experiment was conducted in the months of Nove February which comprised winter season of this region. Du period, the climatic parameters have been shown in table average minimum temperature recorded during study pe 12.54°C, while the average maximum temperature was There were a few showers of rain, ranging from 62 to 123 average was 92.5 cm during this period. The topography o almost even and most of the farm area remains dry round Parasitic infestation was moderate.

Climatological parameters recorded during experiment period

S.No	Climatological Parameters	Average Value	Average Max	Average Min
1.	Environmental temperature(°C)	18.7	24.86	12.54
2.	Relative humidity (%)	70.35	77.68	57.86

Experimental animals

To carry out present investigation, 300 straight run day old Kadaknath Chicks, from college hatchery were got issued. These 300 kadaknath chicks were divided into two batches; each batch consisted of 150 Kadaknath Chicks. Each batch was subdivided in three equal groups of 50 chicks viz. Group1 (sand), Group2(rice hulls), Group3(paddy straw + rice hulls) randomly distributed among three pens. Each pen was equipped with fresh litter, feeder and waterer. All the birds were raised on pukka floor with sand, rice hulls and paddy straw + rice hulls (50:50) as litter materials. Chicks were reared under standard uniform managemental practices up to the age of 42 days and observations for different parameters were recorded simultaneously. Thereafter, a replication was made with the next batch of chicks.

Brooding and rearing of chick

Brooder house

The cold room brooding method was applied for brooding an of Kadaknath Chicks in the brooder house. Brooding was pukka floor using deep litter system. Each group of Kadakna placed in separate pens which were visually isolated from e along with provision of adequate ventilation and artificial li brooder house.

Preparation of brooder house to receive Kadaknath chic

Brooder house was properly scrubbed and cleaned at leas before the trail began. After the house, equipments were cleaned. The house was allowed to dry out thoroughly. The equipments were fumigated using 1% formalin. Three inches litter were made on the floor. Few days before the chick equipments were arranged in brooder house and the elect were started to adjust temperature and light. The temperatu the brooder house was slightly above 35°C. The corners of space were made rounded off with cardboard and metal chi to prevent chicks from piling up in the corner. All these pre

STUDY THE PHYSIO-HEMATOLOGICAL RESPONSE BEFORE AND AFTER DISBUDDING IN CALVES

Shiv Swaroop[1], P.S. Pramanik[1], K.D. Singh[2*], A.K. Verma[1], Vishuddha Nand[1] and A.K. Srivastav[1]
[1]Department of Livestock Production Management, College of Veterinary Science and Animal Husbandry NDUAT, Kumarganj, Faizabad- 224229, Uttar Pradesh, India [2]Department of Livestock Farm Complex, College of Veterinary Science and Animal Husbandry NDUAT, Kumarganj, Faizabad- 224229, Uttar Pradesh, India

Abstract

The aim of the present investigation was to examine the effect on Physio-haematological profile before and after disbudding in calves. The study was carried out at Livestock Farm Complex, College of Veterinary Science and Animal Husbandry, NDUAT, Kumarganj, Faizabad and nearby villages. Twenty four cattle calves were utilized to study Physio-haematological parameters that are Respiration Rate (RR), Pulse Rate (PR), Rectal Temperature (RT), Haemoglobin (Hb (gm/dl), Neutrophil (%), Basophil (%), PCV (%), Lymphocyte (%), Monocyte (%), TLC (10^3/ µl), Eosinophil (%) and N:L ratio) before and after disbudding in to four groups viz. control (T_0), lignocaine (T_L), tramadol (T_T) and lignocaine + tramadol (T_{L+T}). After medication calves were disbudded by hot iron method. The physiological parameters recorded just before (0h) and after disbudding on 1h, 6h and 24h. The blood samples were collected for haematological parameters just before (0h) and after disbudding on 6h, 24h and 72h. The results showed that, at 0h, 1h, 6h and 24h RR were significantly different among treatment groups. Only at 0h PR was significantly different among different treatment groups and during rest of the period up to 24h there is no significant different among groups. There was significant difference for RT only at 24h among different treatment groups. At 24h, T_0 group showed significantly lowest Hb (10.66±0.49%) which was statistically similar to T_T and T_{L+T} groups. At 0h, 6h and 72h means of PCV% were significantly different among treatment groups. There was no significant different in eosinophil, neutrophil and TLC among different treatment groups during the whole period of study. The lowest lymphocytes (54.00±1.00) was observed in T_T group at 6h. The T_0 group showed significantly lowest basophil (0.00±0.00) which was statistically similar to T_T and T_{L+T} groups but significantly different from T_L group at 6h. At the same interval, T_0 group showed significantly lowest monocytes (4.66±0.61) which was significantly different with T_L, T_T and T_{L+T} groups. At 6h, T_0 group showed significantly lowest N/ L ratio (0.15±0.01) which was statistically similar to T_T and T_{L+T} groups but significantly different from T_L group. It may be concluded that generally physiological responses like RR, PR and RT were higher in control groups than treatment groups before and after disbudding. No significant difference was observed in eosinophil%, TLC, neutrophil% and monocyte% counts between control and treatment groups. However Hb%, basophil%, PCV% and lymphocyte% were significantly different between control and treatment groups. N/L ratio was significant only at 6h. Most of the cases T_{L+T} group showed comparatively better performance.

Introduction

Disbudding is painful yet common husbandry practice in the cattle industry, especially on dairy farms, because hornless cattle are safer (ALCASDE, 2009) and injuries to cattle and other animals are reduced (Prayaga, 2007). Dehorned cattle are safer to handle and cause fewer injuries to workers, other cattle, and farm animals (Stafford and Mellor, 2005). Cattle are also dehorned to reduce bruising and hide damage and to meet transport requirements (Goonewardene and Hand, 1991; Faulkner and Weary, 2000; Prayaga, 2007). Several disbudding methods exist, including cautery, the use of caustic paste, and hot iron. All of these methods involve tissue damage and have been described as painful (Stafford and Mellor, 2005; 2011). The *Model Code of Practice for the Welfare of Animals: Cattle*, however, strongly advises against caustic disbudding (PISC, 2004).

Despite this knowledge, dehorning is commonly performed without pain relief because of the costs and impracticalities associated with recognized methods (Petherick, 2005). The breeding of polled cattle eliminates the need for dehorning and because horns are inherited as an autosomal recessive with polledness being dominant (Long and Gregory, 1978). The legislation pertaining to dehorning and disbudding differ between countries like in Sweden, disbudding without local anaesthesia and sedation was banned in the 1992 Animal Rights Act (Stangaard *et al.* 1996), but calves may be dehorned in Denmark without local anaesthesia until they are 4 weeks of age (Grondahl-Nielsen *et al.* 1999). The Council of Europe recommends the use of anaesthesia for the dehorning of calves over 4 wk of age (Oliver, 2009). Pain control is also required for all calves under the *Canadian Code of Practice for the Care and Handling of Dairy* Cattle (NFACC, 2009). Furthermore, the Australian *Model Code of Practice for the Welfare of Animals: Cattle* recommends the use of local analgesics for dehorning calves over 6 month of age (PISC, 2004). Thus, the need to meet industry standards and the availability of suitable dehorning pain relief regimens for commercial production remain a challenge. Very little work has been done on the disbudding distress in Indian dairy animals particularly in indigenous animals.

Materials and Methods

The aim of the present investigation was to examine the Physio-hematological response before and after disbudding in calves. Study was carried out at the Instructional Livestock Farm Complex of the college of Veterinary Science and Animal Husbandry, NDUAT, Kumarganj, Faizabad and around the campus. Twenty four (24) farm born cattle calves of 2 to 3 weeks were randomly divided into four groups within each comprising of 3 males and 3 females. Control (T_0), Lignocaine hydrochloride (2%) @ 1 ml/ bud (T_L) (Tramadol @ 0.25 mg/ kg body weight I/M) (T_T) and Lignocaine + Tramadol at above dose rate (T_{L+T}). Medication was done 5-10 minutes before disbudding. Two doses of lignocaine per bud were injected for cornual nerve block in calves.

(a) Physiological responses

Physiological responses recorded before and after disbudding were as follows-

Respiration rate (no./ minutes)	Pulse rate (no./ minutes)	Body temperature (°F)

(b) Haematological parameters

Haematological responses recorded before and after disbudding were as follows

a) Hb (gm/dl)	d) Neutrophil (%)	g) Basophil (%)
b) PCV (%)	e) Lymphocyte (%)	h) Monocyte (%)

Impact of integrated nutrient management (INM) on growth of Berseem (*Trifoliumalexandrinum* L.) at various cutting stages

Vishuddha Nand, RK Gupta, RS Yadav, KD Singh, RK Yadav and AK Srivastav

Abstract
An experiment was conducted during winter season of 2016-17 on Berseem (cv. Mescavi). The experiment comprised of twelve treatments *viz.* T_1 (control), T_2 (100% RDF, 20 kg N + 80 kg P_2O_5 ha^{-1}), T_3 (100% N through Farm Yard Manure (FYM), T_4 (100% N through Poultry Manure), T_5 (50% RDF +50% N through FYM), T_6 (50% RDF +50% N through Poultry Manure), T_7 (50% N through FYM+50% N through Poultry Manure), T_8 (50% RDF +25%N through FYM +25% N through Poultry Manure), T_9 (75% RDF +25% N through FYM), T_{10} (75% RDF +25% N through Poultry Manure), T_{11} (25% RDF +75% N through FYM) and T_{12} (25% RDF +75% N through Poultry Manure) were tested in Randomized Block Design with three replications. the results revealed that the maximum plant height, fresh weight of leaf and stem, dry weight of leaf and stem, shoot : root ratio $plant^{-1}$ and number of nodules $plant^{-1}$ were observed with the application of 100% RDF (20 kg N + 80 kg P_2O_5 ha^{-1}) fallowed by 75% RDF +25% N through poultry manure and 75% RDF +25% N through FYM.

Keywords: FYM, Poultry manure, INM, growth, RDF, plant height, and leaf

Introduction
Berseem (*Trifoliumalexandrinum* L.) is one of the most important winter forage crop of India, due to high forage yield, palatability and nutritive value. It has become a very popular as *rabi* forage in irrigated areas or all most all over the country. Berseem belongs to one of the largest and most useful plant family leguminaceae and sub family faboideae. Berseem is known as king of fodder crops and it is popular among the world. It is one of the oldest cultivated crops, domesticated in Egypt and later introduced into many other parts of the world. Berseem was introduced in India in 1903 (Roy *et al.*, 2009) [5]. It is now widespread in the irrigated regions of west and south Asia. Most of the farmers conserved the berseem as hay to get cheap, palatable and nutritive forage during scarcity periods or early winter and summer. Berseem is a cheapest source of increasing milk production as well as improving soil fertility. Berseem can be sown in early autumn and can thus provide feed before and during the colder months but the optimum conditions are 18-25 °C. If the winter temperature falls to 6-8° C the crop growth is severely affected. This is nutritious, succulent and palatable fodder available for fairly long period during winter, spring and early summer (Chaterjee and Das, 1989) [2]. Grazing is possible though less common than cutting. The most important cultural practices that need to be carefully adjusted to achieve maximum benefit from the forage grass-legume mixtures. The ability to fix atmospheric nitrogen and convert it to a useable form for plant growth is the main trait to these legumes (Allen and Allen, 1981) [1].
Poultry manure is an excellent soil amendment that provides nutrients for growing crops and also improves soil quality when applied widely, because it has high organic matter content combined with available nutrients for plant growth (Ryssen *et al.*, 1993) [7]. The application of FYM with chemical fertilizers and composted with rock phosphate to improve crops yield is very well established (Shafi *et al.*, 2012) [8]. Fertilizers play an important role in enhancing forage productivity. Chemical fertilizers are soluble and immediately available to the plants; therefore, the effect is usually direct and fast, the price is lower and they are quite high in

GENETIC STUDIES ON REPRODUCTIVE TRAITS OF HARIANA COWS

Abstract

The performance records of 211 Hariana cows, progeny of 27 sires, born during the year 1966 to 1985 having at least records up to second calving were utilized in this study. These cows were maintained at D.D.D. farm, Mathura and livestock farm, Madhurikund (Mathura). The average post partum oestrus interval was estimated to be 185.43± 11.18, the heritability estimate of post partum oestrus interval was estimated to be 0.021±0.175. The magnitude of the effect of sires was non significant and the variation in post partum oestrus accounted due to sires was very small (8.7%) in total variation. The least squares means and their standard errors of number of service per conception were estimated to be 2.19±0.26. The heritability estimate of the number of service per conception was estimated to be 0.294±0.210. The contribution of sires was 21.8% in the total variation of the trait.

Introduction

The cow is an efficient machine for converting farm crops into useful human food like milk and milk products, which are the main source of animal protein in the diet of a large vegetarian population of the country. Hariana breed of zebu cattle has been well established dual-purpose breed known for its milk yield as well as for draught ability. The breed has reduced significantly and is continuing to decline at an alarming rate. Apart from the declining population, Hariana cattle have also deteriorated in their productivity (Joshi et al., 1995).

Materials and Methods

The present study was undertaken on Hariana cows. All the animals taken into consideration were farm bred. The data used in this investigation were collected from the pedigree sheets, milking register and breeding record of Hariana cows maintained at DDD Farm, Mathura. The performance record of 211 cows, having at least record up to second calving were collected for genetic studies. The statistical analysis of the data was carried out by using the LSMLMW (Least Squares and Maximum Likelihood Method)- Harvey (1990) PC-2 version computer programme and Henderson (1953) model were used.

Results and Discussion

The least squares mean of the post-partum oestrus interval along with their standard errors have been presented in table 1. The average post-partum interval was estimated to be 185.43±11.18 days. The frequency of animal in various PPO groups (class interval of 40 days) is about 23.69% animals had post-partum oestrus interval below 90 days. The maximum frequency of animals was in 90 to 130 days group (26.54%). Present observation is comparatively higher than the average of post-partum interval reported by Luktuke and Subramanium (1961), Singh et al., (1964), Arora et al., (1971), Acharya et al. (1971) and Khanna (1998) for Hariana cows. Whereas, Kohli and Suri, 1957, Kohli and Suri, 1960 and Tomar and Arneja, 1972 have reported comparatively higher post-partum oestrus in Hariana cattle.

Least squares analysis of variance was performed to study the effect of farm, period and session of calving are present in table 2. The perusal of the table revealed that the effect of farm was found to be non-significant on post-partum oestrus interval in Hariana cows, although the contribution of farm was highest (83.5%) in total variation. However, Ashraf et al., (2000) observed highly significant farm effect on post-partum oestrus interval. The effect of period and season of calving were found non-significant. However, Mahmoud et al., (1991) observed a significant effect of month of calving.

Heritability estimate of post-partum oestrus interval was estimated to be 0.021±0.175. The magnitude of the effect of sires was non-significant and the variation in PPO accounted for due to sires was very small (8.7%) in total variation. The findings were indicative of zero heritability for this trait in these animals. Similar observations were reported by Prasad (1958) for Tharparkar cattle and Singh et al., (1964) for Hariana cattle.

Conclusion

Any selection programme based on post-partum oestrus interval will not prove beneficial in these cattle because the genetic variability for this character in these animals does not seem to exist. In view of the above observations, improvement in managemental practices may lead improvement in this trait.

2004). Group-II and III had significantly (P<0.05) higher change in BCS than group-I during 30 to 45 days of lactation. This observation of cows with higher BCS at calving had lost more body condition during peak lactation was in agreement with Roche *et al.* (2007), Contrary to this Jilek *et al.* (2008) observed that cows with higher BCSC were maintained high BCS for the next 5 months of lactation. The lowest value of BCS was recorded in around 60 to 75 days of lactation in cows, after that recovery in BCS started. Similarly, Pedron *et al.* (1993) also reported for Italian dairy herds. Respective correlation of BCSC and BCSL were positive and negative with FCM, Fat and SNF (Table-2) are in corroboration with Coffey *et al.* (2002). However, the correlation was significant (P<0.01) only between BCS (at calving and during lactation) and FCM (Table-2). Significant positive correlation between BCSC and FCM are in agreement with the findings of Samarutel *et al.* (2006). Contrarily, Ruegg and Milton (1995) reported that BCSC was not correlated with milk yield. BCSL and milk yield are in a significantly negative correlation is as reported by Veerkamp and Brotherstone, (1997). Kadarmideen, (2004) and Mushtaq *et al.* (2009) also reported that BCS had slightly negative correlation with fat, SNF and milk yield. Our observations are contrast to Roche *et al.* (2007b), who reported a positive correlation between BCS and fat%. Non-significant negative correlation between BCSC and SCS are in agreement with findings of Kadarmideen, (2004) who also reported a slightly negative correlation between BCSC and SCS. However, a positive significant (P<0.01) correlation had been found between BCSL and SCS corroborates with previously documented study of Berry *et al.* (Loc. cit.) and Suriyasathaporn *et al.* (2000). SCS was negatively correlated with FCM, fat%, SNF% and specific gravity but the correlation was only significant (P<0.01) between FCM and SCS (Table-2). Negative significant (P<0.01) correlation between FCM and

Table2: Correlation (2-tailed) among BCS, FCM, milk composition and SCS in cows

	BCSC	BCSL	FCM	Fat	SNF	Specific gravity	SCS
BCSC	1	0.178	0.752**	0.154	0.249	-0.235	-0.238

Abstract
To assess the associations among body condition score at calving (BCSC), BCS during lactation (BCSL), production performance and udder health status of dairy cows, 50 cows (HF cross) at 2nd parity were selected randomly. The animals after random distribution into 3 groups i.e. group I (BCS<3.0, thin), group II (3.0<BCS>3.5, moderate), group III (BCS>3.5, fat) kept in observation for 120 days. The BCS of group-III cows were significantly (P<0.05) higher than group I. The FCM, fat and SNF was positively correlated with BCSC and negative with BCSL. The somatic cell score (SCS) was correlated negatively with BCSC and positively with BCSL.

Key words- BCS, Milk, Milk composition, Udder health, SCS

Introduction

Milk quality is as significant as the milk quantity in dairy animals. High yielding dairy cows had higher incidence of mastitis that can be assessed by somatic cell count (SCC) of milk (Kadarmideen and Bryce, 2001). Optimal body condition of dairy cow is important for obtaining elite herd and quality milk. Low or higher body reserves may pose a risk of lower milk yield and higher SCC in milk respectively (Berry et al., 2007). High yielding dairy cows exhibit negative energy balance after calving which may influence both immune and metabolic system of the individual that predispose the animals to mastitis. Body condition score had a favourable correlation with SCC, but it was not strong (Berry *et al* Loc. cit.). Dang et al., (2010) reported non-significant relationship between BCS and SCC. Hence, it is postulated that there are no consistent results regarding the relationship between body condition score and somatic cell counts of the dairy animals. Therefore, the present study was carried out to investigate the association among body condition score, production performance and udder health status of dairy cows.

Materials and Methods

This study was carried out in the area under subtropical zone of Indo-Gangetic plane. Fifty lactating dairy cows (HF cross) of second parity available at the Teaching Livestock Farm in the College of Veterinary Science and Animal Husbandry, N.D.U.A.T., Kumarganj, Faizabad (U. P.) and in the small dairy farms of the surrounding villages were selected. Observations were recorded for 4 months. The animals in farm and field conditions were maintained under loose housing system and the stanchion system, respectively. The data collected at fortnightly intervals were, the Body Condition Score (BCS), Production performances and Somatic cell count (SCC). Milk yield of selected animals in the farm and the field were recorded on the observation days both morning and evening. Milk samples were collected directly from the animal during milking to assess the milk composition such as fat, SNF (solid not fat), CLR (corrected lactometer reading) by EKO milk ultra, milk analyser (Milkana KAM98-2A). The milk yield was further corrected on 4% fat basis (Fat corrected milk, FCM) according to the formula given by Gaines (1928) as under-

FCM = 0.4 × milk yield (l) + 15 × milk fat (kg).

Body condition score of animals after calving were assessed in the morning milking by the chart formulated by Prasad (1994) having 1-6 scale with 1 indicating under body condition and 6 representing over body condition of the dairy cows. 1 to 6 scales were further splitted in to half or quarter point increment (e.g., 2.5 or 3.25). For the better interpretation of BCS effect on the milk yield, milk composition and udder health status, the animals were divided in to three groups on the basis of BCS at calving i.e. group-I (BCS <3.0, thin), group-II (3.0≤BCS≥3.5, moderate) and group-III (BCS > 3.5, fat). The udder health status was determined by somatic cell count (SCC) of milk immediately after collection as per methodology of IDF (1984). The SCC was log-transformed into the fortnightly test day observation SCS (Somatic cell score) as SCS=$\log_{10}$SCC (Mrode and Swonson, 1996).

The collected data were analyzed by SPSS (version 11.5). The means of various measurements were compared by Duncan's Multiple Range test (Duncan, 1955). The Pearson's correlation coefficient was estimated to find relationships among observations.

Results and Discussion

Out of 50 animals, 13 cows were classified as thin (group–I), 20 as moderate (group–II) and 17 as fat (group–III) at parturition. BCS of cows at calving was 2.83±0.06, 3.38±0.03 and 4.22±0.11, in group I, II and III, respectively (Table-1). BCSC differ significantly (P<0.05) among the three groups of cows. The BCS during calving to 15 days were significantly (P<0.05) higher than rest period of lactation. The declining BCS might be due to mobilization of body fat reserves to cover milk production during early lactation (Buckley *et al.*, 2000, Friggens *et al.*,

Abstract

The genetic worth of a sire can be measured directly but it has to be estimated either on the basis of phenotypic performance or observed value of a trait in the sire itself, or information from relatives in sex-limited traits such as milk yield.

The present investigation was undertaken on 1367 first lactation records of Sahiwal cattle maintained at GLF, Chak Ganjaria, Lucknow (U.P.) over a period of 71 years (1944-2014). The study was conducted on breeding value estimation of sires, relationship between Estimated Breeding Values (EBV's) for first lactation and life time traits using daughter's average, least-squares and best linear unbiased prediction methods of sire evaluation and effectiveness of these methods. The rank correlations among the breeding value of sires estimated from first lactation milk yield and life time milk were medium to high and highly significant (P<0.01). Therefore, the daughters of the sires selected on the basis of high first lactation milk yield would tend to produce higher life time milk yield. The product moment correlations among the estimated breeding value of the sires for first lactation traits by all the three methods ranged from medium to very high and highly significant (P<0.01) in all the three methods of sire evaluation.

Introduction

Cattle rearing has been an important source of livelihood in India and is closely associated with agricultural economy. The agriculture and allied sectors contribute nearly 14 per cent of the Gross Domestic Production. The agriculture and livestock are the main source of employment in rural areas and about 52 per cent of the population is engaged in agriculture and rearing of livestock in our country.

The effectiveness of sire evaluation is the backbone of any breed improvement programme. This investigation was planned to evaluate Sahiwal sires as its performance is remarkable in hot climate and has been recognized worldwide as one of the best milch breed (Ilatsia et al., 2011). Various sire evaluation methods viz. daughter's average, least-squares analysis and best linear unbiased prediction (B.L.U.P.) were used to evaluate the sires and their effectiveness were compared for Sahiwal cattle. The information on the production of first lactation is mainly required for getting genetic improvement through selection, since it serves as an index of life time production in dairy cows. Therefore, it is very much essential for the sire evaluation to correlate the first lactation milk yield with life time milk production.

Materials and Methods

The data for the present investigation were collected over a period of 71 years (1944-2014) from pedigree sheet of 1367 Sahiwal cows born to 112 sires maintained at Government Livestock Farm, Chakganjaria, Lucknow (U.P.). Only the sires having the records on at least three or more daughters were included in the present study. The total duration of the present study was divided into 8 periods.

Out of 8 periods 7 are of 9 years each and 8th period of 8 years only. Each year was divided into three seasons namely winter (November-February), Summer (March- June) and Rainy (July- October). In order to classify the data for different periods and seasons year and season of calving was considered for all the traits.

Statistical Analysis

Rank correlation

After estimation of breeding value of sires, the sires were given rank as per their genetic merit. The Spearman's rank correlation between breeding values of sires derived by various methods was used to judge the effectiveness of different methods. The rank correlation was estimated as per methods developed by Steel and Torrie (1960).

$$r_s = 1 - \frac{6\sum d_i^2}{n(n^2-1)}$$

Where,

r = Rank correlation coefficient

n = Number of sires under evaluation

d_i = Difference of rank between paired items under two methods

The significance of rank correlation was tested by t-test as given below

$$t = r\frac{\sum(n-2)}{(1-r^2)}$$

It was compared with t-table value with (n-2) degree of freedom.

Simple product moment correlations

The simple correlations (r) between the estimated breeding values of bulls by different sire evaluation methods were also calculated by the following formula:

$$r_{(XY)} = \frac{Cov(XY)}{\sqrt{[Var\ (x)\ \ Var\ (Y)]}}$$

Where,

$$Cov\ (XY) = \sum XY - \frac{(\sum X)\ (\sum Y)}{n}$$

$$Var\ (X) = \sum X^2 - \frac{(\sum X)^2}{n}$$

$$Cov\ (Y) = \sum Y^2 - \frac{(\sum Y)^2}{n}$$

Where,

X, Y= The breeding value of sires estimated by two different methods

n= Number of pairs of breeding value

Rank correlation

The rank correlations of most efficient method (LSM) of sire evaluation for LTMY was statistically highly significant (P<0.01) with their values 1.00 ($\overline{D}$ and LSM), 0.71 ($\overline{D}$ and BLUP) and 0.71 (LSM and BLUP). For LTLL, the rank correlation between the different methods were 1.00 ($\overline{D}$ and LSM), 0.79 ($\overline{D}$ and BLUP) and 0.79 (LSM and BLUP). The rank correlation of estimated breeding values of LTMY between daughter's average and least squares method was very high (100%) (Table-1).

It revealed that ranking of sires for the estimated breeding value by daughter's average and least-squares method was similar while ranking of sires from BLUP was different. Similarly, for the LTLL, the rank correlation of estimated breeding values between ($\overline{D}$) and LSM was very high (100%). It revealed that ranking of sires for the estimated breeding value by $\overline{D}$ and LSM was similar while ranking of sires by BLUP was different.

Product moment correlation

The product moment correlations of most efficient method (LSM) of sire evaluation for LTMY with other two methods of sire evaluation (

EFFECT OF DIFFERENT LITTER MATERIALS ON BEHAVIOR OF KADAKNATH FOWLS

College of Veterinary Science and Animal Husbandry, N.D.U.A.T., Kumarganj, Faizabad, Uttar Pradesh- 224229 (India)

Abstract
The present study was conducted to investigate the effect of different litter materials on behavior of Kadaknath chicks. A total 300 Kadaknath chicks were raised on three litter treatments viz. Sand, rice hulls and rice hulls plus chopped paddy straw (1:1) comprising of two replicates in each treatment. The results indicate that Kadaknath chicks reared on sand and rice hull litter had significantly higher proportion of time in activities like drinking, dust-bathing and perching than paddy straw+rice hulls. The behavioral activities like drinking, dust bathing, stretching, standing and perching in sand litter, dust-bathing, peaking, stretching, walking, lying and perching in rice hulls and peaking, stretching and standing in straw+rice hulls were seemed to be significantly differed in morning, noon and evening hour interval.

Keywords: Kadaknath, feed, behavior, sand, rice hulls, litter materials

Introduction

Desi fowls are cheaply reared as scavenging flocks by feeding household left over and their meat and egg taste are preferred over that of exotic chickens (Dessie and Ogle, 2001). Wood shaving has been standard choice for poultry litter for many years. Rice hulls appear to be a favourable alternative to wood shavings (Grimes *et al.*, 2007). Various types of litter materials like sand (shields *et al.*, 2005), sawdust (Grimes *et al.*, 2007), rice and wheat straw (Sreehari Sharma 2010), ground corn cob and soyabean straw (De Avila *et al.*, 2008) have been utilised as bedding materials for rearing of poultry birds. Sand has shown good potential as an alternate litter for more reuse quality and very less caking.

Pine shavings and saw dust are the most desirable and most widely used litter materials for broiler production in the United States. About 60% of farmers used saw dust as litter materials, 16.7% used wood shaving, 20% used both wood shaving and saw dust while 3.3% of farmers do not use bedding materials. The types of litter used by farmer depend on locality and availability (Kalu E. 2015) . Paddy husk is most commonly used litter material in northern India.Sigroha et al., (2017) used saw dust, wheat straw, rice husk, river bed sand and sandy soil litter materials and found higher weight of birds at 42 days of age in wheat straw followed by sandy soil, saw dust, river bed sand and rice husk. As far as seen in literature there is no concert conclusion for litter type and thickness for various regions and climates. In view of above a study was undertaken with following objectives-

- To investigate the effect of litter material on the behavior of Kadaknath fowls

Materials and Methods

The present investigation was carried out to study the effect of different litter materials on growth performance, feed gain ratio of Kadaknath fowl. The study was carried out at the poultry unit of Teaching Livestock and Poultry farm of the College of Veterinary science and Animal Husbandry, N.D.U.A.T. Kumarganj, Faizabad U.P., situated at a distance of 42 km away from Faizabad city and 38 km away from Jagdishpur Industrial area at an altitude of 113 m above sea level and latitude of 26° 47' North and longitude of 82° 12' East and it falls in Eastern plain Zone of Middle Gangetic Plain region of India.

Experimental period and climatic conditions

The experiment was conducted in the months of November to February which comprised winter season of this region. The average minimum temperature recorded during study period was 12.54°C, while the average maximum temperature was 24.86°C. There were a few showers of rain, ranging from 62 to 123 cm and average was 92.5 during this period. The topography of land is almost even and most of the farm area remains dry round the year. Parasitic infestation was moderate.

Experimental animals

To carry out present investigation, 300 straight run day old Kadaknath chicks, from college hatchery were got issued. These 300 kadaknath chicks were divided into two batches; each batch consisted of 150 Kadaknath Chicks. Each batch was subdivided in three equal groups of 50 chicks viz. Group1 (sand), Group 2(rice hulls), Group3 (paddy straw + rice hulls) randomly distributed among three pens. Each pen was equipped with fresh litter, feeder and waterer. All the birds were raised on pukka floor with sand, rice hulls and paddy straw + rice hulls (50:50) as litter materials. Chicks were reared under standard uniform managemental practices up to the age of 42 days and observations for different parameters were recorded simultaneously. Thereafter, a replication was made with the next batch of chicks.

Brooding and rearing of chick

Brooder house

The cold room brooding method was applied for brooding and rearing of Kadaknath Chicks in the brooder house. Brooding was done on pukka floor using deep litter system. Each group of Kadaknath chicks placed in separate pens which were visually isolated from each other along with provision of adequate ventilation and artificial light in the brooder house.

Preparation of brooder house to receive Kadaknath chicks

Brooder house was properly scrubbed and cleaned at least a week before the trail began. After the house, equipments were properly cleaned. The house was allowed to dry out thoroughly. The house and equipments were fumigated using 1% formalin. Three inches depth of litter were made on the floor. Few days before the chicks arrived, equipments were arranged in brooder house and the electric bulbs were started to adjust temperature and light. The temperature under the brooder house was slightly above 35°C. The corners of brooding space were made rounded off with cardboard and metal chick guards to prevent chicks from piling up in the corner. All these preparations were completed for Kadaknath chicks before they were procured to brooder house. A chick guard of about 15 cm height was used at a distance of 30 to 40 cm away from the brooder and was moved away for the every day. It was completely removed after two weeks.

Litter materials

For the present experiment three litter materials namely sand, rice hulls and paddy straw + rice hulls (50:50) were used for rearing the Kadaknath chicks. Rice hulls were procured from the nearby rice mill, paddy straw taken from village shivnathpur and sand was taken from kumarganj market. These litters were clean, dry and free from fungal growth. The thickness of litter was 3.0 cm. After spreading this litter on the floor with proper thickness was covered with newspaper up to 4 days of brooding.

Parameters recorded

Behaviour

The behaviours in the Kadaknath recorded in this study were chosen from preliminary observations and defined as a list of 12 states which have given here.

1. Eating
2. Drinking

Estimation of direct selection parameter in okra [*Abelmoschus esculentus*(L.) Moench]

Shalu Yadav, Vijay Bahadur Singh, Gulab Chand Yadav, Sharvan Kumar and Pankaj Kumar Verma

Abstract
The experiment was conducted at Main Experimental Station, Department of Vegetable Science, Acharya Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya during *Kharif*, 2019 in Randomized Block Design with three replications using thirty six genotypes of okra collected from different sources to study the correlation and path coefficients at phenotypic and genotypic levels among different quantitative characters. Characters like petiole length (0.236) average fruit weight (0.195), have positive significant and desirable association with fruit yield. Thus, there is an ample scope for improving characters through direct selection. Petiole length (0.310) average fruit weight(0.229) plant height(0.109) fruit circumference (0.032) and days to 50% flowering (0.008) were identified as most important traits which had positive direct effect on total fruit yield per plant while, the negative direct effect on yield by rest of the dependent traits were very low.

Keywords: Estimation, parameter, okra, *Abelmoschus esculentus*

Introduction

Okra is the most traditional and popular vegetable in India and it is extensively cultivated in summer and rainy season. It is one of the important vegetable crops which are grown throughout the tropical, subtropical and temperate parts of the world. It has been grown commercially in India, Turkey, Iran, Western Africa, Yugoslavia, Bangladesh, Afghanistan, Pakistan, Burma, Japan, Malaysia, Brazil, Ghana, Ethiopia, Cyprus and the Southern United States. Okra [*Abelmoschus esculentus* (L.) Moench 2n = 2x=130] is one of the important member of the family Malvaceae. Okra is an African word and is native to northern Africa including the area of Ethiopia and Sudan. It is a summer and rainy season crop and is widely cultivated from tropics to sub tropics (Kochar, 1986) [2].

Okra (*Abelmoschus esculentus* L.) is probably an amphidiploids (allotetraploid) derived from *Abelmoschus tuberculatus* (2n = 58), a wild species from India, and a species (*Abelmoschus ficulneus* (L.) Wight and Arn. ex Wight) with 2n = 72 chromosomes. Another edible okra species are *Abelmoschus caillei* (A. Chev.). Stevels occurs in the humid parts of West and Central Africa. There are strong indications that *Abelmoschus caillei*is amphidiploids with *Abelmoschus esculentus*being one of the parental species. The lowest chromosome number 2n=56 reported in *Abelmoschus angulosus* whereas, the highest chromosome number 2n=196 reported in *Abelmoschus manihot* var. *Caillei* (Singh and Bhatnagar, 1975, Siemonsma, 1982a, 1982b) [5, 6, 7]. Largest area and production is in India followed by Nigeria in the world. India ranks first in the world with 72 per cent of the total world production of okra. The information about correlation among different component of yield is necessary for designing efficient plant breeding programme through selection and for simultaneous improvement of yield components. Therefore, such information can be obtained by the studying genotypic and phenotypic correlation coefficient between yield and yield contributing characters. Path coefficients analysis is helpful in portioning the observed correlation coefficient into direct and indirect effect and there effective use in selection programme.

Materials and Methods

The research work was undertaken at the Main Experimental Station, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology Narendra Nagar (Kumarganj), Ayodhya (U.P.) India during the *Kharif*, 2019. Geographically the experimental site (Kumarganj, Ayodhya) falls under humid sub-tropical climate and is located at 26.47° N latitude and 82.12 °E longitude at an altitude of 113 meter above the mean sea level. The experiment was conducted using thirty six genotypes in Randomized Block Design with three replications.

Abstract

The present investigation were undertaken to obtain information about general and specific combining ability in parents and F_1 generation, respectively of eight parental diallel cross (excluding reciprocals) of bottle gourd [*Lagenaria siceraria* (Mol.) Standl.] at Department of Vegetable science, N.D. University of Agriculture & Technology, Kumarganj, Faizabad. Parental line P_2 emerged good general combiner for fruit circumference, number of fruits per plant and fruit yield per plant while parent P_8 showed highly significant general combining ability effect for vine length, number of primary branches per plant and fruit length. The parent P_7 was the best general combiner for all the traits studied except average fruit weight. The cross $P_2 \times P_3$ had highest specific combining ability effects for fruit yield along with number of fruits per plant. The highest specific combining ability for number of branches per plant was indicated by cross $P_5 \times P_8$ while $P_1 \times P_3$ was the best specific combiner for vine length.

Key words **:** *Lagenaria siceraria*, combining ability analysis, GCA (general combining ability) and SCA (Specific combining ability).

Introduction

In the cucurbitaceous vegetable crops, bottle gourd is a cultivated annual monoecious species, belongs to the family cucurbitaceae, having chromosome number 2n = 22, with its high yield potential and adoptability to diverse climatic condition in India. Homozygous are considered an important aspect in any breeding programme aimed improving yield and its related attributes. The diallel mating design is very useful for preliminary evaluation of genetic studies through hybridization programme. Hence a study was undertaken to identify the best combiners among the existing germplasm as well as gene action of different quantitative characters in 8 x 8 diallel set without reciprocal to facilitate the formulation of sound breeding programme.

Materials and Methods

The experimental materials comprised of eight inbred lines namely, Pusa Naveen (P_1), NDBG-504 (P_2), NDBG-509 (P_3), NDBG-525 (P_4), NDBG-601 (P_5), NDBG-603 (P_6), NDBG-624 (P_7) and NDBG-625 (P_8) and 28 hybrids derived from the diallel mating design (excluding reciprocals). The parents and F_1's were grown during summer (*Zaid*) crop seasons of 2008 (Y_1) and 2009 (Y_2) in Randomized Block Design with three replications. The experiment was conducted in single row of 3 meters long with row to row spacing of 3 meters and plant to plant spacing of 50 cm. aparts at Department of Vegetable Science, N.D. University of Agriculture & Technology, Kumarganj, Faizabad. Six plants were maintained in each plot. The recommended agronomic practices were followed to raise a good crops. The observations were recorded for vine length (m), number of primary branches per plant, fruit length (cm), fruit circumference (cm), number of fruits per plant, average fruit weight (kg) and fruit yield per plant (kg). Combining ability variances and their effects were worked out according to Griffing (1956 b).

Results and Discussion

The mean squares due to general combining ability (gca) and specific combining ability (sca) were highly significant for all the characters indicating importance of both additive and non-additive genetic components of variance (Table-1). Similar results were also reported by Khattra *et al.* (1994). Estimates of general combining ability (gca) and specific combining ability (sca) are given in Table-2 and 3, respectively. In respect to vine length parents P_3 (0.38 and 0.25), P_8 (0.32 and 0.25) and P_7 (0.04 and 0.06) during both the years showed significantly positive gca effects. Fourteen and eight crosses were showed highly significant positive sca effects in Y_1 and Y_2, respectively, among these crosses the highest positive sca effects were in cross $P_1 \times P_3$ (1.40 and 1.65) during the both years. For increase number of branches, the best combiners were P_8 (1.10 and 1.32), P_5 (0.95 and 1.32), P_7 (0.83 and 0.34), P3 (0.75 and 0.76) and P6 (0.65 and 0.22) during both the years. The three best crosses showed positive and high

ABSTRACT

The experiment was conducted at Main Experimental Station, Department of Vegetable Science, Acharya Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya during *Kharif*, 2019 in Randomized Complete Block Design with three replications using thirty -six genotypes of okra collected from different sources to study the extent of variability, heritability and genetic advance in per cent of mean for different quantitative traits. The analysis of variance for the design of experiment indicated highly significant differences among the genotypes for all the characters. Based on mean performance of genotypes NDO-37 (210.79) followed by NDO-26 (209.33), NDO-27 (199.41), NDO- 31 (208.97) and NDO-36 (209.12) were found as five most promising genotypes for fruits yield per plant. High magnitude PCV were observed in case of number of branches per plant (16.23) followed by fruit length (9.91), total fruit yield per plant (9.36). High heritability was estimated for total fruit yield per plant (99.3) followed by average fruit weight (93.86), petiole length (92.80) number of branches per plant (84.54). High heritability coupled with high genetic advance were estimated for number of branches per plant (84.54,28.27) followed by total fruit yield per plant (99.13, 19.11) and average fruit weight (93.86, 14.29) which indicating opportunity for high selection response.

Introduction

Okra [*Abelmoschus esculentus* (L.) Moench 2n = 2x=130] is one of the important member of the family malvaceae and is well known by many regional names as lady's finger in England, Gumbo in USA, Dherosh in Bangladesh, Huang GiuKui in China, Quingombo in Spanish, Bhindi in Pakistan and India. Okra is an African word and is native to northern Africa including the area of Ethiopia and Sudan. It is a summer and rainy season crop and is widely cultivated from tropics to sub tropics. Okra (*Abelmoschus esculentus* L.) is probably an amphidiploids (allotetraploid) derived from *Abelmoschus tuberculatus* (2n = 58), a wild species from India, and a species (*Abelmoschus ficulneus* (L.) Wight and Arn. ex Wight) with 2n = 72 chromosomes. According to Vavilov, it was probably domesticated in the Ethiopian region but, according to Murdock, it is originated in

Studies on genetic variability, heritability and genetic advance for growth, yield and its component traits in cucumber (*Cucumis sativus* L.)

Raja Bhaiya, VB Singh, GC Yadav, Navneet Singh, Pankaj Verma and Devesh Tiwari

Abstract
The present investigation conducted at Main Experiment Station, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj) Ayodhya, involving 28 diverse genotypes of cucumber (*Cucumis sativus* L.) in Randomized Block Design replicated thrice to estimate the genetic variability, heritability (bs) and genetic advance in present of mean for planning the leading strategy in the available germplasm. The observations were recorded on different characters like- Days to first male (staminate) flower anthesis, Days to first female (pistillate) flower anthesis, Node number to first staminate flower appearance, Node number to first pistillate flower appearance, Number of primary branches per plant, Vine length (m), Days to first fruit harvest, Fruit length (cm), Fruit diameter (cm), Number of fruit per plant, Average fruit weight (g) and Marketable fruit yield per plant (kg).
The analyses of variance revealed that mean sum of squares due to genotypes were highly significant for all the traits indicating ample variation among the genotypes. The estimates of heritability in board sense and genetic advance as a percentage of mean were studied in the study. The range of heritability in board sense varied from 58.20% to 99.0%. Maximum estimates of heritability was recorded for length of fruit (99.00%). Based on mean performance of genotype NDCC-23 followed by Pusa Uday (1.700 kg), NDCC-4 (1.660 kg), NDCC-5 (1.590 kg), and NDCC-19 (1.560 kg) were found as five most promising t yield per plant.
Hence due emphasis should be given to these characters during selection for developing high yielding genotypes in cucumber.

Keywords: Cucumber, genetic variability, variation and yield

Introduction

Cucumber (*Cucumis sativus* L.) is a member of family Cucurbitaceae, which comprises of about 120 genera and more than 800 species (Rubatzky and Yamaguchi, 1999) [7]. The genus *Cucumis* comprises of about 30 different species in two groups and distributed over two geographically distinct areas. The Asiatic group, to which cucumber belongs, has been found growing wild in the South and East of Himalayas and has diploid chromosome number 2n = 2x = 14 whereas, the African group, including West Indian Gherkin (*Cucumis anguria* L.) and muskmelon (*Cucumis melo* L.) have diploid chromosome number 2n = 2x = 24, have been found wild in Africa and Middle East. The species of one group are genetically and reproductively well isolated from that of other group. Cucumber is in cultivation for last over 3000 years and is thought to be originated in India. It further spread East ward to China and West ward to Asia Minor, North Africa and Southern Europe (Seshadri and Parthasarathy, 2002) [8]. Regarding the ancestral form, Sir Joseph Hooker concluded that Indian wild cucumber (*Cucumis sativus var. hardwickii* Kitamura.) which is found growing wild in the foothills of Himalaya, as either feral or progenitor of present day cucumber. Similar and strong evidence on this aspect was given after six isozyme analysis of Indian wild cucumber carried out by Issihiki *et al.* (1992) [4]. India is the world's second largest producer of vegetables after China, whereas in India it is grown in an area of 0.078 million hectares with a production of 1.142 million tonnes with productivity of 14.64 t/ha (Anonymous, 2017) [1]. For any effective selection programme, it would be desirable to consider the relative magnitude of association of various characters with yield.
Assessment of genetic diversity could be suitable in crop breeding for diverse applications such as identifying diverse parental genotypes. Genetic diversity is the amount of heritable variability between varieties or populations of organisms. Substantial effort has been directed towards collecting, preserving and evaluating genetic variability in crops (Golabadi *et al.*, 2012) [3].

To Study on Heterosis for Yield and Its Contributing Attributes in Brinjal (*Solanum melongena* L.).

P. S. YADAVA, G. C. YADAV AND V. B. SINGH

Department of Vegetable Science, ANDUA&T, Kumarganj, Ayodhya U.P
email: premvegetable@gmail.com

ABSTRACT

A Study was conducted in brinjal to estimate the magnitude of heterosis for yield and its fifteen yield components. 36 F1 hybrids generated by half diallel crosses of nine pure diverse parent and these F_1 along with 8 parents were evaluated in randomized block design with three replication at research farm of main vegetables research station at ANDUA&T, Kumarganj, Ayodhya (India). Appreciable heterosis was found over better and standard parents for all the traits studied in desirable direction. In order of merit F1 hybrids P3xP7 (46.06%) followed by P3xP9 (30.25%) and P3xP6 (27.74%) were observed significant heterosis over maximum heterobeltiosis (better parent heterosis) for fruit yield per plant. In case of standard heterosis, significant and positive heterosis over standard check pant rituraj for fruit yield per plant was observed in hybrids P1xP8 (24.44%) followed by P1xP3 (21.25%) and P3xP7 (21.11%). The present study reveals good scope for isolation of pure line from the progenies of heterotic F_1 as well as commercial exploitation of heterosis in brinjal.

Keywords *Brinjal, Heterosis, Better parent, Standard parent, Diallel.*

Brinjal is an important vegetable crop in india and is grown throughout the year. However, its is widely cultivated in both temperate and tropical regions of the globe mainly for its immature fruits as vegetables (Rai et al., 1995), but in the temperate region it is cultivated mainly during warm season. India is regarded as the primary centre of origin/diversity of brinjal (Vavilov, 1931; Bhaduri, 1951 and Genabus, 1963). Confirmation for this fact was made by Isshiki et al, (1994) based on the isozyme and morphological variation noticed in large germplasm collection from india. There are specific genotypes suited for specific preparation apart from the large genetic variation observed with regard for traits like color, shape and size of fruits. In addition, variation is also noticed for traits like vegetative growth, maturity and presence or obsence of spines on leaves, stem and fruits calyx among the indigeneous material.

To have such a kind of plant architecture, different breeding method can be employed. One of the methods employed is exploitation of hybrid vigour through hybridization. For the first time Bailey and Munson (1891) reported artificial hybridization in brinjal. However, none of the hybrid exhibited any heterosis. Nagai and Kida (1926) were probably the first to observe hybrid vigour in a cross combination of some Japanese varieties of brinjal. To obtain high yield per unit area, exploitation of hybrid vigour is one of the good way and particularly in crop like brinjal, were more seeds per fruit are obtained. Therefore, the present investigation was carried out to study the extent of heterosis in 36 F_1 hybrid over mid parent, better parent and standard parent in a diallel cross set of 9 parents, excluding reciprocals. These studies would be helpful for select potent trensgressive segregants which can be further evaluated for inhanced yield potentiat.

MATERIALS AND METHODS

The experimental material comprised of nine pure diverse parents viz, Siliguri (P1) Mukta kesi (P2), NBD-18-4 (P3), SM 6-6 (P4), Arka Nidhi (P5), Swarna Mani (P6), KS-224 (P7), Pant Rituraj (P8) and NBD-2 (P9) along with its 36 F_1 hybrids generated by half-diallel in all possible combinations excluding reciprocals during *kharif*, 2010-11. Pant Rituraj and NBD-2 used as standard check also. The experiment was laid out in randomized block design with three replications at research farm of main vegetable research station, ANDUA&T Kumarganj, Ayodhya (India) during kharif 2011-12. Each plot consisted of a single row of 10 plants. Inter and intra row spacing was kept 90 and 60 cm, respectively. The observation was recorded in five randomly selected plants from each treatment and replication for fifteen characters

ABSTRACT

The present experiment was carried out with cauliflower var. Snow Crown in randomized block design with three replications. The experiment comprised of eleven different treatment combinations of five different sources of nutrients including organic, inorganic and biofertilizers alone in combinations were applied following the proper procedure as per the treatments. The experimental findings revealed that the treatment T_{11} (Half dose of NPK/ha + Vermicompost @ 2.5 tonnes/ha + *Azospirillium* @ 5 kg/ha + *Vesicular Arbascular Mycorrhiza* @ 5 kg/ha) showed better response to plant growth and its attributes and quality. However, maximum yield 269.33 q/ha and 267.02 q/ha were obtained with the application of half dose of NPK/ha + Vermicompost @ 2.5 tonnes/ha + *Azospirillium* @ 5 kg/ha + *Vesicular Arbascular Mycorrhiza* @ 5 kg/ha followed by T_9 (Half dose of NPK/ha + Vermicompost @ 2.5 tonnes/ha + *Azospirillium* @ 5 kg/ha). On the basis of economic analysis, maximum cost: benefit ratio (3.18 and 3.05) was recorded with the application of half dose of NPK/ha + FYM @ 15 tonnes/ha + *Azospirillium* @ 5 kg/ha + *Vesicular Arbascular Mycorrhiza* @ 5 kg/ha (T_7) during 2009-10 and 2010-11, respectively and this treatment combination was found most beneficial and feasible for cultivation of cauliflower.

Key words *IPNM, Bio-fertilizers, Cauliflower, Yield, Economics.*

Cauliflower (*Brassica oleracea* var. *botrytis* L.) belongs to family cruciferae and most popular Cole crop among the winter vegetables. It is grown for its highly suppressed 'prefloral fleshy apical meristem' branches called "curd." Cauliflower was introduced in India in 1822 by Jemson at Saharanpur (U.P.) during the period of East-India Company. After originating in Cyprus, the cauliflower got established around Mediterranean region, particularly in Italy. India is the second largest producer of cauliflower in the world after China followed by USA, Spain, Italy and France. In India, cultivation of cauliflower is done over an area of about 321000 hectare with a production of 57,97,000 metric tonnes and their productivity is 18.1 metric tonnes per hectare. The highest production of the crop in the country are West Bengal (1.70 million tonnes), followed by Bihar (1.0 million tonnes) and Orissa (0.60 million tonnes) and highest productivity is in Maharashtra 25.30 metric tonnes) and West Bengal (25.10 metric tonnes) followed Uttar Pradesh (20.40 metric tonnes). Cauliflower shares about 4.1% of the total area under vegetables and 4.0% of the total production. However, it is at 4th rank in productivity after tapioca, cabbage and potato (Anon., 2008).

It is one of the most important and a popular vegetable crop being grown round the year throughout the country for its white and tender curd. The use of chemical fertilizers contributes a lot in fulfilling the nutrient demand of cauliflower but irregular, excessive and imbalanced application of nutrients deteriorates the physico-chemical properties of the soil and quality of the cauliflower curd. Organic/inorganic fertilizers alone does not supply the major nutrient element in required quantity hence the integrated plant nutrient management (IPNM) in cauliflower is one of the best method of supplying nutrients to the plants to maintain the soil fertility to sustain the agriculture productivity and to improve the profitability.

It has been reportedly confirmed that continuous sole use and imbalanced use of mineral fertilizers leads to decrease in nutrient uptake efficiency of plants resulting in either yield stagnation or decrease in yield (Samant *et al.*, 1992; Rubeiz *et al.*, 1993 and Rajanna, *et al.*, 1994). Therefore, there is need to increase the productivity of cabbage per unit area by integration of judicious and balanced use of mineral fertilizers with organic manures. The integrated supply and use of plant nutrients from the chemical fertilizers and organic manures have been proved to produced higher crop yields than when each applied alone. This increase in crop productivity results from their combined effect the synergistic effect, improve chemical, physical and biological properties of the soil. Manures and fertilizers are the kingpins of improved technology contributing about 50-60% increase in productivity of vegetable in India irrespective of soil and agro-ecological zone. But without an integrated supply and use of plant nutrient from chemical fertilizers and organic sources, increased production is not possible. The economics of

Direct and indirect effect of yield components on yield of eggplant (*Solanum melongena* L.) by path co-efficient analysis

Satrughan Pandey, Sudhanshu Mishra, Navin Kumar, GC Yadav and VP Pandey

Abstract
The analysis of variance for the design of experiment indicated highly significant differences among the genotypes for all the traits. Based on mean performance of genotypes NDB-5 followed by NDB-5 followed by NDB-15, NDB-6, NDB-4, NDB-7 and NDB-16 were yield per plant, fruit weight and yield per plant indicating opportunity for selection response. Yield per plant had exhibited highly significant and positive association with fruits per plant and early yield while primary branches showed negative and significant association with yield per plant. Fruits per plant, fruit weight and plant height were identified as most important traits which has direct effect on yield per plant while negative direct effect on yield showed by fruit circumference followed by plant height and days to 50% flowering on yield. Path coefficient provide an effective means of entangling direct and indirect causes of association are measure and measure the relative importance of each caused factor.

Keywords: Eggplant, *Solanum melongena* L.

Introduction

Brinjal or eggplant (*Solanum melongena* L.) is one of the most important solanaceous vegetable crop having diploid chromosome number 2n=2x=24. It is grown in the tropics and subtropics of India and other parts of the world. It is called Brinjal in India and Aubergine in Europe. It is extensively grown in India, Japan, Indonesia, China, Bulgaria, Italy, France, USA, Pakistan, Bangladesh, Philippines and several African countries. Due to high productivity and wife adoptability, usually finds its place as the poor man's crop.

Brinjal being most important to growers and consumer, there is pressing need to increase its productivity to fulfill the increasing demands throughout the year. The information usually needed for developing high yield varieties in a particular species pertains to the extent of genetic variability for desirable train in the available germplasm. Evaluation of germplasm is the basic tool for identification of important genotypes. The great extent of natural variation present in various characters among the genotypes suggests good scope of improvement in economic. Degree of association between the various characters and direct effect of yield contributing characters on total yield, is of paramount significance in formulating an appropriate breeding strategy aimed at exploiting the inherent variability of the original population.

Materials and Methods

The present investigation entitled "Variability, character association and genetic divergence in egg plant (*Solanum melongena* L.)" was executed at Main Experiment, Station of Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Faizabad, during *Kharif* 2010, to find out the direct and indirect effect of yield components on yield by path coefficient analysis. The experimental field had sandy loam soil, low in organic carbon, nitrogen, medium in phosphorus, potash, and slightly alkaline in nature with pH 8.5.The mechanical composition of soil was 60.9 per cent, 27.8 per cent silt and 11.3 per cent clay. Experimental material for the study consisted of 30 genotypes including six checks (Arka Nidhi, NDB-2, SM 6-6, Pant Rituraj, KS-224 and S. Mani). The experiment was conducted in Randomized Complete Block Design with three replications. Each treatment consisted 20 plant in two row, having spacing of 60 × 45 cm with net plot size of 4.5 × 1.2 m^2. Observations were recorded on 9 quantitative characters *viz.*, days to 50% flowering, primary branches per plant, plant height (cm), Fruit weight (g), fruit circumference (cm), polar length of fruit (cm), fruits per plant, early yield per plant (g) and yield per plant.

Studies on genetic divergence in sponge gourd (*Luffa cylindrica* L. Roem.)

Veerendra Kumar, VB Singh, GC Yadav, Deepak Maurya and Manjeet Kumar

Abstract
The experiment was conducted during the spring-summer season, 2017 in Eastern Uttar Pradesh, to evaluate the nature and magnitude of genetic divergence among the thirty genotypes of bitter gourd were carried out by using Mahalanobis D^2 statistics. Thirty genotypes were grouped into 7 different non-overlapping clusters. The highest number of genotypes was presented in cluster III which contained 9 entries followed by cluster V which contains 8 entries, cluster VI which contained 5 entries, cluster I which contained 4 entries, cluster IV which contained 3 entries and cluster II possess 1 entries respectively. Highest estimates of genetic advance in per cent of mean was recorded for vine length (80.31%), node number to anthesis of first staminate flower (66.23%), number of fruits per plant (45.65%), total fruit yield/plant (38.42%). Moderate genetic advance in per cent of mean was estimated in number of primary branches per plant (37.86%), node number to anthesis of first staminate flower (37.65%), fruit length (37.40%), number of nodes per vine (35.35%), average fruit weight (31.68%), fruit diameter (29.79%) whereas days to anthesis of first pistillate flower (26.12%), days to anthesis of first pistillate flower (23.80%), days to first fruit harvest (21.58%) showed low genetic advance in per cent of mean. Vine length contributed maximum towards genetic diversity (26.67%), followed by fruits per plant (25.75 %), days to anthesis of first pistillate flower (13.69%), average fruit weight (9.43%), number of primary branches per plant (8.51%), node number to anthesis of first staminate flower (7.36%), fruit length (4.37%) and total marketable fruit yield per plant in sponge gourd.

Keywords: genetic divergence and sponge gourd

Introduction

Luffa [*Luffa cylindrica* L. (Roem) *Syn.* L. *ageyeptica* Mill.] commonly called as sponge gourd, Loofah, vegetable sponge or dish cloth gourd, is a member of family Cucurbitaceae having diploid chromosome number 2n=2x=26.It originated in subtropical Asian region particularly India (Kalloo, 1993) [2]. Sponge gourd is an annual cucurbit plant produces fruits containing a fibrous vascular system with various vines and cylindrical tenangled fruit. Leaves are deltoid to nearly orbicular exteriorly, but pointed at the apex and usually three to seven lobed with dentate margin (Whitaker and Davis, 1962) [6]. Sponge gourd is monoecious crop with branches tendrils. Flowers are yellow and showy having five petals. The inflorescence of staminate flowers is on raceme, while the pistillate flowers are solitary and have short to long peduncle. It is commonly grown for its tender marketable green fruits for vegetable purpose as well as for sponge of mature fruits which is used for scrubbing of body skin and utensil purposes. Fruits are rich in Iron Vitamin A and C. It has certain medicinal uses. The cooked fruit are easily digestible and very appetizing therefore it is recommended to the patients suffering from malaria or other seasonal fevers.

Luffa *(Luffa cylindrica* (L.) MJ. Roem syn. *L. aegyptica* Mill.) commonly called as sponge gourd, loofah, vegetable sponge or dish cloth.It is one of the most important cucurbits grown extensively throughout the tropical and sub-tropical regions of the country and world, The crop belongs to the family Cucurbitaceae which includes about 118 genera and 855 species. Its unripe tender fruits are popular and well known culinary in India with good nutritive value and high yield potentials. The tender fruits are rich in carbohydrates, vitamin A, vitamin C and iron.

Material and Methods

Thirty genotypes (including Pusa Chikni as check variety) of sponge gourd having diverse origin were evaluated at Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad, during the spring-summer season, 2017.

The experiment was lay out in a randomized block design with three replications in individual plot size (3m x 2.5m). The distance maintained between row to row and plant to plant was 2.5

Evaluation of genetic variability, heritability and genetic advance in sponge gourd (*Luffa cylindrica* L. Roem.) for various quantitative traits

Veerendra Kumar, VB Singh, GC Yadav and Deepak Maurya

DOI: https://doi.org/10.22271/chemi.2020.v8.i1ae.8576

Abstract
The present investigation was carried out at Main Experiment Station, Department of Vegetable Science, Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.) during summer season, to evaluate the available germplasms for yield and its component traits of 30 genotypes, with three replications in *Randomized Block Design*. The study revealed that the mean sum squares due to genotypes were significant for all the characters, through the wide range of genetic variability in the material. Genetic variability, heritability and genetic advance were studied in 13 genotypes of sponge gourd. The phenotypic coefficient of variations (PCV) was higher than the genotypic coefficients of variations (GCV) for all traits studied, indicating that the apparent variation is not only genetic but also influenced by the growing environment in the expression of the characters. The genotypic coefficients of variation and phenotypic coefficients of variation were moderate to low for all the characters except Vine length(39.53%, 40.09%) followed by node number to anthesis of first staminate flower (33.12%, 34.13%) and lower value days to first marketable fruit harvest (11.79%, 13.28%), days to anthesis of first staminate flower (12.57%, 13.69%) and days to anthesis of first pistillate flower (13.69%, 14.78%).High heritability coupled with high genetic advance was estimated for most of the traits viz., vine length (97.24%, 80.31%), node number to anthesis of first staminate flower (94.21%, 66.23%) and number of fruits per plant (92.49%, 45.65%)thus indicating that these traits had additive gene effect so that, they are more reliable for effective selection.

Keywords: Genetic variability, heritability and genetic advance, *Luffa cylindrica* L. Roem

Introduction

Luffa [*Luffa cylindrica* (L). Roem.] Commonly called as sponge gourd, Loofah vegetable sponge or dish cloth, having diploid chromosome number 2n = 2x = 26. The sponge gourd large amount of variation has been observed for many economically important traits. In India, wide range of variability is available in the land races or cultivars, in terms of qualitative characters of sponge gourd. The observations were recorded on node number to anthesis of first staminate flower, node number to anthesis of first pistillate flower, days to anthesis of first staminate flower, days anthesis of first pistillate flower, days to first fruit harvest, Vine length (m), number of nodes per vine Number of primary branches per plant, fruit length (cm), fruit diameter (cm), number of fruits per plant, average fruit weight (g) and total marketable fruit yield per plant (kg). Variability in cucurbitaceous crop occurs in the form of land races, traditional cultivars, wild relatives form and related non edible wild weedy species. In India little attention has been given for the genetic improvement of sponge gourd by collecting diverse germplasm, their morphological characterization and assessing the variability parameters like coefficient of variation. The appropriate breeding methodologies may be adopted for genetic improvement of this crop for simultaneously improvement of different characters, information regarding mutual relationship among the characters and direction of correlation analysis provides an effective means of finding out direct and indirect causes of association among causal variables. Though the literature in respect of germplasm evaluation variability and correlation studies in sponge gourd is not meager but these are based on testing of limited number of germplasm. Moreover, the results of the earlier studies on such aspects are relevant only for the materials and environments involved in the particular study and cannot be generalized.

Received 27 January 2020; revised 01 June 2021

Agroforestry is an age-old practice in Assam, the Northeastern state of India. But the documentation of such traditional practices is very meagre. Assam has six agro-ecological zones. This paper attempts to present the different types of traditional agroforestry systems practiced in North bank plains of agro-ecological zone of Assam. The documentation was done through direct observations. A questionnaire survey was done of 500 households in 250 villages distributed across four districts (Dhemaji, Lakhimpur, Sonitpur and Darrang) of Assam. Altogether 11 types of traditional agroforestry systems are recorded. Homegarden is the most common agroforestry system in all the four districts followed by aquaforestry and commercial crops trailed on support trees. The least common agroforestry system is *Machilus*-based agroforestry system and this system is not recorded from Darrang and Sonitpur districts of Assam. The choice of species and their planting pattern are influenced by their tradition, usage pattern and need of the agroforestry system's owner. These traditional agroforestry systems are a part of their traditional knowledge which is intervened with their traditions and culture. It is a blend of time-tested knowledge of indigenous species, their compatibility and species planting pattern such that the yield is maximized. So, the documentation of these environment-friendly traditional practices is essential to advocate climate-smart and sustainable approach in agriculture.

Keywords: Assam, Aquaforestry, *Areca*-based cropping, Live fence, *Machilus*-based agroforestry

IPC Code: Int. Cl.[22]: A01D 9/00, A01G 23/00

The traditional agroforestry is a human-managed land-use system in which woody perennials are intentionally grown in association with agricultural crops, pastures as well as livestock. Most of these traditional farming practices are rainfed and for household consumption purposes. The crops planted, the crop combination and the sequence of cropping in these traditional practices depend upon the edaphic, climatic, topographic conditions of the area and socio-economic status of the people. These practices are passed on from generation to generation but are not documented. In the recent years, these traditional ways of farming and cultivation are gaining importance as these practices are sustainable and environment-friendly. Therefore, emphasis is being given on documentation of these fast-depleting traditional methods of cultivation.

The traditional agroforestry systems and its practices have been documented in many countries such as Africa[1], China[2], Turkey[3] and Bangladesh[4]. In India, though agroforestry is being practiced from ancient times, only a few authors have documented these practices. A thorough literature review highlighted an inventory of the existing agroforestry systems in different states of India such as Kerala[5], Uttar Pradesh[6], Meghlaya[7], Arunachal Pradesh[8], Chattisgarh[9] and Nagaland[10]. Four agroforestry systems namely rainfed agrihorticultural system (*Cocos nucifera, Areca catechu, Citrus* sp., *Zingiber officinale, Curcuma longa*), silvipastoral systems (*Artocarpus* sp., Napier grass, Guinea grass), silvihortipastoral systems (*Bombax ceiba*, Thatch) and irrigated silviagrosystem (*Azadirachta indica, Oryza sativa* and oilseeds) are reported from Assam[11].

It is quite evident from the above that traditional agroforestry systems are present in Northeast India, and there is only a single case of inventory of the systems practiced in Assam. This shows that many agroforestry systems and practices still remain to be documented from this region. Therefore, there is a need to capture the local and traditional plant management practices before these are lost forever. Also, with the increasing

Abstract: Traditional agroforestry systems are designed to provide maximum and diverse yield (ranging from agricultural crops, forest trees, livestock and fish) to people. They also act as sources of food and shelter to wild animals leading to crop destruction, livestock depredation and injuries to people giving rise to negative human-wildlife interactions. The present study was carried out in three different agroforestry systems namely tea gardens, homegardens, and agrisilvicultural systems in Assam to document the attitude of people towards wild animals which damage the crops and livestock, through questionnaire surveys. In agroforestry systems, 13 animals were reported as destructive; rodents at 13% followed by Indian Hare at 12%. The least destructive were birds and bats with 4% each. In tea gardens majority of the people killed animals for meat (95%) and the most common method for killing was the use of catapults (77%). In homegardens and agrisilvicultural systems, owners chased the animals away (82%) by using catapults (68%). Hunting of animals and intolerance of people towards crop destruction and livestock depredation done by wild animals were the two main reasons causing negative human-wildlife interactions in agroforestry systems. The present study concludes that wildlife species found in the agroforestry system in Assam were threatened by local inhabitants and thus, a suitable conservation awareness and policy action plan should be developed in consultation with the owners of agroforestry systems by considering the ecological significance of the wildlife species found therein.

Keywords: Agrisilvicultural systems, agroforestry systems, crop destruction, destructive wildlife species, homegardens, tea gardens.

ABSTRACT

This study conducted from January to June 2018, attempts to determine the density, habitat preferences and attitudes of people towards *Gekko gecko* and its impact on the conservation of this species in human-dominated landscapes in Sonitpur district, Assam. Eight villages at different distances from Nameri Tiger Reserve were chosen for the study. The line transects analyzed using DISTANCE software estimated a density of 7.99 individuals ha^{-1} in fringe villages of Nameri Tiger Reserve which also had higher number of host tree species diversity with higher basal area and density as compared to that of villages distant from Nameri Tiger Reserve. *Gekko gecko* was sighted on a total of 30 trees (6 species, 2 families), the highest being *Ficus rumphii* (40%). Maximum sightings of *Gekko gecko* was done on trees (67%). The occurrence of *Gekko gecko* was highly influenced by distance from forest (12%), followed by source of income (11%) and gender (4%). The majority of the respondents (53.54%) revealed that *Gekko gecko* occurred naturally in the homegardens implying that homegardens provided the habitat that can support the populations of *Gekko gecko*. But 46.45% of the respondents reported that they were adopted (62.16% in villages distant from Nameri Tiger Reserve), which raises serious concerns about the conservation of *Gekko gecko* in homegardens. Though, majority of the people knew that it is illegal to trade *Gekko gecko*, the financial benefits of its trade is very alluring. To make homegardens more favourable for the survival of *Gekko gecko* there should be strict law enforcement, upgradation of the species in the IUCN Red List and options for alternative livelihood.

1. Introduction

Biodiversity conservation is a challenge for the conservationists, as the tropical forests are getting depleted, fragmented and isolated into human-modified landscapes [31,33]. Moreover, the protected areas set aside to protect the species and its habitat [5] are under constant human pressure [27]. Many studies have suggested that the natural habitats outside protected areas also have the ability to conserve species diversity [23]. So, the need of the hour is to conserve biodiversity in these rapidly increasing human-dominated landscapes which are outside the protected areas. But the anthropogenic pressure in these landscapes alters the ecosystems processes [45]. The existence of native fauna in such areas depends upon their ability to traverse through the modified habitats, patches and to adjust with the constant changes in their habitat [13]. Reptiles are conspicuous and abundant in nature making them good candidates for studies on understanding the impact of habitat change [20]. As reptiles are found in diverse habitats and niches, they are very sensitive to landscape level changes and deforestation [22,59]. They are also vulnerable to the micro-habitat level changes due to their ectothermic nature [42]. Yet studies have shown a high persistence of reptiles in altered habitats [54,60].

Northeastern India is known to harbor a good reptile diversity (121 species) with a high percentage of endemic and threatened species [44]. But as conversion of tropical forests into tea plantations, agricultural lands, human habitations etc. is very rapid in the northeastern states of India, it leads to fragmentation, deforestation [10–12] and thus habitat loss and decline in reptilian species [57]. The Sonitpur district of Assam alone has reported conversion of well stocked forests into human-dominated landscapes leading to an overall loss of 232.19 km^2 of forest between 1994 and 2001 [55]. The human-dominated systems like homegardens, agricultural lands, cacao and coffee plantations interspersed with secondary forest patches and remnant vegetation are known to harbor rich reptilian diversity comparable to the adjacent forests [50,60,61]. But in such human-dominated areas, the attitudes of the local communities plays an important role in the conservation of species as such areas are known for their negative interactions with faunal species [66,67]. Due to the dearth of information on the population density

Abstract: Birds have a significant role in maintaining the ecological balance of agro-ecosystems. But yet there is no documentation related to bird diversity in the agricultural landscapes of eastern Uttar Pradesh. This study was conducted from March 2019 to February 2020 using fixed radius point count method in Ayodhya district of eastern Uttar Pradesh. A total of 139 bird species belonging to 107 genera, 49 families and 15 orders were recorded from the study area. Passeriformes was the most dominant order with 28 families and 76 species. Accipitridae and Muscicapidae were the most diverse families with 11 species each and RDi value of 7.91. Among the recorded bird species, 105 species (76%) were resident, 29 species (21%) were winter visitors and only 5 species (4%) were summer visitors. According to the feeding guilds, omnivores (46 species, 33%) were highly represented, followed by insectivores (31%), carnivores (25%), granivores (6%), frugivores (4%) and nectarivores (1%). The Sohawal tehsil was found to have the highest species richness and a Shannon-Weiner diversity index (133, 4.30). *Aquila nipalensis* and *Neophron percnopterus* were the two 'Endangered' species, *Antigone antigone* and *Clanga hastata* were the two 'Vulnerable' species and *Ciconia episcopus*, *Gyps himalayensis*, *Mycteria leucocephala* and *Psittacula eupatria* were the four 'Near Threatened' species found in this region. In addition to this, the region also supported 31 species (22%) whose global population trend is decreasing. This study provides a baseline data on the bird diversity present in agricultural landscapes of this region. Based on which further studies should be designed to understand the factors influencing the diversity of birds in these agricultural landscapes which are continuously subjected to anthropogenic pressures.

Abstract In Assam, a north-eastern state of India, most of the traditional agroforestry systems are still practised. The plant species composition of three agroforestry systems namely homegardens tea gardens and agrisilvicultural systems, were assessed using quadrat method. A total of 516 plant species belonging to 241 genera under 91 families were recorded, which consisted of 134 trees, 143 shrubs (67 shrub species and 76 species of saplings) and 239 herbs (93 herb species, 33 climber species and 113 species of seedlings). Homegardens had the highest species richness (475 plant species) belonging to 234 genera under 90 families. This was followed by agrisilvicultural systems (101 spp., 43 genera, 29 families), and the least was in tea gardens (79 spp., 41 genera, 25 families). The highest average number of plant species per system was recorded in homegarden (108.96 ± 5.96, range 23–207 spp.). A negative correlation was found between the agroforestry system plot size and plant species richness. Sorenson's similarity index showed a very low degree of similarity in the plant species recorded among the three selected systems. Out of 516 plant species recorded across the different agroforestry systems, 1.0% species (n = 3) were vulnerable (*Aquilaria malaccensis, Saraca asoca* and *Santalum album*), 8.9% species (n = 46) were least concerned, 1.6% species (n = 8) were data deficient and 88.6% species (n = 457) were not assessed. Only homegarden recorded all the three plant species under the vulnerable category of IUCN Red List. It can be concluded that the agroforestry systems, specially the homegardens harbour rich plant diversity and act as miniature versions of natural forests by conserving rare, threatened and data-deficient plant species. The results suggest that the agroforestry systems with some management interventions need to be promoted as conservation models in areas with high pressure on tropical forests.

Keywords Assam · Agroforestry system · Homegardens · Tea gardens · Plant species richness

Introduction

Traditionally, the farmers have been known to retain tree cover in agricultural landscapes, around home spaces and in cash crop plantations as shade trees. Apart from these traditional practices, the increasing rate of tropical deforestation has led to an increase in number of forest or secondary forest growth fragments intermingled with human-managed landscapes consisting of agriculture and plantations. These current forms of land-uses usually known as agroforests have now become the prominent landscapes which have a potential of conserving the natural and native vegetation [25]. These agroforestry systems not only provide food, fruits, vegetables, medicines and fuel but also

Conservation of Wildlife Diversity in Agroforestry Systems in Eastern Himalayan Biodiversity Hotspot

Yashmita-Ulman[1] · Manoj Singh[2] · Awadhesh Kumar[3] · Madhubala Sharma[3]

Received: 14 January 2020 / Revised: 22 February 2021 / Accepted: 1 March 2021

Abstract The highly diverse tropical forests are fast being depleted and converted into isolated fragments which endangers the existence of wild animals. These fragments are interconnected by human-dominated agroforestry systems. To conserve the wild animals it is important that such agroforestry systems have the potential habitat to support the survival of the enormous regional biota. The present study was carried out in agroforestry systems (agrisilviculture systems, home gardens and tea gardens) in Assam to understand their role in conservation of different biological groups (mammals, birds, butterflies, reptiles and frogs). Total visual count method was deployed in home gardens and agrisilviculture system and line transects were laid in tea gardens for recording the faunal diversity. Altogether, 364 animal species (consisting of 14 mammal species, 185 bird species, 133 butterfly species, 18 reptilian species and 14 amphibian species) were recorded from the selected study sites of agroforestry systems. The highest animal diversity was found in home garden (311 spp.), followed by tea garden (275 spp.) and agrisilviculture system (187 spp.). Out of the 364 species recorded, only 1.09% were threatened (endangered and vulnerable) species and 1.37% were near threatened species according to the IUCN Red List. Wild animal species richness was significantly and negatively associated with distance from forest and positively associated with fruiting and flowering vegetation. Thus, the agroforestry systems with their flowering and fruiting vegetation, though cannot substitute the forest habitat but can be useful in providing shelter to the generalist species and their populations.

Keywords Home gardens · Tea gardens · Agrisilviculture systems · Mammals · Birds · Butterflies

Introduction

Highly diverse ecosystems like the tropical forests, are being converted or deforested for agricultural expansion, developmental projects and land-use intensification (Pastur et al. 2012). It has resulted in habitat loss, degradation, fragmentation (Harris and Silva-Lopez 1992) leading to biodiversity loss (Flynn et al. 2009). One possible and effective solution to conserve biodiversity may be to manage the remaining contagious forest areas as protected areas and manage the human-dominated agricultural landscapes (Schroth et al. 2004) by adopting age-old methods of agroforestry. Agroforestry is the intentional growing of woody perennials along with annual crops and/or animals in the same unit of land (Nair 1993). Assam, a part of Northeast India region falls under the east Himalayan biodiversity hotspot. This state has abundant forms of agroforestry systems in place since ancient times. Ahmed and Hazarika (2007) broadly classified the agroforestry systems present in Assam into five types namely, Agri-horticultural system (*Ricinus communis*/*Sesamum indicum*/

Agroforestry Systems: A Boon or Bane for Mammal Conservation in Northeastern India?

Yashmita-Ulman[1] · Manoj Singh[2] · Awadhesh Kumar[3] · Madhubala Sharma[3]

Received: 28 December 2019 / Revised: 15 June 2020 / Accepted: 24 June 2020

Abstract The degradation, fragmentation and isolation of tropical forests have led to the formation of small patches of human dominated landscapes interspersed with forest fragments. This affects the wildlife habitat and its population negatively. These human landscapes have been observed to have agroforestry systems as a dominant cropping practice in Assam, India. The present study was carried out in agroforestry systems (agri-silviculture systems, home gardens and tea gardens) to understand their role in the conservation of mammal species. Line transects and camera traps were used for recording mammal diversity. Altogether, 17 species of mammals belonging to 16 genera and 14 families were recorded in the selected agroforestry systems. The highest species richness was found in the home gardens (14) and the lowest was found in the agri-silviculture system (10). Home garden had the highest mammal encounter rate and relative abundance. Only five species of mammals were recorded through camera trapping. According to the IUCN Red List, 6% of mammal species recorded in the selected agroforestry systems were endangered or near threatened and 18% were vulnerable. The highest hunting trap encounter rate was found in tea garden (139 traps, 0.181 traps km^{-1}, 24 captures). Distance from forest was inversely proportional whereas hunting threat was directly proportional to mammal species richness. The only and strongest predictor of mammal species richness was hunting threat which accounted for 53.5% of variation in mammal species richness in the study area, implying that the agroforestry systems are capable of conserving species if hunting pressure is reduced. Therefore, promotion of alternative livelihood and formation of community conservation groups are needed to increase and protect the mammalian diversity in these agroforestry systems. Thus, agroforestry systems can act as a suitable habitat next to forests for the dwindling wildlife population.

Introduction

Agroforestry systems (practice of combining trees with agricultural crops) are known to contribute in wildlife conservation owing to their structure and vegetation composition. Schroth et al. (2004) identified three roles of agroforestry in biodiversity conservation namely, provision of alternative habitats for generalist species, reduction of primary forest conversion rates and conservation of wildlife populations by connecting isolated habitat remnants. The various types of agroforestry systems like live fences, riparian forests and shade-grown crops etc. have been known to provide habitats for animal species such as moths (Ricketts 2001), birds (Greenberg et al. 2000; Klein et al. 2003; Bos et al. 2007; Schroth and Harvey 2007), terrestrial mammals (Estrada et al. 1994) and bats (Estrada et al. 1993; Faria and Baumgarten 2007). Gallina et al. (1996) has studied the mammalian diversity in coffee agroforestry

Summary
This study examines the purple sunbirds' (*Cinnyris asiaticus*) vocalizations in different habitats to assess the vocal adjustments made by the bird to avoid masking of its acoustic signals in noisy conditions. Sampling of acoustic signals of purple sunbird at different sites was done at sites with varying background noise levels by simultaneously recording the audio samples as .wav files, and the corresponding sound pressure levels. We identified twelve different types of vocal signals in purple sunbird based on their morphological appearance in the spectrogram. Correlation analysis between background noise levels and spectral parameters of most of these signals showed weak and statistically non significant association between them. However, a statistically significant positive association was found between song amplitude and background noise levels. While our results support the presence of Lombard effect in purple sunbird vocalizations in noisy conditions, they do not seem to suggest any associated changes in spectral content in such conditions.
PACS no. 43.80.-n

1. Introduction

Globally expanding urban perimeters and fast developing transportation network have been associated with increasing anthropogenic noise [1]. It is now well known that increased noise levels in urban habitats may mask acoustic communication in many bird species, and can cause changes in their acoustic behavior [2, 3, 4, 5, 6]. Birds rely on acoustic communication for a variety of functions such as mate attraction, territory marking, predator alarm, begging for food, contact with neighbours, availability of food and for many other functions [7, 8, 9, 10]. Hence, their survival and reproductive success are adversely influenced by increase in the background noise which tends to mask bird vocalizations [11, 12, 13, 14].

Birds adjust their vocal behavior in different ways to overcome the negative effects of noise on signal communication. This includes shifting the vocalization temporally to quieter periods [15], increasing signal repetition [16], raising the amplitude i.e. Lombard effect [17, 18, 19, 20, 21] and altering the spectral content [22] of vocalization. Among these, the latter two strategies i.e. raising the amplitude and altering the spectral content have drawn considerable attention of researchers across the world.

Slabbekoorn and Peet (2003) reported frequency adjustment in great tits (*Parus major*) in the city of Leiden (The Netherlands) where individuals in territories with higher noise levels were found to sing songs at raised minimum frequencies [22]. Since then, this strategy of song frequency adjustment has been reported repeatedly in many other studies. For instance, similar frequency shift was also reported in other populations of great tits (*Parus major*) [5, 23, 24, 25], song sparrows (*Melospiza melodia*) [26], house finches (*Carpodacus mexicanus*) [27, 28], chiffchaffs (*Phylloscopus collybita*) [29], black-capped chickadees (*Poecile atricapillus*) [30]. Interestingly, many of these studies report that it is the minimum song frequency that is shifted upwards, presumably as a response to avoid signal masking by the low-frequency traffic noise.

However, Brumm and Zollinger (2011) argued that these studies did not measure the song amplitude and that such frequency changes may occur in association with Lombard effect as a byproduct [31]. They suggested that increase in the vocal frequency occurs involuntarily when the bird makes effort to be heard in noisy conditions by raising its amplitude. Such an increase in the vocal frequency coupled with the Lombard effect was reported in budgerigars [32], tinamous [33] and mallards [34], which are non-songbirds. However, other studies [35, 36, 37] reported the absence of such association between Lombard effect and frequency shift in songbirds. Dorado-Correa *et al.* (2018) suggest that songbirds might have developed the capacity to decouple the amplitude and frequency during the Lombard effect [34].

MS 2577 (MS Received 21.06.2020, MS Revised 26.07.2020, MS Accepted 27.07.2020)
(RESEARCH PAPER IN HORTICULTURE)

Abstract

The present study was conducted with aim to find out heterosis and economic heterosis for growth characters, marketable yield and quality attributes. The line × tester mating design was used for the seed production and the lines, testers and their offspring were evaluated for two consecutive years. The evaluation was conducted in randomized block design with three replications. The study revealed that the heterosis for marketable fruit yield per plant, over better parent ranged from -64.64 per cent to 32.36 per cent and the heterosis over standard variety ranged from -44.77 to 50.50 per cent and in Y_2 economic parent ranged from-60.57 per cent to 47.36 per cent and standard heterosis from-53.24 to 20.91 %. The significant and heterotic crosses common in both the seasons for fruit yield per plant were Azad T-6 × CO-3 and Azad T-6 × H-24 over better parent and Arka Abha × NDT-4 and NDT-5 × NDT-4 over standard check (economic parent). Based on the above findings it may be concluded that crosses Azad T-6 × CO-3 and Azad T-6 × H-24 which showed top heterosis over seasons, parents (better and standard) and also possessed attractive fruit shape as per market demand may be exploited as commercial hybrid in future.

Key words: *Tomato, line × tester, economic heterosis, quality*

Introduction

Tomato (*Solanum lycopersicon*(Mill.)**Wettsd.**),2n=24) of nightshade or solanaceae family with primary centre of origin in Mexico-Peru-Equador region was once considered inedible but has evolved into globally leading popular vegetable. It is highly worked crop by the horticulturists and breeders. It has wide range of variation in terms of growth habit, morphological traits and uses making it a repository of glowing traits in its armory. It has determinate vs indeterminate types, cherry to table type, canning to juice type, smooth to ridged, acidic to sweet type, red to orange yellow to striped colour fruits, etc., But whatever may be the type botanically it is same and they are crossable. Botanical nomenclature of tomato has seen a lot of debate, research work and change. It's nomenclature has changed from previously widely used *Lycopersicon esculentum* Miller in *Lycopersicon* genus to originally named *Solanum lycopersicum* L. in *Solanum* genus (named in 1753 by Linnaeus; *lyco* = wolf, *persicum* = peach *i.e.*, wolf-peach). Tomato ranks second in importance next to potato in many countries including India Bose and Som, 1993).

Development of hybrids with extreme earliness, quality, uniformity and adaptability to adverse conditions, is easily possible in tomato as it is self-pollinated crop. The information about various aspects of heterosis with its manifestation is very crucial for development of superior hybrid varieteis.The formulation of plant breeding strategy mainly depends on the support of genetic information provided by studies on inheritance and behaviour of major quantitative traits in which the breeder is interested. Among the several mating designs adopted for the study of genetic architecture in tomato, line x tester mating design (**Kempthorne,1957**) has been widely used for evaluation of more number of genotypes at a time for combining ability effects. This calls for continuous work in tomato improvement in terms of varietal or F_1 hybrid development, identification and management. Many institutions are working on these aspects at national level and are coming out with new genotypes. These new genotypes could be tested for suitability and adaptability in other regions besides using them for hybrid development or getting desirable segregants.

Materials and methods

The experiment was conducted on sandy loam soil, at the Main Experiment Station, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Narendra Nagar, Kumarganj, Faizabad (U.P.) Geographically, Kumarganj falls in the sub-tropical climate and is located in between 24.470 N latitude and 82.12.0 and 83.980 E longitude at an altitude of 113 m gangetic alluvial plains of Eastern Uttar Pradesh. The physical and chemical properties of the soil are good and average fertility level and pH in the range of 7.5 to 8.5. The experimental plant material for present investigation was comprised of 36 F1's developed by crossing nine lines (Arka Abha, Azad T-6, Arka Ahuti, Punjab Chhuhara, HS-7, Angoor Lata, NDT-5, NDT-3, and Arka Abhijeet) with four testers (CO-3, H-24, H-86 and NDT-4) during *rabi*, 2012-13. The experiment was conducted in Randomized Complete Block Design (RBD) with three replications to assess the performance of 36 F1 hybrids and 13 parents (9 lines and 4 testers). Observations were recorded for five randomly selected plants in each replication. Genotype means were used for the analysis of variance (Panse and Sukhatme, 1967). The combining ability analysis was carried out following Kempthorne (1957). Data were recorded on five randomly selected plants for characters under study.

The nature and magnitude of heterosis was worked out using information on various quantitative characters studied. Heterosis expressed as per cent increase or decrease of hybrids (F_1's) over better parent (heterobeltiosis) and standard variety (standard heterosis).

Heterobeltiosis

$$\text{Heterobeltiosis}(\%) = \frac{\overline{F_1} - \overline{BP}}{\overline{BP}} \times 100$$

Where,

$\overline{BP}$ = Mean value of the better parent

$$\text{S.E(d) for } \overline{F_1} - \overline{BP} = \sqrt{\frac{2MSE}{r}}$$

C.D. = S.E(d) × t (at error d.f.)

Standard heterosis

The variety H-86 of tomato involved in crosses was used as standard variety to calculate standard heterosis.

$$\text{Standard heterosis}(\%) = \frac{\overline{F_1} - \overline{SC}}{\overline{SC}} \times 100$$

Where,

Studies on heritability in narrow sense and genetic advance in Tomato (*Solanum lycopersicum* L.) crops

Gaurav Singh, PK Singh, GC Yadav, Angad Singh, VP Pandey and Mayank Singh

DOI: https://doi.org/10.22271/chemi.2020.v8.i4l.9785

Abstract
The present investigation entitled "Studies on heritability in narrow sense and genetic advance in Tomato (*Solanum lycopersicum* L.) crop." was conducted during *Rabi* seasons of 2017-18 (E_1) and 2018-19 (E_2) heritability and genetic advance using diallel mating design at the Main Experiment Station (MES) of the Department of Vegetable Science, Narendra Deva University of Agriculture & Technology, Narendra Nagar, Kumarganj, Ayodhya (U.P.) India. Ten diverse parents of tomato were crossed in a diallel fashion (excluding reciprocals) for generating experimental material. All the Ten parents and their 45 hybrids were grown in Randomized Block design with three replications. Observations were recorded on the 16 characters *viz.*, Days to 50 per cent flowering, Days to first fruit harvest, Plant height (cm), Number of primary branches per plant, Number of fruits per cluster, Number of fruits per plant, Average fruit weight (g), Pericarp thickness (mm), Number of locules per fruit, Fruit length (cm), Fruit diameter (cm), Marketable fruit yield per plant (kg), Total fruit yield per plant (kg), Total soluble solids (%), Titrable acidity (%), Ascorbic acid content (mg/100 g fresh fruit).
High heritability (narrow sense) along with high genetic advance in per cent of mean were observed for most of the important economic traits showing ample scope of improvement.

Keywords: Tomato, heritability, genetic advance, yield

Introduction
Tomato (*Solanum lycopersicum* L.) is one of the most popular solanaceous vegetable crop, having chromosome number 2n=2x=24.Tomato universally treated as "Protective Food" is being extensively grown as annual plant all over the world. Tomato ranks second in importance next to potato in many countries including India (Bose and Som 1993) [3]. It is a highly worked crop by the horticulturists and breeders. Tomato is used as fresh as well as processed vegetable. It is also very important for processing industries as it ranks first as processing vegetable crop in the world. It is a very good source of income for small and marginal farmers. Ripe fruits are widely used for preparation of several items like paste, syrup, juice, ketchup, puree and drinks etc.
Fresh fruits of tomato are in great demand round the year throughout the country. Tomato is a rich source of vitamins, minerals and organic acid. There are various types of flavoring compounds found in the fruits, which enrich the taste. The hundred gram mature tomato fruits contains 94 g moisture, 3.6 g carbohydrates, 0.9 g protein, 0.2 g fat, 585 IU vitamin A, 48 mg calcium, 26 mg vitamin C & Vitamin B (Thiamine 0.12 mg and Riboflavin 0.06 mg) (Choudhary *et al.*, 2009) [4].
Tomato is an herbaceous sprawling plant growing up to 1-3 m in height with weak woody stem. The flowers are yellow in colour and the fruits of cultivated varieties vary in size from cherry tomatoes, about 1–2 cm in size to tomatoes, about 10 cm or more in diameter. Most cultivars produce red fruits when ripe. The plants have taproot system and two types of growth habit, determinate & indeterminate. Fruits bearing of different types. Determinate or bush types bear a full crop at once and top off at a specific height. They are often good choices for container growing and determinate types are preferred by commercial growers who wish to harvest a whole field at one time, or home growers which are interested in canning.

Studies on genetic variability, heritability and genetic advance for certain metric traits in fenugreek (*Trigonella foenum- garacum* L.)

Sharvan Kumar, VB Singh, VP Pandey, GC Yadav and CN Ram

Abstract
The present investigation entitled "Studies on genetic variability, heritability and genetic advance for certain metric traits in Fenugreek (*Trigonella foenum- garacum* L.) " was conducted during *Rabi* seasons of 2018-19 (E1) and 2019-20 (E2) heritability and genetic advance using diallel mating design (excluding reciprocal) at the Main Experiment Station (MES) of the Department of Vegetable Science, Acharya Narendra Deva University of Agriculture & Technology, Narendra Nagar, Kumarganj, Ayodhya (U.P.) India. Ten diverse parents of fenugreek were crossed in a diallel fashion (excluding reciprocals) for generating experimental material. All the Ten parents and their 45 hybrids were grown in Randomized Block design with three replications. Observations were recorded on the 11 characters viz., Days to 50 per cent flowering, Days to maturity, Plant height (cm), Number of branches per plant, pod length (cm), Number of pods per plant, Number of seed per pods, Test weight (g), Biological yield (g), Harvest index (%) and yield per plant (g).
High heritability (broad sense) along with high genetic advance in per cent of mean were observed for most of the important economic traits showing ample scope of crop improvement by selection.

Keywords: Fenugreek, PCV, GCV, heritability, genetic advance, yield

Introduction
Fenugreek (*Trigonella foenum-graecum* L.) 2n=16, locally known as 'Methi' belongs to the family-*Leguminoaceae* and sub-family-*Papilionaceae*, along with it's another cultivated species *Trigonella corniculata* L.
Trigonella comes from Latin words 'little triangle'in reference to triangular shape of small yellowish white flowers. The spices epithet foenum-gracum means 'Greek hay' and according to Rosengarten, the Romans, who got the plant from Greece where it was a very common crop in ancient times, gave it this name it is also called 'ox horn' or goat horn because the two seeds pods projecting in opposite direction usually from the nodes of the stem base that resemble with ox or goat horns.
The wild form of fenugreek is found growing in North Western India, Argentina, Egypt, Southern France, Morocco, Spain, Turkey, China, Pakistan and Lebanon are the leading countries for fenugreek production.
India is one of the dominant producers and exporters of fenugreek. The value-added products of fenugreek such as its seeds, powder and oleoresins are exported to Europe, North America, South Africa and other Asian countries. In India, it occupies an area of about 218 thousand hectare with 220 mt annual productions with share of 2.4 per cent (Anonymous, 2017-18) [2]. Fenugreek is mainly grown in the states of Rajasthan, Gujarat, Punjab, Haryana, U.P., M.P. Maharashtra and Tamil Nadu. Rajasthan alone contributes nearly 60 per cent of total area and 80 per cent of total production of the crop in the country.
Phenotypic variability changes under different environmental conditions while genetic variability remains unchanged and more useful to a plant breeder for exploitation in selection or hybridization. Yield is very complex characteristics controlled by several yield contributing components and it is highly influenced by environmental factors, consequently estimates of heritability and genetic advance are useful for selection.

Material and methods
The present investigation entitled "Studies on genetic variability, heritability and genetic advance for certain metric traits in Fenugreek (*Trigonella foenum- garacum* L.)" was

Study on gene action involved in inheritance of yield and its contributing traits in brinjal (*Solanum melongena* L.)

Manjeet Kumar, CN Ram, GC Yadav, Sharvan Kumar and Devraj Singh

DOI: https://doi.org/10.22271/chemi.2020.v8.i5k.10391

Abstract
The present investigation was carried out to evaluate the 45 F1 hybrids derived from half diallel fashion along with ten parents in randomized block design with three replications during Rabi season of 2018-19 (E_1) and 2019-20 (E_2) at the Main Experiment Station (MES) of the Department of Vegetable Science, Acharya Narendra Deva University of Agriculture & Technology, Kumarganj, Ayodhya (U.P.). The genetic components of variation were determined for sixteen characters *viz*., days to 50 % flowering, leaf length (cm), leaf width, number of flower per inflorescence, days to first harvesting, plant height (cm), primary branches per plant, number of fruit per cluster, number of fruits per plant, average fruit weight (g), fruit length (cm), fruit circumference (cm), yield per plant (g), specific gravity, TSS (%) and dry weight/ 100g. The data were analyzed to fulfill the following objectives to estimates genes action for yield and its component traits analysis of variance revealed significant difference for the parents, F1 S and parent vs. F1s for all the characters indicating wide variation except fruit circumference in both years and fruit length inY1. Both additive and dominance variance were found important in the inheritance of most of the traits, whereas dominance showed over dominance for the most of the traits.

Keywords: *Solanum melongena*, genc action, yield parameters, diallel

Introduction

Brinjal belongs to the family Solanaceous and botanically known as *Solanum melongena* L. The family contains 75 genera and over 2000 species, out of which, about 150-200 are tuber bearing and belong to section Tuberarium. The majority of species (about 1800) are non-tuber bearing. Cytological studies have indicated that chromosome number 2n = 24 is same in almost all species. There are 3 main botanical varieties under the species melongena **(Choudhury, 1976a)**. The common brinjal, to which large, round or egg-shaped fruited forms belong, are grouped under var. *esculentum*. The long, slender types are included under var. *serpentinum* and the dwarf brinjal plants are put under var. *depressum*. Brinjal is considered a native to India where the major domestication of large fruited cultivars occurred. In "Origin of cultivated plants" published in **1886 De Candolle**, stated that the species *S. melongena* has been known in India from ancient times and regarded it as a native of Asia. Vavilov (1928) was of the opinion that its center of origin was in the Indo-Burma region.

In brinjal, heterostyly is a common feature. Four types of flowers have been reported depending on the length of styles, viz. (i) long-styled with large ovary, (ii) medium-styled with medium size ovary, (iii) Pseudo short-styled with rudimentary ovary and (iv) true short-styled with very rudimentary ovary (Krishnamurthi and Subramaniam, 1954).

The de cholestrolizing action is attributed to the presence of polyunsaturated fatty acid (linoleic and linolenic) which are present in flesh and seed of the fruit in higher amount (65.1%). In addition, variation is also noticed for characters like vegetative growth, maturity and presence or absence of spines on leaves, stem and fruit calyx among the indigenous material. Among the various mating designs diallel cross techniques has been most frequently used to determine nature and magnitude of gene action through the estimate of genetic components, general and specific combining ability variances and their effects in many self, often-cross and cross-pollinated crops. In brinjal several workers have used this design for estimating component of variation and combining ability (Bavage *et al*., 2005; Panda *et al*.,

Introduction
Eggplant or brinjal (*Solanum melongena* L. 2n=2x= 24) is a solanaceous vegetable, which is known by various name in India *viz*., Baigan (Hindi) and worldwide known as Aubergine (France) or Guinea squash, is one of the most popular and major vegetable crop in India and other parts of the world. It is an often-pollinated and annual herbaceous crop, originated in India and shows secondary diversity in South East Asia. It is being grown extensively in India, Bangladesh, Pakistan, China, Japan, Philippines, France, Italy and U.S.A. Brinjal has got much potential as raw material in pickle making and dehydration industries. It is highly productive and usually finds its place as the poor man's vegetable. In India, it is being consumed as a cooked vegetable in many ways and also liked by both poor and rich. Availability round the year, easy culture, moderate to high yield and consumption in varieties of ways like salad, bhaji, stuffed brinjal, bhartha, pickles etc., has made brinjal the king of vegetable in India. Further, in recent years, brinjal is being exported in the form of product like Baigan bhartha, pickles etc. to Middle East countries. Brinjal belongs to the family Solanaceae and botanically known as *Solanum melongena* L. The family contains 75 genera and over 2000 species, out of which, about 150-200 are tuber bearing and belong to section Tuberarium. The majority of species (about 1800) are non-tuber bearing. Cytological studies have indicated that chromosome number 2n = 24 is same in almost all species. There are 3 main botanical varieties under the species melongena (Choudhury, 2014) [3]. The common brinjal, to which large, round or egg-shaped fruited forms belong, are grouped under var. *esculentum*. The long, slender types are included under var. *serpentinum* and the dwarf brinjal plants are put under var. *depressum*.
Brinjal is considered a native to India where the major domestication of large fruited cultivars occurred. In "Origin of cultivated plants" published in 1886 De Candolle, stated that the species *S. melongena* has been known in India from ancient times and regarded it as a native of Asia. Abstract

The present investigation was executed at Main Experiment, Station, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Ayodhya, during *Kharif* 2012, with objectives to find out the direct and indirect effect of yield components on yield by path coefficient analysis. Experimental material for the study was consisted of 46 genotypes of brinjal pertaining to four groups including five checks (Arka Nidhi, NDB-2, SM-6-6 Pant Rituraj and KS-224). The experiment was conducted in Randomized Complete Block Design with three replications. Each treatment consisted of 20 plants in two rows, having spacing of 45 cm between row to row and 45 cm plant to plant with net plot size of 4.5x1.2m^2. Observations were recorded on 11 quantitative characters *viz*., days to 50% flowering, primary branches per plant, plant height (cm), fruit weight (g), fruit circumference (cm), flowers per inflorescence, fruit length (cm), fruits per plant, marketable fruit yield per plant (kg), unmarketable fruit yield per plant (kg) and total fruit yield per plant (kg).The analysis of variance for the experiment indicated highly significant differences among the genotypes for all the traits. High magnitude of positive direct effect on yield was exerted by marketable fruit yield per plant followed by fruits per plant and fruit weight. The negative direct effects were showed by days to 50% flowering, fruit length, flowers per inflorescence and plant height but were substantially low. Marketable fruit yield per plant was found to have substantial positive in direct effect for fruit weight, fruit circumference and fruits per plant and negative effect for days to 50% flowering, towards total fruit yield per plant towards total fruit yield per plant.

Key Woords- Brinjal or egg plant (*Solanum melongena* L.) and path analysis

Introduction

Brinjal or egg plant (*Solanum melongena* L.) is one of the most important solanaceous vegetable crop having diploid chromosome number 2n=2x=24. It is worldwide known as aubergine or guinea squash which is one of the most popular and major vegetable crop in India and other parts of the world. It is probably originated in India and showed secondary diversity in South East Asia. It is being grown extensively in India, Bangladesh, Pakistan, China, Japan, Philippines, France, Italy and U.S.A. In Southern Europe, brinjal is a staple vegetable and it is a favourite dish in South East of France. Brinjal has got much potential as raw material in pickle making and dehydration industries. It is highly productive and usually finds its place as the poorman's vegetable. In India, it is being consumed as a cooked vegetable in many ways and is liked by both poor and rich. Year round availability, easy culture, moderate to high yield and consumption in varieties of ways like salad, bhaji, stuffed brinjal, bhartha, chatni, pickles etc., has made brinjal the king of vegetables in India. Further, in recent years brinjal is being exported in the form of products like *baingan bhartha, chatni, pickles* etc. to Middle East countries.

Brinjal contain certain medicinal properties like white brinjal is said to be good for diabetic patients (Choudhary, 1976). It can cure toothache if fried egg plant fruit in til oil is taken (Chen and Li, 1996). It has also been recommended as an excellent remedy for those suffering from liver complaint. One hundred gram edible portion of brinjal fruit contains 92.7% moisture, 24.0% calories, 4.0% carbohydrates, 1.4 g protein, 0.3 g fats, 1.3 g fibres, 124.0 (I.U.) Vitamin A and 12.0 mg Vitamin C (Chen and Li, 1996). It also contains 52.0 mg chlorine, 47.0 mg Phosphorus, 44.0 mg sulphur and other minerals (Aykroyd, 1963).

Brinjal being most important to growers and consumer, there is pressing need to increase its productivity to fulfill the increasing demands throughout the year. Estimation of correlation co-efficient among the yield contributing characters is necessary to understand the direction of selection and maximize yield in the shortest period. Path co-efficient provides an effective means of entangling direct and indirect causes of association of selection and measures the relative importance of each causal factor.

Keeping in view of the above theme, the present investigation was under taken during autumn - winter season 2012, with the following objectives to find out the direct and indirect effect of yield components on yield by path co-efficient analysis.

Materials and Methods

The experiment was conducted in Randomized Complete Block Design with three replications at MES, department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya (UP) India during autumn-winter season 2012 to assess the performance of 46 genotypes of brinjal. Each treatment consisted of two rows. Ten plants were maintained in each row and replicated thrice. Transplanting was done at a spacing of 45 cm between row to row and 45 cm plant to plant having net plot size of 4.5x1.2 m^2.The seed were sown in nursery bed on 03-08-2012 and transplanted on 08-09-2012. All the recommended agronomic package of practices and plant protection measures were followed to raise a good crop. The analysis of variances was worked out by the methods suggested by Panse and Sukhatme (1967) and correlation coefficients as per method suggested by Dewey and Lu (1959).

Results and Discussion

The analysis of variance for different characters is presented in Table 1. The mean squares due to genotypes were highly significant for all the characters. In other words, the performances of the genotypes with respect of these characters were statistically different; suggesting that there exists ample scope for selection in different traits for further improvement.

Path coefficient is simply standardized partial regression coefficient which splits the correlation coefficient in to the measures of the direct and indirect effects of a set of independent variables on the dependent variable. This analysis provides a method for separating out direct and indirect effect of causal factors which affect the yield. The present study on path coefficient analysis revealed that the highest magnitude of positive direct affect on yield per plant was exerted by marketable fruit yield per plant followed by fruits per plant and fruit weight at both phenotypic and genotypic level (Table 2 and 3). This indicated that direct selection based on marketable fruit yield per plant and fruit weight would result in an appreciable improvement of yield per plant. The negative direct effect on yield was shown by days to 50% flowering (-0.057) Polar length of fruit (-0.038), flowers per inflorescence (-0.026), and plant height (-0.005) but were substantially low. Marketable fruit yield per plant was not only found to have maximum direct effect on total fruit yield per plant but it also contributed substantial positive indirect effect for fruit weight (0.3) followed fruit circumference (0.385) and fruits per plant (0.3) and negative indirect effect for days to 50% flowering (-0.178), towards total fruit yield per plant. Therefore during selection these characters should also be taken into consideration. Similar results had also been reported by (Naliyadhara *et al*., 2007; Mishra *et al*., 2007; Bara

Evaluation of F_1 hybrids and parental lines for quantitative and qualitative traits of Brinjal

Rohit Kumar Bajpai, DP Mishra, GC Yadav, Vimlesh Kumar and Sharvan Kumar

DOI: https://doi.org/10.22271/chemi.2020.v8.i5k.10392

Abstract
The present investigation was conducted to know the diversity among the F1 hybrids developed through diallel mating design with the using 8 diverse parents for quantitative and qualitative traits. The study was conducted with the field evaluation of 28 F_1 hybrids and 8 parents during two consecutive years. The wide range of variation observed among the traits during both the years. Perusal of *per se* performance of the parental lines and F_1 hybrids (Table 4.2) for all the traits studied revealed a wide range of mean values which indicated that the parental lines involved in this study were genetically diverse and had good breeding value, which confirmed the predictions of analysis of variance. Out of 28 F_1 hybrids sixteen hybrids *viz*., $P_1 \times P_2$, $P_1 \times P_4$, $P_1 \times P_6$, $P_1 \times P_7$, $P_1 \times P_8$, $P_2 \times P_3$, $P_2 \times P_4$, $P_2 \times P_5$, $P_2 \times P_6$, $P_3 \times P_5$, $P_3 \times P_6$, $P_4 \times P_5$, $P_4 \times P_6$, $P_5 \times P_6$, $P_5 \times P_7$, $P_5 \times P_8$, $P_6 \times P_8$, and $P_7 \times P_8$ produced significantly higher yield than both standard varieties Punjab Sadabahar and Pant Rituraj.

Keywords: brinjal, fruit yield, diallel mating, quality traits

Introduction
Eggplant (*Solanum melongena* L.) or brinjal is a vegetable of family solanaceous, which is worldwide known as aubergine or guinea squash. It is one of the most popular and major vegetable crop in India and other parts of the world. It is self pollinated and annual herbaceous plant, probably originated in India and shows secondary diversity in South East Asia. It is being grown extensively in India, Bangladesh, Pakistan, China, Japan, Philippines, France, Italy and U.S.A. In Southern Europe. Brinjal is a staple vegetable and it is a favourite dish in South East of France. Brinjal has got much potential as raw material in pickle making and dehydration industries (Singh *et al*., 1963) [9]. It is highly productive and being consumed as a cooked vegetable in many ways and liked by both poor and rich. Year round availability, easy culture, moderate to high yield and consumption in varieties of ways like salad, bhaji, stuffed brinjal, bhartha, chatni, pickles etc., is the king of vegetables in India. Further, in recent years brinjal is being exported in the form of products like *baingan bhartha, chatni, pickles* etc. to Middle East countries.

Eggplant is being cultivated in India over an area of 0.735 million ha with an average annual production of 12.95 million tonnes and productivity of 19.1 mt/ha. In Uttar Pradesh, brinjal is being cultivated on an area of 3.0 lakh ha with annual production of 90.9 lakh tonnes. Agra, Meerut, Lucknow, Kanpur, Aligarh, Chitrakoot and Gorakhpur districts contribute more area and production to the state pool (Anon., 2019) [2].

Brinjal fruits are rich source of minerals like calcium, magnesium, potassium, iron, zinc and copper. It is also a fair source of fatty acids and it is used for medicinal purposes in curing diabetes, asthma, cholera, bronchitis and diarrhea. It is reported to stimulate the intrapeptic metabolism of blood cholesterol. Leaf and fruit, fresh or dry produce marked drop in blood cholesterol level. The de-cholestrolizing action is attributed to the presence of polyunsaturated fatty acids (lionleic and linolenic) which are present in flesh and seeds of the fruit in higher amount (65.1%).

Materials and Methods
The experimental materials for the present study comprised of eight promising and diverse pure lines/varieties of brinjal selected on the basis of genetic variability from the germplasm

Abstract

The present investigation was conducted using thirty six genotypes of vegetable pea. Genetic divergence analysis following Mah... D^2 statistics revealed wide range of genetic diversity among thirty six genotypes of vegetable pea for all the fifteen characters u... pertaining to growth, yield and quality traits. The study observed for node at which first flower appears, days to 50 % flowering, ... nodes per plant, internodal length (cm), primary branches per plnat, plant height (cm), length of green pod (cm), width of pod, (cm)... of green pods per plant, number of green pods per cluster, number of seeds per pod, shelling per cent, green pod weight (g), T.S.S.... seed, green pod yield per plant(g). Genetic variation within and between clusters observed. Seven clusters were framed from the D... using Tocher method. Cluster II had highest number of genotypes (18) followed by cluster I (13), Cluster III (1), cluster IV (1) cl... clusterVI (1) and cluster VII (1).

Keywords: Vegetable Pea, Clusters, genetic divergence, germplasm

Introduction

Vegetable pea (*Pisum sativum* L. *var. hortense*) belongs to family Leguminoceae sub family Fabaceae. Pea is an important legume vegetable, extensively cultivated in the temperate regions and restricted to cooler altitudes in the tropics and winter season in the sub tropics. It is a self pollinated crop having diploid chromosome number 2n=2x=14. It is highly nutritious and capable of using atmospheric nitrogen. India ranks third in area after China and USSR under pea cultivation. The total area covered by peas is 4, 33600 hectare with the production of 38, 63600 metric tones with productivity of 8.9 metric tones per hectare **Anonymous, (2013).**

The major growing states of vegetable pea in India are Uttar Pradesh, Madhya Pradesh and Maharashtra. Uttar Pradesh is the leading producer of vegetable pea having alone about 50% of its area and production. It is also grown as summer season crop in the hilly states of India. The major area under vegetable pea cultivation is under mid season because of its suitability in various agro-climatic zones. Large proportion of vegetable pea are processed (canned, frozen and dehydrated and pickle) for consumption. It is mostly consumed as green fresh grains for vegetable purpose. Vegetable pea being most important to growers and consumer, there is pressing need to increase its productivity to fulfil the increasing demands throughout the year. The information usually needed for developing high yield varieties in a particular species pertains to the extent of genetic variability for desirable traits in the available germplasm. Evaluation of germplasm is the basic tool for identification of important genotypes. Mahalanobis D^2 analysis helps in the assessment of genetic diversity among the genotypes and the contribution of each character to the total diversity. Greater the genetic distance better the chance of obtaining desirable hybrids or segregates after hybridization between diverse groups of entries.

Materials and Methods

The experimental material for the present investigation comprised of 36 genotypes of vegetable pea collected from different places in India and being maintained at Main Experiment Station in the Department of Vegetable Science, N.D. University of Agriculture & Technology, Kumarganj, Ayodhya (U.P.). The experiment was conducted in Randomized Complete Block Design with three replications during *Rabi* season in 2013-14 to assess the performance of 36 vegetable genotypes including 3 Check verities. Each genotype consisted of five rows and replicated thrice. Each entry was grown in the plot size of and 3 m x 1.5 m. The line sowing was done with the spacing of 30 cm and 10 cm from seed to seed. The seeds were shown on 23 October 2013. All the recommended agronomic package of practices and plant protection measures were followed to raise a healthy crop. Observations were recorded on randomly selected five plants from each genotype in each replication. Observations were recorded on five randomly selected plants from each treatment in each replication for the following characters, .(i) nodes at which first flower appears, (ii) days to 50% flowering, (iii) number of node per plant (iv) ... length, (v) primary branches per plant, (vi) plant height, (vii) ... pod, (viii) width of pod, (ix) number of green pods per cluster, (xi) number of seeds per ... number of green pods per plant, shelling percent (xiii) pod weight (xiv) TSS of edible seeds ... yield per plant.

Abstract

Eight diverse varieties of tomato were crossed in a half diallel fashion for generating experimental material grown at Main Experimental Station, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya (U.P) India, during *Rabi* season 2012-2013. All the 36 genotypes were grown in Randomized Block Design with three replications. The mean squares due to general combining ability (GCA) and specific combining ability (SCA) were highly significant for all traits studied, except for days to 50 per cent flowering only due to parents *vs* hybrids. On the basis of GCA effects and *per se* performance parents Narendra Tomato 7 followed by Narendra Tomato 4 and Narendra Tomato 5 were found as the best general combiners for fruit yield per plant along with some other traits. In general, the parents, which have best *per se* performance, were also best general combiners, indicating a positive association between these two parameters. Specific combining ability effects of crosses revealed that eleven crosses showed highly significant SCA effects for fruit yield as well as number of fruits per plant. The cross Narendra Tomato 6 x Narendra Tomato 8 were the best specific combiner fruit yield, and fruit weight. The cross Narendra Tomato 4 x Narendra Tomato 7 was the best specific combiner for total soluble solid and fruit circumference. While the cross Narendra Tomato 1 x Narendra Tomato 6 was the specific combiner for days to 50 per cent flowering.

Key Words: Tomato (*Solanum lycopersicum*, general and specific combining ability

Introduction

Tomato (*Solanum lycopersicum* (Mill.) Wettsd.) is the most widely grown vegetable of the World. India is the second largest tomato producer of the world after China, accounting for about 11% of the world tomato production (Indian Horticulture Database, 2011). Tomato is universally treated as 'Protective Food' since it is a rich source of minerals, vitamins, antioxidants and organic acids. The nutrition importance of the tomato indicates there is need to formulate breeding programme and to develop cultivars rich in lycopene, processing traits with high quality of fruit as well as yield. Recent studies indicated that lycopene that give the ripe tomato its bright red colour, is a very effective natural antioxidant and quencher of free radicals (Simon, 1992). Lycopene is especially efficient in neutralizing Reactive Oxygen Species (ROS). These properties of lycopene are due to its unique chemical structure, a very long chain of conjugated double bonds. Efforts are being made to increase its productivity by developing superior varieties. The entire genetic variability observed in the analysis for each trait was partitioned into its components, *i.e.* GCA and SCA as defined by Sprague (1966) and reciprocal effects as sketched by Griffing (1956). They stated that GCA effects were due to additive type of gene action and SCA effects were due to non-additive (dominant or epistatic) gene action.

Combining ability studies are more reliable as they provide useful information for the selection of parents in terms of performance of the hybrids and elucidate the nature and magnitude of various types of gene actions involved in the expression of quantitative traits. Diallel cross analysis provides the estimates of genetic parameters regarding combining ability as well as a

rapid overall picture of the dominance relationship of the parents studied using the first filial generations (F1) with or without reciprocals.

Application of diallel technique in a self-pollinated crop like tomato for this purpose may be appropriate (Griffing, 1956). Hence the study was undertaken to estimate the combining ability in terms of specific and general combing ability in the present work.

Materials and Methods

Present investigation was conducted at the Main Experimental Station, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Narendra Nagar, Kumarganj, Ayodhya (U.P.), India; during *Rabi* 2012-2013. The experiment was conducted using eight diverse parents of tomato which were crossed in a diallel fashion (excluding reciprocal) and obtained twenty eight F_1 of tomato. Seeds were sown in nursery bed on 08th October 2012 and 30 days old healthy seedlings were transplanted in the experimental field on 08th November. 2012 in two row of 4 m length with inter and intra row spacing of 60 and 50 cm, respectively. Two check varieties (NDT-4 Indeterminate type, NDT-7) and 28 hybrids were planted in the field, keeping 8 plants in each row. The 36 genotypes were planted in Randomized Block Design with three replications. All recommended cultural practices were followed to raise good crop stand. Data were recorded for eleven characters *viz.*, days to 50 per cent flowering, plant height (cm), number of primary branches per plant, number of fruits per plant, average fruit weight (g), fruit circumference (cm), pericarp thickness (mm), number of locules per plant, total soluble solid (TSS), fruit length (cm) and fruit yield per plant (kg). The data were analyzed as per methods suggested for combining ability by Griffing (1956).

Results and Discussion

Highly significant variances were observed both for general and specific combining ability for all eleven characters studied (Table-1) . Highly significant gca and sca variance revealed that both additive and non-additive gene action were important in expression of all the traits on the study. Thus, both selection and heterosis breeding methods, respectively might be advantageous for effective utilization of additive and non-additive genetic variance for improvement of these traits. Similar findings had also been reported by Weerasinghe *et. al.* (2004) and Thakur and Joshi (2000).

The information regarding general combining ability (gca) effects of the parents is of prime importance as it helps in successful prediction of genetic potential of crosses. Perusal of gca effects of the parents as presented in Table- 2 and ranking of desirable parents on the basis of estimate of gca effect for eleven characters revealed that it is difficult pick-up a single good combiner for all the characters. However, parental line P_3, P_4, P_8, and P_7 having significant and negative gca effects for days to 50 per cent flowering and parents P_1, P_2 and P_5 showed significant positive gca effects for number of fruits per plant. Thus, these two parents P_3 and P_4, (NDT-3 and NDT-4) appeared to be good general combiner for early flowering while parents P_1, P_2 and P_5 were found good general combiner for fruit yield per plant. While NDT-7 and NDT-4 exhibited good general combining ability for number of fruits per plant (Table-2). This result may be due to low performance of parents P_1, P_2, P_3, P_6, and P_8 for yield per plant. In an attempt to identify most desirable parents based on gca effect as well *per se* performance the three best parents were considered for each traits. This indicated a positive association between the two parameters (gca effect and *per se* performance). Thus, parents P_3 was identify as the best general combiner for earliness, fruits yield per plant, average fruit weight and number of branches per plant. Similar correspondence between these two parameters was observed by Joshi and Kohli (2006) and Mahendrakar *et al.* (2005) in tomato.

Physiological Disorders in Fruit Crops

Anupam Singh[1] Pradip Kumar Saini[2] R. K. Yadav[3] Gulab Chand Yadav[4] Sunil Kumar[5]
[1,5]Department of Agriculture [2,3]Department of Crop Physiology [4]Department of Vegetable Science
[1,5]Integral University, Lucknow, Uttar Pradesh, India
[2,3,4]Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad, Uttar Pradesh, India

Abstract— Physiological disorders mainly affect deciduous tree fruits, such as apples, pears and most citrus fruits. Most of these disorders affect discrete areas of tissue, whether the produce be fruits. Thus, physiological disorder may be defined as the abnormal growth pattern or abnormal external or internal conditions of fruits caused by adverse environmental conditions (such as deviation from normal state of temperature, light, moisture, nutrient, harmful gases and inadequate supply of growth regulators).
Key words: Fruit Crop, Physiological Disorder

I. PAPAYA

Fig. 1: Papaya

A. Skin Freckles

1) Causes

The cause and factors that influence this disorder are unknown. Freckle-like blemishes occurred on ripe papaya fruits (cv. Sunset). Young fruits (less than 40 days old) were free from freckle. The freckle diameter increase during the last phase of fruit growth as the fruits approached the maturity. More freckle were seen on the exposed side of the fruit away from the stem.

2) Treatment

Wrapping young fruits in white paper bags significantly reduced freckle incidence.

B. Malformed Fruits

1) Causes

This melody is due to boron deficiency and it is one of the serious disorders limiting yield in papaya. It results in malformed fruits.

2) Treatment

-Spraying of boric acid 0.1% at 3 months interval from sixth month after planting onwards correct the deficiency.

II. GUAVA

Fig. 2: Guava

A. Bronzing

1) Causes

Bronzing of guava has been observed in places having low soil fertility and low pH. Affected plants show purple to red specks scattered all over the leaves. Under aggravated condition, total defoliation and fruits characterized with brown coloured patterns on the skin, with reduced yield are noticed.

2) Treatment

- Foliar application 0.5 % diammonium phosphate and zinc sulphatein combination at weekly intervals for two months reduced the bronzing in guava.
- Pre-fowering spray with 0.4 % boric acid and 0.3 % zinc sulphate increase the yield and fruit size.
- Spraying of copper sulphate at 0.2 to 0.4 % also increase the growth and yield of guava.

III. PINEAPPLE

Fig. 3: Pineapple

A. Multiple Crowns

1) Causes

Ordinarily fruit bears a single crown but in some cases fruit bears more than one. Consequently the top of the fruit will be flat and broad and fruit will be unfit for canning. Such fruits taste insipid and are corky. It is supposed to be a heritable character, found mostly in Cayenne group to which the variety Kew belongs.

B. Fruit & Crown Fasciation

1) Causes

Fasciated fruits are deformed to such an extent that they are totally useless. In certain cases, proliferation is so extreme that fruit is highly flattened and twisted with innumerable crowns. Fruits and crowns fasciation is associated with high vigour of plants, which take longer time to flower. High fertility of soil, warm weather and calcium r zinc deficiency may favour fasciation.

C. Collar of Slips

1) Causes

The collar of slips is typified by the presence of a large number of slips arising from stem close to the base of the fruit, or even

SCREENING OF POTATO (*SOLANUM TUBEROSUM* L.) VARIETIES/HYBRIDS FOR THEIR ROTTING PERCENTAGE DURING STORAGE UNDER AMBIENT CONDITIONS

Satish Kumar*, G.C. Yadav, C.N. Ram, Nishakant Maurya and Surendra Kumar Verma
Department of Vegetable Science,
N.D. University of Agriculture & Technology, Kumarganj, Ayodhya (U.P.) 224 229

Abstract

The experiment was conducted with thirty six varieties/hybrids replicated thrice in Complete Randomized Block Design (CRD) during the summer of 2007 at the Laboratory of Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Ayodhya (U.P.). The small gunny bags of 5 kg capacity were kept for 120 days at ambient storage condition. Physiological losses due to rotting (by number and weight) was increases continuously in all the treatments from 90 to 120 days of storage period under ambient conditions. Hybrids J/95-242 and B-420(2) showed minimum rotting of tubers at 90 and 120 days under ambient storage conditions.

Key words: Variety/hybrids, Rotting, Potato, post-harvest, ambient condition.

Introduction

The potato (*Solanum tuberosum* L.) is one of the most efficient horticultural food crops. It belongs to family Solanaceae, which constitutes around 85 genera with 2200 species and Solanum is the largest genus with 1700 species. Among major potato growing countries, India ranks third after China and Russian Federation. The present area under potato in India is about 2.117 million hectares with production and productivity of 43.417 million tones and 20.50 t/ha (Anonymous, 2016) respectively.

The potato is an easily grown plant that produces more food on less land. One hectare of potatoes can yield food value of 2-4 hectares of grain. The dry matter production in potato is 47.6 kg/ha/day, whereas in wheat and rice it is 18.1 and 12.4 kg/ha/day, respectively. Storage studies in potatoes stored at higher temperatures have been conducted by different workers but information are insufficient for specific location. Therefore, information on identification of varieties/hybrids with good shelf-life will be desirable for a few months for domestic and processing purposes.

Materials and Methods

The present investigation was carried out in the laboratory of Department of Vegetable Science, Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj) Ayodhya (U.P.) during March to June, 2007. The experimental material comprised of thirty-six varieties/hybrids of potato and were evaluated in Completely Randomized Design with three replications. The recorded data in Complete Randomized Design (CRD) was analyzed statistically by the method suggested by Cochran and Cox (1963).

Results and Discussion

Studies on changes during ambient storage of different varieties/hybrids of potato revealed that physiological loss due to rotting increases continuously in all the varieties/hybrids from 30th to 120th days of storage period. During ambient storage, stored potatoes losses weight mainly due to two physiological processes *i.e.*, transpiration and respiration. The rotting percentage of all the varieties/hybrids from 30th to 120th days of storage period has been presented in Table- 1 and Table-2.

Table-1: Rotting percentage by number in different varieties/hybrids of potato under ambient storage

Studies on character association and path analysis in garden pea (*Pisum sativum* L. sub sp. *hortense* Asch.)

Nishakant Maurya, GC Yadav, CN Ram, Mahendra Kumar Yadav and Sachi Gupta

DOI: https://doi.org/10.22271/chemi.2020.v8.i1j.8327

Abstract
Forty four genotypes of garden pea including checks were evaluated to estimate correlation and path coefficient for seventeen yield contributing traits and identification of superior recombinants for their utilization in crop improvement programme during *Rabi*, 2016-17, at Main Experimental Station, Department of Vegetable Science, Acharya Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya, in Randomized Block Design with three replication. The most important trait pod yield per plant had exhibited highly significant positive phenotypic correlation with number of pods per plant (0.794) followed by number of nodes per plant (0.253), primary branches per plant (0.231), pod circumference (0.190), shelling percentage (0.184), and number of seeds per pod (0.166). Higher magnitude of positive direct effect on pod yield per plant was exerted by plant height (1.2567) followed by number of pod per plant (0.6431), days to 50% flowering (0.2599), number of seeds per 100g pod (0.1655), node to first flower appears (0.1249), T.S.S. (0.1055), primary branches per plant (0.0940) pod length (0.0439) and 100-seed weight (0.0360). Direct contribution of these traits indicates the scope of improvements through selection for number of pods per plant and number of seeds per pod in the available germplasms.

Keywords: Garden pea (*Pisum sativum* L. sub sp. *hortense* Asch.), correlation and path analysis

Introduction

Garden pea (*Pisum sativum* L. sub sp. *hortense* Asch.) belongs to Leguminosae family and sub family Fabaceae having diploid chromosome number 2n=2x=14. It is one of the most popular vegetable crop grown as cool season crop in all over the world. The crop is grown for its green pods and dried seeds. It is harvested at tender immature stage and consumed fresh or preserved through canning or freezing. It has a prime place among all the vegetables because of its high amount of health benefiting phytonutrients such as carbohydrates, vitamin A, B and C, minerals like calcium, phosphorus, magnesium with no cholesterol and is known for its superior quality protein like lysine content, which is limiting in cereals (Monti, 1983) [8]. Moreover, pea contributes to yield of the succeeding crop in rotation by improving nitrogen status of the soil due to presence of root nodules (Sattar *et al.* 1998) [5].

Garden pea is an annual, herbaceous plant with tap root system. It is highly self-pollinated due to hermaphrodite flower, homogamy *i.e.* maturation of stigma and anthers at the same time. Most of the early cultivars the first flower produce from 5 to 11 nodes and the late cultivars start flowering at about 13 to 15 nodes. Early cultivars are often single flowered or bear some single and some double flowers while, late cultivars are usually double/triple flowered.

Breeding efforts have contributed substantially to improve yield potential, regional adaptation through resistance or tolerance to abiotic and biotic stresses, plant type and grain characteristics. The path coefficient analysis provides the partitioning of correlation coefficients into direct and indirect effect giving the relative impotence of each causes factors. The understanding of association of characters is of prime impotence in developing an efficient breeding programme.

Correlation studies provide an opportunity to study the magnitude and direction of association of one character with another, while path coefficient analysis gives the direct and indirect contribution of independent variables on dependent variable (Rathi and Dhaka, 2007) [9].

Studies on variability, heritability (Narrow sense) and genetic advance analysis for growth, yield and quality traits in pumpkin (*Cucurbita moschata* Duch. ex. Poir)

MK Singh, VB Singh, GC Yadav and Pushpendra Kumar

Abstract
The experiments were laid out in RBD with three replications having each experimental unit of single row with spacing of 3.0 m (R×R) × 0.5 m (P×P) involving 7 parents namely, Narendra Agrim (P_1), Narendra Amrit (P_2), Narendra Upkar (P_3), NDPK-76-1 (P_4), NDPK-724 (P_5) and NDPK-39-2 (P_6) and NDPK-12-10 (P_7) of pumpkin and their 21 F_1 hybrids produced in diallel mating design excluding reciprocals at MES, Vegetable Science, NDUA.&T, Kumarganj, Faizabad (U.P.) India in *Zaid*, 2016. The observations were recorded on parents and F_1's for twenty quantitative traits including six quality traits *viz*., node number to first male flower appearance, node number to first female flower appearence, days to first male flower anthesis, days to first female flower anthesis, days to first fruit harvest, vine length (m), internodal length (cm), number of primary branches per plant, fruit weight (kg), number of fruits per plant, equatorial circumference of fruit (cm), polar circumference of fruit (cm), flesh thickness (cm), fruit yield per plant (kg), and six quality/biochemical traits namely ascorbic acid, reducing sugars (%) non-reducing sugars (%), total sugars (%), dry matter content and total soluble solids. Analysis of variance revealed that the mean square differences due to genotypes, parents and hybrids were found highly significant for all the traits. The mean squares due to parents *vs*. hybrids was also found significant for all traits studied in experiment except for node number to first male and female flower appearance, days to first male and female flower anthesis, days to first marketable fruit harvest, average fruit weight and total sugars. The highest phenotypic as well as genotypic coefficients of variation were observed in case of node number to first male flower appearance, vine length, fruit yield per plant recorded high estimates of PCV and GCV suggesting substantial variability for the observed traits, thereby ensuring ample scope for improvement of these traits through selection. The estimates of high heritability coupled with high genetic advance as per cent of mean were observed for node number to first male flower appearance, node number to first female flower appearance and non-reducing sugar. The most important trait fruit yield per plant had exhibited significant and positive phenotypic correlation with number of fruits per plant, average fruit weight, total soluble solids, vine length, flesh thickness, ascorbic acid content, total sugars, number of primary branches per plant, equatorial circumference of fruit and negative significant association with days to first male flower anthesis, days to first female flower anthesis, days to first fruit harvest, inter nodal length and node number to first male flower appearance at phenotypic level.

Keywords: Pumpkin (*Cucurbita moschata* Duch. ex. Poir), variability, heritability (narrow sense) and genetic advance

Introduction

Pumpkin (*Cucurbita moschata* Duch. ex. Poir) is one of the most important vegetable crop of family Cucurbitaceae. It is grown throughout the world due to its good nutritional value and also higher returns to the farmers. The centre of orgin of pumpkin is central Mexico. Pumpkin is a herbaceous annual, sexually propagated vegetable allopolyploid having chromosome number 2n=2x=40. Stem is angular, five ridged without hairs, trailing and branched. Trailing vine strikes roots at nods. Leaves are deeply or shallowly lobed not pinnatifid. Fruits have diuretic and vermetic action. Seeds are non bitter, tasty and nutritious. The flowers are large and yellow coloured with showy companulate corolla. Ovary is inferior and tricarpellary. Corolla is companulate, gamopetalous, lobed. Plants are monoecious, highly cross pollinated, entamophilous with three anthers. The word pumpkin was derived from the Greek word *pepon*, which means "large melon", something round and large.
Based on commercial significance the cultivated *Cucurbita* species rank among the 10 leading vegetable crops worldwide. China and India lead the world production and other major producers are U.S., Egypt, Mexico, Ukraine, Cuba, Italy, Iran and Turkey (Ferriol and Pico,

ABSTRACT

The present investigation was carried out with aims to assess the combining ability involving 7 parents namely, Narendra Agrim (P_1), Narendra Amrit (P_2), Narendra Upkar (P_3), NDPK-76-1 (P_4), NDPK-724 (P_5) and NDPK-39-2 (P_6) and NDPK-12-10 (P_7) of pumpkin and their 21 F_1 hybrids produced in diallel mating design excluding reciprocals at MES, Vegetable Science, NDUA.&T, Kumarganj, Faizabad (U.P.) India in *Zaid*, 2016. The experiments were laid out in RBD with three replications having each experimental unit of single row with spacing of 3.0 m (R×R) × 0.5 m (P×P).The observations were recorded on parents and F_1's for twenty quantitative traits including six quality traits *viz.*, node number to first male flower appearance, node number to first female flower appearence, days to first male flower anthesis, days to first female flower anthesis, days to first fruit harvest, vine length (m), internodal length (cm), number of primary branches per plant, fruit weight (kg), number of fruits per plant, equatorial circumference of fruit (cm), polar circumference of fruit (cm), flesh thickness (cm), fruit yield per plant (kg), and six quality/biochemical traits namely ascorbic acid, reducing sugars (%) non-reducing sugars (%), total sugars (%), dry matter content and total soluble solids. The analysis of variance for combining ability revealed that there were significant differences for all the traits. Mean squares due to general combining ability were observed significant for all the traits and specific combining ability were observed significant for all traits except days first fruit harvest and average fruit weight. The parents Narendra Upkar (P_3), NDPK-39-2 (P_6) and NDPK-12-10 (P_7) were found good general combiner for fruit yield per plant and number of fruits per plant. Out of the best five significant specific crosses with high *per se* performance for fruit yield per plant, three crosses NDPK-76-1 x NDPK-39-2 (P_4 x P_6), Narendra Upkar x NDPK-12-10 (P_3 x P_7) and (Narendra Upkar x NDPK-724) P_3 x P_5 indicated good specific combing ability. Both additive and dominance variance were found important in the inheritance of most of the traits, whereas dominance variance were found more prominent than the additive variance. Average degree of dominance revealed the presence of over dominance for all the traits. The proportions of genes ($\hat{H}_2/4\hat{H}_1$) in the parents were less than 0.25 for all the traits indicating asymmetrical distribution of alleles at loci showing dominance. In general the proportions of dominant and recessive genes in parents $[4\hat{D}\,\hat{H}_1)^{1/2}+\hat{F}\,/\,(4\hat{D}\,\hat{H}_1)^{1/2}-\hat{F}]$ were more than unity with positive $\hat{F}$ value for all traits indicating major contribution of dominant genes.

ESTIMATION OF GENETIC VARIABILITY, HERITABILITY AND SCOPE OF IMPROVEMENT IN GARDEN PEA UNDER ALKALI SOIL CONDITION (*Pisum sativum* L. sub sp. *hortense* Asch.)

Department of Vegetable Science
Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.) 224 229

Abstract

Forty four genotypes of garden pea including checks were evaluated for magnitude of genetic variability, heritability and genetic advance for seventeen yield contributing traits during Rabi, 2016-17, at Main Experimental Station, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad, in Randomized Block Design and replicated thrice. The phenotypic coefficient of variation (PCV) was higher than their corresponding genotypic coefficient of variation (GCV) for all the characters. High genotypic coefficient of variation (GCV) as well as phenotypic coefficient of variation (PCV) was observed for primary branches per plant (36.34 and 34.46) and pod yield per plant (24.12 and 21.79). High heritability coupled with high genetic advance in per cent of mean were observed for primary branches per plant and pod yield per plant. High estimate of heritability along with high genetic advance in per cent of mean indicates the scope of improvements through selection in the available germplasms.

Key words: Garden pea (Pisum sativum L. sub sp. hortense Asch.), variability, heritability, genetic advance, genotypic coefficient of variation (GCV) and phenotypic coefficient of variation (PCV).

Introduction

Garden pea (*Pisum sativum* L. sub sp. *hortense* Asch.) belongs to Leguminosae family and sub family Fabaceae having diploid chromosome number 2n=2x=14. It is one of the most popular vegetable crop grown as cool season crop in all over the world. It is harvested at tender immature stage and consumed fresh or preserved through canning or freezing. It has a prime place among all the vegetables because of its high amount nutrient content mainly digestible proteins and other health benefiting phytonutrients such as carbohydrates, vitamin A, B and C, minerals like calcium, phosphorus and magnesium with no cholesterol. Moreover, pea contributes to yield of the succeeding crop in rotation by improving nitrogen status of the soil due to presence of root nodules (Sattar *et al.* 1998).

Garden pea is an annual herbaceous plant with tap root system. It is highly self-pollinated due to hermaphrodite sex form, homogamy *i.e.* maturation of stigma and anthers at the same time. Most early cultivars produce the first flower from nodes 5 to 11 and the late cultivars start flowering at about nodes 13 to 15. Early cultivars are often single flowered or bear some single and some double flowers while, late cultivars are usually double/triple flowered.

Breeding efforts have contributed substantially to improve yield potential, regional adaptation through resistance or tolerance to abiotic and biotic stresses, plant type and grain characteristics. The quantum of genetic variability and the extent, to which heritable and non-heritable variations are related to the characters determines the extent of genetic improvement. Therefore, present investigation was carried out to assess the genetic variability and nature of association between yield and its component traits in garden pea.

The study of genotypic and phenotypic coefficients of variation give a clear cut data about extent of variability present in a plant population and a relative measure of efficiency of selection of genotypes based on phenotype in a highly variable population.

The present investigation was carried out to assess the nature and magnitude of genotypic and phenotypic coefficients of variation, heritability in broad sense, genetic advance and genetic advance as per cent of mean in 44 different genotypes for 17 characters under Faizabad conditions.

Materials and Methods:

The experimental material for the present investigation was comprised of 44 genotypes including 4 checks were replicated thrice in Randomized Complete Block Design. The experiment was carried out at Main Experiment Station, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Faizabad, during *Rabi* season of 2016-17. The whole investigation was conducted under the scientific management practices. During study, observations for 50% flowering, plant height, number of nodes per plant, intermodal length, node to first flower appearance, node to first pod appearance, primary branches per plant, pod circumference, pod length, number of seeds per pod, number of pods per plant, shelling per cent, 100-seed weight, number of seeds per 100g pod, number of pods per 100g, total soluble solid (T.S.S.) and pod yield per plant were recorded on five randomly selected plants from each treatment.

The recorded data from experiment for seventeen characters in garden pea was subjected to the following statistical analysis such as analysis of variance for the design of experiment (Panse and Sukhatme, 1967), estimation of genotypic and phenotypic coefficients of variation, heritability in broad sense and genetic advance (Burton and de Vane, 1953) and expected genetic advance in per cent of mean (Johnson *et al.*, 1955).

Results and Discussion:

The mean sum of squares due to genotypes were highly significant for all the characters (Table- 1), indicating that there are considerable variation among the genotypes with respect to the characters under study. In other words, the performance of all the genotypes with respect to characters studied were statistically different. The result indicating the better chance of selection in the available garden pea genotypes.

Table- 1: Analysis of variance for seventeen quantitative characters in garden pea

S. No.	Characters	Source of variation		
		Replications	Treatments	Error
	d.f.	2	43	86
1.	Days to 50% flowering	0.70	115.23**	3.10

Studies on genetic divergence in sponge gourd (*Luffa cylindrica* L. Roem.)

Veerendra Kumar, VB Singh, GC Yadav, Deepak Maurya and Manjeet Kumar

Abstract
The experiment was conducted during the spring-summer season, 2017 in Eastern Uttar Pradesh. to evaluate the nature and magnitude of genetic divergence among the thirty genotypes of bitter gourd were carried out by using Mahalanobis D^2 statistics. Thirty genotypes were grouped into 7 different non-overlapping clusters. The highest number of genotypes was presented in cluster III which contained 9 entries followed by cluster V which contains 8 entries, cluster VI which contained 5 entries, cluster I which contained 4 entries, cluster IV which contained 3 entries and cluster II possess 1 entries respectively. Highest estimates of genetic advance in per cent of mean was recorded for vine length (80.31%), node number to anthesis of first staminate flower (66.23%), number of fruits per plant (45.65%), total fruit yield/plant (38.42%). Moderate genetic advance in per cent of mean was estimated in number of primary branches per plant (37.86%), node number to anthesis of first staminate flower (37.65%), fruit length (37.40%), number of nodes per vine (35.35%), average fruit weight (31.68%), fruit diameter (29.79%) whereas days to anthesis of first pistillate flower (26.12%), days to anthesis of first pistillate flower (23.80%), days to first fruit harvest (21.58%) showed low genetic advance in per cent of mean. Vine length contributed maximum towards genetic diversity (26.67%), followed by fruits per plant (25.75 %), days to anthesis of first pistillate flower (13.69%), average fruit weight (9.43%), number of primary branches per plant (8.51%), node number to anthesis of first staminate flower (7.36%), fruit length (4.37%) and total marketable fruit yield per plant in sponge gourd.

Keywords: genetic divergence and sponge gourd

Introduction
Luffa [*Luffa cylindrica* L. (Roem) *Syn.* L. *ageyeptica* Mill.] commonly called as sponge gourd, Loofah, vegetable sponge or dish cloth gourd, is a member of family Cucurbitaceae having diploid chromosome number 2n=2x=26.It originated in subtropical Asian region particularly India (Kalloo, 1993) [2]. Sponge gourd is an annual cucurbit plant produces fruits containing a fibrous vascular system with various vines and cylindrical tenangled fruit. Leaves are deltoid to nearly orbicular exteriorly, but pointed at the apex and usually three to seven lobed with dentate margin (Whitaker and Davis, 1962) [6]. Sponge gourd is monoecious crop with branches tendrils. Flowers are yellow and showy having five petals. The inflorescence of staminate flowers is on raceme, while the pistillate flowers are solitary and have short to long peduncle. It is commonly grown for its tender marketable green fruits for vegetable purpose as well as for sponge of mature fruits which is used for scrubbing of body skin and utensil purposes. Fruits are rich in Iron Vitamin A and C. It has certain medicinal uses. The cooked fruit are easily digestible and very appetizing therefore it is recommended to the patients suffering from malaria or other seasonal fevers.
Luffa *(Luffa cylindrica* (L.) MJ. Roem syn. *L. aegyptica* Mill.) commonly called as sponge gourd, loofah, vegetable sponge or dish cloth.It is one of the most important cucurbits grown extensively throughout the tropical and sub-tropical regions of the country and world, The crop belongs to the family Cucurbitaceae which includes about 118 genera and 855 species. Its unripe tender fruits are popular and well known culinary in India with good nutritive value and high yield potentials. The tender fruits are rich in carbohydrates, vitamin A, vitamin C and iron.

Material and Methods
Thirty genotypes (including Pusa Chikni as check variety) of sponge gourd having diverse origin were evaluated at Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad, during the spring-summer season, 2017.
The experiment was lay out in a randomized block design with three replications in individual plot size (3m x 2.5m). The distance maintained between row to row and plant to plant was 2.5

Abstract
The experiment was conducted with thirty six varieties/hybrids replicated thrice in Completely Randomized Design (CRD) during the summer of 2007 at the Laboratary of Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Ayodhya (U.P.). The small gunny bags of 5kg capacity were kept for 120 days at ambient storage condition. The minimum sprouting was observed by numbers and sprout weight (g per kg tubers) in varieties/ hybrids B-420 (2), J/95-229, Kufri Pushkar, Kufri Ashoka and Kufri Lalima after 120 days of storage at ambient conditions. However, maximum sprouting was recorded in hybrids DSP-19, MS/92-1090, and MS/99-1871 after 120 days of storage in ambient conditions.

Keywords: Variety/hybrids, sprouting, potato, ambient condition

Introduction
The potato (*Solanum tuberosum* L.) is one of the most efficient horticultural food crop. It belongs to family solanaceae, which constitutes around 85 genera with 2200 species and Solanum is the largest genus with 1700 species. Among major potato growing countries, India ranks third after China and Russian Federation. The present area under potato in India is about 2.117 million hectares with production and productivity of 43.417 million tones and 20.50 t/ha (Anonymous, 2016) [1] respectively.

The potato is an easily grown plant that produces more food on less land. One hectare of potatoes can yield food value of 2-4 hectares of grain. The dry matter production in potato is 47.6 kg/ha/day, whereas in wheat and rice it is 18.1 and 12.4 kg/ha/day, respectively. Storage studies in potatoes stored at higher temperatures have been conducted by different workers but information are insufficient. In the present status of information on identification of varieties/hybrids with good shelf-life for a few months are desired.

Method and Materials
The present investigation was carried out at the laboratory of Department of Vegetable Science, Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj) Ayodhya (U.P.) during March to June, 2007. The experimental material comprised of thirty six varieties/hybrids of potato and were evaluated in Completely Randomized Design with three replications.

The recorded data in Completely Randomized Design (CRD) were analyzed statistically by the method suggested by Cochran and Cox (1963) [3].

Result and Discussion
Studies on changes during ambient storage of different varieties/hybrids of potato revealed that the minimum sprouting was observed by numbers and sprout weight (g per kg tubers) in varieties/ hybrids B-420 (2), J/95-229, Kufri Pushkar, Kufri Ashoka and Kufri Lalima after 120 days of storage at ambient conditions. The result of sprouting behavior and sprout weight (g per kg tubers) of all the varieties/hybrids from 30th to 120th days of storage period has been presented in Table- 1 and Table- 2, respectively.

Correlation coefficient and path analysis for yield and its component traits in Brinjal (*Solanum melongena* L.)

Devesh Tiwari, GC Yadav, Vipin Kumar Maurya, Aman Kumar and Sriom

Abstract
The study conducted to know the association among different morpho-economical traits of brinjal. The experiment comprising forty diverse genotypes, grown in randomized block design with three replications. The experiment was conducted in Randomized Complete Block Design with three replications at the Main Experiment Station, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology Narendra Nagar, (Kumarganj), Ayodhya (U.P.), during autumn-winter season 2016-17. The most important trait, total fruit yield per plant had exhibited highly significant and positive phenotypic correlation with marketable fruit yield per plant (0.9635), followed by unmarketable fruit yield per plant (0.6003), fruits per plant (0.5405), crop duration (0.4345), primary branches per plant (0.3156) and fruit length (0.2426). The higher magnitude of positive direct effect on fruit yield was exerted by marketable fruit yield per plant (0.8423) and unmarketable fruit yield per plant (0.2470) at phenotypic level. However, the positive direct effects of rest of the traits were very low. The negative direct effect on yield by either of the dependent traits were very low. However, plant height and average fruit weight contributed considerable negative direct effects on total fruit yield per plant.

Keywords: correlation, path, direct indirect, brinjal, *Solanum melongena*

Introduction

Brinjal (*Solanum melongena* L., 2n=2x=24) belongs to sub genus Leptostemonum section Melongena of the family Solanaceae, sub family Solanoideae and Tribe Solaneae. It is worldwide known as aubergine or guinea squash which is one of the most popular and major vegetable crop in India and other parts of the world.

Brinjal or egg plant is a perennial but grown commercially as annual crop. Inflorescence is often solitary but some time it constitutes a cluster of 2-5 flowers. Solitary or clustering nature of inflorescence is a varietal character. Flower is complete and hermaphrodite. Heterostyly is a common feature, and fruit setting flower consist of long (70-85%) and medium styled (12-55%) flower. The non-fruit setting flowers consist of short styled and pseudo styled.

Egg plant is usually self-pollinated but the extent of cross-pollination has been reported as high as 29% and hence it is classified as often cross-pollinated or facultative cross-pollinated. Flower generally emerges 40-45 days after transplanting. Anthesis occurs at about 6-8 a.m. in August-September and usually between 9.30-11.15 a.m. during winter (December-January). Stigma receptivity is highest during anthesis *i.e.* flower opening. Anthers usually dehisce 15-20 minutes after the anthesis.

It is easily cultivated in almost all parts of India except higher altitudes. It is a warm season crop and highly susceptible to frost. A long and warm growing season is desirable for successful brinjal production. The main crop of brinjal is raised during autumn- winter season however; some production is obtained during spring-summer season also. But during spring-summer season high temperature (above 35°C) causes drastic reduction in brinjal production due to poor fruit set. The optimum temperature for growth and fruit set is 15.5-21.1°C. Many of the round varieties usually set fruit at slightly lower temperature and are susceptible to frost and long-fruited varieties set fruits at higher temperature and show tolerance to frost.

Materials and Methods

The study comprised 40 genotypes of Brinjal including four checks. The experiment was conducted in Randomized Complete Block Design with three replications at the Main Experiment Station, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology Narendra Nagar, (Kumarganj), Ayodhya (U.P.), during autumn-winter season 2016-17.

Studies on extent of variability, heritability and genetic advance in okra [*Abelmoschus esculentus* (L.) Moench]

Vipin Kumar Maurya, Gulab Chand Yadav, Aman Kumar, Devesh Tiwari, Nishakant Maurya and Sriom

Abstract
The experiment was conducted at Main Experimental Station, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya during *Kharif*, 2016-17 in Randomized Complete Block Design with three replications using thirty genotypes of okra collected from different sources to study the extent of variability, heritability and genetic advance in per cent of mean for different quantitative traits. The analysis of variance for the design of experiment indicated highly significant differences among the genotypes for all the characters. Based on mean performance of genotypes NDO-33 (212.16) followed by NDO-31 (199.03), NDO-24 (195.50), NDO- 35 (190.20) and NDO-17 (189.23) were found as five most promising genotypes for fruits yield per plant. High magnitude PCV were observed in case of unmarketable fruit yield per plant (31.34) followed by marketable fruit yield per plant (21.46), number of fruits per plant (20.78), total fruit yield per plant (19.70) and branches per plant (14.60). Moderate PCV along with GCV were recorded for number of branches per plant (14.60, 9.57) followed by fruit circumference (12.86, 8.11), fruit length (12.26, 8.36), average fruit weight (10.23, 9.42) and plant height (10.88, 9.00). High heritability were estimated for total fruit yield per plant (93.82) followed by unmarketable fruit yield per plant (87.68), average fruit weight (84.86), days to 50% flowering (84.54) and marketable fruit yield per plant (81.13). High heritability coupled with high genetic advance were estimated for total fruit yield per plant (93.82, 38.80) followed by unmarketable fruit yield per plant (87.68, 56.60) and marketable fruit yield per plant (81.13, 35.87) which indicating opportunity for high selection response.

Keywords: Variability, PCV, GCV, heritability, genetic advance, okra (*Abelmoschus esculentus* (L.) Moench)

Introduction

Okra [*Abelmoschus esculentus* (L.) Moench 2n = 2x=130] is one of the important member of the family malvaceae and is well known by many regional names as lady's finger in England, Gumbo in USA, Dherosh in Bangladesh, Huang Giu Kui in China, Quingombo in Spanish, Bhindi in Pakistan and India. Okra is an African word and is native to northern Africa including the area of Ethiopia and Sudan. It is a summer and rainy season crop and is widely cultivated from tropics to sub tropics.

Okra (*Abelmoschus esculentus* L.) is probably an amphidiploids (allotetraploid) derived from *Abelmoschus tuberculatus* (2n = 58), a wild species from India, and a species (*Abelmoschus ficulneus* (L.) Wight and Arn. ex Wight) with 2n = 72 chromosomes. Another edible okra species are *Abelmoschus caillei* (A. Chev.).Stevels occurs in the humid parts of West and Central Africa. There are strong indications that *Abelmoschus caillei* is amphidiploids with *Abelmoschus esculentus* being one of the parental species. The lowest chromosome number 2n=56 reported in *Abelmoschus angulosus* (Ford, 1938) whereas, the highest chromosome number 2n=196 reported in *Abelmoschus manihot* var. *Caillei* (Singh and Bhatnagar, 1975; Siemonsma, 1982a, 1982b) [14, 15].

According to Vavilov, it was probably domesticated in the Ethiopian region but, according to Murdock, it is originated in West Africa (Joshi *et al*., 1974) [6]. Okra was earlier included in the genus *Hibiscus*, section *Abelmoschus* in the family malvaceae (Linnaeus, 1753). The section *Abelmoschus* was subsequently proposed to be raised to the rank of distinct genus by Medikus, 1787. The wider use of *Abelmoschus* was subsequently accepted in the taxonomic and contemporary literature. This genus is distinguished from the genus *Hibiscus* by the characteristics the calyx, spathulate, with five short teeth, connate to the corolla and caduc[illegible] flowering (Kundu and Biswas, 1973 and Terrell and Winters, 1974) [8].

Importance of PGRs in vegetable production: A review

Pradip Kumar Saini[1], Kuldeep Kumar[2], Dr. DP Singh[3], Dr. RK Yadav[4], Dr. GC Yadav[5]
[1, 4, 5] Narendra Deva University of Agriculture and Technology Kumarganj, Ayodhya, Uttar Pradesh, India
[2, 3] Chandra Shekhar Azad University of Agriculture & Technology, Kanpur, Uttar Pradesh, India

Abstract
Indian Agriculture become more mechanized and science based by using inputs and the PGRs are among of them; PGRs has quicker impact on vegetative as well as yield of the crops. As it has various advantages like less time consuming to treat the plant and environment friendly. Vegetables crops are rich sources of vitamins and minerals. Use of growth regulators in vegetable production must be specific their action and toxicologically and environmentally safe. The physiological activity of vegetable crops regulate and after the application of growth regulator finally enhance the vegetable production.

Keywords: vegetable crop, PGRs, production

Introduction
Plant hormones are chemicals in plants that regulate cellular processes. They are usually found in small amounts throughout the plant. These hormones are very important as they determine many different attributes of a plant. Plant hormones can be natural or synthetic. Plant hormones are also known as phytohormones. Thimann in 1948 was coined the term "Phytohormone" The five major plant hormones are auxins, gibberellins, cytokinins, abscisic acid, and ethylene. (P. Hazra and M.G. Som, 2006) [10]. These hormones will work independently or together to influence plant growth and health. Auxins and gibberellins help promote plant growth, particularly in stem elongation. Cytokinins promote cell division and are produced in growing areas of plants. Abscisic acid plays a role in cell dormancy and is involved in the opening and closing of the stomata on leaves. Finally, ethylene is a gas that is produced by ripening fruits. Ethylene is one particular hormone that is often synthetically produced so gardeners can purposefully ripen fruits of many plants at the same time. The classes are discussed in following table 1

Auxin
Charles Darwing was the first who proposed the existence of auxin in 1880. It was the first class growth regulator that was discovered. Auxins are those compounds that give positive effect on formation of bud, enlargement of cell and root initiation and they are also helpful for the formation of other growth hormones. IAA is natural occurring hormone while NAA, IBA, 2-4D etc. are synthetic in nature.

Gibberellin
Kurosava was the Japanese scientist who discovered gibberellins in 1926. It is the second growth regulator. It was extracted from the fungus "*Gibberella fujikuroi*" which is the causal organism of "foolish seedling disease". GA stimulate germination of seed and maturation of flower and fruit.

Cytokinins
Skoog in 1995 experimented that when pith tissues of "*Nicotiana tabaccum*" were separated from the vascular tissues they grew without division of cell. There are so many different synthetic cytokinins such as 6-benzylamino purine (BAP), kinetin, 6-(benzyl-amino)-9-(2-tetrahydropyranyl)-9H-purine (PBA), 1,3-diphenylurea, thidiazuron (TDZ), etc.

Abscisic acid
It is also called plant stress hormone. It act as inhibitory chemical compound that gives direct effect on growth of bud, seed and dormancy of bud. It has inhibitory effect and occurs naturally in plants. It inhibit mRNA and synthesis of protein.

Ethylene
This hormone is a gaseous plant hormone which is synthesized from methionine and it is synthesized in all organs of plant.

Contribute of PGRs in vegetable production
Chilli
The treatments 2,4-D @ 2ppm, triacontanol @ 5ppm, NAA 40ppm and GA_3@ 10ppm produced 28.75%, 25.70%, 13.61% and 2.30% maximum fruit yield over control. It was recorded that maximum net profit and B: C ratio was found in case of 2ppm 2,4-D. The use of GA_3 as foliar spray was not economical (Chaudhary *et al.*, 2006) [7]. Maximum seed yield per plant (8.30 g), seed yield per fruit (0.35 g), per plant average fresh weight of fruits (39 g) and per plant average dry weight of fruits (19.67 g) were obtained by spraying of NAA @ 40ppm as against control (Patel *et al.*, 2016) [16]. In capsicum, NAA @ 60ppm gave maximum plant height (120.59 cm), number of branches (16.05), days to first flowering (32.51), per plant number of flowers (11.83), weight of fruit (169.66g), per plant number of fruits (9.87), per fruit number of seeds (110.78), per plant yield (1.67 kg) and per plot yield of fruit (15.07kg), yield per hectare (69.76t) were recorded (Singh *et al.*, 2017) [17]. Different concentrations of growth regulators such as NAA (25, 50 and 75ppm), GA_3 (20, 40 and 60ppm), 2, 4-D (5, 7.5 and 10ppm) and ethrel (300, 400 and 500ppm) were used in chilli and applied after 30 and 60 days after transplanting. It was recorded that NAA @ 75ppm gave maximum yield per plant (182.31g) and yield per hectare (6.37t). On the other hand, GA_3 @ 20 and 60ppm treated plants gave maximum plant

Evaluation of potato (*Solanum tuberosum* L.) varieties/hybrids for their post-harvest physiological weight losses under ambient conditions

Satish Kumar, GC Yadav, Nishakant Maurya, Atul Yadav and Manjeet Kumar

Abstract
The experiment was conducted with thirty six varieties/hybrids replicated thrice in Completely Randomized Design (CRD) during the summer of 2007 at the Laboratary of Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj) Ayodhya (U.P.). The small gunny bags of 5kg capacity were kept for 120 days at ambient storage condition. The physiological losses in weight was increases continuously in all the treatments from 30 to 120 days of storage period under ambient conditions. The minimum physiological loss in weight was recorded in varieties/hybrids J/95-229, Kufri Sutlej, J/95-221 and B-420(2) after 120 days of storage under ambient conditions.

Keywords: Variety/hybrids, Weight loss, Potato, post-harvest, ambient condition

Introduction
The potato (*Solanum tuberosum* L.) is one of the most efficient horticultural food crop. It belongs to family solanaceae, which constitutes around 85 genera with 2200 species and Solanum is the largest genus with 1700 species. Among major potato growing countries, India ranks third after China and Russian Federation. The present area under potato in India is about 2.117 million hectares with production and productivity of 43.417 million tones and 20.50 t/ha (Anonymous, 2016) [1] respectively.

The potato is an easily grown plant that produces more food on less land. One hectare of potatoes can yield food value of 2-4 hectares of grain. The dry matter production in potato is 47.6 kg/ha/day, whereas in wheat and rice it is 18.1 and 12.4 kg/ha/day, respectively. Storage studies in potatoes stored at higher temperatures have been conducted by different workers but information are insufficient. In the present status of information on identification of varieties/hybrids with good shelf-life for a few months are desired.

Method and Materials
The present investigation was carried out at the laboratory of Department of Vegetable Science, Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj) Ayodhya (U.P.) during March to June, 2007. The experimental material comprised of thirty six varieties/hybrids of potato and were evaluated in Completely Randomized Design with three replications.

The recorded data in Completely Randomized Design (CRD) were analyzed statistically by the method suggested by Cochran and Cox (1963) [3].

Result and Discussion
Studies on changes during ambient storage of different varieties/hybrids of potato revealed that physiological loss in weight increases continuously in all the varieties/hybrids from 30th to 120th days of storage period. During ambient storage, stored potatoes losses weight mainly due to two physiological processes *i.e.*, transpiration and respiration. The result of physiological losses of all the varieties/hybrids from 30th to 120th days of storage period has been presented in Table- 1.

Extent of genetic variability, heritability genetic advance for quantitative traits in tomato (*Solanum lycopersicon* [mill.]Wettsd.)

Mahendra Kumar Yadav, CN Ram, GC Yadav, Nishakant Maurya, Durga Prasad and Arun Kumar Verma

Abstract
The present investigation was carried out to evaluate 47 genotypes with 3 check varieties in respect of genetic variability, heritability and genetic advance for twelve yield contributing traits. Analysis of varience revealed, moderate to high level of genetic variability among different genotypes for all yield contributing triats. In general the value of phenotipic coefficient of variation (PCV) was higher than their respective genotypic coefficient of variation (GCV), but the extent was quite low. This indicates that there is very less environmental influence on the expression of characters. High value of GCV was recorded for the characters such as number of fruit per plant (53.15), unmarketable fruit yield per plant (46.93), average fruit weight (38.67), marketable fruit yield per plant (35.73), total fruit yield per plant (35.33). While low magnitude of coefficient of variability was exhibited by total soluble solid (6.19) and days to 50 per cent flowering (8.70).

Keywords: Genetic variability, Gcv, Pcv, heritability (h^2), genetic advance, tomato (*Solanum lycopersicon* [mill.] Wettsd.)

Introduction
Tomato (*Solanum lycopersicon* [Mill.] Wettsd.) Belongs to Solanaceae family and the genus *Solanum*. It is a herbaceous annual to perennial in nature and sexually propagated crop plant with perfect flowers. It is a day neutral plant and mainly self-pollinated but a certain percentage of cross-pollination also occurs. It is a warm season crop reasonably resistant to heat, drought and grows under wide range of soil and climatic conditions. It is widely cultivated vegetable throughout the world and ranks second in importance after potato in many countries including India. In India, total area was 0.808 million hectares with production 19.69 million tonnes and there productivity 24.4 tonnes per hectare (Anonymous, 2016) [1].
There are four to eight flowers in each compound inflorescence. Anthesis occurs from 7:00-8:00AM and dehiscence from 9:00-11:00AM. All the species of tomato are native to western South America (Rick, 1976) [1]. Growth habit ranged from strongly determinate (bushy type) to indeterminate types.
Tomato is considered as "Poor man's Orange" and universally treated as 'Protective Food'. Tomato fruits are eaten raw or cooked. Tomato in large quantities is used for the preparation of several processed items like soup, juice, ketchup, puree, paste, powder and ripen fruits are used as raw vegetable in salad. Tomato is a good appetizer and its soup is said to be a good remedy for patients suffering from constipation.
Genetic variability and its inheritance pattern is paramount significant in challenging out strategy for effective crop improvement in terms of selection response. Keeping in view the present study was under taken to find out the presence of variability, pattern of heritability and to judge the genetic advance under selection.

Materials and Methods
The experiment was conducted with 47 genotypes including 3 checks *viz*. Arka vikas, NDT-7 and DBRT-2-1 in Randomized Block Design with three replications at Main Experimental Station of Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Ayodhya, Uttar Pradesh, India. The observations were recorded on yield and its attributing traits.

ABSTRACT

The present investigation entitled "Study the correlation coefficient and path coefficient for the yield and yield component of bitter gourd (*Momordica charantia* L.) was carried out at Main Experiment Station, Department of Vegetable Science, Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.) during summer-2017, to evaluate the available genotypes, to estimate the correlation coefficient and to work out the path coefficient analysis for yield and its component traits of 30genotypes, with three replications in randomized block design. Estimates of correlation and path coefficients can define the mutual relationship between plant characters and determine component characters on which selection can be based for improvement in yield. It might be easier to increase yield by increasing the smallest yield components on an otherwise good cultivar. Thirty genotypes of bitter gourd were evaluated for yield contributing characters to observe their associations and direct and indirect effect on fruit yield. In most cases the genotypic correlation coefficient was higher than the respective phenotypic correlation coefficients indicating the suppressive effect of environment modified phenotypic expression of these characters by reducing phenotypic correlation values. The higher magnitude of coefficient of variation at phenotypic as well as genotypic levels were observed for phenotypic in no. of fruit per plant followed by fruit yield per plant (kg), vinelength (m), fruit length (cm), node no. to anthesis of first staminate flower, average fruit weight (g), node no. to anthesis of first pistillate flower, no. of nodes per vine and lower value in days of first fruit harvest followed by days to anthesis of first pistillate flower, days to anthesis of first staminate flower, fruit diameter. The phenotypic correlation coefficients between different characters were generally similar in magnitude and nature to the corresponding genotypic correlation coefficient. The significant and positive correlation with yield per plant was observed at phenotypic level with average fruit weight and no. of fruits per plant. The analysis of path coefficient indicating appreciable amount of direct positively effect of no. of fruits per plant and fruit yield per plant followed by vine length on fruit yield per plant.

Heterosis for earliness and yield contributing traits in brinjal (*Solanum melongena* L.)

Maneesh Pandey and GC Yadav

Abstract
The present investigation was conducted to found out the magnitude of the heterosis in brinjal. Eight parents were crossed in diallel excluding reciprocal to developed 28 crosses. The hybrids al song with parents were evaluated in 2 consecutive years. The data were recorded on plant height, number of primary branches per plant, days to 50% flowering, days to first fruit harvest, harvest duration, average fruit weight, marketable fruit yield, which are contributing earliness and yield. For days to 50% flowering, and days to first fruit harvest maximum negative standard heterosis, and heterobeltiosis, were shown by cross combination $P_5 \times P_7$ and $P_3 \times P_8$, respectively. For days to first fruit harvest, high magnitude of standard heterosis and heterobeltiosis were shown by $P_5 \times P_7$. For marketable fruit yield, of $P_5 \times P_7$ and $P_2 \times P_7$ were found promising for earliness and yield. The cross combinations inbred P_1, P_2, P_6, and P_8 were prosing, therefore these parental lines could be used for development hybrids for early and high yield.

Keywords: Heterosis, heterobeltiosis, brinjal, earliness, yield

Introduction
Eggplant (*Solanum melongena* L. 2n=24) or brinjal is a important solanaceous vegetable, which is known by various name in India *viz.*, Baigan (Hindi), Badanekai (kannada), Vangi (Marathi), Kathirikai (Tamil), Vankai (Telugu) and worldwide known as aubergine (France) or guinea squash. Brinjal is one of the most popular and major vegetable crop in India and some other parts of the world. It is a self-pollinated and annual herbaceous crop, probably originated in India and shows secondary diversity in South East Asia. It is being grown extensively in India, Bangladesh, Pakistan, China, Japan, Philippines, France, Italy and U.S.A. In India, brinjal occupies an area of 6.62 lakh ha with annual production of 125.88 lakh metric tonnes & productivity stand at 18.9 metric tons per hectares. In Uttar Pradesh, Agra, Meerut, Lucknow, Kanpur, Aligarh, Chitrakoot and Gorakhpur districts having maximum area and production (Annonymous, 2016) [1].

The heterosis breeding programme mainly depends on the choice of superior parents for hybridization and the knowledge of combining ability and magnitude of gene action involved in the expression of component traits. Among the various mating designs diallel cross techniques has been most frequently used to determine general and specific combining ability variances and their effects in brinjal (Bavage *et al.* 2005; Panda *et al.* 2005; Suneetha *et al.* 2006 & Hazra *et al.* 2010) [4, 11, 13, 7]. Hence this study was conducted to develop brinjal hybrid with early and higher yield.

Materials and Methods
Field experiment was conducted at (MES) Department of Vegetable Science, N.D. University of Agriculture & Technology, Kumarganj, Faizabad (U.P.) India. The materials for the present investigation comprised of 8 divers genotype of brinjal viz.; Siliguri (P_1), Mukta Kesi (P_2), Pant Rituraj (P_3), NDW-White-1 (P_4), Punjab Sadabahar (P_5), NDB-S-1-1 (P_6), KS-224 (P_7) and NDB-3 (P_8). The genotypes were crossed in the all possible combinations, excluding reciprocals to develop 28 hybrid combinations. The 28 Hybrids along with parents were evaluated for two successive years in 2016-17 and 2017-18 *kharif* season in Randomized Block Design with three replications. The crop was planted in rows spaced at 1.5 x 3.0 meters apart with a plant to plant spacing of 75 x 50 (cm). The analysis of heterosis was done over better parent and standard variety for days to 50% flowering, plant height (cm), number of

Exploitation of heterobeltiosis and economic heterosis for horticultural yield, and its attributes and biochemical traits in pumpkin (*Cucurbita moschata* Duch. ex. Poir) under salt affected soil

Vimlesh Kumar*, D. P. Mishra, G. C. Yadav and Satish Yadav

Department of Vegetable Science, Narendra Dev University of Agriculture and Technology, Kumarganj, Faizabad 224 229, India

Pumpkin crop can be improved by exploitation of heterosis. This study was carried out during three different seasons, *Kharif*, 2015 (E_1), *Rabi* 2015–16 (E_2) and summer-season, 2016 (E_3) in Eastern Uttar Pradesh, India. The objective was to find out the magnitude of heterobeltiosis, economic heterosis and suitable cross-combination for higher quality fruit yield in pumpkin. Fifteen F_1 hybrids were developed through diallel mating design of six parental lines excluding reciprocals. The evolution of hybrids revealed significant heterobeltiosis as well as economic heterosis for all the traits in all three seasons independently (E_1, E_2 and E_3) and combined. Crosses $P_1 \times P_5$, $P_4 \times P_6$ and $P_1 \times P_2$ may be exploited as commercial hybrids for profitable yield in pumpkin. Significant heterobeltiosis and economic heterosis indicates the importance of heterosis breeding for the developing high yield hybrids.

Keywords: Diallel mating, fruit yield, heterobeltiosis, pumpkin, β-carotene.

PUMPKIN (*Cucurbita moschata* Duch. ex. Poir), originated in central Mexico and is one of the most important vegetable crops of the family Cucurbitaceae grown throughout the world. It provides better nutrition to consumers and higher returns to farmers. Pumpkin is a herbaceous annual, sexually propagated vegetable with chromosome number $2n = 2x = 40$.

Based on commercial significance, the cultivated *Cucurbita* sp. ranks among the 10 leading vegetable crops worldwide. China and India lead the world production and other major producers are the US, Egypt, Mexico, Ukraine, Cuba, Italy, Iran and Turkey. The three economically important species, *Cucurbita pepo*, *C. moschata*, and *Cucurbita maxima* are highly polymorphic in fruit characteristics, inspiring much research in their genetics, although most such studies have been in *C. pepo* and *C. maxima*. The colour of pumpkin is due to orange pigments. The main nutrients are lutein and both α- and β-carotene, the latter of which is a precursor of vitamin A. Pumpkins are versatile for cooking. Most parts of the pumpkin are edible, including fleshy shell, seeds, leaves and even flowers. In the United States and Canada, pumpkin is a popular Halloween and Thanksgiving staple. Pumpkin purée can be frozen for later use. Pumpkin is relatively high in energy and carbohydrates and a good source of vitamins, especially high caretenoid pigments and minerals. It may certainly contribute to the nutritional status of people, particularly the vulnerable groups, with respect to vitamin A requirement. Night-blindness is a serious problem in South Asian countries. Encouraging the masses to consume more pumpkin can easily solve the problem.

Pumpkin crop can be improved by assessing the genetic variability and exploitation of heterosis. Because of the monoecious nature of the crop, large flower size, ease of pollination, high proportion of fruit set of pollinated female flowers, large number of seeds per fruit and low seed rate required per unit area, pumpkin is highly amenable for heterosis breeding. During the last three decades considerable studies have been done on hybrid vigour in pumpkin and a high amount of heterosis has been reported[1–6]. Several hybrids have been released by public and private sectors for its commercial cultivation. The area under F_1 hybrids is growing fast, which has helped to enhance the productivity and production of this crop.

The present study was carried out at the main experiment station, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Faizabad (UP), India, during *Kharif*, 2015 (E_1), *Rabi* 2015–16 (E_2) and *Zaid* (E_3) of 2016. The experimental farm falls under humid subtropical climate and is located between 24.47° and 26.56°N lat and 82.12° and 83.58°E long at an altitude of 113 m amsl. The experimental farm had saline alkali soil with pH above 8.

The experimental materials comprised of six promising and diverse inbreds and varieties of pumpkin selected on the basis of genetic variability from the germplasm stock maintained in the laboratory. The selected parental lines, i.e. Narendra Upkar (P_1), NDPK-120 (P_2), Narendra Agrim (P_3), NDPK-39-2 (P_4), Kashi Harit (P_5) and NDPK-11-3 (P_6) were raised and crossed in all possible combinations, excluding reciprocals, during *Zaid*, 2015 to get 15 F_1 hybrid seeds for the study of heterobeltiosis and economic heterosis.

The experiments were conducted in randomized block design (RBD) with three replications to assess the performance of 15 F_1 hybrids and 6 parents. The treatments were planted in rows spaced 3 m apart with a plant to plant spacing of 0.5 m. The seeds were sown on 23 July 2015, 7 November 2015 and 26 March 2016 for *Kharif*, *Rabi* and *Zaid* crops respectively. All recommended agronomic practices and plant protection measures were followed.

Estimation of direct selection parameter in okra [*Abelmoschus esculentus* (L.) Moench]

Vipin Kumar Maurya, Gulab Chand Yadav, Aman Kumar, Devesh Tiwari and Sriom

Abstract
The experiment was conducted at Main Experimental Station, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad during *Kharif*, 2016 in Randomized Block Design with three replications using thirty genotypes of okra collected from different sources to study the correlation and path coefficients analysis at phenotypic and genotypic levels for different quantitative characters. Characters like marketable fruit yield per plant (0.8522), unmarketable fruit yield per plant (0.7458), number of fruits per plant (0.7449), plant height (0.7204), days to 50% flowering (0.5720), days to first fruit harvest (0.5482), crop duration (0.5330) and fruit length (0.4370) have positive significant and desirable association with fruit yield. Thus there is an ample scope for improving characters through direct selection. Marketable fruit yield per plant (0.6192), unmarketable fruit yield per plant (0.4635), number of fruits per plant (0.0670) and days to first fruit harvest (0.0667) were identified as most important traits which had positive direct effect on total fruit yield per plant while, the negative direct effect on yield by rest of the dependent traits were very low.

Keywords: estimation, parameter, okra, *Abelmoschus esculentus*

Introduction

Okra is the most traditional and popular vegetable in India and it is extensively cultivated in summer and rainy season. It is one of the important vegetable crops which are grown throughout the tropical, subtropical and temperate parts of the world. It has been grown commercially in India, Turkey, Iran, Western Africa, Yugoslavia, Bangladesh, Afghanistan, Pakistan, Burma, Japan, Malaysia, Brazil, Ghana, Ethiopia, Cyprus and the Southern United States. Okra [*Abelmoschus esculentus* (L.) Moench 2n = 2x=130] is one of the important member of the family Malvaceae. Okra is an African word and is native to northern Africa including the area of Ethiopia and Sudan. It is a summer and rainy season crop and is widely cultivated from tropics to sub tropics (Kochar, 1986) [6].

Okra (*Abelmoschus esculentus* L.) is probably an amphidiploids (allotetraploid) derived from *Abelmoschus tuberculatus* (2n = 58), a wild species from India, and a species (*Abelmoschus ficulneus* (L.) Wight and Arn. ex Wight) with 2n = 72 chromosomes. Another edible okra species are *Abelmoschus caillei* (A. Chev.). Stevels occurs in the humid parts of West and Central Africa. There are strong indications that *Abelmoschus caillei* is amphidiploids with *Abelmoschus esculentus* being one of the parental species. The lowest chromosome number 2n=56 reported in *Abelmoschus angulosus* (Ford, 1938) whereas, the highest chromosome number 2n=196 reported in *Abelmoschus manihot* var. *Caillei* (Singh and Bhatnagar, 1975 Siemonsma, 1982a, 1982b) [11, 9, 10].

Largest area and production is in India followed by Nigeria in the world. India ranks first in the world with 72 per cent of the total world production of okra. In India the total area covered under okra is 0.51 million hectare with the production of 6.00 million tonnes green fruits in the year 2016-17. Leading okra producing state in India is West Bengal followed by Gujarat and Bihar (Anonymous, 2017) [2].

The information about correlation among different component of yield is necessary for designing efficient plant breeding programme through selection and for simultaneous improvement of yield components. Therefore, such information can be obtained by the studying genotypic and phenotypic correlation coefficient between yield and yield contributing characters.

Path coefficients analysis is helpful in portioning the observed correlation coefficient into direct and indirect effect and there effective use in selection programme.

Genetics of yield and its contributing traits of brinjal (*Solanum melongena* L.)

Maneesh Pandey and GC Yadav

Abstract
The study on genetic components of variation revealed that the importance of non-additive systems operating in inheritance of yield and its important components. Degree of dominance was in range of over dominance range for all the characters and close to complete dominance for plant height. The traits *viz.* days to 50% flowering, days to first fruit harvest, average fruit weight, harvest duration and fruit yield per plant, exhibited non significant environmental effect. For days to 50% flowering, days to first fruit harvest, average fruit weight, harvest duration and fruit yield per plant dominant genes were more frequently distributed in the parents. The result suggested preponderance of dominance gene in the expression of traits studied. Therefore, heterosis breeding approach might be advantageous rather than selection to develop superior hybrids for high fruit yield in brinjal.

Keywords: Binjal, genetics, gene action, brinjal, additive

Introduction
Among Solanaceous vegetables, brinjal (*Solanum melongena* L.) is one of the important crops. It is commercially grown in both temperate and tropical regions of the world mainly for its immature fruits as culinary vegetables. Indian collections havemarked diversity in brinjal, as India is the primary centre of origin. (Vavilov, 1931 and Bhaduri, 1951) [6, 8]. Less attention has been paid by the researchers for the development of brinjal cultivars with better fruit quality and as per market preference. The local landraces were have not been fully utilized in anygenetic improvement programme such as selection and hybridization. In brinjal improvement programme, it is very imperative to know the nature and magnitude of gene action and also to know the combining ability of parental lines. In brinjal, the information generated in the breeding process can be used to understand the magnitude of heterosis. However, gene action of different yield and flowering traits has been reported by Chadha *et al.*, (1990) [9]. Due to gene and environment interactions, direct selection in brinjal is not successful. Knowledge of the gene action for targeted traits under selection is most important component of breeding strategy. Hence, a present study on gene action in brinjal is performed to estimate the genetic component, which will be helpful to formulate the future breeding strategies of brinjal.

Methods & Materials
Field experiment was conducted at (MES) Department of Vegetable Science, N.D. University of Agriculture & Technology, Kumarganj, Faizabad (U.P.) India. The materials for the present investigation comprised of 8 divers genotype of brinjal viz.; Siliguri (P_1), Mukta Kesi (P_2), Pant Rituraj (P_3), NDW-White-1 (P_4), Panjab Sadabahar (P_5), NDB-S-1-1 (P_6), KS-224 (P_7) and NDB-3 (P_8). Eight inbred differing in growth habit, fruit and yield characters were selected as parents and were crossed in a diallel fashion excluding reciprocals. The experimental materials comprising 36 treatment *viz.*; 8 parents and 28 F_1s were sown in Randomized Block Design with three replications. Observations were recorded on eight competitive plants in each of parents and F_1's for 5 characters viz.; days to 50% flowering, days to first fruit harvest, average fruit weight (g), harvest duration (days) and yield per plant (kg). The data were subjected to analysis of variance (Panse and Sukhatme, 1967) [10], diallel cross analysis (Hayman, 1957, Jinks and Hayman, 1953) [11, 3] for analytical approach.

Assessment of genetic variation for growth and economic traits among the genotypes of tomato [*Solanum lycopersicum* (Mill.) Wettsd.]

Rohit Kumar Bajpai, GC Yadav, Vishal Tripathi, Devraj Singh and Prateek Kumar

Abstract
The present study was conducted with the objective to assess the extent of variability among the genotypes of tomato. The experimental material comprising forty six genotypes were evaluated during *Rabi* season of 2014-15. The experiment was conducted in randomized complete block design with three replications and observations were recorded on yield and quality attributes. The analysis of variance revealed that wide ranges of variation were found among the genotypes for all the traits. The estimates of phenotypic coefficients of variation (PCV) were higher than genotypic coefficients of variation (GCV) for all the characters. The estimates of high PCV as well as GCV were observed for number of locules per fruit (25.27 and 24.42) and plant height (21.12 and 20.66), while the high PCV (20.33) was noted for Pericarp thickness. High heritability coupled with high genetic advance in percent of mean was estimated for plant height (95.69 and 41.64), number of locules per fruit (78.67 and 40.96), primary branches per plant (80.67 and 29.73), number of fruits per plant (89.51 and 23.50) and fruit circumference (82.37 and 22.63), which showed ample scope of improvement in these traits through selection.

Keywords: Tomato, PCV, GCV, heritability and genetic advance

Introduction
Tomato (*Solanum lycopersicum* (Mill.) Wettsd.), 2n=2x=24 is one of the most versatile vegetable crop grown throughout the world because of its wider adaptability, high yielding potential and suitability for uses either fresh or processed as the consumers. The red pigment (lycopene) in tomato is now being considered as the world's most powerful natural antioxidant. Therefore, tomato is one of the most important "protective foods" because of its special nutritive value.

Keeping in the potentiality of this crop, there is a need for improvement and to develop varieties suited to specific agro-ecological conditions and also for specific end use. A thorough knowledge regarding the amount of genetic variability existing for various characters is essential for initiating the crop improvement programme. May research workers such as Ahmed *et al.* (2006), Dhar and Sharma (2012) and Prema *et al.* (2011) also worked on the same theme? But the estimates of coefficients of variation, heritability and genetic advance varied with environmental situation and genetic materials used under study therefore, the present experiment was conducted with the objective to estimate the extent of variability present in the available germplasm and the degree of inheritance of the traits to adjudged the expected gain after selection.

Materials and Methods
The experiment was conducted during *Rabi*, 2014-2015 at Main Experiment Station, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology Narendra Nagar (Kumarganj), Faizabad (U. P.). Geographically this area falls under humid sub-tropical climate and is located in between 24.47° and 26.56° N latitude and 82.12° and 83.98° E longitude at an altitude of 113 m above the mean sea level in the Genetic alluvial plains of Eastern Uttar Pradesh.

The experiment was laid out in Randomized Block Design with three replications to assess the performance of 46 genotypes of tomato including three check varieties H-24, H-86 and DVRT-2 taken from IIVR, Varanasi. Seed were sown in nursery bed on 07 October 2014 and 31 days old healthy seedling were transplanted in the experimental field on 07 November 2014 in two row of 4.5 m length with inter and intra row spacing of 60 cm x 45 cm respectively. Fertilizer @ 120kgN: 80kgP_2O_5: 50kg K_2O/ha were applied to the crop.

Abstract
The experiment was conducted in randomized block design with three replications at the Main Experiment Station of the Department of Vegetable Science, N.D. University of Agriculture & Technology, Kumarganj, Faizabad, during the summer season 2017 to evaluate the genetic variability, heritability and genetic advance in available genotype. Observations recorded on twelve quantitative characters.

Analysis of variance revealed that the genotypes evaluated differed significantly among all the treatment for all the twelve traits. The PCV (phenotypic coefficient of variation) were higher than corresponding GCV (genotypic coefficient of variation), it reveals that variation is due to genotypes as well as environmental factors. The estimates of genotypic as well as phenotypic coefficient of variability were observed higher for no. of fruit per plant followed by fruit yield per plant, vine length and node no. of first staminate flower, fruit length whereas, average fruit weight, node number to anthesis of first pistillate flower, and were moderate coefficient of variability. High estimates of heritability were observed for all the character except days to anthesis of first pistillate flower, days to anthesis of first staminate flower, node no. of first pistillate flower, which indicated moderate heritability, while days to first fruit harvest and fruit diameter indicated low heritability. High estimates of genetic advance in per cent of mean recorded for no. of fruit per plant followed by fruit yield per plant, vine length, fruit length, node number to anthesis of first staminate flower, average fruit weight, while no. of nodes per vine and showed moderate genetic advance in per cent of mean.

Keywords: Studies, genetic variability, heritability, genetic advance, bitter gourd

Introduction

Bitter gourd (*Momordica charantia* L.; 2n=2x=22) is one of the important commercial cucurbitaceous vegetable cultivated in India. It is also known as bitter melon, bitter gourd, bitter cucumber, bitter squash, balsam pear, karela, cassilla and maiden apple (Morton, 1967) [13].

The term "cucurbits" is given by Hyde Bailey for cultivated species of family Cucurbitaceae. Bitter gourd (*Momordica charantia* L.) belongs to the family Cucurbitaceae, genus *Momordica* Family Cucurbitaceae includes about 118 genera and 825 species. *Momordica* is a large genus with approximately 80 known species of annual and perennial climbers of which *Momordica charantia* L. is widely cultivated. The other species grown for edible fruits are *M. cochinchinensis* (giant spine gourd or kakrol), *M. dioica* (kartoli), *M. tuberose* and *M. balsamina* (balsam apple). The wild species *M. charantia* var. *abbreviata* of Asia is perhaps the proginator of the cultivated bitter gourd.

The bitterness in bitter gourd is due to momordicine (momordicosides-glycosides of tetracyclic triterpinoids with cucurbitane skeleton) an alkaloid, which is different from cucurbitacins present in other cucurbits. It is bitter to taste, the Karela juice (Bitter Gourd) is abundant amount of essential nutrients. Not only is it highly nutritional, in addition to, considered a wonderworking of health drink. Karela juice has innumerable health benefits. It is an essential tonic for diabetic patients. Not only patients, but in fact, everyone can get some or the other benefit out of this juice. The immature fruits and tender vine tips are used in a variety of culinary preparations. The fruits are soaked in salt water to remove of their bitterness and then boiled, fried or pickled.

The fruit of bitter gourd is higher nutritional value compared to other cucurbits except vitamin C. Fruits are considered as a rich source of vitamins and minerals and 88 mg vitamin C and 210 IU vitamin A per 100 g. Fruits are used after cooking and delicious preparations are made after stuffing and frying. The vine tips are an excellent source of vitamin A. The medicinal value of the gourd in the treatment of infectious diseases and diabetes is attracting of scientists worldwide

Abstract
Correlation and path coefficient analysis studies conducted in forty diverse genotypes of taro with objective to know association among character viz., Days to sprouting, length of leaf (cm), width of leaf (cm), girth of plant (cm), petiole length (cm), sheath length (cm), height of Plant (cm), length of cormels(cm), girth of cormels(cm), number of cormels/plant, weight of cormels/plant(g), length of corm (cm), girth of corms (cm), weight of corms/plant (g),dry matter (%), yield/plant(g). Present study revealed that the trait yield/plant had significant and positive phenotypic and genotypic correlation with Weight of cormels per plant(g), weight of corms per plant (g), number of cormels per plant and dry matter (%). Inter relationship study revealed that for improvement of taro weight of cormels/plant (g), weight of corms plant, girth of cormels (cm) and dry matter (%) at phenotypic level. Path coefficient analysis revealed by weight of cormels per plant followed by weight of corms per plant, length of leaf (cm), dry matter (%), girth of cormels per plant (cm), days to sprouting. exhibited greater direct effect on tuber yield p/plant (g). Therfore, therse character appear to be the most important traits for colocasia improvement programme.

Keywords: Colocasia (*Colocasia esculenta* var. antiquorum), Tuber yield/plant (g), Correlation and path analysis

Introduction
Taro (*Colocasia esculenta* var. antiquorum) is one of the oldest and most important tuber crop. It is also known as eddoes type taro, arvi and ghuia. It is grown mostly as staple or subsistence crop throughout the tropics and subtropics.
The corms and cormels are mostly used as vegetables or as subsidiary food after roasting, baking or boiling. Young leaves and petioles are widely consumed as vegetable. The corms and cormels are rich in starch which contains 17-25 percent amylase. Its flour is considered good baby food because its starch is easily digestible. It helps in constipation problems and supplements iron (Onwueme, 1999). The nutritive value of colocasia per 100g of corms and cormels are moisture 73.1g, Carbohydrate 21.1g, Protien 3.1g, Fat 0.1g, β-carotene 24 µg, Thiamine 0.09mg, Riboflavin 0.03mg, Calcium 40mg, and Iron 1.7mg which can be used as supplements of these nutrients.
The corms are acrid due to presence of calcium oxalate crystals. However, it has got a very good potential as an important tuber crop because of its higher yield potential and better keeping quality. In addition to this, it has got very good medicinal values too. Various parts of the plant are also used in traditional medicine practice (Tsitsiringos, 2002). The juice of the leaves is used against colic and constipation, the acrid juice extracted from leaf stalk is astringent and styptic. The corm is mild lucrative and diuretic. It is generally used against piles, constipation and dropsy in the form of gruel. The ash of the corm is used as antihelminthic, mixed with honey, and it is applied in the aphthus condition of the mouth.

Material and Method
The experimental were comprised of forty genotype collected from All India Coordinate Research on Tuber Crops. The experiments were carried out at two location i.e. NDUAT Kumarganj, Faizabad, UP and Farmer' s field Belakhra, Faizabad, UP for two consecutive seasons i.e. 2015 and 2016 in the randomized block design with three replications. Cormels of each genotype was planted in the month of March at inter and intra row spacing of 60 cm having plot size of: 2.40m x 1.80 m. The standard packages of practices were followed to raise the crops was harvested in November.

Genetic variability, heritability and genetic advance in brinjal (*Solanum melongena* L.)

Devesh Tiwari, GC Yadav, Aman Kumar, Vipin Kumar Maurya and Devraj Singh

Abstract
The present investigation conducted at Main Experiment Station, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj) Ayodhya involving 40 diverse genotypes of brinjal (*Solanum melongena* L.) in Randomized Block Design replicated thrice during *kharif-Rabi*-2017 to estimate the genetic variability, heritability (bs) and genetic advance in present of mean for planning the leading strategy in the available germplasm of brinjal. The observations were recorded on twelve quantitative traits *viz.* days to 50% flowering, plant height (cm), primary branches per plant, days to first fruit harvest, crop duration, fruits per plant, fruit length (cm), fruit circumference (cm), average fruit weight (g), marketable fruit yield per plant (kg), unmarketable fruit yield per plant (kg) and total fruit yield per plant (kg) and qualitative traits viz. fruit colour, fruit shape and calyx colour. The analyses of variance revealed that mean sum of squares due to genotypes were highly significant for all the traits indicating ample variation among the genotypes. Whereas, the higher magnitude of coefficient of variation at phenotypic level observed for fruits per plant (53.98%) followed by average fruit weight (43.36%), fruit circumference (34.63%), unmarketable fruit yield per plant (30.73%), marketable fruit yield per plant (26.64%) and total fruit yield per plant (23.99%). However, low variability recorded in the case of crop duration (5.62%). High heritability (>75) coupled with high genetic advance (>30) was observed for most of the traits except days to 50 per cent flowering, plant height, days to first fruit harvest and crop duration which indicated opportunity for selection response in available germplasm of eggplant.

Keywords: brinjal or *Solanum melongena* L. mean performance, PCV, GCV, heritability

Introduction

Brinjal or eggplant (*Solanum melongena* L.) is one of the most important solanaceous vegetable crop having diploid chromosome number 2n=2x=24. It is grown in the tropics and subtropics of India and other parts of the world. It is called brinjal in India and aubergine in Europe.

It is undoubtedly of Indian origin and has been cultivated for long time (Thompson and Kelly, 1957) [16]. Vavilov (1951) suggested China as the centre of origin. Wild brinjal types are available in southern coastal area of Africa.

Brinjal is being cultivated in India over an area of 0.73 million hectares with an average annual production of 12.51 million tonnes and productivity of 17.06 million tonnes/hectares. It is widely distributed in Orissa, Bihar, Karnataka, West Bangal, Andhra Pradesh, Maharashtra and Utter Pradesh. In Uttar Pradesh, brinjal is being cultivated on an area of 4.10 lakh ha with annual production of 136.16 lakh tonnes (Anonymus. 2017) [1].

Brinjal an annual herbaceous plant has inflorescence with a cluster of 2-5 flowers. Both solitary and cluster type flowering are found. Heterostyly is common feature. Four types of flowers have been identified depending upon the length of style, these are long styled with large ovary, medium styled with medium ovary, pseudo-styled with rudimentary ovary and true short styled with very rudimentary ovary. Fruit setting in long styled is 70-85% while medium styled varies from 12-15%. Brinjal is usually self-pollinated but the extent of cross-pollination as high as 29 per cent has been reported. It is consider as often cross pollinated and out crossing takes place with the help of insects. Flower emerges 40-45 days after transplanting. Anthesis occurs at 6-8 am in August-September and usually 9:30-11:15 am in December-January. Stigma receptivity is highest during anthesis *i.e.* flower opening. Anthers usually dehisce 15-20 minutes after the anthesis.

Abstract
Thirty genotypes including three check varieties (Determinate Punjab Chhuhara, Indeterminate Pusa Ruby and Indeterminate NDT-8) of tomato (*Solanum Lycopersicon Mill.*) were assessed to work out the association of different yield traits, direct and indirect effects of their various attributes on yield per plant. The most important trait fruit yield per plant had highly significant and positively correlated with marketable fruit yield per plant (0.82), number of fruits per plant (0.61), average fruit weight (0.26) and primary branches per plant (0.15). Pericarp thickness had highly significant and negatively correlated with days to 50 per cent flowering (-0.26). Number of fruit length (0.75) and locules per fruit (0.74) were highly significant and positively correlated with diameter of fruit. Number of fruits per plant was highly significant and negatively correlated with average fruit weight (-0.43). The higher direct effect showed by number of fruits per plant (0.55), followed by average fruit weight (0.49). Number of marketable fruits per plant showed highly indirect and positively effect *via* marketable fruit per plant (0.34), fruit length (0.14). While average fruit weight (-0.24) and total soluble solids (-0.15) showed negatively indirect effect *via* number of fruits per plant.

Keywords: Tomato (*Solanum Lycopersicon Mill.*), Character association, path analysis and fruit yield

Introduction

Vegetables are valuable source of carbohydrates, protein, vitamins, minerals, fat, elemental salts and crude fibers. In addition to nutritional richness, vegetables add a variety of taste, colour and texture to the diets. India is credited as the second largest producer of vegetables in the world next only to China. Because of varied agro-climatic conditions in India, a large number of vegetable crops are grown here and a great deal of research work has been conducted in the disciplines of vegetable breeding, production technology, plant protection, seed production and post harvest technology. Number of processed items are prepared on large scale for consumption as well as for export purposes. All the species of tomato are native to Western Southern America (Rick, 1976). Tomato is used as fresh vegetable and is also very important for processing purposes like soup, ketchup, sauce, concentrate, puree, juice, chutney etc. Unripe green fruits are used for preparation of pickles and chutney. Tomatoes are important source of lycopene (an antioxidant), ascorbic acid and ß-carotene and valued for their colour and flavour. It is rich source of mineral, vitamins and organic acids essential amino acid and dietary fibers. It is rich source of vitamin A and C. Tomato also contains minerals like iron, phosphorus. Tomato fruits are eaten raw or cooked. It supplies vitamin C and adds variety of colours and flavours to the food. It has many other uses; tomato seeds contain 24 per cent oil used as salad oil and in the manufacture of margarine. Tomato is known for its outstanding nutritive value, which is given as; per 100 g of edible part of tomato fruits contain- 93.1g moisture, 3.6g carbohydrate, 1.9 g protein, 0.1g fat, 0.6g minerals, 0.7g fibers, 320 I.U. vitamin A, 31mg vitamin C (Ascorbic acid), 36 mg phosphorus, 15 mg magnesium, 45.8 mg sodium, 38 mg chlorine, 114 mg potassium, 1.8 mg iron, and 192 mg. b-carotene etc. Tomato is also rich in medicinal value. The pulp and juice are digestible, a promoter of gastric secretion and blood purifier. It is said to be useful against cancer of the mouth and sour mouth, etc. It is one of the best vegetables which keep our stomach and intestine in good order. It is one of the most popular and widely cultivated vegetable throughout the world and ranking second in importance after potato in many countries including India (Anonymous, 2013-14). The total area of world in tomato under cultivation is 4.58 m ha and total production is 150.51 million tonnes with 32.8 tonnes per hectare productivity. In India, total area is 0.88 million hectare and production is 18.23 million tonnes with 20.7 tonnes per hectare productivity,

Character association and their direct and indirect relationship between yield and its contributing traits in taro (*Colocasia esculenta* L. *var.* Antiquorum)

Vivek Yadav, CN Ram, GC Yadav, Sriom, Shiv Prakash Shrivastav, KK Bhargav and Akshay Jain

Abstract
Twenty seven genotypes including two check varieties (NDC-1 and NDC-2) of taro (*Colocasia esculenta* L. *var.* Antiquorum) were assessed to work out the association of different yield traits, direct and indirect effects of their various attributes on yield per plant. The yield per plant had shown significant and positive correlation at phenotypic level with weight of cormels per plant (0.695), number of cormels per plant (0.595), weight of corms per plant (0.451), day to sprouting (0.293). However, this character had negative and significant association with plant height (-0.364), petiole length (-0.303), leaf width (-0.287), leaf length (-0.296). Among other traits days to sprouting had positive and significant association with number of cormel per plant (0.343), yield per plant (0.293), weight of cormels per plant (0.285), at phenotypic level. At phenotypic level weight of cormels per plants (0.543) followed by weight of corm per plant (0.499), number of cormels per plant (0.217), length of leaf (0.183), and petiole length (0.072) exerted high positive direct effect on total yield per plant. Length of leaves had negative and significant association with yield per plant (-0.296) which was mainly due to indirect effects by weight of cormels per plant (-0.130) and width of leaf (-0.121). Petiole length *via* indirect effects of weight of cormels per plant (-0.149) and plant height (-0.101) was showed negative and significant association with yield per plant (-0.303).

Keywords: taro (*Colocasia esculenta* L. *var.* antiquorum), character association, path coefficient analysis and yield per plant

Introduction

Tuber crops, the third most important food crop constitute staple and or important subsidiary food for about a fifth of people of the world considering the adaptability and suitability to the varied climate, more attentions need to be focused on tuber crops. Among tuber crops, Taro (*Colocasia esculenta* var. Antiquorum) is one of the oldest and most important tuber crop. It is also known as eddoes type taro, arvi and ghuian. It is grown mostly as staple or subsistence crop throughout the tropics and subtropics. Although this crops is not treated as economically important and was often considered as poor man's crop. Which is most extensively consumed low income by the group in the rural areas. However, in the recent part, economic importance of this crop has region up considerably and therefore the availability of quality planting materials has become an important agenda for taro crops growers.

Tropical root and tuber crops have been instrumental in filling the hungry stomach of millions of small holder operators since ages. In any places, they served as the alternate food source for livelihood security. Today when the over ground food crops are facing the production challenge due to a likely vegetative impact of climate change hopes are now being pinned on root and tuber crops since they are less likely to suffer from such impact.

Colocasia belongs to the monocotyledonous family Araceae whose members are known as aroids (Van Wyk, 2005) [5]. Taro is one of the most important edible species under the genus *Colocasia* and usually they are polyploidy, but mostly found triploid in nature with chromosome no. 2n=3x=42. India to Southern Asia is the centre of origin of *colocasia* from where it has traveled east to all the Island of Occeania, Phillipines, China and Japan. Although, India is known as native of taro. Africa ranks first in area and production of *Colocasia* followed by Asia. In India, it is mainly cultivated in Eastern and Southern States. Faizabad, Varanasi, Sitapur, Sultanpur and some parts of Jhansi.

The corms and cormels are mostly used as vegetables or as subsidiary food after roasting, baking or boiling. Young leaves and petioles are widely consumed as vegetable. The corms

Perse performance of pumpkin genotypes for growth and yield traits under Eastern Uttar Pradesh Conditions

Vimlesh Kumar, DP Mishra, GC Yadav, Satish Yadav, Sandeep Kumar, Shivam and Harikesh

Abstract
The present investigation was conducted with the using of fifteen F_1 hybrids developed by the using of diallel mating of six parents excluding reciprocals. The hybrids and parents were evaluated consecutively different three seasons during 2015-16 and pooled analysis was worked out. The observations were recorded on fourteen quantitative traits *viz.*, days to first female flower anthesis, days to first male flower anthesis, node number to first male flower appearance, node number to first female flower appearance, days to first fruit harvest, vine length (m), internodal length (cm), number of primary branches per plant, fruit weight (kg), number of fruits per plant, equatorial circumference of fruit (cm), polar circumference of fruit (cm), flesh thickness (cm), fruit yield per plant (kg). The analysis of variance revealed that mean squares due to genotypes found significant for all the quantitative traits indicating wide range of variability among the genotypes (hybrids and parents). The hybrids *viz.*, $P_3 \times P_5$, $P_1 \times P_3$ and $P_1 \times P_2$ were showed earliness for flowering and marketable fruit yield.

Keywords: Fruit yield, diallel, pumpkin

Introduction
Based on commercial significance the cultivated *Cucurbita* sp. ranks among the 10 leading vegetable crops worldwide. China and India lead the world production and other major producers are U.S., Egypt, Mexico, Ukraine, Cuba, Italy, Iran and Turkey (Ferriol and Pico, 2008) [3]. The total area of pumpkin in India is 19,760 hectares whereas, the total production is 0.42 million tonne with productivity 21.25 MT/ha (Annonymous, 2015). Robinson and Decker-Walters (1999) [5] concluded that in genus *Cucurbita*, there are 5 cultivated and 10 wild species. Seshadri and More (2009) [6] also stated that the recent recognition of synonyms and taxonomic changes have reduced the number of *Cucurbita* species to 15 or even less. The five cultivated species are *C. argyrosperma* (earlier *C. mixta*), *C. pepo*, *C. maxima*, *C. moschata* and *C. ficifolia*. In India, pumpkin and squashes were introduced from South America by foreign navigators and emissaries. *Cucurbita moschata* is more widely cultivated than other four cultivated species in our country. Since *Cucurbita moschata* is amenable to hotter climates more than other cultivated species, it is also the most widely grown vegetable throughout the tropics of both hemispheres. Pumpkins, like other squash, are thought to have originated in North America. The oldest evidence, pumpkin-related seeds dating between 7000 and 5500 BC, were found in Mexico.

The color of pumpkin is due to the orange pigments. The main nutrients are lutein and both α and β-carotene, the latter of which generates vitamin A in the body. Pumpkins are very versatile in their uses for cooking. Most parts of the pumpkin are edible, including the fleshy shell, seeds, leaves, and even flowers. In the United States and Canada, pumpkin is a popular Halloween and Thanksgiving staple. Pumpkin purée is sometimes prepared and frozen for later use.

Pumpkin is relatively high in energy and carbohydrates and a good source of vitamins, especially high caretenoid pigments and minerals. It may certainly contribute to improve nutritional status of the people, particularly the vulnerable groups in respect of vitamin A requirement. Night-blindness is a serious problem of South Asian countries. Encouraging the mass people to take more pumpkin can easily be solved the problem.

Materials and Methods
The experiments were conducted in Randomized Block Design (RBD) with three replications to assess the performance of 15 F_1 hybrids and 6 parents (in two seasons (*Kharif* and *Rabi*

Studies on genetic component analysis and gene action for growth, yield and yield attributing traits of pumpkin

Vimlesh Kumar, DP Mishra, GC Yadav and Umesh Babu

Abstract
Fifteen hybrids of pumpkin developed through diallel mating (excluding reciprocals) using six parents were evaluated for three seasons with the objective to know the nature of inheritance of growth and yield attributes. The present study revealed that the both additive and dominance variance were found important in the inheritance of most of the traits, whereas dominance variance were more prominent than the additive variance in all three seasons. Average degree of dominance revealed the presence of over dominance for all traits in all three seasons (E_1, E_2, E_3). Highly significant values of additive ($\hat{D}$) and dominance ($\hat{H}_1$ and $\hat{H}_2$) effects of components were observed for most of the traits studied in all three seasons (E_1, E_2, E_3) except the values of $\hat{D}$ for node number to first male flower appearance, number of primary branches per plant, polar circumference of fruit and intermodal length in all three seasons and for days to first male flower anthesis in E_2, for equatorial fruit circumference in E_1 and E_2 which were found non-significant. In general the proportions of dominant and recessive genes in parents [4 $\hat{D}$ $\hat{H}_1)^{1/2}+\hat{F}$ / (4 $\hat{D}$ $\hat{H}_1)^{1/2}-\hat{F}$] were more than unity with positive $\hat{F}$ value for all the traits in all three seasons except fruit length in Y_2 indicating major contribution of dominant genes.

Keywords: Pumpkin, gene action, yield, non-additive

Introduction

Based on commercial significance the cultivated *Cucurbita* sp. ranks among the 10 leading vegetable crops worldwide. China and India lead the world production and other major producers are U. S. Egypt, Mexico, Ukraine, Cuba, Italy, Iran and Turkey (Ferriol and Pico, 2008). The total area of pumpkin in India is 19,760 hectares whereas, the total production is 0.42 million tonne with productivity 21.25 MT/ha (Annonymous, 2017). Robinson and Decker-Walters (1999) [17] concluded that in genus *Cucurbita*, there are 5 cultivated and 10 wild species. Seshadri and More (2009) [18] also stated that the recent recognition of synonyms and taxonomic changes have reduced the number of *Cucurbita* species to 15 or even less. The five cultivated species are *C. argyrosperma* (earlier *C. mixta*), *C. pepo*, *C. maxima*, *C. moschata* and *C. ficifolia*. In India, pumpkin and squashes were introduced from South America by foreign navigators and emissaries. *Cucurbita moschata* is more widely cultivated than other four cultivated species in our country. Since *Cucurbita moschata* is amenable to hotter climates more than other cultivated species, it is also the most widely grown vegetable throughout the tropics of both hemispheres. Pumpkins, like other squash, are thought to have originated in North America. The oldest evidence, pumpkin-related seeds dating between 7000 and 5500 BC, were found in Mexico.

The three economically important species, *C. pepo*, *C. moschata*, and *C. maxima* are highly polymorphic in fruit characteristics, inspiring much research into their inheritance although most of such studies have been done in *C. pepo* and *C. maxima*. The gene list of *Cucurbita* sp. includes 79 loci for phenotypic/morphological traits and 48 polymorphic allozyme loci along with linkage and gene mapping (Paris and Brown, 2005) [15]. However, information on simply inherited characters documented in the gene list is almost lacking for *C. moschata*, and among the few that have been reported so far are Trifluralin (a herbicide) tolerance controlled by a dominant gene "*T*" (Adeoye and Coyne, 1981) [1], naked kernel (absence of tough seed coat) trait

ABSTRACT

The field experiment was conducted for determination of most suitable planting dates for cultivation of potato during *Rabi* season of 2011-12 and 2012-13 at Main Experiment Station, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (U.P.). Five planting dates (17 October, 27 October, 7 November, 17 November and 27 November) and four varieties (Kufri Ashoka, Kufri Pushkar, Kufri Bahar and Kufri Arun) were arranged in Randomized Block Design with factorial concept, replicated four. Total tuber yield (q/ha), total number of tubers/plant, total number and weight of "A" grade (>75g), "B" grade (50-75g), "C" grade (25-50g) and "D" grade (0-25g) tubers/plant. The result revealed that planting on 17 November produced maximum tuber yield i.e. 391.59 quintal and 404.59 quintal per hectare during 2011-12 and 2012-13, respectively. However, the minimum total tuber yield i.e. 282.61 q/ha and 291.74 q/ha was recorded when planted on 27 November during both the years of investigation. Among the varieties the maximum total tuber yield was obtained i.e. 376.33 quintal per hectare in variety Arun followed by Kufri Pushkar. However the variety Kufri Ashoka and Kufri Bahar found to be at par during 2011-12 and 2012-13, respectively.

Introduction

Potato (*Solanum tuberosum* L.) belongs to family 'solanaceae' is one of the most important vegetable crops grown throughout India. The major state of the country growing potato are Uttar Pradesh, West Bengal, Bihar and Gujarat, however, the maximum productivity of the crop is found in West Bengal followed by Gujarat. Potato plays an important role in Indian diet since multifarious preparations are prepared from it. It is consumed as cooked vegetable and being versatile can be mixed with almost every cooked vegetable. It is also used for making chips, potato powder, French-fries and for the extraction of starch. In some areas, it is often consumed as a substitute of cereals. It is also used as thickener in soups and gravies. Potato starch has molding cast candies, such as jelly bens and gumdrops, as thickening agent in synthetic jellies and ice creams, as dusting agent mixed with powdered sugars, for candy gums, chewing gums etc. Potato is considered a protective food since potato supply a substantial

ABSTRACT

Field experiment was carried out during 2011-12 and 2012-13 at main experiment station Department of vegetable science, Narendra Dev University of Agriculture and Technology Kumarganj, Faizabad (UP). To evaluate the effects of five planting dates 17 October, 27 October, 7 November, 17 November and 27 November an incidence of late blight (*Phytophthora infestance*) in four potato cultivars Kufri Ashoka, Kufri Pushkar, Kufri Bahar and Kufri Arun during crop season 2011-12 and 2012-13. The maximum incidence of late blight was recorded in variety Kufri Ashoka when planted on 27 November while the minimum incidence was recorded in variety Kufri Arun was early planted on 17 October. The production of potato tubers was obtained i.e. 471.48q. and 487.48q/ha was significantly highest with 17 November planting of variety Kufri Arun during 2011-12 and 2012-13, respectively. Thus, the results revealed that the best time for planting of potato in eastern Uttar Pradesh on 17th November which shifted from 7th November of planting due to climate change.

Keywords

Potato (*Solanum tuberosum* L.), late blight, yield

Introduction

Potato (*Solanum tuberosum* L.) belongs to family 'solanaceae' is one of the most important vegetable crops grown throughout India. Potato plant is very sensitive to climate factors such as temperature and day length, which exert a considerable influence on its growth and development. A temperature of 15-20^{0}C is optimum for sprouting and emergence of tubers. Maximum tuberization taken place a mean temperature of about 20^{0}C. Soil has great influence on yield and quality of the potato tubers. Crop grown on coarse textured (light) soils produces better quality tubers with characteristic shape and bright skin colour, which fetches higher price in the market, however, tuber grown in loamy soils have comparatively better keeping quality than those grown in sandy soils, as the latter become too hot by the time of main and late crops are harvested (Anonymous, 1960).

The criteria for working out the optimum time of planting is that the temperature at planting should be below 32^{0}C, while minimum temperature should be less than 20^{0}C by about 25-30 days after planting and the available growing period with this

RESEARCH PAPER

Study of genetic variability in cucumber

SHASHANK SHEKHAR SINGH •GC YADAV •KHUSHBOO KATHAYAT

Received: July 24, 2017, Revised: February 6, 2018, Accepted: February 28, 2018

ABSTRACT Twenty three genotypes of cucumber along with two checks (Pant Khira-1 and Pant Khira-3) were studied for extent of genetic variability, character association and path coefficient analysis with respect to yield and yield contributing traits at Vegetable Research Center, NDUAT, Faizabad. Analysis of variance indicated substantial variability among the progenies for all the traits. Highest genotypic and phenotypic coefficient of variation was exhibited by number of fruits per plant (54.22 and 55.93, respectively) and lowest in days to first fruit harvest (8.75 and 10.05, respectively). High heritability with high genetic advance (GA) was observed for fruit yield per plant followed by number of fruits per plant, which is an indicative of greater proportion of additive genetic variance and consequence a high genetic gain from selection. Correlation analysis revealed that number of fruits per plant had significant positive correlation for fruit yield/plant. Path analysis revealed that number of fruits per plant had highest positive direct effect on fruit yield/plant followed by average fruit weight on fruit yield per plant at both genotypic and phenotypic level indicating for greater emphasis on these traits during selection for improvement of yield.

INTRODUCTION

Cucumber (*Cucumis sativus* L., 2n = 2x = 14) is one of the most important member of Cucurbitaceae family, having 118 genera and 825 species. It is thought to be originated from India and China, is considered as secondary center of diversity. In India, cucumber is cultivated in an area of 43000 ha with annual production of 678000 m (Anonymous 2014). The important growing states of India are Arunachal Pradesh, Assam, Haryana, Bihar, Odisha, Punjab, Rajasthan, Uttar Pradesh and West Bengal. It is an ideal summer vegetable crop mainly grown for its edible tender fruits, preferred as salad ingredient, pickles, desert fruit and as a cooked vegetable. Improvement of crop depends on the magnitude of genetic variability in economic characters, therefore, the evaluation and utilization of genetic variability is important for yield improvement programme. The extent of genetic variability in a specific breeding population depends on the genotypes included in it and its selection history. In this regard, it is necessary to survey the available useful variability in the various plant characters. Variation at phenotypic level is the combination of genetic as well as environmental variability, which does not help in effective selection. Hence, the decisive factors primarily rest on genotypic variability or more specifically additive genetic variability on which selection operates. Statistics like coefficient of variation, heritability and genetic advance provide basic information on the variation of a character at phenotypic and genotypic level. A rational choice of characters on which selection is exercised for higher yields requires an understanding of the association of characters with yield and among themselves. Further path coefficient analysis is an efficient tool to elucidate the direct and indirect effect of each character towards yield. Hence, the present investigation was taken up to study the association of yield and its component traits in cucumber.

Abstract- The present experiment was conducted with aim to know the nature of inheritance of biochemical traits *viz.*, ascorbic acid (mg/100g), reducing sugars (%) non-reducing sugars (%), total sugars (%), dry matter content, total soluble solids, β-carotene (mg/100g). The fifteen F_1 hybrids developed through the diallel mating excluding reciprocals with the using of six parents. Highly significant values of additive ($\hat{D}$) and dominance ($\hat{H}_1$ and $\hat{H}_2$) effects of components were observed for most of the traits studied in all three seasons (E_1, E_2, E_3) except the values of $\hat{D}$ for total sugars, reducing sugars and ascorbic acid in all three seasons. Average degree of dominance revealed the presence of over dominance for all traits in all three seasons (E_1, E_2, E_3). The proportions of genes ($\hat{H}_2/4\hat{H}_1$) in the parents were less than 0.25 for all the traits indicating asymmetrical distribution of alleles at loci showing dominance in all three seasons (E_1, E_2, E_3). In general the proportions of dominant and recessive genes in parents [$4\hat{D}\hat{H}_1)^{1/2} + \hat{F}$ / $(4\hat{D}\hat{H}_1)^{1/2} - \hat{F}$] were more than unity with positive $\hat{F}$ value for all the traits in all three seasons indicating major contribution of dominant genes. The ratio of ($\hat{h}^2/\hat{H}_2$) which estimates the number of gene groups revealed that atleast one gene group was involved in the inheritance for total soluble solids during all three seasons. While, for dry matter content, total sugars and reducing sugars exhibited similar number of gene group only during E_2 and rest of traits showed involment of less than one gene group.

Key words- Quality Traits, Pumpkin, B-Carotene.

Introduction

The three economically important species, *C. pepo*, *C. moschata*, and *C. maxima* are showed variation for fruit characteristics, during spining season although much research into their inheritance although most of such studies have been done in *C. pepo* and *C. maxima*. The gene list of *Cucurbita* sp. includes 79 loci for phenotypic /morphological traits and 48 polymorphic allozyme loci along with linkage and gene mapping [1]. In case of *C. moschata* information regarding inheritance of characters documented in the gene list is almost lacking and among the few that have been reported so far are Trifluralin (a herbicide) tolerance controlled by a dominant gene "*T*" [2], naked kernel (absence of tough seed coat) trait controlled by a pair of recessive genes [3] and mottled light and dark green fruit colour, monogenic dominant ("*Mldg*") over dark green fruit [19]. A wide range of expression of the trait "silver leaf mottling" was observed in *C. moschata*although all the reports indicated that this trait showed dominance over non-mottled leaf. Latha and Gopalkrishnan,[4]and a single gene "*M*" [5]. Information on polygenic inheritance of quantitative characters in pumpkin is also meager. for number of seeds/fruit, 100-seed weight and seed size index [6]; over-dominance [7] and dominance [8]. Over-dominance gene action for all the nutritional traits, namely, total soluble solids, carotenoids, ascorbic acid, calcium, and iron content [9] clearly suggested the importance of exploiting heterosis commercially. The color of pumpkin is due to the orange pigments. The main nutrients are lutein and both α and β-carotene, the latter of which generates vitamin A in the body. Pumpkins are very versatile in their uses for cooking. Most parts of the pumpkin are edible, including the fleshy shell, seeds, leaves, and even flowers. In the United States and Canada, pumpkin is a popular Halloween and Thanks, giving staple. Pumpkin purée is sometimes prepared and frozen for later use. Pumpkin is relatively high in energy and carbohydrates and a good source of vitamins, especially high caretenoid pigments and minerals. It may certainly contribute to improve nutritional status of the people, particularly the vulnerable groups in respect of vitamin A requirement. Night-blindness is a serious problem of South Asian countries. Encouraging the mass people to take more pumpkin can easily be solved the problem.

Materials and Methods

The experimental materials for the present study comprised of six promising and diverse inbreds and varieties of pumpkin selected on the basis of genetic variability from the germplasm stock maintained in the Department of Vegetable Science, N.D. University of Agriculture & Technology, Kumarganj, Faizabad (U.P.) India. The selected parental lines i.e. Narendra Upkar (P_1), NDPK-120 (P_2), Narendra Agrim (P_3), NDPK-39-2 (P_4), Kashi Harit (P_5) and NDPK-11-3 (P_6) were raised and crossed in the all possible combinations, excluding reciprocals, during Zaid, 2015 to get 15 F_1 hybrid seeds for the study of character association for fourteen quantitative traits. The experiments were conducted in Randomized Block Design (RBD) with three replications to assess the performance of 15 F_1 hybrids and 6 parents. The treatments were planted in rows spaced at 3.0 meters apart with a plant to plant spacing of 0.5 meter. The seeds were sown on 23th July, 2015 and 7th November 2015, 26th March, 2016 for Kharif, Rabi and Zaid crops, respectively. All the recommended agronomic package of practices and plant protection measures were followed to raise good crop.

Correlation and path analysis for growth and morpho-economic characters in tomato (*Solanum lycopersicon* (Mill.) Wettsd)

Rohit Kumar Bajpai, Yadav GC and Vimlesh Kumar

Abstract
The study conducted to know the association among different morpho-economical traits of tomato with the using path analysis. The experiment comprising forty six diverse genotypes, grown in randomized block design with three replications. The study revealed that the general, genotypic correlation coefficients were higher than the corresponding phenotypic correlation coefficients suggested a strong inherent relationship in different pairs of the traits. Number of fruits per plant (0.634), plant height (0.382), primary branches per plant (0.255) and fruit length (cm) (0.167) has positive significant and desirable association with fruit yield and selection of these traits would be effective for yield improvement in tomato. Path coefficient analysis revealed appreciable amount of direct positive effect of fruits per plant (1.260) followed by average fruit weight (0.8495).

Keywords: tomato, correlation, path analysis, fruit yield

Introduction

The study of correlation between different characters is essential in improving the efficiency of selection. Correlation coefficient is a measure of the degree of association between the two traits worked out at the same time. Total correlation does not give the true genetic picture of the relationship between two traits in which a breeder is interested, because it includes environmental influence on the covariance between two characters. This component is measured as environmental correlation.The genotypic correlation is essential for assessing the real genetic variation in traits of significance. The basic concepts of correlation was put forth by Galton (1889) and elaborated by Fisher (1918) and Wright (1921). Engledow and Wadham (1923) advocated the physiological basis of yield and correlation between physiological components and yield.

The estimates of correlation coefficients indicate only the inter-relationship of the character but, do not furnish information on the cause and effect relationships. Wright (1921) has devised the analysis of path coefficient to provide effective means of finding out direct and indirect causes of association which permits the critical examination of specific forces acting to produce a given correlation and measures the relative importance of each causal factor. Dewey and Lu (1959) were the first to demonstrate the utility of path coefficient analysis in breeding programme using crested wheat grass progenies.

Tomato (*Solanum lycopersicon* (Mill.) Wettsd.), 2n=2x=24 is one of the most versatile vegetable crop grown throughout the world because of its wider adaptability, high yielding potential and suitability for uses in fresh as well as processed food industries. It is one of the most popular and widely cultivated vegetable throughout the world and ranking second in importance after potato in many countries including India (Anonymous, 2015). In India, total area is 0.77 million hectare and production is 18.28 million tonnes with 23.74 tonnes per hectare productivity, which is very low as compared to average productivity of world.

Adapting the potentiality of this crop, there is a need for improvement and to develop varieties suited to specific agro-ecological conditions and also for specific end use. A thorough knowledge regarding the amount of genetic variability existing for various characters is essential for initiating the crop improvement programme. With limited variability much cannot be achieved and the breeder will have to enrich the germplasm or resort to create greater variability through hybridization, mutation and polyploidy.

The objective of present investigation was to know the association among the economic traits using path coefficient analysis.

Genetic variability, heritability and genetic advance in vegetable pea (*Pisum sativum* L. var. *hortense*)

Maneesh Pandey*, V.B. Singh and G.C. Yadav, Pradip Pandey[1], and Yamuna Prasad Singh

Received: June 2017 / Accepted: July 2017

Vegetable pea (*Pisum sativum* L. var. *hortense*) belongs to family Leguminoceae sub family Fabaceae. Pea is an important legume vegetable, extensively cultivated in the temperate regions and restricted to cooler altitudes in the tropics and winter season in the sub-tropics. It is a self-pollinated crop having diploid chromosome number, 2n=14. It is highly nutritious and capable of fixing atmospheric nitrogen. Being most important to growers and consumer, there is an urgent need to increase its productivity to fulfill the increasing demands throughout the year. The information usually needed for developing high yield varieties in a particular species pertains to the extent of genetic variability for desirable traits in the available germplasm. Evaluation of germplasm is the basic tool for identification of improved genotypes. The great extent of natural variation present in various characters among the genotypes suggests good scope of improvement in economic traits. Large variability ensures better chance for selection of new genotypes. Variability parameters like genotypic and phenotypic coefficient of variation, heritability and genetic advance as well as degree of association between the various characters along with direct and indirect effect of yield contributing characters on yield, and genetic divergence among the genotypes for quantitative traits is of paramount significance in formulating an appropriate breeding strategy aimed to exploit the inherent variability of the original population.

The experiment was conducted at NDUAT, Faizabad, UP by using Randomized Complete Block Design with three replications during *Rabi* season of 2013 to assess the performance of 36 vegetable pea genotypes. Each genotype consisted of five rows and replicated thrice. Each entry was grown in the plot size of and 3.0×1.5 m. The line sowing was done with the spacing of 30 cm and 10 cm from seed to seed. All the recommended agronomic package of practices and plant protection measures were followed to raise a healthy crop. Observations were recorded on five randomly selected plants from each treatment in each replication for; (i) nodes at which first flower appears, (ii) days to 50% flowering, (iii) number of nodes per plant (iv) inter-nodal length (cm), (v) primary branches per plant, (vi) plant height (cm) (provide units), (vii) length of pod (cm), (viii) width of pod (cm), (ix) number of green pods per plant, (x) number of green pods per cluster, (xi) number of seeds per pod (xii) shelling percent (xiii) pod weight (g), (xiv) TSS of edible seeds (Brix), (xv) pod yield per plant (g). The mean squares for error was subtracted from the mean squares due to genotypes and the difference was divided by number of replications for obtaining the genotypic variance, which was calculated according to the method suggested by Burton (1952). Environmental variance is the mean squares due to error. Phenotypic variance was calculated by adding genotypic variance and environmental variance, which was suggested by Burton and de Vane (1953). Heritability in broad sense (h^2_{bs}) was calculated using the formula suggested by Burton and de Vane (1953).Genetic advance (GA) was estimated by the method suggested by Johnson et al. (1955).

The mean squares due to genotypes were highly significant for all the fifteen traits (Table 1), indicating significant differences among the genotypes with respect to all the traits under study. In general, the phenotypic coefficient of variability (PCV) was higher than the respective genotypic coefficients of variability (GCV) for all the characters which indicates that environment played an important role in the expression of the traits. The highest phenotypic and genotypic coefficient of variation was observed for plant height, green pod yield per plant, days to 50% flowering, shelling per cent and number of green pod per plant. Singh and Dhillon (2004) and Kumaran et al. (1995) also reported higher GCV and PCV for number of green pod per plant, weight of

Gene action for growth, yield and quality traits in bottle gourd [*Lagenaria siceraria* (Mol.) Standl]

Deepak Kumar Gautam and GC Yadav

Abstract
The present investigation was carried out in two different seasons with aim to find out the gene action for inheritance of morphological, yield and quality traits in bottle gourd. The present study was comprised of 45 crosses developed through diallel mating design using 10 parents namely, NDBG-49-2 (P_1), N. Rashmi (P_2), N. Prabha (P_3), N. Pooja (P_4), Pusa Naveen (P_5), Pb. Komal (P_6), NDBG S-1 (P_7), PBOG-3 (P_8), NDBG-11 (P_9) and Faizabadi Local (P_{10}) at MES, Vegetable Science, NDUA &T, Kumarganj, Faizabad (U.P.) India during *kharif* 2015 (E_1), and *Rabi*, 2015-16 (E_2). The experiments were laid out in RBD with three replications having each experimental unit of single row with spacing of 3.0 m × 0.5 m. The observations were recorded on parents and F_1's for eighteen quantitative traits including six quality traits *viz* days to first staminate flower anthesis, days to first pistillate flower anthesis, node number to first staminate flower, node number to first pistillate flower appearance, days to first fruit harvest, vine length at last picking stage (m), number of primary branches per plant, fruit length (cm), fruit circumference (cm), fruit weight (kg), number of fruits per plant, fruit yield per plant (kg), total soluble solids (°B), ascorbic acid (mg/100 g fresh fruit), reducing sugar (%), non-reducing sugar (%), total sugars (%) and dry matter content in fruit (%). The present study revealed that Highly significant values for additive ($\hat{D}$) and dominance ($\hat{H}_1$ and $\hat{H}_2$) effects of components were observed for most of the eighteen traits in both the seasons (E_1, E_2) except the values of $\hat{D}$ for days to first staminate flower anthesis, number of fruit per plant, reducing sugar and total sugars and node number to first staminate flower appearance and days to first fruit harvest in E_1 and values of $\hat{H}_1$ for node number to first staminate flower appearance, node number to first pistillate flower appearance in E_1 which showed non-significant Both additive and dominance variance were found important in the inheritance of most of the traits, whereas dominance variance were more prominent than the additive variance. Average degree of dominance revealed the presence of over dominance for all the characters in during both the seasons (E_1, E_2). The proportions of genes ($\hat{H}_2/4\hat{H}_1$) in the parents were less than 0.25 for all the traits indicating asymmetrical distribution of alleles at loci showing dominance during both the seasons (E_1, E_2).

Keywords: Bottle gourd, gene action, quality attributes fruit yield and diallel mating

Introduction

Bottle gourd [*Lagenaria siceraria* (Mol.) Standl., 2n =2x= 22] is an important cultivated annual cucurbitaceous crop grown throughout the country. Being warm season vegetable crop it thrives well in warm and humid climate but at present it's off season cultivation has progressively stretched throughout the year in northern Indian plains. According to De Candolle (1882), bottle gourd has been found in wild form in South Africa and India. However, Cutler and Whitaker (1961) [2] are of the view that probably it is indigenous to tropical Africa on the basis of variability in seeds and fruits. The tender fruits of bottle gourd can be used as a vegetable or for making sweets (e.g. *Halva, kheer, petha* and *burfi* etc.), kofta and pickles. The fruit is rich in pectin also, which showed good prospects for jelly preparation. A decoction made from the leaf is a very good medicine for jaundice. The fruit has cooling effect, it is a cardiotonic and diuretic, good for people suffering from biliousness, indigestion and convalescences *i.e.*, regain health after illness. The pulp is good for overcoming constipation, cough, and night blindness and as an antidote against certain poisons. The plant extract is used as a cathartic and seeds are used in dropsy. In addition, the seeds and seed oil are edible. The fruits contain 96.3 per cent moisture, 2.9 per cent carbohydrate, 0.2 per cent protein, 0.1 per cent fat, 0.5 per cent mineral matter and 11 mg of vitamin C (Ascorbic acid) per 100 g fresh weight (Thamburaj and Singh, 2005) [11]. The existence of significant amount of non-additive gene action is a prerequisite for exploitation of heterosis. The specific combining ability variance largely is the measure of dominance variance. If heterosis is high for specific cross and observations made are true for economic trait like yield, it is possible to utilize the cross as a commercial hybrid provided that the pollination system of the crop permits commercial seed production of hybrids or there exists a male sterility, fertility restoration system.

Abstract
The present investigation was conducted using 36 cross combination obtained by crossing 9 lines with 4 tester in Line × Tester mating design to know the gene effects with to respect to its nature and magnitude for growth, yield and quality characters. The study revealed estimates of sca variance were higher than gca variances for all most of the traits. The value of sca variances were found significant and positive for all the characters. Likewise, positive and significant gca variances were also exhibited by almost all the characters. The value of degree of dominance was more than unity (1) for all the traits except for plant height (0.76), pericarp thickness (0.74), number of fruits per plant (0.83) and ascorbic acid (0.90) and revealed over dominance in 2012 -2013. The value of degree of dominance was more than unity (1) for all the traits except for plant height (0.68) and ascorbic acid (0.83) and revealed over dominance in 2013-2014. Plant height, pericarp thickness and ascorbic acid in fruit exhibited average degree of dominance less than unity (1) indicating partial dominance. These results clearly indicates that in the majority growth, yield quality non-additive gene action were in preponderance practice of exploration of hybrid vigor in tomato.

Keywords: Gene action, average degree of dominance, tomato, combining ability, line × tester

Introduction
Tomato (*Solanum lycopersicon* (Mill.) Wettsd.), 2n=24) of nightshade or Solanaceae family with primary center of origin in Mexico-Peru-Equador region was once considered inedible but has evolved into globally leading popular vegetable. It is highly worked crop by the horticulturists and breeders. It has wide range of variation in terms of growth habit, morphological traits and uses making it a repository of glowing traits in its armory. It is used as fresh as well as processed vegetable. The total area of tomato in India is 9205 hectare which is 9.6 per cent of vegetables area. While, the total production is 18226.6 mt which is 11.2 per cent of total vegetables production(20.7 mt/ha). The leading tomato producing states are U.P. (12.1%), West Bengal (15.7%), Bihar (10.16%), Gujrat (6.2%) and Punjab (4.3%) (Annonymous, 2014) [5] It is also very important for processing industry as it ranks first as processing vegetable crops in the world.Ripe tomato is widely used for the preparation of several processed items like paste, syrup, juice, soup, ketchup, drinks, whole peeled tomato and canned tomato etc, in the processing industry on large scale. Being very good appetizer, tomato is rich source of minerals, vitamins and organic acids. Its nutritional importance is enlarged with antioxidant properties of lycopene and its anticancerous properties. Growing consumption of tomato in processed or fresh form is driven by its versatile, palatable, culinary and attractive properties apart from its health benefits. It was introduced in India in 17th century by Europeans and today it has become part and parcel of Indian food besides becoming one of the leading vegetable with lot of research work and outcomes seen in it. Globally, India is the third largest producer of tomato after China and USA. Hence the present study to understand the ene effects governing various growth, yield and quality traits.

Materials and methods
The present investigation was carried out at the Main Vegetable Research Station, Division of Vegetable Science, and in the laboratory of the College of Horticulture and Forestry, Narendra Deva University of Agriculture and Technology Narendra Nagar (Kumarganj). Faizabad, India, during 2012- 13 and 2013-14. The farm is situated at 26.56° N latitude and 82.12° E longitudes at an altitude of 113 m above the mean sea level. The soil type of experimental site was sandy loam. This area falls in sub-tropical zone of Eastern India and experimental designs adopted, statistical procedures followed and methodology adopted is described here under.

Determining relationships between different growth and yield traits in pumpkin with path coefficient analysis

Vimlesh Kumar, DP Mishra, GC Yadav and Umesh Babu

Abstract
The objective of this study was to determine the relationships among fruit yield per plant (Kg), growth and economic traits using twenty one genotypes (15 F_1 hybrids and 6 Parents) of pumpkin during three seasons (E_1, E_2, E_3) and pooled analysis worked out. The observations were measured on growth and yield attributing traits. The present investigation revealed that the fruit yield per plant had exhibited significant and positive phenotypic correlation with number of fruits per plant, average fruit weight, total soluble solids, vine length, flesh thickness, number of primary branches per plant, equatorial circumference of fruit and negative significant association with days to first male flower anthesis, days to first female flower anthesis, days to first fruit harvest, inter nodal length and node number to first male flower appearance at phenotypic level during all three seasons and over seasons (pooled) except node number to first male flower appearance during E_1 and E_2. Analysis of path coefficient revealed that highest positive direct effect on fruit yield per plant was exerted by number of fruit per plant followed by average fruit weight at phenotypic level. Whereas, higher negative direct effects exerted by days to first fruit harvest.

Keywords: Pumpkin, correlation, fruit yield per plant, path analysis

Introduction
Pumpkin (*Cucurbita moschata* Duch. ex. Poir) is one of the most important vegetable crops of family cucurbitaceae grown throughout the world not only for providing better nutrition to the consumers but also higher returns to the farmers. It is originated from central Maxico. Pumpkin is a herbaceous annual, sexually propagated vegetable with chromosome number 2n=2x=40. The word pumpkin was originated from the Greek word *pepon*, which means "large melon", something round and large.

Pumpkin is relatively high in energy and carbohydrates and a good source of vitamins, especially high caretenoid pigments and minerals. It may certainly contribute to improve nutritional status of the people, particularly the vulnerable groups in respect of vitamin A requirement. Night-blindness is a serious problem of South Asian countries. Encouraging the mass people to take more pumpkin can easily be solved the problem.

Pumpkin exhibits great variability in its fruit shape, size, colour and yield along with other agronomic attributes (Singh, 2005 and Singh *et al.*, 2005) [16]. Like other cucurbits pumpkin is warm season crop and hence it may be cultivated round the year in central and southern states of the country, whereas, in northern parts of the country which face cooler winter months, it is generally cultivated during summer and rainy seasons for which sowing is generally done from January to July. Villagers in north India plant it in month of July-August after onset of monsoon in the mounds or hills in the vicinity of house and the growing plants are trained on thatches, hutments and other abandoned spaces. These genotypes used for planting in the vicinity of household are usually land races traditionally maintained by villagers and locally termed as *Bhadhavaha Kohara* (rainy season type pumpkin). *Bhadhavaha Kohara* is considered relatively tolerant to cool temperature and performs well during rainy season and extends fruiting in offing winter months. Hence, these genotypes are also referred to as winter type pumpkin. The rainy season or winter season type genotypes produce adequate number of both staminate and pistillate flowers from late August to early September (which happens to be *Bhadrapada* month or *Bhadhau* month of Hindi calendar year) and bear prolific fruits during September-October and also in short days of November-December. If not damaged by frost they may remain productive with very shy bearing in forthcoming January-February.

ABSTRACT

The present investigation conducted on thirty five diverse genotypes of brinjal(Solanum melongena L.)to know the variability among the genotypes.The observations were recorded on 9 quantitative characters viz., days to 50% flowering, days to first fruit harvest, fruit length (cm), fruit circumference (cm), plant height (cm), primary branches per plant, fruits per plant, average fruit weight (g) and total fruit yield per plant (kg). The present study revealed that the variance due to treatments were highly significant for all the characters indicating sufficient variability existing in the genotypes. Whereas, the higher magnitude of coefficient of variation at phenotypic as well as genotypic levels observed for average fruit weight followed by fruits per plant, fruit circumference, total fruit yield per plant fruit length and primary branches per plant. Days to first fruit harvest exhibited low value of variability. High heritability coupled with high genetic advance in per cent of mean were recorded for average fruit weight, fruits per plant, fruit circumference, total fruit yield per plant and fruit length indicating opportunity for selection response. In general, the phenotypic coefficient of variability was higher than genotypic coefficient of variability for all the nine characters under study which indicates that environment played a considerable role in the expression of their traits.

Keywords :Brinjal, PCV, GCV, Heritability and Genetic Advance

Received 12.07.2017 Revised 20.09.2017 **Accepted 09.10.2017**

INTRODUCTION

Brinjal (*Solanum melongena* L., 2n=2x=24) belongs to the family Solanaceae. It is worldwide **known as aubergine or guinea** squash which is one of the most popular and major vegetable crop in India **and other parts of the world.** It is probably originated in India and showed secondary diversity in South **East Asia. It is being grown extensively** in India, Bangladesh, Pakistan, China, Japan, Philippines, France, **Italy and U.S.A. Brinjal** is being cultivated in India over an area of 0.68 million ha with an **average annual production of** 12.70 million tonnes and productivity of 18.26 mt/ha. It is distributed in **Orissa, Bihar, Karnataka,** West Bangal, Andhra Pradesh, Maharashtra and Utter Pradesh. In Uttar **Pradesh, brinjal is being cultivated** on an area of 4.10 lakh ha with annual production of 136.16 lakh tones [1]. **Brinjal being most important** to growers and consumer, there is pressing need to increase its productivity **to fulfil the increasing** demands throughout the year. The information usually needed for developing **high yielding varieties in a** particular species pertains to the extent of genetic variability for desirable **traits in the available germplasm.** Evaluation of germplasm is the basic tool for identification of important **genotypes. The great extent** of natural variation present in various characters among the genotypes **suggests good scope of improvement** in economic traits. Large variability ensures better chance of producing **new forms. Variability** parameters like genotypic and phenotypic coefficient of variations, heritability and **genetic advance,** along with degree of association between the various characters and direct effect of yield contributing characters on total yield, is of paramount significance in formulating an appropriate breeding strategy aimed at exploiting the inherent variability of the original population. Phenotypic variability changes under different environmental conditions while genetic variability remains unchanged and more useful to a plant breeder for exploitation in selection or hybridization. Yield is very complex characteristics controlled by several yield contributing components and it is highly influenced by environmental factors, consequently estimates of heritability and genetic advance are useful for selection.

ABSTRACT

Correlation and path analysis studies conducted during Rabi in Randomized complete block design thirty six genotypes of vegetable pea with the objective to know association among the characters viz.,node at which first flower appears, days to 50 % flowering, number of nodes per plant, intermodal length (cm), primary branches per plant, plant height (cm), length of green pod (cm), width of pod, (cm), number of green pods per plant, number of green pods per cluster, number of seeds per pod, shelling per cent, green pod weight (g), T.S.S of edible seed, green pod yield per plant(g).Present study revealed that number of green pods, T.S.S of edible seeds number of node per plant, length of pod (cm), plant height (cm),significantly and positively associated with green pod yield per plant (g) both at phenotypic as well as genotypic levels while negatively correlated with width of pod (cm).It may be concluded that improvement of characters like number of green pods per plant, pod weight, number of green pod per cluster, length of pod, number of nodes per plant and plant height would help in improving pod yield in vegetable pea and should be considered as selection criteria for yield improvement. Path coefficient analysis revealed that green pod yield followed by number of green pods per plant, pod weight exerted high positive direct effect at phenotypic level. Therefore, these characters appear to be the most important traits for vegetable pea improvement programme.

Received 12.07.2017 Revised 25.09.2017 Accepted 01.10.2010

INTRODUCTION

Vegetable pea (*Pisum sativumL. var. hortense*) belongs to family Leguminoceae sub family Fabaceae. Pea is an important legume vegetable, extensively cultivated in the temperate regions and restricted to cooler altitudes in the tropics and winter season in the sub tropics. It is a self pollinated crop having diploid chromosome number 2n=2x=14. It is highly nutritious and capable of using atmospheric nitrogen. India ranks third in area after China and USSR under pea cultivation. . India ranks third in area after China and USSR for pea cultivation. The total area covered by peas is 498000 hectare with the production of 4811000 metric tons with productivity of 10 tons per hectare [1].

The major growing states of vegetable pea in India are Uttar Pradesh, Madhya Pradesh and Maharashtra. Uttar Pradesh is the leading producer of vegetable pea having alone about 50% of its area and production. It is also grown as summer season crop in the hilly states of India. The major area under vegetable pea cultivation is under mid season because of its suitability in various agro-climatic zones. Large proportion of vegetable pea are processed (canned, frozen and dehydrated and pickle) for consumption. It is mostly consumed as green fresh grains for vegetable purpose. Phenotypic variability changes under different environmental conditions while genetic variability remains unchanged and more useful to a plant breeder for exploitation in selection or hybridization, consequently estimates of heritability and genetic advance are useful for selection [2]. Yield is very complex characteristics controlled by several yield contributing components and significantly influenced by environmental factors. Estimation of correlation co-efficient among the yield contributing characters is necessary to understand the direction of selection and maximize yield in the shortest period. Path co-efficient provides an effective means of entangling direct and indirect causes of association of characters and measures the relative importance of each causal factor.

Genetic diversity assessment for morphological, yield and biochemical traits in genotypes of pumpkin

Vimlesh Kumar, DP Mishra, GC Yadav and DK Dwivedi

Abstract
The investigations were conducted with the using of twenty one genotypes (15 F_1 hybrids and 6 parents) of pumpkin. The germplasms were evaluated for twenty one morphological, yield and biochemical traits viz., days to first male flower anthesis, days to first female flower anthesis, node number to first male flower, node number to first female flower, days to first fruit harvest, number of primary branches per plant,7. Equatorial circumference of fruit, polar circumference of fruit, Flesh thickness, internodal length (cm), vine length (m), average fruit weight (kg), number of fruits per plant, Fruit yield per plant (kg), dry matter content, total soluble solids, total sugars, reducing sugars, non-reducing sugars, ascorbic acid content and β-carotene. The evaluations were conducted consecutively three seasons during 2015-16. The study revealed that mean squares due to genotypes were significant for all the traits during all three seasons (E_1, E_2, E_3). However, the analysis of variance on the basis of pooled revealed that mean squares due genotypes, environments, overall sum found significant for all the traits except overall sum for traits viz., flesh thickness, dry matter content and total sugars content. The investigations further revealed that high phenotypic and genotypic coefficient of variation were observed for vine length, number of fruits per plant, fruit yield per plant, reducing sugars and β-carotene. High heritability coupled with high genetic advance were observed for number of fruits per plant, fruit yield per plant, reducing sugars, ascorbic acid and β-carotene indicated that the improvement of these traits through selection.

Keywords: PCV, GCV, fruit yield per plant, heritability and genetic advance

1. Introduction
Pumpkin (*Cucurbita moschata* Duch. ex. Poir) is one of the most important vegetable crop of cucurbitaceae family grown throughout the world not only for good sources of nutrition to the consumers but also for its higher returns to the farmers. It is originated from central Maxico. Pumpkin is a herbaceous annual, sexually propagated vegetable having an identical genomic formula 2n=2x=40. The word pumpkin originates from the word *pepon*, which is a Greek word meaning for "large melon", something round and large.

Based on commercial significance the cultivated *Cucurbita* species rank collectively among the 10 leading vegetable crops worldwide. China and India lead the world production. Other major producers are U.S., Egypt, Mexico, Ukraine, Cuba, Italy, Iran and Turkey (Ferriol and Pico, 2008). The total area of pumpkin in India is 19760 hectare whereas, the total production is 0.42 million tonne (Annonymous 2016) [1]. Robinson and Decker-Walters (1999) [19] concluded that in genus *Cucurbita* there are 5 cultivated and 10 wild species. Seshadri and More (2009) [20] also stated that the recent recognition of synonyms and taxonomic changes have reduced the number of *Cucurbita* species to 15 or even less.

The color of pumpkins is derived from the orange pigments abundant in them. The main nutrients are lutein and both alpha and beta carotene, the latter of which generates vitamin A in the body. Pumpkins are very versatile in their uses for cooking. Most parts of the pumpkin are edible, including the fleshy shell, the seeds, the leaves, and even the flowers. In the United States and Canada, pumpkin is a popular Halloween and Thanksgiving staple. Pumpkin purée is sometimes prepared and frozen for later use.

The continuous variation exhibited by quantitative traits with which the breeders have to deal with, include the heritable and non-heritable components. Though, it is difficult to assess the genotype directly but it is possible through the assessment of phenotypic expression (which is an outcome of interplay of the genotype and environment) in the existing material and thus, the study of phenotypic variability for yield and its component traits is very important.

Materials and Methods
The experiments of the present research work were conducted during *Kharif*, (E_1) *Rabi* seasons (E_2) and summer-season (E_3) of 2015-16 at Main Experiment Station of Department of

Heritability (narrow sense) and genetic advance of for growth, yield and quality traits in bottle gourd [*Lagenaria siceraria* (Mol.) Standl.]

Deepak Kumar Gautam and GC Yadav

Abstract
Carried out in two different seasons with aims to assess the extent of heritability and genetic advance involving 10 parents namely, NDBG-49-2 (P_1), N. Rashmi (P_2), N. Prabha (P_3), N. Pooja (P_4), Pusa Naveen (P_5), Pb. Komal (P_6), NDBG S-1 (P_7), PBOG-3 (P_8), NDBG-11 (P_9) and Faizabadi Local (P_{10}) at MES, Vegetable Science, NDUA.&T, Narendra Nagar (Kumarganj), Faizabad (U.P.) India during *kharif* 2015 (E_1) and *Rabi*, 2015-16 (E_2). The experiments were laid out in RBD with three replications having each experimental unit of single row with spacing of 3.0 m × 0.5 m. The observations were recorded on parents and F_1's for eighteen quantitative traits including six quality traits *viz.*, days to first staminate flower anthesis, days to first pistillate flower anthesis, node number to first staminate flower, node number to first pistillate flower appearance, days to first fruit harvest, vine length (m), number of primary branches per plant, fruit length (cm), fruit circumference (cm), fruit weight (kg), number of fruits per plant, fruit yield per plant (kg), total soluble solids (°B), ascorbic acid (mg/100 g fresh fruit), reducing sugar (%), non-reducing sugar (%), total sugars (%) and dry matter content in fruit (%).The higher values of heritability (h^2n) estimates (> 30) were observed only for fruit length (52.20%, 37.50% and 35.17%) and fruit circumference (61.50%, 33.50% and 31.50%) during both the seasons and pooled. High genetic advance in per cent of mean were estimated for four traits, *viz.* number of fruit per plant (32.58%, 42.73% and 21.33%), fruit yield per plant (24.60%, 32.40% and 25.82%), reducing sugars (22.01%, 25.10% and 22.42%) and non- reducing sugar (27%, 38.96% and 28.01%) during both the seasons and pooled.

Keywords: bottle gourd, Heritability (narrow sense) and genetic advance, fruit yield per plant

Introduction

Bottle gourd [*Lagenaria siceraria* (Mol.) Standl., 2n =2x= 22] is an important cultivated annual cucurbitaceous crop grown throughout the country. Being warm season vegetable crop it thrives well in warm and humid climate but at present it's off season cultivation has progressively stretched throughout the year in northern Indian plains. According to De Candolle (1882), Bottle gourd has been found in wild form in South Africa and India. However, Cutler and Whitaker (1961) [1] are of the view that probably it is indigenous to tropical Africa on the basis of variability in seeds and fruits. The tender fruits of bottle gourd can be used as a vegetable or for making sweets (e.g. *Halva, kheer, petha* and *burfi* etc.), kofta and pickles. The fruit is rich in pectin also, which showed good prospects for jelly preparation. A decoction made from the leaf is a very good medicine for jaundice. The fruit has cooling effect, it is a cardiotonic and diuretic, good for people suffering from biliousness, indigestion and convalescences *i.e.*, regain health after illness. The pulp is good for overcoming constipation, cough, night blindness and as an antidote against certain poisons. The plant extract is used as a cathartic and seeds are used in dropsy. In addition, the seeds and seed oil are edible. The fruits contain 96.3 per cent moisture, 2.9 per cent carbohydrate, 0.2 per cent protein, 0.1 per cent fat, 0.5 per cent mineral matter and 11 mg of vitamin C (Ascorbic acid) per 100 g fresh weight (Thamburaj and Singh, 2005) [6]. The exploitation of heterosis is much easier in cross-pollinated vegetable crops. Bottle gourd being monoecious provides ample scope for the utilization of the hybrid vigour for yield improvement of this crop. The selection of suitable parents for hybridization on the basis of phenotypic performance alone is not a sound procedure as phenotypically superior lines may yield poor recombinants in the segregating generations. It is, therefore, essential that parents should be selected on the basis of their genetic potential.

Materials and methods

The experimental materials consisted of 10 promising parental lines of bottle gourd and their

Abstract

The experiment was conducted in Augmented Block Design at Main Experimental Station of Department of Vegetable Science, Narendra Deva University of Agriculture, Narendra Nagar (Kumarganj), Faizabad (U.P.) during *Rabi* 2014-15 with the following objectives (1) To find out phenotypic and genotypic coefficient of variation (PCV & GCV), (2) to estimate heritability and genetic advance, Experimental material for the present study consisted of thirty genotypes. In single plot sized 2.0 X 0.30 cm with the distance of 30 cm row to row and 10 cm plant to plant. Observation were recorded on plant height (cm), leaves per plant, length of leaf (cm), width of leaf (cm), neck thickness of bulb (cm), cloves per bulb, weight of clove (g), length of clove (cm), length of bulb (cm), width of clove (cm), diameter of bulb (cm), total soluble solids (%) and bulb yield per plant (g).Analysis of variance for design of experiment indicated highly significant differences among treatments for all the characters, based on mean performance of genotypes, the NDG-43, NDG-49, Punjab Garlic, NDG-48 and NDG-45, were identified as most promising genotypes for bulb yield per plant. The higher magnitude of coefficient of variation at genotypic as well as phenotypic levels observed for leaves per plant, length of leaf, length of clove. High heritability coupled with high genetic advance in per cent of mean was recorded for number of cloves per bulb, Bulb yield per plant, weight of clove and width of leaf. It is suggested that selection for these traits will directly increase bulb yield per plant.

Introduction

Garlic (*Allium sativum* L.) having diploid chromosome number 2n=2x=16 belongs to the family Amaryllidaceae (Alliaceae); known as *Lahsun* in Hindi, is one of the important bulb crop grown in India. It has long been recognized as a valuable spice and condiments in India. It is a frost hardy bulbous, erect annual herb with narrow flat leaves and bears small white flowers and bulbils (Janick, 1979). Garlic is a scapigerous foetid perennial

Determining relationships between different Horticultural and Yield Traits in sponge gourd (*Luffa cylindrica* Roem.) Genotypes with path coefficient analysis

Amar Nand Yadav, VB Singh, GC Yadav and Vimlesh Kumar

Abstract
The aim of experiment was to study the inter-relationship and direct-indirect effect among yield and yield attributes in sponge gourd. The analysis of variance revealed that the mean sum of squares due to genotypes were significant for all the eleven traits. The genotypic correlation in general was greater than the phenotypic correlation. The significant and positive correlation with yield per plant was observed at phenotypic level with average fruit weight (0.462) and number of fruits per plant (0.476). Path coefficient revealed appreciable amount of direct positive effect of number of fruit per plant (0.653) followed by average fruit weight (0.571) and days to anthesis of firs pistillate flower (0.156) on fruit yield per plant. The study concluded that the average fruit weight and number of fruits per plant in due consideration for improvement of genotypes in respect to yield.

Keywords: Luffa (*Luffa cylindrica* Roem.), correlation, path analysis, fruit yield.

1. Introduction
Luffa (*Luffa cylindrica* Roem.) commonly called as sponge gourd, loofah vegetable sponge or dish cloth, having diploid chromosome number 2n = 2x = 26. It is one of the most important cucurbits grown throughout the country and world. It belongs to the family Cucurbitaceae which includes about 118 genera and 825 species. In India, a number of major and minor cucurbits are cultivated which share about 5.6 per cent of the total vegetable production.
The prime objective of the present investigation is to make an improvement in yield, but yield is a complex character and a combined result of a number of component traits. Since yield is controlled polygenically and influenced greatly by the environmental fluctuations. Therefore, the selection of superior genotype based on yield alone would not be effective. One has to put attention on the component characters, which contribute yield in positive direction. In India little attention has been given for the genetic improvement of sponge gourd by collecting diverse germplasm, their morphological characterization and assessing the variability parameters like coefficient of variation, coefficient of correlation and path analysis. The appropriate breeding methodologies may be adopted for genetic improvement of this crop for simultaneously improvement of different characters, information regarding mutual relationship among the characters and direction of correlation analysis provides an effective means of finding out direct and indirect causes of association among causal variables. Keeping in view, of the above facts the present experiment was conducted to determining association of yield and its attributes for yield improvement in sponge gourd.

2. Material and Methods
Thirty genotypes of sponge gourd were evaluated in Randomized Complete Block Design with three replications at Department of Vegetable Science, N.D. University of Agriculture & Technology, Narendra Nagar (Kumarganj), Faizabad (U.P.) India. The crop was planted in 3.0 m. for row length, spaced 3.0 m. apart where, 0.5m. Plant to plant spacing was maintained. The experiment was sown in summer on 2nd April, 2010. All the recommended agronomic package and practices and plant protection measures were followed to raise a good crop. Observations were recorded on five randomly selected plants for eleven characters *viz.*, node no. to anthesis of first staminate flower, node no. to anthesis of first pistillate flower, days to anthesis of first staminate flower, days to anthesis of first pistillate flower, days of first fruit harvest, average fruit weight (g), fruit length (cm), fruit diameter (cm), number of fruits/plant, fruit yield/plant (kg) and vine length (m).

The investigations were conducted with the using of 15 F_1 hybrids developed through diallel excluding reciprocals with 6 parents of pumpkin. The germplasms were evaluated for seven biochemical traits, *viz.*, dry matter content, total soluble solids, total sugars, reducing sugars, non-reducing sugars, ascorbic acid content and β-carotene. The analysis of variance revealed wide range of variation among genotypes for all the traits. On the basis of mean performance the hybrids namely, $P_2\times P_4$ and $P_3\times P_5$ for dry matter content, $P_5\times P_6$ and $P_1\times P_5$ for total soluble solids, $P_2\times P_3$ and $P_1\times P_4$ for total sugars (%), $P_2\times P_5$ and $P_3\times P_5$ for reducing sugars (%), $P_1\times P_3$ and $P_2\times P_3$ for non-reducing sugars (%), $P_1\times P_2$ and $P_4\times P_6$ for ascorbic acid (mg/100g) and $P_3\times P_6$ and $P_1\times P_2$ for β-carotene were first and second ranker on the basis of merit during pooled analysis respectively. The study concluded that these hybrids can be exploited for cultivation.

Introduction

Pumpkin (*Cucurbita moschata* Duch. ex. Poir) is one of the most important vegetable crop of cucurbitacea family grown throughout the world not only for good sources of nutrition to the consumers but also for it s higher returns to the farmers. It is originated from central Maxico. Pumpkin is a herbaceous annual, sexually propagated vegetable having an identical genomic formula 2n=2x=40. The word pumpkin originates from the word *pepon*, which is a Greek word meaning for "large melon", something round and large.

Cytogenetically, the species of *Cucurbita* show amazing uniformity in chromosome number and all the species have 20 pairs (2n = 40) of small, dot like chromosomes (Whitaker and Robinson 1986) and isozyme studies indicate the allotetraploid origin of the genus (Weeden, 1984; Kirkpatrick *et al.*, 1985). Based on commercial significance the cultivated *Cucurbita* species rank collectively among the 10 leading vegetable crops worldwide. China and India lead the world production. Other major producers are U.S., Egypt, Mexico, Ukraine, Cuba, Italy, Iran and Turkey (Ferriol and Pico, 2008). The total area of pumpkin in India is 19760 hectare whereas, the total production is 0.42 million tonne (Annonymous, 2015). Robinson and Decker-Walters (1999) concluded that in genus *Cucurbita* there are 5 cultivated and 10 wild species. Seshadri and More (2009) also

ABSTRACT

Thirty-five genotypes of tomato were evaluated for yield and yield attributing characters at the Main Experiment Station, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Faizabad (U.P.) during winter 2013-2014. Observations were recorded on nine quantitative characters viz., days to 50 per cent flowering, plant height (cm), number of primary branches per plant, number of locules per fruit, pericarp thickness (mm), average fruit weight (g), total soluble solids, number of fruits per plant and fruit yield per plant (g). High magnitude of phenotypic as well as genotypic coefficients of variation were observed in case of fruit yield per plant followed by average fruit weight, number of locules per fruit, number of fruits per plant, plant height and number of primary branches per plant. Days to 50 per cent flowering exhibited low level of variability. High heritability coupled with high genetic advance were estimated for all the traits except days to 50 per cent flowering indicating opportunity for selection response.

Key words: *Tomato, Colour, Flavour, Genetic variability, Phenotypic, Genotypic*

INTRODUCTION

Tomato [*Solanum lycopersicon* (Mill.) Wettsd] is one of the most important solanaceous vegetable crop having diploid chromosome number 2n=2x=24. It is herbaceous, annual to perennial, prostrate and sexually propagated crop plant with bisexual flowers. There are four to eight flowers in each compound inflorescence. There is a light protective anther cone surrounding the stigma leading to self-pollination. Considering the potentiality of this crop, there is a need for improvement and to develop varieties suited to specific agro-ecological conditions and also for specific use. Since, it is used as fresh vegetable and it also in processing industry for preparations of various value added products such as soup, ketchups, sauces, concentrates, purees, juices etc. It contributes as an important source of lycopene (an antioxidant), ascorbic acid and ß-carotene.

ABSTRACT

An experiment was conducted to identify the potential genotype of tomato with high productivity and good quality. Thirty-five genotypes of tomato collected from various location were evaluated for ten quantitative characters in Randomized Complete Block Design with three replications at Main Experiment Station, Department of Vegetable Science, Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Faizabad (U.P.) during 2013-2014. The most important economic trait, fruit yield per plant exhibited highly significant and positive phenotypic correlation with number of fruit per plant followed by average fruit weight and number of primary branches per plant. Path coefficient analysis revealed appreciable amount of direct positive effect of fruit per plant followed by average fruit weight. On fruit yield per plant. Substantial positive indirect effect by number of fruits per plant and average fruit weight on fruits yield per plant was exerted via primary branches per plant.

Key words: *Tomato, Colour, Flavour, Productivity, Fruit*

INTRODUCTION

Tomato [*Solanum esculenton* (Mill.) Wettsd.] is one of the most important vegetable crop with diploid chromosome number 2n=2x=24. Ripe fresh tomato fruit is consumed fresh as salads and consumed after cooking and utilized in the preparation of range of processed products such as puree, paste, powder, ketchup, sauce, soup and canned whole fruits. Unripe green fruits are used for preparation of pickles and chutney. All the species of tomato are native to Western South America[9]. Tomatoes are important source of lycopene (an antioxidant), ascorbic acid and ß-carotene and valued for their colour and flavour. It is one of the most popular and widely cultivated vegetable throughout the world and ranking second in importance after potato in many countries including India[1]. Tomato is a typical day neutral plant and is mainly self-pollinated, but a certain percentage of cross-pollination also occurs. It is a warm season crop reasonably resistant to heat and drought and grows under wide range of soil and climatic conditions.

ABSTRACT

The present investigation was carried out in two different environments with aim to assess genetic variation among the genotypes for growth, yield attributes. The present investigation was comprised forty diverse genotypes of taro. The present study revealed that the significant differences for sixteen traits among genotypes of taro which indicated that the presence of adequate variability which could be harnessed for developing yield potential cultivars. The phenotypic and genotypic coefficients of variation were high for width of leaf, weight of corms per plant, number of cormels per plant and petiole length. Moderate to high heritability was evident for all the traits and was accompanied with high genetic advance for weight of corm, girth number of cormels, weight of cormels, of corm, length of leaf, width of leaf, and petiole length which suggests the role of additive gene action and thus, a high genetic gain is expected from selection of these traits. Moreover, high heritability along with moderate genetic advance for sheath length, height of plant, reveals the presence of additive and non-additive gene action simultaneously. On the other hand, dry matter showed low genetic advance along with high heritability that reflects the presence of non-additive action.

Introduction

Taro (*Colocasia esculenta* var. antiquorum) is one of the oldest and most important tuber crop. It is also known as eddoes type taro, arvi and ghuia. It is grown mostly as staple or subsistence crop throughout the tropics and subtropics. Although this crops is not treated as economically important and was often considered as poor man's crop which is most extensively consumed by the low income group in the rural areas.

India to Southern Asia is the centre of origin of Colocasia from where it has travelled east to all the Island of Occeania, Phillipines, China and Japan although, India is said to the native of taro. Africa ranks first in area and production of Colocasia followed by Asia. In India, it is mainly cultivated in Eastern and Southern States – Faizabad, Varanasi, Sitapur, Sultanpur, and some parts of Jhansi etc. Deoria are the leading districts with regard to Arvi production particularly in Eastern districts of Uttar Pradesh. The objective of the present study, therefore, was to examine the variability, extent of inheritance and character association for various traits of economic importance in 40 genetically diverse

ABSTRACT

The present investigation was carried out in two different seasons with aim to assess the heterobeltosis and standard heterosis in bottle gourd. The present study was comprised of 45 crosses developed through diallel mating design using 10 parents namely, NDBG-49-2 (P_1), N. Rashmi (P_2), N. Prabha (P_3), N. Pooja (P_4), Pusa Naveen (P_5), Pb. Komal (P_6), NDBG S-1 (P_7), PBOG-3 (P_8), NDBG-11 (P_9) and Faizabadi Local (P_{10}) at MES, Vegetable Science, NDUA&T, Kumarganj, Faizabad (U.P.) India during *kharif* 2015 (E_1), and *Rabi*, 2015-16 (E_2). The experiments were laid out in RBD with three replications having each experimental unit of single row with spacing of 3.0 m × 0.5 m. The observations were recorded on parents and F_1's for eighteen quantitative traits including six quality traits *viz* days to first staminate flower anthesis, days to first pistillate flower anthesis, node number to first staminate flower, node number to first pistillate flower appearance, days to first fruit harvest, vine length at last picking stage (m), number of primary branches per plant, fruit length (cm), fruit circumference (cm), fruit weight (kg), number of fruits per plant, fruit yield per plant (kg), total soluble solids (°B), ascorbic acid (mg/100 g fresh fruit), reducing sugar (%), non-reducing sugar (%), total sugars (%) and dry matter content in fruit (%).The present heterobeltiosis for fruit yield per plant heterosis range from -3.84 (P_2 x P_7) to 64.49 % (P_5 x P_8) in pooled in over better parent. The best five crosses which showed positive and significant heterosis over better parent were P_3 x P_9 (67.26 %), P_5 x P_8 (64.49 %), P_6 x P_9 (63.58 %), P_4 x P_5 (60.66 %) and P_2 x P_4 (58.76 %) Standard heterosis range from were 9.80 (P_4 x P_8) to 69.17 % (P_3 x P_9) in pooled. The best five crosses which showed desirable and significant positive standard heterosis in the pooled analysis were P_3 x P_9 (69.17 %), P_6 x P_9 (65.45 %), P_3 x P_8 (64.49 %), P_4 x P_5 (60.66 %) and P_7 x P_9 (56.80) for fruit yield per plant indicating that there was a great scope of realizing higher yield in bottle gourd through heterosis breeding.

Introduction

Bottle gourd [*Lagenaria siceraria* (Mol.) Standl, 2n =2x= 22] is an important cultivated annual cucurbitaceous crop grown throughout the country. Being warm season vegetable crop it thrives well in warm and humid climate but at present it's off season cultivation has progressively stretched throughout the year in northern Indian plains. According to De Candolle (1882), bottle gourd has been found in wild form in South Africa and India. However, Cutler and Whitaker (1961) are of the view that probably

ABSTRACT

The present investigation was conducted in Randomized Block Design with 38 genotypes (including three checks) of tomato in three replications for thirteen quantitative traits. The objectives were to assess the correlation for fruit yield and yield contributing characters. The association studies showed that fruit yield per plant had highly significant and positive correlation with marketable fruit yield per plant, average fruit weight, equatorial diameter, unmarketable fruits yield per plant and number of fruits per plant at both phenotypic and genotypic levels.

Keywords: Tomato; randomized block design; Solanum lycopersicum; protective food.

1. INTRODUCTION

Tomato is universally treated as "Protective food" and considered as "Poor man's Orange". Tomato is a native of Peru Equador region (Rick, 1969) and having chromosome number 2n=24. Tomato fruits are consumed raw or cooked. It is grown at farm and kitchen garden for slice, soup, sauce,

ABSTRACT

Present investigations were carried out in bottle gourd to assess the heritability and genetic advance for yield and quality traits. Fifteen hybrids of bottle gourd generated along with their six parents evaluated in a randomized complete block design with three replication at the Main Experiment Station, Department of Vegetable Science A.N.D. University of Agriculture & Technology, Narendra Nagar, Kumarganj, Ayodhya during the season of *Zaid* 2020 and *Zaid* 2021. High heritability was observed for number of primary branch per plant, days to first pistillate flower anthesis, days to first fruit harvest, days to first staminate flower anthesis and vine length during in Y_1, days to first staminate flower anthesis, node number to first pistillate flower appearance, days to first fruit harvest, days to first pistillate flower anthesis and non-reducing sugar during in Y_2, days to first pistillate flower anthesis, days to first staminate flower anthesis, days to first fruit harvest and non-reducing sugar during in pooled. High genetic advance as percent of mean was observed for average fruit weight, number of fruit per plant, fruit yield per plant and reducing sugar during seasons Y_1 and Y_2. The results indicated that these traits had additive gene effect and therefore, these are more reliable for effective selection for their further improvement.

Estimation of genetic diversity among the genotypes of brinjal (*Solanum melongena* L.)

Hari Shanker Verma, GC Yadav, Shravan Kumar and Prashant Verma

Abstract
The research experiment was conducted to study genetic diversity for quantitative traits among genotypes of brinjal (*Solanum lycopersicum* L.). The investigation was conducted during 2020-21 at the Main Experiment Station, Department of Vegetable Science, Acharya Narendra Deva University of Agriculture and Technology Narendra Nagar, (Kumarganj), Ayodhya (U.P.) using Mahalanobis D^2 statistic. The 40 genotypes were grouped into five clusters, indicating the presence of sufficient diversity among the genotypes for different traits. The cluster first had the highest number containing 25 genotypes followed by cluster II containing ten genotypes. However, the cluster III, IV and V were monotypic containing one genotypes. The maximum intra-cluster distance was recorded within cluster IV (1.73) and the maximum inter-cluster distance was observed between clusters IV and V (31.520). On the basis of cluster mean analysis, the superior and genetically divergent genotypes can be used in crop improvement programme in brinjal.

Keywords: Genetic diversity, *Solanum melongena*, brinjal, cluster

Introduction
Brinjal or egg plant (*Solanum melongena* L.) is one of the most valuable tropical and sub-tropical vegetables grown in India. The name brinjal is popular in Indian subcontinents and derived from Arabic and Sanskrit, whereas the name eggplant has been derived from the shape of the fruit of some varieties, which are white and resemble in shape to chicken eggs. It is also called aubergine (French word) in Europe. Brinjal or guinea Squash belongs to the family Solanaceae (Nightshades) with diploid chromosome number 2n=2x=24. It is known by different names in different regions of India like bagun (Bengali), ringna (Gujarati), baingan (Hindi). It is popular among people of all social strata and hence, it is rightly called the vegetable of masses.

Considering the importance of this crop, there is a need for improvement and to develop varieties suited to specific agro-ecological conditions and also for specific end use. Study of genetic divergence among the existing genetic stocks provides an opportunity for selecting the diverse parents for hybridization. Such parents are expected to produce superior segregants in combination with others and thus are most valuable for breeders. Moreover, evaluation of genetic diversity is important to know the source of genes for a particular trait within the available germplasm. D^2 technique of Mahalanobis appears to be a fruitful approach which is based on multivariate analysis and serves as a good index for estimating genetic diversity. Information on genetic divergence among the available genotypes is vital to plant breeders for an efficient choice of parents for hybridization. It is an established fact that genetically diverse parents are likely to contribute desirable segregates. It is noticed that more diverse the parents greater the chance of obtaining high heterotic F1's and broad spectrum of variability in segregating generations. Hence, this experiment was conducted to study genetic diversity for quantitative traits among genotypes of brinjal (*Solanum lycopersicum* L.).

Material and Methods
The present experiment was carried out during winter season 2020-21, at the Main Experiment Station, Department of Vegetable Science, Acharya Narendra Deva University of Agriculture and Technology (Narendra Nagar), Kumarganj, Ayodhya (U.P.). The experimental materials for the present investigation were comprised of 40 different genotype (39 genotype + 1 check) of brinjal selected on the basis of genetic variability from the germplasm stock maintained in the Department of Vegetable Science, Acharya Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya (U.P.) India.

ABSTRACT

Brinjal or eggplant (*Solanum melongena L.*) is one of the most important cultivated solanaceous vegetable, mainly grown for its edible fruits. The present investigation was carried out in order to obtained *per se* performance of parents and their cross combinations for genetic improvement in brinjal. Ten parents were crossed in diallel fashion excluding reciprocal. Half diallel set of crosses and their all possible 45 F_1's (excluding reciprocals) in brinjal (*Solanum melongena L.*)were evaluated in Randomized Complete Block Design (RBD) with three replications for nineteen yield and yield contributing traits during *Kharif* 2020-21 (Y_1) and 2021-22 (Y_2) at the Main Experiment Station (MES) of Department of Vegetable Science, Acharya Narendra Deva University of Agriculture and Technology, Narendra Nagar, Kumarganj, Ayodhya (U.P.) India. The study revealed that highly significant differences were observed for most of the traits under study. Based on the *per se* performance, the parentP_9 (2.61 kg) registered highest fruit yield per plant followed by P_7 (2.49 kg) in both the year and pooled. The *per se* performance of crosses *viz.*, $P_2 \times P_9$ (3.11 kg), $P_4 \times P_9$(2.66 kg), $P_1 \times P_8$(2.55 kg)and $P_6 \times P_7$(2.42 kg) were produced significantly highest fruit yield per plant than the general mean. These hybrids may be subjected to multi-locational and multi-seasonal trials for their release for commercial cultivation. The findings with respect to salinity tolerance must be correlated to develop the salt tolerant cultivars.

Studies on genetic variability, heritability and genetic advance in garden pea (*Pisum sativum* L. var. hortense)

Putan Yadav, CN Ram, GC Yadav, Shiva Nath and Sharvan Kumar

Abstract
The present experiment was carried out to find out the diversity among the different genotypes with the using 42 diverse genotypes including two checks for quantitative traits and qualitative traits. The study was conducted with the field evaluation of 44 genotypes during 2019-20. The wide range of variation variability among the traits during 2019-20. The observation was recorded Days to 50 per cent flowering, primary branches per plant, node to first flower appears, node to first pod appears, length of pod (cm), pod diameter (cm), number of seeds per pod, number of pods per plant, number of pods per 250g, number of seeds per 250g, weight of seed per 250g, shelling (%), T.S.S.(°B) and pod yield per plant (g). Genotypes involved in this study were genetically diverse and have good breeding value, which confirmed the predictions of analysis of variance. Out of 44 genotypes among eighteen genotypes were produced significantly higher yield than best check PC-521.

Keywords: Garden pea, heritability, variability, PCV, GCV and genetic advance

Introduction
Garden Pea (*Pisum sativum* L. var. *hortense*) belongs to family Leguminaceae sub family Fabaceae and is an important legume vegetable grown throughout world during cool season. It is a self-pollinated crop having diploid chromosome number 2n = 14. It is most extensively cultivated in the temperate regions and restricted to cooler altitudes in the tropics and winter season in the sub tropics. It is highly nutritious and capable of using atmospheric nitrogen. Pea has low nitrogen requirement and does not show any marked response to application of nitrogenous fertilizer. Phosphorus is however essential for growth of nitrogen-fixing organism. On poor soil as well as on soil where the crop is newly grown inoculation of the soil with bacterial culture and adequate manuring with complete fertilizer are essential to increase the yield and to improve the quality of pod. India ranks third in area after China and USSR under pea (vegetable and pulse pea) cultivation. The total area covered by peas is 563 million hectares with the production of 5703 metric tonnes whereas, productivity is 10.12 metric tonnes per hectare (Anonymous, 2019-20 II Estimate). The main objectives in breeding pea crop are yield, regional adaptability, suitable plant type, lodging and shattering resistance disease and insect resistance, environmental stress resistance, quality and effective nitrogen fixation. At present, the yield potential of pea for green pod as well as for the grain is very low and there exists a scope for its improvement. The environmental factor limiting the yield should be considered, while developing genotypes for yield. Pod and grains characteristics, which directly influence the yield and its quality, should be given due consideration. The information usually needed for developing high yielding varieties in a particular species pertains to the extent of genetic variability for desirable traits in the available germplasm. Evaluation of germplasm is the basic tool for identification of important genotypes. The great extent of natural variation available for various characters among the genotypes suggests good scope for improvement in economic traits. Large variability ensures better chance of producing new forms. Variability parameters like genotypic and phenotypic coefficient of variations, heritability and genetic advance, and degree of association between the various characters and direct effect of yield contributing characters on total yield, is of paramount significance in formulating an appropriate breeding strategy aimed at exploiting the inherent variability of the original population. Phenotypic variability changes under different environmental conditions, while genetic variability remains unchanged and more useful to a plant breeder for exploitation in selection or hybridization. Yield is a complex trait controlled by several yield contributing components.

Assessment of Correlation coefficients analysis in fenugreek (*Trigonella foenum-graecum* L.)

Satish Kumar Gautam, CN Ram, GC Yadav and Mohit Lal

Abstract
The present investigation entitled "Studies on combining ability, heterosis and gene action in fenugreek (*Trigonella foenum-graecum* L.) for yield and quality attributing traits" at Main Experiment Station (MES) of the Department of Vegetable Science A.N.D. University of Agriculture and Technology, Kumarganj, Ayodhya (U.P.) during *rabi* season of 2019-20 (Y_1) and 2020-21(Y_2). The experiment was conducted in a Randomized Complete Block Design (R.B.D.) with three replications on 54 genotypes (40 F_1 + 10 line + 4 testers). Observations were recorded for 11 characters *viz.*, days to 50% flowering, plant height (cm), number of branches per plant, days to maturity, pods length (cm), biological yield per plant (g), harvest-index (%), number of pods per plant, number of seeds per pods, 1000-seed weight (g) and seed yield per plant (g). The findings of the present investigation revealed that phenotypic and genotypic correlation coefficients analysis for yield and quality economic traits.

Keywords: Fenugreek, *Trigonella foenum-graecum* L., phenotypic and genotypic correlation coefficients

Introduction
Fenugreek (*Trigonella foenum- graecum*) belongs to family Fabaceae, 2n=16. It is seed spice as well as leafy vegetable. It has been originated in Egypt. Fenugreek can be grown in the tropical and in temperate regions. It is grown from sea level up to an altitude of 2000 m. There are two species of the genus *Trigonella*, which are of economic importance, *viz.*, *Trigonella foenumgraecum* or the commonly called "methi" and *Trigonella corniculata* or the "kasthuri methi." Fenugreek is an annual herb, 30 to 90 cm tall and has light green leaves which are pinnately trifoliate. The flowers are papillonaceaus and white or yellow in colour and produces stander, beaked pods of approximately 10-15 cm long and each pod contains 10-20 small hard yellowish brown seed possessing smooth and oblong, about 3 mm long, each grooved across one corner, giving them a hooked appearance. India is also known as land of spices. India is one of the dominant producers and exporters of fenugreek. The value-added products of fenugreek such as its seeds, powder and oleoresins are exported to Europe, North America, South Africa and other Asian countries (Anonymous, 2019-20). In India, it occupies an area of about 127 thousand hectare with 184 mt productions with share of 2.4 percent. Fenugreek is mainly grown in the states of Rajasthan, Gujarat, Punjab, Haryana, U.P., M.P. Maharashtra and Tamil Nadu. Rajasthan alone contributes nearly 60 per cent of total area and 80 per cent of total production of the crop in the country. The present investigation was to evaluate the germplasm and unveil the phenotypic and genotypic correlation coefficients studies for yield and yield attributing traits as such information forms the basis for designing breeding strategies to improve the yield potential.

Material and Methods
The experiment was conducted on fenugreek (*Trigonella foenum-graecum* L.) at Main Experiment Station (Vegetable Research Farm), ANDUA&T Kumarganj Ayodhya (U.P.) India, during *rabi* season of 2019-20 (Y_1) and 2020-21(Y_2). The experiment was conducted in a Randomized Complete Block Design (R.B.D.) with three replications and 54 genotypes (40 F_1 + 10 line + 4 testers). The crop was planted in row length spaced 30 cm. apart where, 10 cm. plant to plant spacing was maintained. The experimental plant material for present investigation was comprised of 40 hybrid developed by crossing 10 line (NDM-3, NDM-4, NDM-8, NDM-10, NDM-5, NDM-63, NDM-14, NDM-23, and NDM-19 with 4 testers PEB, NDM-2, Hisar Sonali (check) and NDM-1.The observations were recorded on five plants randomly selected from each genotype in each replication on eleven characters, *viz.*, days to

Studies on heritability and genetic advance for the quantitative traits in Bottle gourd [*Lagenaria siceraria* L. (Moll.) Standl.]

Mohit Lal, CN Ram, GC Yadav and OP Rao

Abstract
Bottle gourd [*Lagenaria siceraria* L. (Moll.) Standl.] is an important tropical species characterized by a wide range of diversity and a low yield, mainly due to number of selection for improved varieties. The present investigations were carried out at the Main Experiment Field, Vegetable Science, ANDUA&T, (Kumarganj), Ayodhya, during the season of *Zaid* 2019 and 2020. The experiment laid out in randomized complete block design (RBD) with three replications. High heritability coupled with high genetic advance as per cent of mean was observed for fruit length (cm), reducing sugar (%), total sugar (%), and days to first male flower anthesis (days), node number to first female flower appearance (days), primary branches per plant (days), total soluble solids (%) and non-reducing sugar (%). The results indicated that these characters had additive gene effect and therefore, these are more reliable for effective selection for their further improvement.

Keywords: Genetic advance and heritability in *Lagenaria siceraria* L.

Introduction
Bottle gourd [*Lagenaria siceraria* L. (Moll.) Standl.] is an important cucurbitaceous crop having range of uses and is largely cultivated in the tropics and subtropics for its edible fruits. Bottle gourd is one of the largest produced cucurbit vegetables in the world having chromosome number of 2n = 22. The genus *Lagenaria* is derived from the world *Lagena*, meaning bottle. It is also known as Calabash, Doodhi and Lauki in different parts of India (Deore *et al.*, 2009) [4]. Bottle gourd is a monoecious and cross pollinated crop in large amount of variation has been observed for many economically important characters. The fruits of bottle gourd are used are for making sweets, halva, kheer, petha, burfi and pickles. Kofta is a most popular preparation of bottle gourd. As a vegetable it is easily digestible therefore used even by patients. Fruit has cooling effect, cardiatonic and diuretic. The fruit is rich in pectin also, which showed good prospects for jelly preparation. A decoction made from the leaf is a very good medicine for jaundice. The fruit has cooling effect, it is a cardiotonic and diuretic, good for people suffering from biliousness, indigestion and convalescences *i.e.*, regain health after illness. The pulp is good for overcoming constipation, cough and night blindness and as an antidote against certain poisons. In addition, the seeds and seed oil are edible. The fruits contain 96.3 per cent moisture, 2.9 per cent carbohydrate, 0.2 per cent protein, 0.1 per cent fat, 0.5 per cent mineral matter and 11 mg of vitamin C (Ascorbic acid) per 100 g fresh weight (Thamburaj and Singh, 2005) [9]. Bottle gourd was one of the first plant species to be domesticated for human use, providing food, medicine and a wide variety of utensils and musical instruments made from the large hard shelled mature fruits. It travelled to India, where it has evolved into numerous local varieties and from India to China, Indonesia and New Zealand. At present time, the annual running or climbing monoecious vine crop is cultivated throughout the tropical and subtropical regions of the world for food and useful gourds (Whitaker and Davis, 1962) [2]. Dry hard shells of the fruits have been used for making a wide range of articles of common use, including bowls, bottles, containers, floats for finishing nets and musical instruments (Wikipedia, 2018) [12].
The genetic parameters such as heritability, genetic advance provide effective tools in hand of a breeder to select a genotype having the most desirable characters for yield. Many of the quantitative characters such as number of fruits per plant and yield per plant are highly influenced by environment conditions to use partitioning the overall heritable and non-heritable components which will be of the immense help in any planned breeding programme.

Constraints analysis of mango growers in Saharanpur district of Uttar Pradesh

Mohit Kumar, SN Singh, RR Yadav, RK Doharey, Abhishek Kumar, DP Singh and Surender Kumar

Abstract
A study was conducted in Rampur Maniharan Block of district Saharanpur selected purposely. A total number of 100 Mango growers were selected through random sampling from five villages. The structured schedule was developed keeping in view the objectives and variable to be studied. The respondents were contacted personally for data collection. Out of 13 common problems the maximum number of the respondents 95% with adopt a rank of first were agreed with the statements that "Low price for produce" is the common problem, followed by "High cost of chemical fertilizers" 92% at ranks second, "Lack of Education" 91% at rank third, respectively. The maximum number of the respondents 85% with adopt a rank of first were agreed with the statements that "Flexible sources of credit" is the common problem, followed by "Training for Mango grading" 82% at ranks second, "Mango processing unit should establish" 79% at rank third, "Efforts should be made for providing fertilizers on appropriate rate" 78% at rank fourth, respectively.

Keywords: Adoption, constraints, Practices and suggestion

1. Introduction
Mango (*Mangifera indica* L.) is one of the most important fruit of India and as the "king of fruits". It belongs to the family *Anacardiaceae* and genus *Mangifera and species indica*. It is indigenous to Indo-Burma region. It is under cultivation in India for more than 4000 years and hence conspicuous bonds have been between the fruit and cultural history of the country. India still dominates the world mango production and rank first with a total production of 18431.0 thousand Million tonnes from an area of 2516.0 thousand ha. In India, mango is cultivated almost all the states, where as Uttar Pradesh is leading state in production with 4300.98 thousand Million tonnes from an area of 262.16 thousand ha. (NHB Data base, 2014) [5]. India has the richest collection of mango cultivars. Mango is recognized as one of the choicest and well accepted fruit all over the world due to its taste, flavour, attractive colour and nutritive value. It plays important role in balancing the diet of human being by providing about 64-66 calories per hundred grams of ripe fruits. It is a good source of vital protective nutrients like vitamins such as vitamin A (1400 I.U.), and C. Mango fruit contains 73.0-86.7 per cent moisture, 11.6-24.3 per cent carbohydrate, 0.3-1.0 per cent protein, 0.1-0.8 per cent fat, 0.3-0.7 per cent mineral, 650-25900 µg vitamin 'A' and 3-83 mg vitamin 'C' per 100 gram fruit. Seed kernels contain 9.5 per cent protein, 8-12 per cent fat, 79.2 per cent starch, 2 per cent mineral matter and 2 per cent fibers (Dock Worth, 1979) [2]. Raw fruits are also used for making chutney, amchur, pickles and juices. The ripe fruits are also utilized for preparing several productions like ready to serve, nectar, squash, panna syrup, mango leather, mango powder, toffee, jams, jelly etc. Maximum 57.50 per cent mango orchardists have full adoption of 10 m x 10 m planting distance. Most of the orchardists have full adoption of Dashehari, Langra and Chausa varieties for plantation in mango orchard (Tanwar, 2013) [6]. In fertilizers and manure application, most of the mango growers were have full adoption. Most of orchardists have partial adoption of ring and furrow method for irrigation, while 67.50 orchardists have full adoption of flood method for irrigation, There was 100 per cent full adoption in wettable sulpher, 97.50 per cent karathan and hexaconazal for disease control. Most of the orchardists have full adoption in Monocrtophos, Endosulphan and Imidacloprid for pest management. Maximum farmers were having full adoption in grading and packing of mango, while few orchardists have partial adoption in processing practices in mango. The 100 per cent mango orchardists have full adoption in Mandi samities for marketing of fruits, while most of the orchardists have no adoption of direct sale of fruits to consumers and whole sellers in same town, village and export of fruits. Mango post-harvest diseases cause maximum losses in the quality and marketing of fresh mango fruits.

ABSTRACT

This study was conducted in Karwi block of Chitrakoot district by conducting personal interview with 100 respondents which were selected through random sampling technique. There were 65 percent respondents found in middle age group and observed to be literate (67%), belonging to backward caste (70%), residing in nuclear families (63%). The maximum respondents (63 %) were having small farmers land holding and agriculture was observed as main occupations (88%). The 55 per cent respondents were found such who had family annual income Rs. 26001-79000. The mobile (100%) were observed as main communication media. A maximum number of respondents were found in low level of scientific orientation (41%), and medium level of economic motivation and risk orientation with 80 per cent and 55 per cent respectively.

Introduction

Red gram has wide adaptability and low input requirements mostly grown in *kharif*. The heavy shedding of leaves adds considerable organic matter to the soil. Pigeonpea has multiple uses such as tender green seeds used as vegetables, stem and roots as fuel wood, crushed dry seeds as animal feed and to make huts, baskets etc. besides its main use as dhal. It has been recognized as a valuable source of protein (17.9 to 24.39/100g) particularly in the developing countries where majority of the population depends on the vegetarian foods for meeting its dietary requirements (Ali and Kumar, 2005). It has nitrogen fixing ability, and also play an important role in sustaining intensive agriculture by improving physical chemical and biological properties of soil and are considered excellent crop for diversification of cereal based cropping system.

Pigeonpea is one of the important pulse crops of India and 91% of the world's pigeonpea is produced in India. Myanmar is the second largest producer of pigeon pea with 15% of global production followed by lesser producers Kenya, Uganda, and Malawi. The productivity of pigeonpea in India (7.99q/ha)

ABSTRACT

This study was conducted in Karwi block of Chitrakoot district by conducting personal interview with 100 respondents which were selected through random sampling technique. There were 65 percent respondents found in middle age group and observed to be literate (67%), (70%) respondents belonging to backward caste, 63 per cent residing in nuclear families. The maximum respondents (63 %) were having small farmers land holding and agriculture was observed as main occupations (88%). The 55 per cent respondents were found such who had family annual income Rs. 26001-79000. The majority of respondents (66%) were observed overall material possession in medium level(62 to 76 score). A maximum number of respondents were found in low level of scientific orientation (41%), medium level of economic motivation and risk orientation with 80 per cent and 55 per cent respectively. Besides, among all 14 agricultural practices of pigeon pea cultivation, time of sowing (93%) were rank at 1st as far as knowledge possessed by the respondents were concerned. Out of 14 variables studied the variables *i.e.* Knowledge extent of scientific pigeon pea cultivation practices, education, Annual income and social participation was found highly significant and positively correlated with knowledge extent.

Key words : *Socio-economic profile, knowledge, communication technology etc.*

Red gram *[Cajanus cajan (L.) Millsp.]* belongs to family Leguminosae. Numerous nodules are present on roots, these nodules contain rhizobium bacteria, which fixes atmospheric nitrogen. The flowers are self-pollinated but cross-fertilization may also occur to some extent. The fruit of the red gram is a pod. Seeds are round or lens shaped. Numerous species of *Cajanus* are known, differing in height, habit, time of maturity, colour, size and shape of pods and seeds. All these cultivated types belong to two categories, one of *Cajanus cajan var.* bicolor: This group includes late maturing varieties, having tall bushy plants and bear flowers at the end of the branches. The pods are relatively longer and contain 4-5 seeds, and other *Cajanus cajan var. flavus*. This group includes early maturing varieties, having smaller plants and flowers at several points along the branches. The pods are also shorter which bear 2-3 seeds.

Red gram has wide adaptability and low input requirements mostly grown in *kharif*. The heavy shedding of leaves adds considerable organic matter to the soil. Pigeon pea has multiple uses such as tender green seeds used as vegetables, stem and roots as fuel wood, crushed dry seeds as animal feed and to make huts, baskets etc. besides its main use as dhal. It has been recognized as a valuable source of protein (17.9 to 24.39/100g) particularly in the developing countries where majority of the population depends on the vegetarian foods for meeting its dietary requirements (Ali and Kumar, 2005). It has nitrogen fixing ability, and also play an important role in sustaining intensive agriculture by improving physical chemical and biological properties of soil and are considered excellent crop for diversification of cereal based cropping system.

Pigeon pea is one of the important pulse crops of India and 91% of the world's pigeon pea is produced in India. Myanmar is the second largest producer of pigeon pea with 15% of global production followed by lesser producers Kenya, Uganda, and Malawi. The productivity of pigeon pea in India (7.99q/ha) is far below the average productivity (8.48 q/ha) of world. In India, it occupies an area of about 4.09 million hectares producing 3.27 million tons with an average productivity of 7.99 q/hectare (Anonymous 2010).

Pigeon pea is the 4th ranked pulse crop in the world. In India, pigeon pea is the 2nd most important pulse crop after chickpea. Besides India, it is also grown in south East Asia, Africa, and America. In India, production of pigeon pea was 3.17mt, on area of 3.88 m ha. with yield of 817 kg/ha. (Anonymous, 2014). In India, the crop is mainly grown in Andhra Pradesh, Bihar, Uttar Pradesh, Karnataka, Gujarat, Madhya Pradesh, Maharashtra, Orissa and Tamilnadu. In Uttar Pradesh, it is grown 311.0 thousand ha area producing 325.0 thousand tons, with an average yield of 1040 kg/ha (Anonymous, 2014).

Pigeon pea in India is the most important pulse crop which is cultivated in the gross cropped area (3.58 million hectare) under pulses providing 20% of the national pulse production (2.51 million tons). Besides being rich source of protein, they are also important for sustainable agriculture, enriching the soil through biological nitrogen fixation. Pigeon pea is one of the most important legumes grown in Uttar Pradesh which has 10.61% area (0.38 million hectare) and 13.87% in terms of production (0.38 million tons) in the country. The productivity of pigeon pea in Uttar Pradesh is 9.82 q/ha, which is lower than the

This study was conducted in Khairabad block of Sitapur district (U.P.) by conducting personal interview with 100 respondents which were selected through random sampling technique from 5 sample villages on the basis of majority of sugarcane grower. There were the majority of the respondents 60% were found in middle categories (38-59) of age group, like this 68 % literate, 99% married, 67% other backward caste, 100% Hindu religion, 54% nuclear family, 67% medium family size (5-11 members), 47% marginal land holding size (less than 1 ha.), 78% agriculture main & 67% subsidiary occupation, 80% annual income (45001-172000), 41% mixed houses, , 71% overall material possession (41-84 equipment).

Introduction

Sugarcane is an important cash crop grown all over the world. It belongs to the grass family poaceae. Sugarcane is the world largest crop. In 2012 FAO estimate it was cultivated on about 26.00 million hectare land, in more than 90 countries, with a worldwide harvest 1.83 billion tonnes. India is the largest producer of sugarcane in the world. The next five major producers in amount production are Brazil, China, Thailand, Pakistan and Mexico.

Sugarcane is a tropical, perennial grass that forms lateral shoots at the base to produce multiple stems, typically three to four meter height and about five centimeters diameter. Sugarcane is a cash crop, but it is also used as livestock fodder.

Sugarcane is moderately non-sunny weather loving plant is grown in two distinct climate regions; the tropical and subtropical. The total area under sugarcane in India is 5.06 million hectare with 356.56 million tonnes production in 2014-15, out which 70% lies in the subtropical region and the remaining 30% in the tropical belt.

Major sugarcane growing states in India are U.P, Maharashtra, Karnataka, Tamilnadu, Andhra Pradesh and Punjab etc., but northern India having subtropical climate. The important sugarcane growing states of the northern region are U.P, Haryana, Punjab, Bihar and Jharkhand. Uttar Pradesh is the highest sugarcane producing State in sub-

ABSTRACT

The study was conducted in 4 main agricultural universities in Uttar Pradesh, by interviewing 300 respondents who were selected through proportionate random sampling technique on the criteria of having four year degree programme of B.Sc.(Ag.), two year degree programme M.Sc.(Ag.) and three year degree programme Ph.D.(Ag.). The study depicted that the highest number of respondents in age category of 22 to 26 years belonged to nuclear families (79%) and having 5-10 members in their families (72%) Except 7 per cent respondents all were unmarried and backward caste respondents were more in comparisons to other categories of caste. The economic motivation, risk orientation and value orientations were observed of medium levels. The mobile phone is most useful of communication media. The agriculture was observed as main occupation of majority of the respondent's families and having annual income of Rs. 100001 to 200000 (31%). The 51% respondents were found having pucca type houses, 35% of the respondents was found in the land holding category of small farmers. 64.66 percent medium level of decision pattern of Father. The maximum number of respondents was observed in medium category of communication technology use in day and most usefulness of communication technologies in career preferences was mobile phone. The majority Purpose in use of communication technology was 'computer information retrieval or data updating' at ranked first. The father followed by mother, brother, friends, relative mean score value 2.11, 1.03, 0.71, 0.60 and 0.60 respectively were found to be important motivational sources among all.

Introduction

Agriculture is still the largest employer of India. However, there was not much education regarding the same in the past. Agricultural education is now given importance so that the farmers can adopt environmentally and technologically advanced faming tactics and consequently increase productivity as well as profitability.

ABSTRACT

The study was conducted in Bundelkhand Region during the year 2010-2011, To know the adoption level of the Zinger growers regarding Zinger cultivation practices. For this purpose 4 villages' peripheral and 4 distant villages were randomly selected from Bundelkhand region. From each village 10 respondents were purposively selected. Thus total sample size was of 80 Zinger growers for the study. It was observed that 36.04% peripheral farmers adopting improved varieties, 51.87% field preparation practices, 70.83% sowing rainfed and irrigated conditions, 58.33% adopting optimum seed rate, 53.33% line sowing, 69.16% sowing optimum depth, 50.83% adopting thinning practices, 49.16% adopted balance use of fertilizers and 34.16% adopting storage practices. While 33.91% distant farmers were using improved varieties, 43.95% field preparation, 45.83% sowing Zinger in rainfed and irrigated conditions, 40.83% using optimum seed rate, 44.16% line sowing adopted, 41.66% sowing optimum depth, 39.16% adopting thinning practices, using optimum irrigation, 41.66% using balance fertilizers and 22.33% adopting storage practices. There were minor difference found in between regarding peripheral farmers and distant farmers regarding adoption of plant protection measure in Zinger cultivation.

Introduction

India has been the "Home of spices" since time immemorial. It is the world's largest producer, consumer and exporter of seed spices which are being cultivated widely in the country over different agro-climatic zones. Zinger is used as a crude drug to enhance the body's resistance and is prescribed in amebiasis. It is a potent antimicrobial agent. Due to its multiple properties, ginger is used to cure cough, gastric problem, stomachache, bloat as well as urinary troubles. In view of the above medicinal and nutritional properties of Zinger, the production technology of zinger cultivation is essential. Keeping this fact in view the present study was conducted in Jhansi district. Spices are extensively used as flavoring agent in various food products and in pharmaceutical industries in preparation of various Ayurvedic medicines. The aromas in

KNOWLEDGE ABOUT FORMATION, IMPLEMENTATION AND FUNCTIONING OF DIFFERENT WOMEN SHGS IN KANPUR DEHAT DISTRICT (U.P.)

Shalu gautam[1], R.K. Doharey[2], and Prakash Singh[3]
1,2&3 Department of Extension Education, College of Agriculture, NDUA&T,Kumarganj, Ayodhya(U.P.)-224229

Abstract
The study was conducted in Akbarpur block of Kanpur Dehat district selected purposively. A total number of 100 respondents of women SHG were selected purposively which were selected from 20 Villages randomly. The structured schedule was developed keeping in view the objectives and variables under study. The respondents were contacted personally for data collection. The analysis of data was done by using the percentage, mean, standard deviation, and correlation coefficient for drawing the inferences. The data revealed that the maximum number of women SHG members (62%) had medium level of knowledge about formation, implementation and functioning of different women SHG followed by low (20%), high (18%) respectively. It is evident from the values of correlation coefficient as appeared in that out of 17 variables. The 4 variables *viz.*, annual income, social participation, extension contact, awareness about of ICT tools, were found to be significant and positively correlated with degree of knowledge about formation, implementation and functioning of different women SHG at 0.05% probability and one variable 'caste' was found to highly significant and negatively correlated with degree of knowledge about formation, implementation and functioning of different women SHG at 0.01% probability. The variables like education, family type, family size, housing pattern, scientific orientation, and accessibility to computer were found to be non-significant but positive correlated with degree of knowledge about formation, implementation and functioning of different women SHG. The variable like 'caste' was found highly significant and negatively correlated with degree of knowledge about formation, implementation and functioning of different women SHG. This led to conclusion that out of 17 variables 4 variables which were significant influenced the degree of knowledge about formation, implementation and functioning of different women SHG means that as the annual income, social participation, extension contact, awareness about of ICT tools, etc.

Key words: Knowledge about formation, implementation and functioning of different women SHGs.

Introduction

The Self-Help Groups (SHG) is a small voluntary association of poor people, preferably from the same socio-economic background. They come together for the purpose of solving their common Problems through self-help and mutual help. The SHG promotes small savings among its members and these savings are kept with a bank. This common fund is in the name of the SHG. The SHG is a group formed by the community which has specific number of members like 15 or 20. Usually, the number of members in one SHG does not exceed twenty. In such a group the poorest would come together for emergency, disaster, social reasons economic support to each other have ease of conversation, social interaction and economic interactions.

A self-help group is defined as a "self-governed, peer-controlled information group of people with similar socio-economic background and having a desire to collectively perform common purpose. The Self-help groups have been able to mobilize small savings either on weekly or monthly basis from persons who were not expected to have any savings. They have been able to effectively recycle the resources generated among the members for meeting the productive and emergent credit needs of members of the group.

The SHGs are novel and innovative organizational setup in India for the women upliftment and welfare. All women in India are given chance to join any one of SHGs for training and development, so as to be prospective entrepreneur and skilled worker. The SHGs are promoted by the Government as if women in India may not be resourceful enough to be entrepreneurs. When the SHGs arrange training facilities to carry out certain kind of work which are suitable for women in India, bank must arrange financial assistance to carry out manufacturing and trading activities, arranging marketing facilities while the Governments will procure the product of SHGs, arrange for enhancing the capacity of women in terms of leadership quality and arranging for the management of SHGs by themselves so as to have administrative capacity. As a social movement with government support SHGs become more or less a part and parcel of the society.

The Government has been implementing various programmes which support women programmes to take up new venture and start self-employment, which has been categorized under four heads:

- Empowering strategies: Indira Mahila Yojana (IMY) Mahila Samiridhi Yojana MSY: DWCRA.
- Employment and income generation: TRYSEM; Support for Training and Employment Programme (STEP) SGSY, SJSRY, Urban Self Employment Programme (USEP), JRY.
- Welfare and support services: Hostels for Working Women (HWW) Short Stay Homes (SSH), Swadhar Creches/day Care Centres for the Children of Working and Ailing Mothers.

Other enabling measures: Rashtriya Mahila Kosh (RMK), a national level mechanism to meet micro credit needs of poor and asset less women in the informal sector also known as the National Credit Fund for Women (NCFW). The total number of Self Help Groups (SHGs) promoted under National Rural Livelihoods Mission (NRLM) was 1864742 as on 31.03.2014. Their number increased to 2305513 as on 31.07.2015, recording a growth of 440771 SHGs as compared to 31.03.2014. In percentage terms, the progress made in the number of SHGs between 31.03.2014 and 31.07.2015 was 23.64%.

The SHGs have given a new lease of life to the women in villages for their social and economic empowerment. Economic development plays an important role in the development and growth of any society. The importance of promoting women to engage in economic activities is being increasingly realized in all developing countries which has two folds: of to empower the women by bringing them into the mainstream developing and improving their economic status and to provide new employment opportunities by way of income generation, self-employment and entrepreneurship to women for different socio-economic sector.

The constitution of SHGs is sometimes exclusively on particular social groups or a mix. The impact of SHGs on social harmony has also been mixed while it has been observed that the groups with mixed membership had group's leaders that came from a variety of the social groups. SHGs have impact on the community at large. These have been few instances of significant contributing to education, family planning, eradication of child labour and hygiene. The SHGs have helped their members and their communities by taking a leadership role in community development, hence SHG are perceived to be a guiding force for village. The loans that SHG members received are intended to improve their livelihood so that they can receive greater and steadier cash flows.

The concept of Self-help groups had its origin in the co-operative philosophy and the co-operators by and large, including the National Federations in the credit sector, could not think of any better SHG than a primary co-operative credit society itself, as SHG are small and economically homogenous affinity groups of rural poor, they are

Abstract

The study was conducted in Akbarpur block of Kanpur Dehat district selected purposively. A total number of 100 respondents of women SHG were selected purposively which were selected from 20 Villages randomly. The structured schedule was developed keeping in view the objectives and variables under study. The respondents were contacted personally for data collection. The analysis of data was done by using the percentage, mean, standard deviation, and correlation coefficient for drawing the inferences. The data revealed that the maximum number of women SHG respondents *i.e.* (61%) were found in middle age (27-45years).The majority of the categories belonged to scheduled caste, the dominancy of joint family system (55%) was observed. The women SHG members (60%) had medium family size (5 to 7 members) in their families and possess small land holding position. The majority of women SHG members (59%) reported agriculture as their main occupation. respondents 68% were found such who had earning annual income of (Rs. 25001-2750000) and (62%) respondents reported having mixed type house, respectively. The maximum of women SHG members (62%) were found members of one organization, (25%) member of two organizations and (13%) member of more than two organizations or office bearer. The cycle has immersed most important transportation.

Key words: Socio-economic profile and awareness etc.

Introduction

The Self-Help Groups (SHG) is a small voluntary association of poor people, preferably from the same socio-economic background. They come together for the purpose of solving their common problems through self-help and mutual help. The SHG promotes small savings among its members and these savings are kept with a bank. This common fund is in the name of the SHG. The SHG is a group formed by the community which has specific number of members like 15 or 20. Usually, the number of members in one SHG does not exceed twenty. In such a group the poorest would come together for emergency, disaster, social reasons economic support to each other have ease of conversation, social interaction and economic interactions.

A self-help group is defined as a "self-governed, peer-controlled information group of people with similar socio-economic background and having a desire to collectively perform common purpose. The Self-help groups have been able to mobilize small savings either on weekly or monthly basis from persons who were not expected to have any savings. They have been able to effectively recycle the resources generated among the members for meeting the productive and emergent credit needs of members of the group.

The SHGs are novel and innovative organizational setup in India for the women upliftment and welfare. All women in India are given chance to join any one of SHGs for training and development, so as to be prospective entrepreneur and skilled worker. The SHGs are promoted by the Government as if women in India may not be resourceful enough to be entrepreneurs. When the SHGs arrange training facilities to carry out certain kind of work which are suitable for women in India, bank must arrange financial assistance to carry out manufacturing and trading activities, arranging marketing facilities while the Governments will procure the product of SHGs, arrange for enhancing the capacity of women in terms of leadership quality and arranging for the management of SHGs by themselves so as to have administrative capacity. As a social movement with government support SHGs become more or less a part and parcel of the society.

The Government has been implementing various programmes which support women programmes to take up new venture and start self-employment, which has been categorized under four heads:

- Empowering strategies: Indira Mahila Yojana (IMY) Mahila Samiridhi Yojana MSY: DWCRA.
- Employment and income generation: TRYSEM; Support for Training and Employment Programme (STEP) SGSY, SJSRY, Urban Self Employment Programme (USEP), JRY.
- Welfare and support services: Hostels for Working Women (HWW) Short Stay Homes (SSH), Swadhar Creches/day Care Centres for the Children of Working and Ailing Mothers.

Other enabling measures: Rashtriya Mahila Kosh (RMK), a national level mechanism to meet micro credit needs of poor and asset less women in the informal sector also known as the National Credit Fund for Women (NCFW). The total number of Self Help Groups (SHGs) promoted under National Rural Livelihoods Mission (NRLM) was 1864742 as on 31.03.2014. Their number increased to 2305513 as on 31.07.2015, recording a growth of 440771 SHGs as compared to 31.03.2014. In percentage terms, the progress made in the number of SHGs between 31.03.2014 and 31.07.2015 was 23.64%.

The SHGs have given a new lease of life to the women in villages for their social and economic empowerment. Economic development plays an important role in the development and growth of any society. The importance of promoting women to engage in economic activities is being increasingly realized in all developing countries which has two folds: of to empower the women by bringing them into the mainstream developing and improving their economic status and to provide new employment opportunities by way of income generation, self-employment and entrepreneurship to women for different socio-economic sector.

The constitution of SHGs is sometimes exclusively on particular social groups or a mix. The impact of SHGs on social harmony has also been mixed while it has been observed that the groups with mixed membership had group's leaders that came from a variety of the social groups. SHGs have impact on the community at large. These have been few instances of significant contributing to education, family planning, eradication of child labour and hygiene. The SHGs have helped their members and their communities by taking a leadership role in community development, hence SHG are perceived to be a guiding force for village. The loans that SHG members received are intended to improve their livelihood so that they can receive greater and steadier cash flows.

The concept of Self-help groups had its origin in the co-operative philosophy and the co-operators by and large, including the National Federations in the credit sector, could not think of any better SHG than a primary co-operative credit society itself, as SHG are small and economically homogenous affinity groups of rural poor, they are voluntarily coming together for achieving the: (1) To save small amount of money regularly (2) To mutually agree to contribute a common fund (3) To meet their emergency needs (4) To have collective decision making (5) To solve conflicts through collective leadership mutual discussion and (6) To provide collateral free loan with terms decided by the group at the market driven rates.

The SHG is a group of rural poor who have volunteered to organize themselves into a group for eradication of poverty of the members. The basic principles of the SHGs are group approach, mutual trust, organization of small and manageable groups, group cohesiveness, spirit of thrift, demand-based lending, collateral free, Women friendly loan, peer group pressure in repayment, skill training capacity building

Effect of herbicides on weed control efficiency (%), yield attributes, yield and profitability of wheat (*Triticum aestivum* L.)

Rajesh Kumar, Vishuddha Nand, SK Verma, RK Doharey, Anjali Kumari and Raju

Abstract
A field experiment entitled "Evaluation of herbicide for control of complex weed flora in wheat (*Triticum aestivum* L.)" was conducted at Crop Research Station, Masodha (U.P.) during *Rabi* season of 2011-12 and 2012-13 with an objective to evaluate the herbicide against grassy and broad leaved weeds. To find out the effect of weed control on weeds, yield of wheat and to find out the economics of various treatment combinations. The soil of the experimental field was silt loam, having pH 7.6, organic carbon 0.42, available N, P and K 145, 17.5 and 224 kg ha^{-1}, respectively. Field trial was laid out in RBD with three replication, having fourteen treatments viz. Metribuzin 210 g ha^{-1}, Clodinafop 60 g ha^{-1}, Pinoxaden 40 g ha^{-1}, Sulfosulfuron 25 g ha^{-1}, Clodinafop + Metribuzin 60 + 210 g ha^{-1}, Pinoxaden + Metribuzin 40 + 210 g ha^{-1}, Sulfosulfuron + Metribuzin 25 + 210 g ha^{-1}, Accord Plus (Fenoxaprop+Metribuzin) (120+210 gha^{-1}) 1500 ml ha^{-1},Total (Sulfosulfuron + Metsulfuron) (32 g ha^{-1},) 40 g ha^{-1}, Atlantis (Mesosulfuron + Iodosulfuron) (14.4 g ha^{-1}) 400 g ha^{-1}, Vesta (Clodinafop + Metsulfuron) (60+4 g ha^{-1}) 400 g ha^{-1} and Isoproturon + 2,4-D 1000+500 g ha^{-1}, weed free and weedy check. The herbicides treatment were executed at 35 DAS with the help of manually operated knapsack sprayer fitted with flat fan nozzle. The minimum weed dry weight and maximum WCE(88.76%) were recorded with with Vesta (Clodinafop + Metsulfuron) (60+4 g ha^{-1}) 400 g ha^{-1} which was at par with Tota l(Sulfosulfuron + Metsulfuron) (32 g ha^{-1},) 40 g ha^{-1}, and significantly better for effective weed control as compared to rest of the herbicidal treatment. All the yield contributing characters viz., no. of spike m^{-2}, no. of grain $spike^{-1}$, 1000-grain weight as well as grain yields were significantly higher in weed free over rest of the treatments. Among herbicides maximum no. of spike m^{-2} (437.85) no. of grain (40.12)$spike^{-1}$, 1000-grain weight (37.33g) as well as grain yields (52.81q/ha.) were recorded with Vesta (Clodinafop + Metsulfuron) (60+4 g ha^{-1}) 400 g ha^{-1} With respect to economics, Vesta (Clodinafop + Metsulfuron) (60+4 g ha^{-1}) 400 g ha^{-1} recorded maximum net return (Rs. 59895) and B-C ratio (Rs. 2.43).

Keywords: wheat, herbicides, weed dry weight, yield attributes, yield

Introduction
Wheat is an important prime cereal crop among the food-grain is grown in an area of 29.65 m ha in India, with the production 93.5 million tonnes and average productivity 31.53 q ha^{-1} (FAO, 2013). There are a number of factors responsible for lower productivity of wheat crop as compared to certain developed countries. Biotic as well as the abiotic factors are also posing serious threats in realizing the full potential. Among the abiotic factors, the global warming consequently increase in the temperature at milking stage of the crop is the major threat affecting the productivity adversely. Wheat crop is infested with a number of weeds namely *Phalaris minor, Cyperus rotundus, Cynodon dactylon, Chenopodium album, Anagallis arvensis, Avena fatua, Convolvulus arvensis* etc which can cause upto 33% reduction in wheat yield. *Phalaris minor* is one of the very serious problems in wheat. Significant reduction in wheat yield due to severe infestation of weeds ranging from 18-73% has been reported by Pandey and Verma (2004) [8]. However, some broad leaf weeds are also causing a threat but their control is comparatively easier and effective as compared to that of *Phalaris minor*, really serious challenge. The wild oat reduce grain yield of winter wheat by 17-62% depending upon cultivars.

There are several options like manual weeding and herbicidal application, available for the efficient management of weeds applied before sowing and successive crop growth stages. 2, 4-D is a stage specific herbicide and even tolerant cereal crops are very sensitive to 2, 4-D when applied at germination and seedling stages resulting in malformation of the spikes (Gill & Walia, 1987). Wheat found most sensitive to 2, 4-D applied at the 3 leaf to early tillering stags and most tolerant at the 4th to 5th leaf stages (Voevodim *et al.*, 1975)[11].

KNOWLEDGE LEVEL OF OKRA GROWERS WITH RESPECT TO SCIENTIFIC PRODUCTION TECHNOLOGY IN KANNAUJ DISTRICT (U.P.)

R.K. Doharey[1], Kamal Kishore[2], Prakash Singh[3], Shalu Gutam[4],
[1,2,3&4]Department of Extension Education, College of Agriculture, NDUA&T., Kumarganj, Ayodhya(U.P.)- 224229

Abstract

The study was conducted in Chhibramau and Talgram blocks of Kannauj district (UP) selected purposively, because these blocks one more popular for area and production of okra. A total number of okra growers were selected through random sampling from eight selected village's panchayats on the basis of ten respondents from each selected village panchayats. The some structured schedule was developed keeping in view the objectives and variables under study. The respondents were contacted personally for data collection. The results of the study depicted that the majority of the respondents were found in knowledge level field preparation (96%) were rank at 1st as far as knowledge possessed by the respondents were concerned. The insect/pest rank at 2nd rank (94%), followed by seed rate at rank 3rd (93.%), method of sowing of okra at 4th rank (92%),intercropping and weed management time of 5th (91.05%), suitable variety at rank 6th (90%), crop rotation at rank 7th (87%), irrigation management at rank 8th (86%), manure and fertilizer 9th (77%), disease control at rank 10th (73.75%), seed treatment rank 11th (61%), distance at rank 12th (58%), time of treatment 13th (51%), harvest and postharvest at rank 14th (37.05%) respectively. The overall knowledge index was calculated to be 77.62%. It can be calculated that the extent of knowledge about scientific okra cultivation seems to be satisfactory.

Key words : Knowledge level of okra growers with respect to scientific production technology.

Introduction

Indian subcontinent is endowed with favorable climate which permits growing of vegetables throughout the year. Vegetables play an important role in balanced nutrition as they are valuable source of carbohydrates, proteins, vitamins and minerals. The Per capita consumption of the vegetables in India is 160 g per day per person as against recommendation of 300 g per day per person. According to these statistics, we need to produce approximately 0.3 MT of vegetables per day for the present population. The present earning through vegetables export is little bit exceeding to Rs. 300 crores. Nature has endowed our country with vast diversity of land, soil and agro-climatic conditions which enables to produce varied types of vegetable crops. The area and production of vegetables are increasing year after year after the green revolution. There is substantial increase in production and productivityof vegetable crops. Due to growing of improved hybrid varieties and adoption of improved cultivation technologies, India"s share in the world production of vegetables is about 7 per cent (Anonymous, 1999).

Okra or ladies finger is an important vegetable of the tropical countries and most popular in India, Nigeria, Sudan, Iraq, Pakistan, etc. Okra is found in it's wild state on the alluvial banks of the Nile and the Egyptians were the first to cultivate it in the basin of the Nile (12'th century BC). It was propagated then through North Africa to the Mediterranean, the Balkans, and India. It arrived then in the America at Brazil (1658), Dutch Guinea and at New Orleans before extending in the United States and going up to Philadelphia in 1781. Its scientific name is "Abelmoschus esculents" and also "Hibiscus esculents", it belongs to the family Malvaceae. It is a tropical plant, 15 which grows best in warmer climates. It"s ready to harvest in around 60 days when the blooms begin to open, and is slightly tough. They have to be picked about 4-5 days after flowering in the fall. Okra varies in shades of green and can be smooth or has ribbed surfaces. (Varmudy, 2010).

Area and production of okra in India is 452,000 ha. and 4,803,000 MT. in Nigeria 387,000 ha. and 1,039,000 MT. and in Sudan 21,926 ha. and 223,650 MT. Here the share of India is 67.1 per cent, followed by Nigeria at 15.4 per cent and Sudan at 9.3 per cent. (FAO, 2010). In India, okra is grown throughout except in the mountain regions. The major producers are West Bengal, Bihar, Orissa, Andhra Pradesh and Gujarat. As far as area under okra cultivation in India is concerned, Orissa has an area of 74 thousand ha, West Bengal has an area of 73.1 thousand ha under okra cultivation followed by Gujarat, Andhra Pradesh, Jharkhand and others states. In terms of okra production, it is 0.83 million tones in West Bengal, 0.65 million tones in Orissa and 0.43 million tonnes in Andhra Pradesh. The average productivity in India is 10.5 tones per hectare. The highest productivity is in Andhra Pradesh at 15 tones per hectare followed by Jharkhand at 14 tons per hectare. The total area under this crop has increased over the years.

We eat food for good growth of our body. The food we eat contains nourishing substances called nutrients. There are five major nutrients, namely carbohydrates, proteins, fats, minerals and vitamins. It has an average nutritive value of 3.21 gm, which is higher than tomato, pumpkin and ashgourd. It contains 27 gm of carbohydrates, 2.2 gm of proteins, 0.29 gm of fat, 90 mg of calcium, 50 mg of phosphorus, 15 mg of iron and 6 mg of vitamin C per 100 gm of edible portion. The seeds contain 18-20 per cent oil and 20-23 per cent crude protein. Soups and stews of okra are popular dishes in India. The seeds, when ripe are sometimes roasted and used as a substitute for coffee. The roots and stems of okra are used for clarification of sugarcane juice before it is converted into jiggery and brown sugar. The crop is used in the paper industry and fiber is extracted from its stem. Okra is considered by many as a super-vegetable with a lot of nutrition and medicinal benefits. Fibre also helps in stabilizing blood sugar. The mucilage not only binds cholesterol but also the bile acid carrying toxins dumped into it by the liver. Its fiber absorbs water and helps to prevent constipation. In fact, its slippery characteristics, which people dislike, facilitates elimination of excess cholesterol and toxins from the body.

There is many medicinal importance of okra; (i) The tender fruit is boiled and administered in fevers, gastric ulcers, catarrh, inflammation of the mucous membrane, difficulty in urination and dysentery. (ii) It is also considered remedy for spermatorrhea (involuntary discharge of the semen), syphilis, gonorrhea, and other disorders of the genitals. (iii) The fruit is also reported to increase sexual potency. (iv) The unripe fruit is eaten for tuberculosis of the lungs. (v) The infusion of the seeds will induce perspiration etc.

Okra can be grown in a wide range of soils – sandy loams to clay loams, provided they are well drained and supplied with enough organic matter. Main Okra growing season is Kharif (rainy season) June-July. However, it can be grown in September-October, January-February and also in summer season, where assured irrigation facilities are available (www.indiaagronet.com). Out of 137.00 lakh hectares geographical area of Chhattisgarh, 43 per cent area comes under cultivation. On the basis of climate and topography the state is divided into three agro climatic zones i.e. Chhattisgarh plains, Northern hills and Bastar Plateau. Horticulture exports has helps the country to earn 14,000 crore tones in the year of 2011-2012. Indian horticulture has crossed of production all time of over 240 million tones in the year of 2011-2012.

Keeping this in view, the present research entitled "To study the knowledge level of okra growers with scientific production technology"

Materials and Methods

Maize is one of the most important cereal crops in the world agricultural economy both as food for man and feed for animals including poultry. It is also known as "queen of cereals'' because of very high yield potential, it is giving low yields because of lack of appropriate information about plant geometry and fertilizer management. Nitrogen, phosphorus and potassium are the major plant nutrients, which limit normal plant growth. Increasing productivity per unit area through agronomic management is one of the important strategies to increase the production of maize grain. Keeping this in view, various experiments were have been carried out on the effect of plant geometry and different dose of various inorganic fertilizers have seen very widely on hybrid and composite variety of maize in winter season. The information available on growth parameters *viz*, plant height, no of leaves/plant, LAI, dry weight/plant, CGR, RGR and NAR at various stages of crop growth as affected by varieties of maize and plant geometry and in conjunction with nitrogen, phosphorus, potash and zinc is also reviewed.

Keywords

Maize, hybrid, composite, plant geometry, growth, NPK and Zn and yield

Introduction

Maize (*Zea mays* L.) is one of the most versatile emerging crops having wider adaptability under varied agro-climatic conditions. Globally, maize is known as queen of cereals because it has the highest genetic yield potential among the cereals. It is cultivated on nearly 150 m ha in about 160 countries having wider diversity of soil, climate, biodiversity and management practices that contributes 36 % (782 m t) in the global grain production. The United States of America (USA) is the largest producer of maize contributes nearly 35 % of the total production in the world and maize is the driver of the US economy. The USA has the highest productivity (> 9.6 t ha-1) which is double than the global average (4.92 t ha-1). Whereas, the average productivity in India is 2.43 t ha^{-1}.

It is also one of the most important cereal crops in the world agricultural economy both as food for man and feed for animals including poultry. Green cobs are roasted and consumed by people with great interest. The grains of special variety called the 'popcorn', are characterized by a hard corneous interior structure are converted into the 'popped' form, which is the favourite food for children in urban areas. Several food dishes including *chapaties*are prepared out of maize flours and grains. It is

Effect of fertilizers and cutting schedule on growth and quality of dual purpose barley crop (*Hordeum vulgare* L.)

Vishuddha Nand, R Yadav, Rajesh Kumar, RK Doharey, SK Verma, Neeraj Yadav and RK Yadav

Abstract
A field experiment was carried out at Agronomy Research Farm,Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.) during Rabi season 2016-17.The experiment was laid out in Split Plot Design with three replications. Main plot were treated with fertilizer levels, F_1 (60 kg N+ 30kg P_2O_5 ha^{-1}), F_2(80 kg N+40 kg P_2O_5 ha^{-1}), F_3 (100 kg N+50 kg P_2O_5 ha^{-1}) and F_4 (120 kg N+60 kg P_2O_5 ha^{-1}) and sub plot were treated with cutting schedule as 45 DAS, 55 DAS, 65 DAS and 75 DAS. The results revealed that the growth parameters like, plant height, dry weight of plant, leaf area index (LAI) and no. of tillers at first cutting and at harvest were recorded maximum with the application of 120 kg N + 60 kg P_2O_5 ha^{-1} followed by 100 kg N + 50 kg P_2O_5 kg ha^{-1} and 80 kg N + 40 kg P_2O_5 ha^{-1} respectively and significantly higher over the application of 60 kg N +30 kg P_2O_5 ha^{-1}. The maximum plant height (77.28 cm) was recorded when barley crop cut as 75 DAS which was higher tune to the 12.6%, 17.57% and 32.51% over 65, 55 and 45 days after sowing. The dry matter accumulation, leaf area index and no. of tillers were also maximum in the same cutting. However, the quality parameters *viz*, crude protein (12.88%), crude fiber (31.87%),TDN (65.93%), WSC(10.40%), ADF (31.34%), NDF (52.49%) and Ash (13.34%) were recorded maximum with the application of 120 kg N + 60 kg P_2O_5 ha^{-1} while in case of cutting schedule the maximum crude fiber (31.49%), WSC (10.80%), ADF (33.58%), NDF (54.02%) and Ash (15.20%) were found at first cut (75 DAS) where as crude protein (13.13%) and TDN (65%) obtained at first cut (45 DAS).

Introduction
India is the largest milk producing country in the world with livestock population of 529 million and milk production 133 mt. It contributes nearly 7% in the global cereal production. Barley grain largest use as animal feed in all over the world and in India also, a major share of barley grain is used as animal feed either alone or mixture with fodder crops. Barley has tremendous potential and variation for production of very high amount of digestible dry matter as well as protein yield per hectare. It is grown successfully in a wider range of climatic conditions than any other cereals. Barley has such morpho-physiological traits that make it suitable for dual purpose cultivation for fodder and grain production than other cereals. It is highly efficient in the utilization of water and nutrients in limiting conditions. It is high capacity of crop for tillering and regenerate after cutting and additional capacity for large accumulation of biomass. It sets seed rapidly after re-growth, thus escaping terminal stress due to high temperature and warm winds often experienced in the region. Thus, as a dual purpose (green forage and feed/grain) crop it provides a welcome boost to the confidence of forage growers and fits well for crop diversification in the integrated crop+livestock farming system. Area under barley in world is 47.5 mha with 123.7 mt production and 2.68 t/ha Productivity. Russian federation holds first position in all over the world in terms of area and production with 4.94 mha and 8.35 mt respectively.

In India, barley crop was grown over an area of 695.0 thousand hectare with a production of 1743.2 thousand tones and productivity of 2.51 t ha^{-1} during 2012-13 (Anonymous, 2013) [1]. Uttar Pradesh is one of the most important barley growing states of India. In Uttar Pradesh, the area under cultivation of barley is about 168.0 thousand ha^{-1} with a production of 441.0 thousand tonnes and productivity of 2.63 t ha^{-1} (Anonymous, 2013) [1]. Dual purpose barley is an excellent alternate crop for fodder purpose. The nutritive value of green fodder is highest at 50% flowering stage and decreases after flowering stage in most of the crops. In dual purpose barley crop, stage of harvesting also determine the regenerative potential of the crop, the regeneration capacity is adversely affected by the higher stage of harvesting for green fodder.

Abstract

The study was under taken in two parts of Uttar Pradesh state *i.e.* Eastern and Western. From Eastern part the district Faizabad and Western part the district Bulandshahar were selected purposively. A total number of 100 dairy farmers (50 from Faizabad and 50 from Bulandshahar) were selected through proportionate random sampling from four sampled villages on the basis of herd size. The interview schedule was developed keeping in view the objectives & variables under study. Finding that both the farmers i.e. Eastern district Faizabad and Western district bulandshahar had cell phone (98.33% & 98.33%), followed by mobile (94% & 96%), T.V. (74% & 88%), respectively. It may be, therefore, concluded that the position of communication media possession of Faizabad dairy farmers was found to be better as compared to bulandshahar dairy farmers. No social participation reported by Faizabad dairy farmers (32%) and the bulandshahar dairy farmers (12%).

Introduction

The Government of India has launched several rural development programme time to time since independence. One such progarmme was launched during seventies was the Integrated Rural Development Programme (IRDP). IRDP as a centrally sponsored scheme aims to provide financial assistance to poorer sections of society in form of subsidies and loans to economically beneficial activities, which could generate sufficient income for enable them to cross the poverty line.

In spite of India's position as highest producer of milk, productivity per animal is very poor. It is only about 987 kg/lactation as against world average of 2,038 kg/ lactation. The low productivity is due to the gradual genetic deterioration and neglecting of animals rearing over the centuries consequently due to the rise in the population of non-descriptive cows (80%) and buffaloes (50%). Other factors contributing to low productivity include continuing draughts in some parts of the country, chronic shortages of feed & fodder coupled with their poor nutritive value and poor fertility of dairy animals. Hence, we have to face a twin challenge :

Increase milk productivity of animals with the limited resources on one hand and make best use of the available milk by processing it into hygienic packaged milk and milk products of high quality on other hard. The average milk production of indigenous cattle in the country is hardly 500 kg/lactation. This is partly due to poor feeding. These animals, if properly fed, will definitely produce better milk production. Even the programme of producing large number of cross-breed in cows with quality of high yield potential must also be supported by balanced and economic feeding practices for optimum milk production.

Cattle is believed to be the first step of the primitive man toward civilization. Livestock has played a crucial role in the development and progress of mankind. They have provided human beings with food, energy, clothing and nutrition besides helping in transport and agricultural activities. They have also been mute companions to humans. Today, cattle rearing has become a subsidiary vocation for many house hold generating additional

Effect of leaf colour chart based nitrogen management on growth and uptake of rice (*Oryza sativa* L.) cultivar in eastern Uttar Pradesh

Anil Kumar, Vishuddha Nand, Rajesh Kumar, RK Doharey, MP Singh and SK Verma

Abstract
N urea +LCC<3, 25%N FYM +LCC<4, 25%N urea +LCC<4, 25%N FYM +LCC<5, 25%N urea +LCC<5, along with the recommended dose of NPK (150:60:40 kg/ha) were taken for study. The growth parameters likes, plant height (123.66, 121.14cm), number of shoots (528.25, 523.67), dry matter (842.81, 831.67 g), and Leaf area index (7.14, 6.62) were maximum recorded in PA-6444 which was significantly higher over PHB-71 and NDR-359, respectively. While, PA-6444 recorded highest nitrogen, phosphorus and potassium uptake by grain, straw and total which was significantly higher over the both variety PHB-71 and NDR-359.Among nitrogen levels, 25% N urea +LCC<5 was recorded highest nitrogen, phosphorus and potassium uptake by grain, straw and total. The maximum grain yield was obtained with rice cultivar PA-6444 (65.92-64.51 q/ha) which was superior over NDR-359 (59.01-55.99 q/ha) and at with par PHB-71 (63.85-63.30 q/ha). Among the LCC nitrogen based management. The highest biological yield was recorded under 25% N basal as Urea + LCC<5 which was significantly superior over rest of treatments.

Introduction
Rice is the bulk of food security of the global population. In 21st century there will be the need of about 250 million tons of food grains to feed the rapidly increasing population. To meet this challenge, intensive cropping pattern were adopted which resulted in decline nutrient status of soil. There is an indication of stagnation on even declining in the production of rice crop; this may be due to decline organic matter, over mining of nutrients reserve, indiscriminate and imbalanced use of chemical fertilizers and continuous mono cropping. Since, fertilizer N losses are estimated to range from 10-65% of the applied N (Cassman *et al.* 1998; Singh & Singh, 2003) [13, 1]. Hence, its management strategies must be responsive to temporal variations in crop N demands and soil N supply in order to achieve supply-demand synchrony for minimizing N losses. When N application is not synchronized with crop N demand, N losses from the soil–plant system are large, leading to low N fertilizer use efficiency. In many field situations, more than 60% of applied N is lost because of the lack of synchrony of plant demand with N supply (Singh and Singh, 2003) [1]. Peng *et al.* (1998) [13] demonstrated that RE (Recovery efficiency) of top dressed urea during panicle initiation stage could be as high as 78%. Hence, plant need-based application of N is important for achieving high yield and high N use efficiency. Improving the synchrony between crop N demand and the N supply from soil and/or the applied N fertilizer is likely to be the most promising strategy to increase nitrogen use efficiency in rice. Current fertilizer recommendations for rice in most rice growing countries of Asia typically consist of fixed rate and timing on a regional scale. Most of the farmers generally apply fertilizer N in several split applications, but the number of splits, amount of N applied per split, and the time of applications vary substantially.
The apparent flexibility of rice farmers in adjusting the time and amount of fertilizer application offers potential to synchronize N application with the real-time demand of the rice crop. Due to enormous farm to- farm variability in soil N supply, blanket recommendations for fertilizer N application for a large region generally lead to low NUE. To avoid the risk of N deficiency, many time farmers apply fertilizer N in excess, which also leads to low N recovery by rice. Real-time N management strategies aim at meeting fertilizer N supply with actual crop

ABSTRACT

An experiment was conducted at Crop Research Center of Sardar Vallabhbhai Patel University of Agriculture & Technology, Meerut, Uttar Pradesh during Rabi seasons of 2012-13 and 2013-14 to assess the effect of seed rate and weed management practices on yield attribute and yield of late sown wheat (*Triticum aestivum* L.). The treatment consisted of three seed rate 100,125 and 150 kg ha^{-1} in main plot and six weed management practices *viz*. Sulfosulfuron 25 g ha^{-1}, Sulfosulfuron + Metsulfuron (30 + 2 g ha^{-1}), Clodinafop + Metsulfuron (60 + 4 g ha^{-1}), Fenoxaprop-p-ethyl + Metribuzin (120 + 210 g ha^{-1}), two hand weeding (120 and 40 DAS) and weedy check in sub-plots. The experiment was laid out in split plot design with three replications. Maximum number of spike m^{-2} was recorded at 150 kg ha^{-1} seed rate was significantly higher than 100 and 125 kg ha^{-1} seed rate. Other yield contributing characters like spike length, number of spikelets spike^{-1}, number of grain spike^{-1} and weight of 1000 grains were not influenced considerably, 100 kg ha^{-1} seed rate registered higher value of above yield contributing characters than 125 and 150 kg ha^{-1} seed rate. All weed management practices produced significantly higher no. of spike per unit area, no. of spikelets spike^{-1} and no. of grain spike^{-1} over weedy check while test weight and length of spike was found non-significant but numerically higher with weed management practices over weedy check. Two hand weeding produce maximum no. of spike m^{-2}, no. of spikelets spike^{-1} and no. of grain spike^{-1} which was at par with clodinofop + metsulfuron (60 + 4 g ha^{-1}) and sulfosulfuron + metsulfuron (30 + 2 g ha^{-1}. A seed rate of 150 kg ha^{-1} produced significantly higher grain, straw and biological yield than its lower level of 100 and 125 kg ha^{-1} seed rates. All weed management practices exception of fenoxaprop-p-ethyl + metribuzin (120 + 210 g ha^{-1}) had significant effect on grain, straw and biological yield, two hand weeding produce maximum grain, straw and biological yield which was at par with clodinofop + metsulfuron (60 + 4 g ha^{-1}) and sulfosulfuron + metsulfuron (30 + 2 g ha^{-1}). Fenoxaprop-p-ethyl + Metribuzin (120 + 210 g ha^{-1}) had Phytotoxic effect on wheat plants and produce minimum yield which was at par with weedy check.

Introduction

Wheat is an important prime cereal crop among the food-grain is grown in an area of 29.65 m ha in India, with the production 93.5 million tonnes and average productivity 31.53 q ha^{-1} (FAO, 2013). Among several causes of low productivity in Uttar Pradesh,

Effect of seed rate and weed management practices on growth parameters and dry matter accumulation of late sown wheat (*Triticum aestivum* L.)

Rajesh Kumar, Vishuddha Nand, RK Doharey, Sanjay Kumar Verma and Raju

Abstract
An experiment was conducted at Crop Research Center of Sardar Vallabhbhai Patel University of Agriculture & Technology, Meerut, Uttar Pradesh during Rabi seasons of 2012-13 and 2013-14 to assess the effect of seed rate and weed management practices on growth parameters and dry matter accumulation of late sown wheat (*Triticum aestivum* L.). The treatment consisted of three seed rate 100,125 and 150kg ha^{-1} in main plot and six weed management practices viz. Sulfosulfuron 25 g ha^{-1}, Sulfosulfuron + Metsulfuron (30 + 2 g ha^{-1}), Clodinafop + Metsulfuron (60 + 4 g ha^{-1}), Fenoxaprop-p-ethyl + Metribuzin (120 + 210 g ha^{-1}), two hand weeding (120 and 40 DAS) and weedy check in sub-plots. The experiment was laid out in split plot design with three replications. Sowing with 150 kg ha^{-1} seed rate recorded maximum germination count at 15 DAS, number of tillers/m^1 row length, Plant height, leaf area index (LAI), and dry matter accumulation which were significantly higher than 100 and 125 kg ha^{-1} seed rate. Germination count of wheat at 15 DAS was almost similar under all the weed management practices. At 30 DAS two hand weeding produce significantly higher number of tillers m^{-1} row length and plant height than rest of the weed management practices, while LAI and dry matter accumulation was non-significant. At 60, 90 DAS and at harvest number of tillers, Plant height, LAI and dry matter accumulation recorded maximum with two hand weeding which was at par with Clodinafop + Metsulfuron (60 + 4 g ha^{-1}), Sulfosulfuron + Metsulfuron (30 + 2 g ha^{-1}), Sulfosulfuron 25 g ha^{-1} and significantly higher than Fenoxaprop-p-ethyl + Metribuzin (120 + 210 g ha^{-1}) and weedy check. Fenoxaprop-p-ethyl + Metribuzin (120 + 210 g ha^{-1}) had Phytotoxic effect on wheat plants was produce minimum number of tillers, plant height, leaf area index and dry matter accumulation at all the stages of observation taken which was at par with weedy check.

Keywords: seed rate, herbicide, LAI, growth character's and Dry weight

Introduction
Wheat is an important prime cereal crop among the food-grain is grown in an area of 29.65 m ha in India, with the production 93.5 million tonnes and average productivity 31.53 q ha^{-1} (FAO, 2013) [4]. Among several causes of low productivity in Uttar Pradesh, adoption of rice-wheat rotation is one. Late transplanting of rice or use of long duration varieties in low land fields delays the sowing of wheat. The preceding crop like sugarcane, potato, paddy and toria etc. vacate the field late in season after normal sowing date of wheat and other factors enforce the crop be sown as much late as in the end of December and beginning of January. Late sown crop experiences high temperature, declining relative humidity and hot dissecting winds in later stage of crop growth, particularly during grain filling stage. Yield potential and productivity of wheat under late sown condition is poor due to less exploitation of potentialities of the crop. Emergence of seedling due to low temperature curtailing the periods from emergence to maturity in late sown condition optimum plant population can be maintain by optimum seed rate (Singh and Singh, 1987) [17]. Late sowing of wheat tends to reduce germination count due to low temperature at germination and tillers $unit^{-1}$ area because of rise in temperature during tillering phase of the crop and consequently increase in the temperature at milking stage of the crop is the major threat affecting the productivity adversely. To mitigate the deleterious effect of delayed sowing, increasing seed rate will be a viable and economic option to compensate the reduction germination count and number of tillers per unit area. Seed

Study about the interaction effects on varieties and plant geometry on growth and yield of hybrid and composite maize (*Zea mays* L.) on *rabi* season

Vishuddha Nand, Rajesh Kumar, RK Doharey, MP Singh and SK Verma

Abstract
An experiment was conducted at Agronomy research Farm of C.S.A University of Agriculture and Technology, Kanpur (U. P), during winter season in 2010-11 and 2011-12. The experiment was laid out in split plot design with three replications. The main plots were occupied by maize hybrid (cv DHM-117) and composite (cv Madhuri) along with three plant geometry, 45cm x 20 cm (1,11,111 plants/ha), 60cm x 20 cm (83,3,33 plants/ha) and 60cm x 25 cm (66,6,66 plants/ha) and sub plot was allotted by three fertility levels *viz*, F_1- N, 120 kg, P_2O_5, 60 kg, K_2O, 40 kg and $ZnSo_4$, 15 $kgha^{-1}$, F_2 - N, 150 kg, P_2O_5, 80 kg, K_2O, 60 kg and $ZnSo_4$, 20 $kgha^{-1}$ and F_3 - N, 180 kg, P_2O_5, 100 kg, K_2O, 80 kg and $ZnSo_4$, 25 $kgha^{-1}$. The experiment results revealed that all the growth and yield parameters like plant height (cm), number of leaves/plant, dry weight (g/m^2) and leaf area index (LAI), maize grain and stover yield (t/ha) and harvest index % (HI%) at harvest stage were found significant interaction between varieties and plant geometry. The maize hybrid was found better than Composite in among parameters. Plant geometry 60cm x 20cm was obtained significantly maximum yield (6.7 t/ha) compared to plant geometry 45cm x 20cm (6.20 t/ha), 60cm x 25cm (6.15 t/ha), respectively. In various fertility levels F_3 was found superior followed by F_2 and F_3 treatments, respectively. While the harvest index (%) and Shelling (%) were did't found significant in among the treatments.

Keywords: Maize, plant geometry, interaction, NPK and Zn, LAI, HI%, yield

Introduction
Maize (*Zea mays* L.) is one of the important cereal crops next to wheat and rice in the world. In India, it ranks third after rice and wheat. Maize is being consumed both as food and fodder and also required by the various industries. In the world, it is grown over an area of 131 mha with an annual production of 506 mt with productivity of 3890 kg ha^{-1} (Anonymous, 2013-14) [2]. In India, it is cultivated over an area of 9.3 mha with an annual production of 24.2 mt and productivity of 2602 kg /ha during *rabi* season (Anonymous, 2013-14) [2]. In Uttar Pradesh, the area, production and productivity of maize were 0.70 m ha, 2.30 mt, 3131 kg/ha, respectively (Anonymous, 2012-13). In India, about 35 per cent of the maize produced, which 60 per cent is used for human consumption, 25 per cent each in poultry feed and cattle feed and 15 per cent in food processing like corn flakes, popcorn *etc.* and in other industries mainly starch, dextrose, corn syrup and corn oil *etc.* Maize yield is closely related to plant population. More plants mean higher yield. However, there is limitation to increasing plant population under humid, tropical conditions. Maize becomes more susceptible to pests and diseases when temperature, rainfall, and humidity are high. The number of plants per unit area is influenced by the distance between row and distance between plants in row. Select an optimum plant spacing that allows for ease of the field operations, such a fertilizer application and weeding, minimizes competition among plants for light, water and nutrients and creates a favorable micro-climate for the canopy that reduced the risk for pests and diseases. Narrow row width of about 50 to 70 cm is recommended to ensure that sunlight falls on the plants and not on bare soil. This reduced weed competition and loss of soil moisture from evaporation. Maize is one of the most important cereal crops grown in tropical and temperate region of the world. Despite its high yield potential, it is giving low yields because of lack of appropriate information on varieties, plant geometry and fertilizer management. Nitrogen, phosphorus and potassium are the major plant nutrients, which limit normal plant growth increasing productivity per unit area through inorganic management is one of the important strategies to increasing the production of maize grain.

Extent of Knowledge and Adoption of Potato Growers in Kannauj District of Uttar Pradesh

Ashwani Kumar Verma[1], R.K.Doharey[2], S. K. Dubey[3], Satyapriya[4], Sitaram Bishnoi[5], Om Prakash[6] and Kaushik Prashad[7]

ABSTRACT

Potato is the most important stable and widely distributed food crop in the world with a capacity to slake off hunger among farmers. However, the productivity has stagnated and remained low due to the adoption of poor cultivation practices by farmers. To stave off this situation, better technologies and practices should be prioritized which already exists. In Uttar Pradesh, Kannauj district is anabundant producer of the potato crop. To assess the adoption level and knowledge gap of scientific potato cultivation practices the study was conducted in Jalalabad block of Kannauj district of Uttar Pradesh. A simple random sampling method was used to select 125 respondents out of total 1338 potato growers from the selected five villages. The finding revealed that the majority of the respondents have 100 per cent knowledge in mixed cropping, sequence cropping, and field preparation. There is a huge variation among the cultivation practices in respect of their adoption, the highest being 82.40 per cent for sequence cropping and the lowest 50.40 per cent for seed rate and seed treatment with the overall adoption of 68.30 per cent. Out of 16 independent variables four variable age, marital status, family type, and occupation were not significant but positively correlated with knowledge level. Only one variable education was found highly significant and positively correlated with adoption level.

Key words: Extent of adoption, level of knowledge, potato growers, scientific practices.

INTRODUCTION

Potato *(Solanumtuberosum L.)* is one of the major vegetable crops of the world. In India, it is cultivated during winter season in the plains and on hills during summer season. Its productivity is affected by both environmental factors and crop management practices. It also varies considerably between the regions, between areas with the region and with cultivation practices even at high fertility level.

Among the food crops, potato ranks fourth in importance next only to rice, wheat and maize, covering an area of 21.64 million hectares and fifth in production, yielding 46545.6 million tonnes annually after sugarcane, rice and maize (Annual Report 2016-17, GOI.) (Table1).

Table 1: Area (000ha), Production (000mt) and Yield (Mt/ha) of potato in India and U.P.

	India			U.P.		
Year	Area	Production	Yield	Area	Production	Yield
2013-14	1973.0	41555.0	21.1	546.25	13808.76	24.47
2014-15	2075.9	48009.2	23.1	607.32	14879.34	24.50
2015-16	2116.9	43417.0	20.5	607.32	13851.76	22.81
2016-17	2164.1	46545.6	21.5	611.15	13916.00	22.77

Source: Horticultural Statistics at a glance (2017), Ministry of Agriculture and Farmers Welfare, GOI.

During last four years, the area under potato has marginally increased (Table 1). Uttar Pradesh is one of the major potato growing states where area under potato has phenomenally increased during the same Period (Table 1).

Study the effect of integrated disease management approach on germination, plant height and yield of potato and on severity of late blight of potato *Phytophthora infestans* (Mont.) de Bary.

Vinay Kumar, Ramesh Singh, RK Doharey, Ramesh Chand, Sushant Srivastava and Rabindra Kumar

DOI: https://doi.org/10.22271/chemi.2020.v8.i2b.9501

Abstract
Late blight of potato caused by *Phytophthora infestans* (Mont.) de Bary is one of the most serious diseases of potato. Several management practices have been adopted so for to minimize the disease. But in present investigation based on laboratory and glass house condition revealed that soil application and tuber seed dressing with bioformulation provided good protection against late blight and also stimulate the germination. The data showed that the plant height of potato was maximum in treatments T1(Soil application of FYM @ 125gm/pot +mushroom waste with *T. harzianum* @ 5gm/gm+tuber treatment with *Azotobacter* @ 5%+foliar spray with Ridomil @ 0.25%) with the value of 44.9 cm at 30 days age of plant. Tuber treatment with bio agents stimulated the germination per cent of the tuber. The Maximum germination per cent was noted in case of T1(Soil application of FYM @ 125gm/pot+mushroom waste with *T. harzianum*@ 5gm/kg+tuber treatment with *Azotobacter*@5%+foliar spray with Ridomil@0.25%). Growth promoting effects of the soil amendment+ tuber treatment + foliar spray were also perceived. The fungicides and bio agents were found to increase the plant length over control. Foliar spray with the fungicides pathogenic inoculation protected the plants against infection resulting reduced disease severity. The minimum disease severity (10.66) was reported from treatments were given as treatment T1(Soil application of FYM 125gm/pot+ mushroom waste with *T. harzianum* 5gm/kg +tuber treatment with *Azotobacter* @5%+foliar spray Ridomil @ 0.25%) treated plants against 82.33% disease severity in case of control. The integrated effect o FYM+ mushroom waste as soil application bioformulation as tuber 51.67gm, and total weight of tuber 338.33gm, where trea tment was given as soil application of FYM @125gm/pot+ mushroom waste with *T. harzianum*@ 5gm/kg+tuber treatment with *T. harzianum* @5%+foliar spray with 665.02gm was recorded from treatment T1(Soil application of FYM 125gm/pot +mushroom waste *T. harzianum* @ 5gm/kg+tuber treatment with *Azotobacter*@ 5%+foliar spray with Ridomil @ 0.25%).

Keywords: Late blight, *Azotobacter*, mushroom waste, *Trichoderma*

Introduction
Potato can be used as a vegetable alone or in combination with other vegetables such as cabbage, cauliflower, tomato, brinjal, beans etc. It is also used in the preparation of chips, puffs and raw pulp. It is served in meals as well as snacks preparation. Thus, potato is important for small- hold farmers as well as a cash crop. The daily need of potato is increasing day by day resulting from increasing population growth of the world. Therefore, there is a demand for more production from per capital available land. Though, production of potato is increasing continuously but productivity rate per unit area of land is very low as per other countries of the world, which has the main reason of biotic factors caused by fungi, bacteria, virus, viroid and nematodes etc. Among them late blight of potato caused by *Phytophthora infestans* (Mont.) de Bary is one of the most serious and destructive diseases of potato all over world, including India. The great Irish famine in 1845, due to late blight is one of the most dramatic episodes caused by a plant pathogen in human history (Khurana *et al*., 1998) [1]. The Irish famine affected food production as well as economic and social aspect of communities (Large, 1940) [2]. The disease is also the major bottleneck in potato production in Ethiopia and other parts of the world (Goodwin *et al*. 1995) [3].

Evaluation of the effect of different fungicides against *Phytophthora infestans* (Mont) de Bary *(In vitro)*

Vinay Kumar, Ramesh Singh, RK Doharey and Satendra Kumar

Abstract
Late blight of potato caused by *Phytophthora infestans* (Mont.) de Bary is one of the the most serious disease of potato. Several management practices have been adopted for so for to minimize the disease. Butin the present investigation based on Laboratory condition. The efficacy of six different fungicides tested on mycelial growth of the *Phytophthora infestans* (Mont.) de Bary that minimum radial growth with 0.75 mm in diameter was recorded at 300 ppm concentration which was followed by 200 ppm, and 100ppm and 50 ppm. However, nomycelial growth recorded at 400 ppm. As per concern of percent inhibition the highest with 100 % inhibition was recorded from 400 PPM concentration of Metalaxyl. . Hence, the use of fungicides is the very effective method for management of plant disease and continuous use both systemic and even protective fungicides of fungicides may supressed growth of a develop strain of the *Phytophthora infestans* (Mont.) de Bary.

Keywords: Phytophthora, Late blight, Mycelium, Fungicides, Radial growth, ppm

Introduction
Potato (Solanumtubersom L) ranks third in importance as a food crop, following wheat and rice belonging to the family Solanaceae (Hawkes, 1989) [2]. It is considered as a good source of energy and proteins, sodium, potassium, thiamin, calcium, phosphorus, magnesium, vitamin B, folic acid and other vitamins. Late blight of potato caused by *Phytophthora infestans* (Mont.) de Bary is one of the most serious and destructive diseases of potato all over world, including India. The great Irish famine in 1845, due to late blight is one of the most dramatic episodes caused by a plant pathogen in human history (Khurana *et al*., 1998 [3]. Worldwide losses due to late blight of potato are estimated to exceed $5 billion annually and thus the pathogen is regarded as a threat to global food security. The disease caused yield losses ranging from 31-100%.The use of fungicides is the very effective method for management of plant disease. Several management practices have been adopted for so for to minimize the disease. But in the present investigation condition use of six different fungicides tested on mycelial growth of the *Phytophthora infestans* (Mont.) de Bary. In India, late blight pathogen attacked the potato crop in severe form wherever it is grown. However, it is comparatively more devastating in Himalayan and Nilgiri hills and causes severe crop losses. In Indo-Gangetic plains, depending upon prevailing weather conditions, the early appearance of late blight of potato may seriously damage the potato crop and causing heavy loss of potato growers.

Materials and Methods
The present investigations based on Glasshouse experiment was undertaken at Department of Plant Pathology, Chandra Shekhar Azad University of Agriculture and Technology Kanpur during crop season 2016-18. The procedure and techniques applied during the course of investigations were elucidated as below:

Isolation, purification, identification and maintenance of *Phytophthora infestans* (Mont) de Bary Collection of infected plant samples
Late blight infected leaves were collected from the potato field at Vegetable Research Farm, C. S. Azad University of Agriculture and Technology, Kanpur. Infected leaves with sporulation lesions were taken from the field and washed in sterilized water. The leaves were then placed in a humidity chamber with the leaf an axial side up. They were incubated at 18±1°C in BOD, until sporulation appeared. Small pieces of infected tissue along with healthy portion from the sporulating border were cut and placed under potato slices in empty sterilized Petri-plates. The Petri-plates were incubated at 18± 1°C for 10 days until there was a growth of abundant

Constraints in Respect of Formation, Implementation and Functioning of Different Women SHG Faced by the Women Self-Help Group members, Government Officials and Bank Officials' Different Women SHGs In Kanpur Dehat District (U.P.)

Shalu Gautam[1], R.K. Doharey[2], and Kamal Kishore[3]

ABSTRACT

The study was conducted in Akbarpur block of Kanpur Dehat district selected purposively. A total number of 100 respondents of women SHG were selected purposively which were selected from 20 Villages randomly. The structured schedule was developed keeping in view the objectives and variables under study. The respondents were contacted personally for data collection. The analysis of data was done by using the percentage, mean, standard deviation, and correlation coefficient for drawing the inferences. The data revealed that the out of 8 personal constraints as perceived by women SHG women *viz*., 'lack of pertinent knowledge about new innovation' was ranked I followed by lack of awareness due to dependency on male 'ranked II, out of 7 social constraints faced by women SHG members the majority of the women SHG members were reported the constraints *viz*.,' prevailed negative social attitude about women role outside the home in rural society' ranked I followed by 'due to "parda system" women are restricted within home boundaries' ranked II, out of 4 economic constraints in were reported 'women have financial dependency on male' ranked I, followed by 'unavailability of loan facility' ranked II, out of 5 constraints in women SHG group formation faced by the women SHG members were reported 'illiteracy among women' ranked I, followed by 'lack of cooperation among women' ranked II, out of 2 constraints in functioning of women SHG were reported 'lack of leadership among members' ranked I, followed by 'lack of working ability of members' ranked II, out of 4 technological constraints maximum respondent were reported 'lack of training programmes related to women SHG' ranked I, followed by 'lack of technical knowledge of preparing of women SHG of rural women 'ranked II, out of 3 constraints of Government officials were reported 'Government not come with a special policy to create a separate cell for solving problems of women SHG' ranked I, followed by 'Government not encourage and support NGOs to attempt and create favorable policy environment for women' ranked II and out of 3 constraints in bank transaction were reported 'lack of information about banking procedures' ranked I, followed by 'rules and regulation which the members cannot fulfill' ranked II.

Key words: Constraints in respect of formation, implementation and functioning of different women SHG faced by the women self-help group members, government officials and bank officials' different women SHGs in Kanpur dehat district (U.P.)

INTRODUCTION

The Self-Help Groups (SHG) is a small voluntary association of poor people, preferably from the same socio-economic background. They come together for the purpose of solving their common problems through self-help and mutual help. The SHG promotes small savings among its members and these savings are kept with a bank. This common fund is in the name of the SHG. The SHG is a group formed by the community which has specific number of members like 15 or 20. Usually, the number of members in one SHG does not exceed twenty. In such a group the poorest would come together for emergency, disaster, social reasons economic support to each other have ease of conversation, social interaction and economic interactions.

A self-help group is defined as a "self-governed, peer controlled information group of people with similar socio-economic background and having a desire to

Abstract

Nowadays diabetes is the most dreadful disease for humankind in the whole world. Indians are more centrally obese at a given level of BMI compared to white Caucasians and that Indians are more insulin resistant even at lower level of BMI so they are more prone to have diabetes. Consumption of cereal bran decreases the blood glucose level as its amount is inversely associated with insulin resistance.

A detailed clinical examination done on selected patients. The criteria for the selection are as follows: 1. All patients are sedentary middle aged workers. 2. Patients with complications like were not included 3. Patients selected were explained the outline and aim of the study. They were advised to have cereal bran in the form of powder. 4. We made 2 groups. Group A fed with methi dana and group B fed with cereal bran. 5. Patients were recalled after each month for the investigation to know the proper effect. 6.The investigations include Anthropometric data, GTT, blood glucose, and serum lipid profile. The test applied for clinical estimation of blood glucose is GOD-POD (glucose oxidase peroxiadse) method. So, this study proves that consumption of methi dana is effectively applicable in lowering blood glucose level than cereal bran.

Keywords: diabetes, cereal bran, methi dana, polysaccharide etc.

Introduction

Diabetes Mellitus is a chronic disease that has affected humankind throughout the world. The life span of diabetics is shorter than that of non-diabetics at nearly all ages. Diabetes has been defined as a genetically and clinically heterogeneous group of disorder all of which show glucose intolerance.[1,4,5,11]

Prevalence- Diabetes is on increase in India. The multicenter ICMR study showed a prevalence of 2.5 % in the urban and 1.8% in the rural population above the age of 15 years. One in every eight individuals in India is a Diabetic. There are 171 million people worldwide suffering from diabetes in 2000 according to World Health Organization (WHO) statistics and this number would be more than double by 2030 (WHO 2008). The disease is responsible for 3.2 million deaths every year (WHO 2008).

- Diabetes mellitus is characterized by high blood glucose level with typical manifestations of thirst, polyuria, polydipsia, and weight loss.
- It is caused by partial or total lack of insulin and alteration in carbohydrate, protein and fat metabolism that creates defects in insulin-mediated signal pathways, resulting in decreased glucose transportation from blood into muscle and fat cells.
- The major risk is vascular injury leading to heart disease, which is accelerated by increased lipid levels and hypertension. Management of diabetes includes: control of blood glucose level and lipids; and reduction of hypertension.

As this study is a comparative study of soluble and insoluble complex polysaccharides. For the study methi dana (fenugreek seed) is selected as soluble complex polysaccharide and cereal bran is used as insoluble complex polysaccharide.

Fenugreek seeds are 55 percent soluble fiber. This gel-forming fiber absorbs water as it passes through the gut and swells up, binding with the food. It delays gastric emptying, slows down carbohydrate absorption and inhibits glucose transport. Nearly 50% dry weight of seeds as well as SDF is edible dietary fiber, making it the highest concentration among all-natural sources of fiber. About 30% of SDF (w/w) is gel-forming SOLUBLE fibers similar to guar gum, psyllium husk and oat bran. The INSOLUBLE fiber (20% of SDF), is bulk-forming like wheat bran.[3,4,5]

Comparison of Fiber content in some major food grains:

COMPOSITION of NATURAL SOURCES of VEGETABLE FIBER					
Source	Total Fiber	Soluble Fiber	Insoluble Fiber	Protein	Fat
Fenugreek Seeds	46 - 48%	20 - 28%	18 - 24%	26 - 30%	4 - 8%
Soya Bean	20%	15 - 18%	3 - 5%	40 - 43%	19%
Oats	15 - 18%	7 - 8%	7 - 8%	14 - 19%	N/A
Wheat	12%	1 - 3%	9 - 11%	10 - 12%	1 - 3%
Guar Bean	40%	25%	15%	28%	10 - 15%
Psyllium seed	24 - 26%	24 - 25%	1 - 2%	5%	Trace

Several human intervention trials demonstrated that the antidiabetic effects of fenugreek seeds ameliorate most metabolic symptoms associated with type-1 and type-2 diabetes in humans by reducing serum glucose and improving glucose tolerance.[3,4]

Bran is also the part of the grain that is the most nutrient dense. It contains proteins, omega 3 and omega 6 fatty acids, and antioxidants. Cereals made from whole wheat bran, without added sugar or hydrogenated or partially hydrogenated oils, are a good source of whole grains that are high in fiber, folic acid, B vitamins, and potassium.[8,9,11] Bran is particularly rich in dietary fiber and essential fatty acids , Because of their high fiber content, they are usually very filling. It is high in nutritional content and low in calories. When bran is removed from grains, the grains lose a portion of their nutritional value.

Cereal fibers also help normalize blood glucose levels by slowing the rate at which food leaves the stomach and by delaying the absorption of glucose following a meal. Viscous fibers also increase insulin sensitivity. As a result, high intake of cereal fibers plays a role in the prevention and treatment of type 2 diabetes.[10] In addition, by slowing the rate at which food leaves the stomach, viscous fibers promote a sense of satiety, or fullness, after a meal, which helps to prevent overeating and weight gain.[7,10]

Fenugreeks seeds have fiber in it which when consumed tend to swell in the stomach and give a feeling of satiety and thus will consume less of other fatty foods in meal.

Fenugreek seeds burn fat and help absorption. They are useful for dissolving fat within the liver. They are one of nature's super-foods due to their beneficial effect on fat metabolism, blood sugar and also their cancer-fighting properties. *(Claudia Bruchtl, L.Ac, 2001)*.

Fenugreek seeds are rich in fiber, as each 1 tbsp. serving contains 3 g, which comprises half of the carbohydrates in the serving. Fiber can be beneficial for weight loss, as it helps keep your blood sugar levels in

It delays gastric emptying, slows down carbohydrate absorption and inhibits glucose transport. Nearly 50% dry weight of seeds as well as SDF is edible dietary fiber, making it the highest concentration among all-natural sources of fiber. About 30% of SDF (w/w) is gel-forming SOLUBLE fibers similar to guar gum, psyllium husk and oat bran. The INSOLUBLE fiber (20% of SDF), is bulk-forming like wheat bran.[3,4,5]

Comparison of Fiber content in some major food grains:

COMPOSITION of NATURAL SOURCES of VEGETABLE FIBER					
Source	**Total Fiber**	**Soluble Fiber**	**Insoluble Fiber**	**Protein**	**Fat**
Fenugreek Seeds	46 - 48%	20 - 28%	18 - 24%	26 - 30%	4 - 8%
Soya Bean	20%	15 - 18%	3 - 5%	40 - 43%	19%
Oats	15 - 18%	7 - 8%	7 - 8%	14 - 19%	N/A
Wheat	12%	1 - 3%	9 - 11%	10 - 12%	1 - 3%
Guar Bean	40%	25%	15%	28%	10 - 15%
Psyllium seed	24 - 26%	24 - 25%	1 - 2%	5%	Trace

Several human intervention trials demonstrated that the antidiabetic effects of fenugreek seeds ameliorate most metabolic symptoms associated with type-1 and type-2 diabetes in humans by reducing serum glucose and improving glucose tolerance.[3]

Bran is also the part of the grain that is the most nutrient dense. It contains proteins, omega 3 and omega 6 fatty acids, and antioxidants. Cereals made from whole wheat bran, without added sugar or hydrogenated or partially hydrogenated oils, are a good source of whole grains that are high in fiber, folic acid, B vitamins, and potassium.[8, 9, 11] Bran is particularly rich in dietary fiber and essential fatty acids. Because of their high fiber content, they are usually very filling. It is high in nutritional content and low in calories. When bran is removed from grains, the grains lose a portion of their nutritional value.

Cereal fibers also help normalize blood glucose levels by slowing the rate at which food leaves the stomach and by delaying the absorption of glucose following a meal. Viscous fibers also increase insulin sensitivity. As a result, high intake of cereal fibers plays a role in the prevention and treatment of type 2 diabetes.[10] In addition, by slowing the rate at which food leaves the stomach, viscous fibers promote a sense of satiety, or fullness, after a meal, which helps to prevent overeating and weight gain.[7,10]

Materials and Methods

A detailed clinical examination was carried out and recorded. The criteria for the selection of patients are as follows:

- All patients are sedentary middle aged postmenopausal females.
- Patients with complications were not included.

Abstract

Nowadays diabetes is the most dreadful disease for humankind in the whole world. Indians are more centrally obese at a given level of BMI (Body Mass Index) compared to white Caucasians and that Indians are more insulin resistant even at lower level of BMI so they are more prone to have diabetes. Consumption of cereal bran decreases the blood glucose level as its amount is inversely associated with insulin resistance.

A detailed clinical examination done on selected patients. The criteria for the selection are as follows:

1. All patients are sedentary middle aged workers.
2. Patients with complications like were not included.
3. Patients selected were explained the outline and aim of the study. They were advised to have cereal bran in the form of powder.
4. We made 2 groups, Group A fed with methi dana and group B fed with cereal bran.
5. Patients were recalled after each month for the investigation to know the proper effect.
6. The investigations include Anthropometric data, GTT, blood glucose, and serum lipid profile.

So, this study proves that consumption of methi dana is effectively applicable in lowering blood cholesterol level than cereal bran.

Keywords: diabetes, cereal bran, methi dana, polysaccharide etc.

Introduction

Diabetes Mellitus is a chronic disease that has affected humankind throughout the world. The life span of diabetics is shorter than that of non-diabetics at nearly all ages. Diabetes has been defined as a genetically and clinically heterogeneous group of disorder all of which show glucose intolerance.[4,5,11]

Prevelance- Diabetes is on increase in India. The multicenter ICMR study showed a prevalence of 2.5 % in the urban and 1.8% in the rural population above the age of 15 years. One in every eight individuals in India is a Diabetic. There are 171 million people worldwide suffering from diabetes in 2000 according to World Health Organization (WHO) statistics and this number would be more than double by 2030 (WHO 2008). The disease is responsible for 3.2 million deaths every year (WHO 2008).

- Diabetes mellitus is characterized by high blood glucose level with typical manifestations of thirst, polyuria, polydipsia, and weight loss.
- It is caused by partial or total lack of insulin and alteration in carbohydrate, protein and fat metabolism that creates defects in insulin-mediated signal pathways, resulting in decreased glucose transportation from blood into muscle and fat cells.
- The major risk is vascular injury leading to heart disease, which is accelerated by increased lipid levels and hypertension. Management of diabetes includes: control of blood glucose level and lipids; and reduction of hypertension.

As this study is a comparative study of soluble and insoluble complex polysaccharides. For the study methi dana (fenugreek seed) is selected as soluble complex polysaccharide and cereal bran is used as insoluble complex polysaccharide.

Fenugreek seeds are 55% soluble fiber. This gel-forming fiber absorbs water as it passes through the gut and swells up, binding with the food. It delays gastric emptying, slows down carbohydrate absorption and inhibits glucose transport. Nearly 50% dry weight of seeds as well as SDF is edible dietary fiber, making it the highest concentration among all-natural sources of fiber. About 30% of SDF (w/w) is gel-forming SOLUBLE fibers similar to guar gum, psyllium husk and oat bran. The INSOLUBLE fiber (20% of SDF), is bulk-forming like wheat bran.[1,4,5]

Comparison of Fiber content in some major food grains

COMPOSITION of NATURAL SOURCES of VEGETABLE FIBER					
Source	**Total Fiber**	**Soluble Fiber**	**Insoluble Fiber**	**Protein**	**Fat**

Materials and Methods

Bran is also the part of the grain that is the most nutrient dense. It contains proteins, omega 3 and omega 6 fatty acids, and antioxidants. Cereals made from whole wheat bran, without added sugar or hydrogenated or partially hydrogenated oils, are a good source of whole grains that are high in fiber, folic acid, B vitamins, and potassium.[8,9,11] Bran is particularly rich in dietary fiber and essential fatty acids, Because of their high fiber content, they are usually very filling. It is high in nutritional content and low in calories. When bran is removed from grains, the grains lose a portion of their nutritional value.

In people with type II diabetes, fenugreek supplementation has been shown to significantly lower overall cholesterol, low-density lipoprotein (known as LDL or "bad cholesterol," associated with cardiovascular disease), and triglycerides (blood fats) all while easing diabetic symptoms *(Alternative Medicine Review 2003)*. In another study of non-diabetics suffering from high cholesterol, fenugreek was found to significantly lower triglycerides and LDL levels *(Phytotherapy Research 1991)*[12,13]

Fenugreek seeds contain chemicals that may lower cholesterol absorption from the intestines and also possibly decrease the amount of cholesterol made by the liver. The dietary fiber in fenugreek may also add to fenugreek's cholesterol-lowering effects. According to the PAMF (Palo Alto Medical Foundation), preliminary human studies have shown that fenugreek may decrease total cholesterol, low density lipoprotein, which is known as bad cholesterol, and triglycerideWhole grain cereals are a good source of fiber, which helps keep your digestive system regular, and they also have cholesterol lowering

COMMUNICATION AND PSYCHOLOGICAL BEHAVIOR OF THE OKRA GROWERS IN KANNAUJ DISTRICT (U.P.)

Kamal Kishore[1], Prakash Singh[1], R.K. Doharey[3]& Shalu Gautam[4]
[1,2,3&4]Department of Extension Education, College of Agriculture,N.D.U.A &T.,Kumarganj, Ayodhya (U.P.)- 224229

Abstract

The study was conducted in Chhibramau and Talgram blocks of Kannauj district (UP) selected purposively, because these blocks one more popular for area and production of okra. A total number of okra growers were selected through random sampling from eight selected village's panchayats on the basis of ten respondents from each selected village panchayats. The some structured schedule was developed keeping in view the objectives and variables under study. The respondents were contacted personally for data collection. The results of the study depicted that the majority of the respondents were found in various Communication and psychological behavior characters like, The radio was found as main communication media with the respondents. Thus, it may be concluded that the degree of independent variable is increases the level of knowledge and adoption about scientific okra cultivation will increase towards positive. The maximum number of respondents was found in low level of economic motivation, medium level risk Orientation and scientific orientation high (32.50%), (23.75%) and (21.00%) respondents, respectively.

Key words : Socio-economic profile, knowledge and adoption, awareness, etc.

Introduction

Agriculture helps to meet the basic needs of human and their civilization by providing food, clothing, shelters, medicine and recreation. Hence, agriculture is the most important enterprise in the world. It is a productive unit where free gifts of nature namely land, light, air, temperature and rain water etc., are integrated into single primary unit indispensable for human beings. Secondary productive units namely animals including livestock, birds and insects, feed on these primary units and provide concentrated.

Agriculture has been back bone of the Indian economy and accounted for 14.6 per cent of the country's gross domestic product (GDP) in 2009-10 and 10.23 per cent of the total exports. Agriculture sector provided employment to 58.2 per cent of the work force of India.

The total geographical area of India is 328.7 million hectares of which 140.3 million hectares is net sown area, while 193.7 million hectares is the gross cropped area (Anonymous, 2009-10). India is the world's largest producer of vegetable next only to China with an annual production estimated around 50.99 million tons from 4.5 million hectares. However, vegetables occupy hardly 2 per cent of the total cropped area of the country which is very low in view of the national need. The production per unit area of various crops grown in India is very less, as compared to developed countries. Due to low agricultural productivity, it becomes very difficult to feed the ever-increasing population. Increasing is production and productivity is essential to uplift the socio economical level of poor farmers. The basic challenge before India is to enhance the production of nutritious food in sustainable manner which, besides feeding the country's large population, it can play a major role to reduce the mal nutrition among the women and children of rural area. Vegetables being short duration crops can give six to ten time more yield than any cereals crop in a year and thus, can provide cash money to the rural farmers. The vegetable being cash crop with nutritional value generate income for the poor households. Higher profits could be achieved by increasing the production of a vegetable crops throughout the year by efficient irrigation system used. The production of fruits and vegetables has comparative advantagenious particularly under conditions where arable lands are scarce, a labor is abundant and markets are accessible (Lumpkin et al., 2005).

The horticulture sector encompasses a wide range of crops e.g., fruit crops, vegetables crops, potato and tuber crops, ornamental crops, medicinal and aromatic crops, spices and plantation crops. While the first few Five Year Plans assigned priority to achieving self-sufficiency in food grain production, over the years, horticulture has emerged as an indispensable part of agriculture, offering a wide range of choices to the farmers for crop diversification. It also provides ample opportunities for sustaining large number of agro-industries which generate substantial employment opportunities. The horticulture sector contributes about 24.5 per cent of the GDP from about An area of 21 million hectares and contributes over 230 MT to the food basket of the country. India ranks first in the world with 3.5 million tones (70% of the total world production) of okra produced from over 0.35 million ha land (FAO STAT 2010).

India is the second largest producer of vegetables and is a leader in the production of peas and okra. Besides, India occupies the second position in the production of brinjal, cabbage, cauliflower and onion and third position in potato and tomato in the world. Highlighting the virtues of protected cultivation to boost 14 horticulture productivity, a Rs 30,000 crore (US$ 6.07 billion) outlay has been proposed for bringing at least 10 per cent of the horticulture crop area in India under this high-tech cultivation practice in the 12th Five Year Plan (2012-2017).

Keeping this in view, the present research project entitled "Study on knowledge and adoption level of scientific production technology of okra in kannauj district of Utter Pradesh."

Materials and Methods

The study was conducted in purposively selected kannauj district of Uttar Pradesh. There are 8 community development blocks in this district out of that is two block Chhibaramu and Talgram were selected purposively. Thetotal 90 villages in Chhibaramau block and 85 villages in Talgram block, 8 villages (4 villages from Chhibaramau block and 4villages from Talgram block) were selected purposively.The number of total villages were 175 from which 8 villages were selected purposively, and then the list of total farmers were prepared for each selected villages. Thereafter 80 farmers were selected as respondents though random sampling techniques with respect to the categories of the farmers for each selected village. Data were collected with the help of semi-structured interview schedule specially developed on standard scales with some modifications in the light of objectives and analyzed with suitable statistical methods respectively.

Results and Discussion

Communication media possession:

Table 1.1: Distribution of the respondents on the basis of communication media possession N=80

S.No.	Communication media	Respondents	
		Number	Percentage
	T.V.	80	100
	Radio	32	40.00
	Mobile phone	80	100
	Tape recorder	00	00.00

Abstract

The study was conducted in Chhibramau and Talgram blocks of Kannauj district (UP) selected purposively, because these blocks one more popular for area and production of okra. A total number of okra growers were selected through random sampling from eight selected village's panchayats on the basis of ten respondents from each selected village panchayats. The some structured schedule was developed keeping in view the objectives and variables under study. The respondents were contacted personally for data collection. The results of the study depicted that the majority of the respondents were found in various socio-economic profile characters like, age composition of 45-55 years (68%), literate (80%), other backward caste (60%), nuclear families (58.75%), families size of 6-7 members (55%) and size of land holding small farmers categories 1-2 ha. (53%), respectively. Agriculture was observed as main and dairying was subsidiary occupations with (82%) and (70%) and (47%) respondents were found such who had earning annual income of (Rs. 25001-350000) and (87%) respondents reported having mixed type house, respectively. The maximum (28.75%) respondents were found such show had participation in one social organization. The cycle has immersed most important transportation growers.

Key words : Socio-economic profile, knowledge and adoption, awareness, etc.

Introduction

Indian subcontinent is endowed with favorable climate which permits growing of vegetables throughout the year. Vegetables play an important role in balanced nutrition as they are valuable source of carbohydrates, proteins, vitamins and minerals. The Per capita consumption of the vegetables in India is 160 g per day per person as against recommendation of 300 g per day per person. According to this statistic, we need to produce approximately 0.3 MT of vegetables per day for the present population. The present earning through vegetables export is little bit exceeding to Rs. 300 crores. Nature has endowed our country with vast diversity of land, soil and agro-climatic conditions which enables to produce varied types of vegetable crops. The area and production of vegetables are increasing year after year after the green revolution. There is substantial increase in production and productivity of vegetable crops. Due to growing of improved hybrid varieties and adoption of improved cultivation technologies, India"s share in the world production of vegetables is about 7 per cent (Anonymous, 1999).

Okra or ladies finger is an important vegetable of the tropical countries and most popular in India, Nigeria, Sudan, Iraq, Pakistan, etc. Okra is found in it's wild state on the alluvial banks of the Nile and the Egyptians were the first to cultivate it in the basin of the Nile (12'th century BC). It was propagated then through North Africa to the Mediterranean, the Balkans, and India. It arrived then in the America at Brazil (1658), Dutch Guinea and at New Orleans before extending in the United States and going up to Philadelphia in 1781. Its scientific name is "Abelmoschus esculents" and also "Hibiscus esculents", it belongs to the family Malvaceae. It is a tropical plant, 15 which grows best in warmer climates. It"s ready to harvest in around 60 days when the blooms begin to open, and is slightly tough. They have to be picked about 4-5 days after flowering in the fall. Okra varies in shades of green and can be smooth or has ribbed surfaces. (Varmudy, 2010).

Area and production of okra in India is 452,000 ha. and 4,803,000 MT. in Nigeria 387,000 ha. and 1,039,000 MT. and in Sudan 21,926 ha. and 223,650 MT. Here the share of India is 67.1 per cent, followed by Nigeria at 15.4 per cent and Sudan at 9.3 per cent. (FAO, 2010). In India, okra is grown throughout except in the mountain regions. The major producers are West Bengal, Bihar, Orissa, Andhra Pradesh and Gujarat. As far as area under okra cultivation in India is concerned, Orissa has an area of 74 thousand ha, West Bengal has an area of 73.1 thousand ha under okra cultivation followed by Gujarat, Andhra Pradesh, Jharkhand and others states. In terms of okra production, it is 0.83 million tones in West Bengal, 0.65 million tones in Orissa and 0.43 million tonnes in Andhra Pradesh. The average productivity in India is 10.5 tones per hectare. The highest productivity is in Andhra Pradesh at 15 tones per hectare followed by Jharkhand at 14 tones per hectare. The total area under this crop has increased over the years.

We eat food for good growth of our body. The food we eat contains nourishing substances called nutrients. There are five major nutrients, namely carbohydrates, proteins, fats, minerals and vitamins. It has an average nutritive value of 3.21 gm, which is higher than tomato, pumpkin and ashgourd. It contains 27 gm of carbohydrates, 2.2 gm of proteins, 0.29 gm of fat, 90 mg of calcium, 50 mg of phosphorus, 15 mg of iron and 16 mg of vitamin C per 100 gm of edible portion. The seeds contain 18-20 per cent oil and 20-23 per cent crude protein. Soups and stews of okra are popular dishes in India. The seeds, when ripe are sometimes roasted and used 16 as a substitute for coffee. The roots and stems of okra are used for clarification of sugarcane juice before it is converted into jaggery and brown sugar. The crop is used in the paper industry and fiber is extracted from its stem. Okra is considered by many as a super-vegetable with a lot of nutrition and medicinal benefits. Fibre also helps in stabilizing blood sugar. The mucilage not only binds cholesterol but also the bile acid carrying toxins dumped into it by the liver. Its fiber absorbs water and helps to prevent constipation. In fact, its slippery characteristics, which people dislike, facilitates elimination of excess cholesterol and toxins from the body.

There are many medicinal importance of okra; (i) The tender fruit is boiled and administered in fevers, gastric ulcers, catarrh, inflammation of the mucous membrane, difficulty in urination and dysentery. (ii) It is also considered remedy for spermatorrhea (involuntary discharge of the semen), syphilis, gonorrhea, and other disorders of the genitals. (iii) The fruit is also reported to increase sexual potency. (iv) The unripe fruit is eaten for tuberculosis of the lungs. (v) The infusion of the seeds will induce perspiration etc.

Okra can be grown in a wide range of soils – sandy loams to clay loams, provided they are well drained and supplied with enough organic matter. Main Okra growing season is Kharif (rainy season) June-July. However, it can be grown in September-October, January-February and also in summer season, where assured irrigation facilities are available (www.mdaagronet.com). Out of 137.00 lakh hectares geographical area of Chhattisgarh, 43 per cent area comes under cultivation. On the basis of climate and topography the state is divided into three agro climatic zones i.e. Chhattisgarh plains, Northern hills and Bastar Plateau. Horticulture exports has helps the country to earn 14,000 crore tones in the year of 2011-2012. Indian horticulture has crossed of production all time of over 240 million tones in the year of 2011-2012.Keeping this in view, the present research entitled "To study the personal socio-economic profile of okra growers"

Abstract

The soybean (*Glycine max*.) was introduced in India in 1960s .The area under soybean was only 32000 hectare during in 1970s. It has been increased many fold and still there is vast potential of area expansion and productivity enhancement, however, area and production of soybean is stagnating since last 10 years at around 10 to 11 million hectare and production at around 10 to 12 Million Tones. Soybean cultivation has been expended in many countries because of its nutritive and economic importance and diverse domestic usage. India's share in the world's total area is about one percent and in production about 0.38 % at present, however, area expansion as well as production of Soybean in the country during the last 40 years is rated as one of the striking occurrences in the agricultural development process. It is a prime source of vegetable oil in the international mark. Proximate composition of soybean whole seed contains 18-22% Oil, 39-42% Protein, 31-37% Carbohydrates, 4.9-5.0% Ashes. Out of total oilseed production of 29.25 Million Tones, we produce 11.54 Million Tones soybean, which is 39 % of total production. Similarly, Soy oil is a primary source of edible oil and has 19% share in total consumption of vegetable oils in our country. Our domestic production of Soybean Oil is 1.66 M.T and consumption is 4.64 M.T. To meet our domestic requirement, country is importing around 3.00 Million Tones Soybean oil annually by incurring about 19000/- crores. The average globally, area, production and productivity of soybean is around 116.48 M hectares, 303.06 M T, 26.02 qtls/ha. respectively during 2013-16. The major five countries like USA, Brazil, Argentina, India and China account for more than 87% area and 90% production of soybean globally. The three major countries i.e USA, Brazil and Argentina alone comprising 71.13 % area 82% Production of Soybean globally.

Introduction

Soybean is one among the major industrial and food crops grown in every continent. Soybean cultivation has been expended in many countries because of its nutritive and economic importance and diverse domestic usage. It is also a prime source of vegetable oil in the international mark. Proximate composition of soybean whole seed contains 18-22% Oil, 39-42% Protein, 31-37% Carbohydrates, 4.9-5.0% Ashes. The fatty acid composition of soybean oil includes Palmitic (7-12%), Stearic (2-5.5%), Oleic (19-30%) and Linoleic (48-58%). The oil of Soybean has 85% unsaturated fatty acids, considered to be cholesterol-free. Similarly, among the essential amino acids, it has lysine, Methionine, Cysteine, Tryptophan, Threonine, Isoleucine and Leucine, which are considered to be very good for human health. The soybean contains very little of starch (4.66-7%) and quite a lot of Hemicellulose and Pectins. These Polysaccharides have several health benefits in human's life. Both play an important role in preventing certain type of cancer and helping in digestion and weight loss.

Protein of soybean products characterized much quantity of lysine, Tryptophan, Isoleucine, Valine and Threonine. Number of Nutraceutical compounds such as Isoflavons, Tocopherol and lecithin has made it one of the most valuable agronomic crops in the world. Soybean has great potential as exceptionally nutritive and very rich protein food. Soybean oil has an important fatty acid, lecithin as well as vitamin A and D. Lecithin is used for reducing fatty build-up in the liver and treating memory disorders such as dementia and Alzheimer's disease. It is pertinent to mention that 90% of Indians are deficient of Vitamin –D. Soybean oil is very good for Vitamin – D diffident people. It can supply much needed protein to human diet, because, it contains 40% protein of superior quality and all the essential amino acids similar to cow milk and animal proteins. In view of its nutritional values, it is a complete food for vegetarians

It improves soil fertility being leguminous crop. Soybean is capable of transforming nearly 60-100 kg atmospheric nitrogen in to 30-40 kg nitrogen per hectare in the soil, controls the *Striga hermonthica*, a parasitic weed and also provides protein rich fodder for the animals and soybean cake for egg layering birds. It is a rich protein food used in the form of Soy oils, nutri- nuggets, tofu, soy-milk, soy-cheese, soy-fish, soya-flour, Soya-chaap, Soya-noodles and so on. It has largest consumption among the vegetable oil in the world as well as in the Country. As per FAO's Agricultural Market Information System, global production of soybean during 2018-19 is estimated at 359.6 million tonnes, a new record, from an area of 129.27 million hectares. Production estimates for 2017-18 has been revised slightly upward to 337.9 million tonnes recently from 336.8 million tonnes projected during March, 2018 from an area of 124.25 million ha.

Out of total oilseed production of 29.25 Million Tones (Avg. 2011-16), we produce 11.54 Million Tones soybean, which is 39 % of total production. Similarly, Soy oil is a primary source of edible oil and has 19% share in total consumption of vegetable oils in our country. Our domestic production of Soybean Oil is 1.66 M. T and consumption is 4.64 M.T. To meet our domestic requirement, country is importing around 3.00 Million Tones Soybean oil annually by incurring about 19000/- crores.

2. Global Scenario:

The average globally, area, production and productivity of soybean is around 116.48 M hectares, 303.06 M T, 26.02 qtls/ha. respectively during 2013-16. The major five countries like USA, Brazil, Argentina, India and China account for more than 87% area and 90% production of soybean globally. The record production of soybean was estimated during 2016-17 at 349 million tones. The three major countries i.e USA, Brazil and Argentina alone comprising 71.13 % area 82% Production of Soybean globally. The average productivity of these three countries is 30 qtls per ha. as against the world average is 26.02 qtls/ha. and 10.45 qtls/ha in India. Area, production and productivity of five major soybean producing countries (2013-16) are summarized as here under:

No.	Country	Average Area (M.ha),	Average Production (M. T)	Average Yield Qtls/ha.
	USA	32.40	101.07	31.19
	Brazil	31.02	91.80	29.59
	Argentina	19.43	55.84	28.74
	India	**11.04**	**11.54**	**10.45**
	China	06.84	12.08	17.68
	Total (1 to 5)	**100.73**	**272.33**	
	Other countries	16.35	30.73	
	World	**116.48**	**303.06**	**26.02**

Abstract

The Social Governance is enshrined in the Indian Constitution. The Social Governance is a concept of Government in which the state plays a key role in the protection and promotion of the economic and social well-being of its citizens. The Preamble of the Constitution has used the terms like **"Socialist", "Social Economic and Political Justice", "Equality of Status and of Opportunity" Liberty of Thoughts, Expression, Belief, Faith and Worship etc,** these terms indicate that the state would extensively involve in social welfare of people, and would try to establish an egalitarian society. The Directive Principles of state policy provides guidelines to the central and state Governments of India, to be kept in mind while framing laws and policies. The concept behind Directive Principles of State Policy is to establish a "welfare State" rather than a police state such as of Colonial era. In other words motive behind inclusion of Directive Principle of State Policy is establish Social and economic democracy rather than political democracy. However, it has been observed that the state is shirking from the duties and responsibilities of a welfare state and resources are being accumulating in certain business houses. The rich are becoming richer and poor are not getting their due share. The benefits of the schemes and provisions are not reaching to the real needy and last person standing in the line.

Introduction

India is considered to be a welfare state and moreover the largest democracy in the world. Marginalized sections in India are generally classified by their social status in the stratified Indian society and caste based stigmatized professions for their livelihood. They are not at par in respect of education, economic position and social status in society. Among the majority community of the Hindu which represents 93 percent of population in India are included the 430 million marginalized sections especially scheduled castes, scheduled tribes and other backward classes. Women form the half of the population of the country and were and are being subjugated to male domination. Scheduled caste and scheduled tribe people live in abject poverty under deprived conditions of life in respect of health, education, nutrition, human dignity, land, livelihood, employments and minimum wages with their families sharing and dying prior to general life expectancy. Their share in demography strengthened voting democracy and their significant contributions to national productivity support the wheels of the whole country's prosperity. In return they can hardly meet both ends and the basic needs of life. Thus, all the woes of existence embrace them from birth to death beyond imagination.

In today's time it seems that the concept of social welfare has not been taken by the government as sincerely, as it must have. The attitude of the government is not very friendly and cooperative towards the people, and it is visible from the recent debate on the Lokpal Bill and the controversy relating to the determination of poverty line for poor people. The government does not seem to be sincere about its responsibility towards serving the people as many scams and irregularities have come up in the central and state governments. The skewed policies relating to the expansion of capitalism, the forceful acquisition of lands from poor peasants, and neglect for the development of agriculture and rural development are making the situation worse.

Governance:

Now even after 70 years of independence, if analyze the Governance, it reveals that maximum benefit of liberalization privatization and globalization priority programme initiated by Government in the name of economic reforms has gone to well established business houses in India. The resources of Government created since Independence in the form of Public Sector Undertakings (PSUs), Corporations, Authorities, Institutions, Manufacturing Units/ organizations involved in the development of Nation have gone in the hands of big business houses. The Government is also not willing to bear the responsibility of marginalized sections and surprisingly expecting from business houses in the name of Corporate Social Responsibility (CSR). Now all the business houses have created their own institutions to use the funds earmarked for CSR.

Histriography

Dalit historiography throws a challenge to colonial, nationalist, Marxist and right wing and even to the so-called historians of subaltern studies. In this context, Ambedkar's method of constructing the history from dalit perspective is path breaking and provides insights for contemporary historians of all shades. 'Time is infinite and earth is vast, someday there will be born a man who will appreciate what I have said'- Bhavabhuti quoted by Dr Ambedkar in his preface to 'Who were the Shudras?' One may derive Ambedkar's 'historical method' in all his major writings on Indian history, culture and philosophy. In the year 1946, Ambedkar identified five streams of thoughts among the Hindus of Indian society in his writing on 'who are Shudras' **Orthodox, Arya samajists, Respecters of law, Political minded** (Swaraj is important than social reform) and **Rationalists** (regard social reform as primary and even more important than Swaraj). Among these five classes, Ambedkar would like to identify his position with rationalist, who were arguing for social reform as immediate agenda rather than any other.

In the historical method of Ambedkar; man is the maker of history. Ambedkar evaluates the three different views on the causes of historical changes, Augustine, Buckle and Marx. According to, history is only an unfolding of divine plan in which mankind is to continue through war and suffering **Augustinian** until that divine plan is completed at the day of judgment. Ambedkar pointed out that this is not acceptable to many except theologians. For **Buckle**, history was made by geography and physics. As per **Marx**, history was the result of economic forces.

Ambedkar finds the limitations of these three arguments by holding the opinion that none of these would admit that history is the biography of great men. Indeed, they deny man any place in making of history. He considers there is a truth in Buckle and Marx, but their views do not represent the whole truth. They are quite wrong in holding that impersonal forces are everything and that man is no factor in the making of history. That these impersonal forces are a determining factor can't be denied, however, the effect of impersonal forces depends on man must also be admitted."

Dr Ambedkar's perspective:

The Government agencies do their best to alleviate their social and economic deprivation and the more they implement measures for their amelioration the greater is their plight highlighted through indigenous and outside Vaux populi. At the turn of 68th year of Indian Republic, this is high time to ponder over the problems of marginalized sections of society and their remedies with reference to Dr. Ambedkar's Perspective through Indian historiography. Dr Ambedkar said that

Abstract

The 2016 demonetization policy in India in which the government decided to demonetize the 500 and 1000 rupee notes affected trading activities of the MSMEs in respect of payment mode by individual customers. The objective of this study is to provide insight on the significance of cashless transaction among MSMEs (micro, small and medium-sized enterprises) following the 2016 demonetization exercise in India. With convenient sampling technique the study employed 200 respondents. Primary data was mainly collected from respondents in the MSME segment in Mumbai and Bangalore and secondary data from MSME annual report 2017-18. The study noted that customers switched to alternative payment avenues and that mobile wallet companies became the biggest beneficiaries as they offered easy mode of payment via the use of mobile phone. The results of the Pearson correlation confirms that there is a positive relationship between cashless transaction and demonetization. It is therefore recommended that more and more Indian customers must be encourage to continue in the habit of making cashless business transactions on account of its enormous economic benefits to individuals, MSMEs and the Indian economy as a whole.

Key words: Demonetization, Currency notes, MSME sector, Cashless transaction, Mobile-wallet

Introduction

The act of stripping an existing currency note of its status as a legal tender and removing it completing from circulation and subsequently replacing it with new notes is known as Demonetization. Sometimes a higher or totally different denomination is introduced in place of the former currency which was pulled out from the system.

The demonetization exercise that took place in November 2016 in India came as a shock though it was not new in the country's economic history. This is because India's initial demonetization action happened in 1946, and the second one occurred in 1978. The first one which was recorded in 1946 after World War II, was believed to have been inspired by their colonial master Britain who first withdrew the British 10 pound note from circulation as a form of demonetization program.Government of countries take such anaction so as to check the activitiesof black money dealers and the evasion of tax. In 1946, the Indian government decided to demonetize high denomination currency notes of Rs. 1,000 and Rs. 10,000 but this action really did nothave much impact on Indian economy because higher denomination was not accessible to the general public.

In the year 1978 demonetization in India suggested by the Wanchoo committee, a direct tax inquiry committee (established in the 1970s). Prime minister of India Muraji Desai declared Rs 1000, Rs. 5000 and Rs 10, 000 currency notes out of circulation. Main reason of Indian 1978 demonetization was to "Freeze secret Funds" of the opposition political parties that created corruption and black money in economy. The public were given a very limited time of three days to exchange the affected currency and theIndian Prime minister publicly announced that the ban or removal of said notes was a measure against black money operations, corruption and terror financing.

Experts say that the impact of 1978 demonetization was very less because people did not have black money in hard cash as they were mostly deposited at the Swiss bank. The comment made by the citizenry also attest to the fact that many were not bothered nor affected. For example, it was reported in an interview that someone said "I never saw a Rs. 1,000 notes. I am not bothered. However, the price of gold and other commodities dropped between 5% and 10% within 7 days after the announcement of the 1978 demonetization exercise.

The recent demonetization in the year 2016 under the regime of the Indian Prime Minister Shri Narendra Modi, was activated on 8th November via an unscheduled live televised address at 8:00 PM Indian standard time. The Prime Minister declared that the use of all Rs. 1000 and Rs. 500 Mahatma Gandhi series of banknote would be illegal past midnight, he further added in his declaration that the issuance of Rs 500 and Rs. 2000 new Mahatma Gandhi series bank notes will be used in place of the old banknotes.

Government of India claimed that this action was necessary in order to curb the shadow economy and crack down on the creation of counterfeit money which is also used to fund other illegal activities such as the issue ofterrorism. The RBI governor and economic affairs **Messrs Urjit Patel and Shakti Kanta Das (2016)** noted in a press conference that one purpose of this move was to fight terrorism funded by counterfeit notes. A period of 50 days was allowed by RBI in regards to the transition of the old currency to the newly proposed notes with December 30th as the deadline todeposit the old Rs. 500 and Rs. 1000 banknotes as credit in banknotes.

1.1 Indian MSME

Micro small and medium enterprises is' no standard, universal definition. Different agencies have defined MSMEs using Different parameters like scale, number of employees working, investment in plant and equipment etc. The small and medium enterprise department of the World Bank consider "Number of employees" as the criterion for identification whereas the BASEL committee (International Settlements of Central Bank of Member Countries) stated in uses the annual sales as its parameter (BASEL Committee, 2004).

MSME play essential role in Indian the overall industrial economy of the country. In recent year the MSME higher growth rate has consistently registered compared with the overall industrial sector and dynamism.

In India highly heterogeneous in terms of its size of it enterprises numbers of products and services, and level of technology by micro small and medium enterprise. MSME sector employs and calculated near about Rs. 579 lakh people spread over the Rs. 261 lakh Enterprise. This sector accounts for 45% of the manufacturing output and near about 40% of its total export of it nation (according to 4th census of MSME sector). Today MSME sector are Exposed to great opportunities for expansion and diversification across the sectors.

1.2New Classification of MSMEs

Classification of the MSME	New Classification (annual turnover)	Previous classification – Ceiling on Investment in Plant and Machinery (in Rs)
Micro	Not exceeding Rs 5 crores	Below 25 lakhs
Small	Between Rs 5 crores to Rs 75 crores	25 lakhs to 5 crores

SOCIO ECONOMIC PROFILE OF THE WOMEN SHGS IN KANPUR DEHAT DISTRICT (U.P.)

R.K. Doharey, Shalu gautam, Prakash Singh, Kamal Kishore and Shagufta wasim
Department of Extension Education, College of Agriculture N.D.U.A &T., Kumarganj, Ayodhya (U.P.)- 224229

Abstract

The study was conducted in Akbarpur block of Kanpur Dehat district selected purposively. A total number of 100 respondents of women SHG were selected purposively which were selected from 20 Villages randomly. The structured schedule was developed keeping in view the objectives and variables under study. The respondents were contacted personally for data collection. The analysis of data was done by using the percentage, mean, standard deviation, and correlation coefficient for drawing the inferences. The data revealed that the maximum number of women SHG respondents *i.e.* (61%) were found in middle age (27-45years).The majority of the categories belonged to scheduled caste, the dominancy of joint family system (55%) was observed. The women SHG members (60%) had medium family size (5 to 7 members) in their families and possess small land holding position. The majority of women SHG members (59%) reported agriculture as their main occupation. respondents 68% were found such who had earning annual income of (Rs. 25001-27500/-0) and (62%) respondents reported having mixed type house, respectively. The maximum of women SHG members (62%) were found members of one organization, (25%) member of two organizations and (13%) member of more than two organizations or office bearer. The cycle has immersed most important transportation.

Key words: Socio-economic profile and awareness etc.

Introduction

The Self-Help Groups (SHG) is a small voluntary association of poor people, preferably from the same socio-economic background. They come together for the purpose of solving their common problems through self-help and mutual help. The SHG promotes small savings among its members and these savings are kept with a bank. This common fund is in the name of the SHG. The SHG is a group formed by the community which has specific number of members like 15 or 20. Usually, the number of members in one SHG does not exceed twenty. In such a group the poorest would come together for emergency, disaster, social reasons economic support to each other have ease of conversation, social interaction and economic interactions.

A self-help group is defined as a "self-governed, peer-controlled information group of people with similar socio-economic background and having a desire to collectively perform common purpose. The Self-help groups have been able to mobilize small savings either on weekly or monthly basis from persons who were not expected to have any savings. They have been able to effectively recycle the resources generated among the members for meeting the productive and emergent credit needs of members of the group.

The SHGs are novel and innovative organizational setup in India for the women upliftment and welfare. All women in India are given chance to join any one of SHGs for training and development, so as to be prospective entrepreneur and skilled worker. The SHGs are promoted by the Government as if women in India may not be resourceful enough to be entrepreneurs. When the SHGs arrange training facilities to carry out certain kind of work which are suitable for women in India, bank must arrange financial assistance to carry out manufacturing and trading activities, arranging marketing facilities while the Governments will procure the product of SHGs, arrange for enhancing the capacity of women in terms of leadership quality and arranging for the management of SHGs by themselves so as to have administrative capacity. As a social movement with government support SHGs become more or less a part and parcel of the society.

The Government has been implementing various programmes which support women programmes to take up new venture and start self-employment, which has been categorized under four heads:

- Empowering strategies: Indira Mahila Yojana (IMY) Mahila Samridhi Yojana MSY: DWCRA.
- Employment and income generation: TRYSEM, Support for Training and Employment Programme (STEP) SGSY, SJSRY, Urban Self Employment Programme (USEP), JRY.
- Welfare and support services: Hostels for Working Women (HWW) Short Stay Homes (SSH), Swadhar Creches/day Care Centres for the Children of Working and Ailing Mothers.

Other enabling measures: Rashtriya Mahila Kosh (RMK), a national level mechanism to meet micro credit needs of poor and asset less women in the informal sector also known as the National Credit Fund for Women (NCFW). The total number of Self Help Groups (SHGs) promoted under National Rural Livelihoods Mission (NRLM) was 1864742 as on 31.03.2014. Their number increased to 2305513 as on 31.07.2015, recording a growth of 440771 SHGs as compared to 31.03.2014. In percentage terms, the progress made in the number of SHGs between 31.03.2014 and 31.07.2015 was 23.64%.

The SHGs have given a new lease of life to the women in villages for their social and economic empowerment. Economic development plays an important role in the development and growth of any society. The importance of promoting women to engage in economic activities is being increasingly realized in all developing countries which has two folds: of to empower the women by bringing them into the mainstream developing and improving their economic status and to provide new employment opportunities by way of income generation, self-employment and entrepreneurship to women for different socio-economic sector.

The constitution of SHGs is sometimes exclusively on particular social groups or a mix. The impact of SHGs on social harmony has also been mixed while it has been observed that the groups with mixed membership had group's leaders that came from a variety of the social groups. SHGs have impact on the community at large. There have been few instances of significant contributing to education, family planning, eradication of child labour and hygiene. The SHGs have helped their members and their communities by taking a leadership role in community development, hence SHG are perceived to be a guiding force for village. The loans that SHG members received are intended to improve their livelihood so that they can receive greater and steadier cash flows.

The concept of Self-help groups had its origin in the co-operative philosophy and the co-operators by and large, including the National Federations in the credit sector, could not think of any better SHG than a primary co-operative credit society itself, as SHG are small and economically homogenous affinity groups of rural poor, they are voluntarily coming together for achieving the: (1) To save small amount of money regularly (2) To mutually agree to contribute a common fund (3) To meet their emergency needs (4) To have collective decision making (5) To solve conflicts through collective leadership mutual discussion and (6) To provide collateral free loan with terms decided by the group at the market driven rates.

The SHG is a group of rural poor who have volunteered to organize themselves into a group for eradication of poverty of the members. The basic principles of the SHGs are group approach, mutual trust, organization of small and manageable groups, group cohesiveness, spirit of thrift, demand-based lending, collateral free, women friendly loan, peer group pressure in repayment, skill training capacity building

KNOWLEDGE LEVEL OF OKRA GROWERS WITH RESPECT TO SCIENTIFIC PRODUCTION TECHNOLOGY IN KANNAUJ DISTRICT (U.P.)

R.K. Doharey[1], Kamal Kishore[2], Prakash Singh[3], Shalu Gutam[4],
[1,2,3&4]Department of Extension Education, College of Agriculture, NDUA&T., Kumarganj, Ayodhya(U.P.)- 224229

Abstract

The study was conducted in Chhibramau and Talgram blocks of Kannauj district (UP) selected purposively, because these blocks one more popular for area and production of okra. A total number of okra growers were selected through random sampling from eight selected village's panchayats on the basis of ten respondents from each selected village panchayats. The some structured schedule was developed keeping in view the objectives and variables under study. The respondents were contacted personally for data collection. The results of the study depicted that the majority of the respondents were found in knowledge level field preparation (96%) were rank at 1st as far as knowledge possessed by the respondents were concerned. The insect/pest rank at 2nd rank (94%), followed by seed rate at rank 3rd (93.%), method of sowing of okra at 4th rank (92%),intercropping and weed management time of 5th (91.05%), suitable variety at rank 6th (90%), crop rotation at rank 7th (87%), irrigation management at rank 8th (86%), manure and fertilizer 9th (77%), disease control at rank 10th (73.75%), seed treatment rank 11th (61%), distance at rank 12th (58%), time of treatment 13th (51%), harvest and postharvest at rank 14th (37.05%) respectively. The overall knowledge index was calculated to be 77.62%. It can be calculated that the extent of knowledge about scientific okra cultivation seems to be satisfactory.

Key words : Knowledge level of okra growers with respect to scientific production technology.

Introduction

Indian subcontinent is endowed with favorable climate which permits growing of vegetables throughout the year. Vegetables play an important role in balanced nutrition as they are valuable source of carbohydrates, proteins, vitamins and minerals. The Per capita consumption of the vegetables in India is 160 g per day per person as against recommendation of 300 g per day per person. According to these statistics, we need to produce approximately 0.3 MT of vegetables per day for the present population. The present earning through vegetables export is little bit exceeding to Rs. 300 crores. Nature has endowed our country with vast diversity of land, soil and agro-climatic conditions which enables to produce varied types of vegetable crops. The area and production of vegetables are increasing year after year after the green revolution. There is substantial increase in production and productivityof vegetable crops. Due to growing of improved hybrid varieties and adoption of improved cultivation technologies, India"s share in the world production of vegetables is about 7 per cent (Anonymous, 1999).

Okra or ladies finger is an important vegetable of the tropical countries and most popular in India, Nigeria, Sudan, Iraq, Pakistan, etc. Okra is found in it's wild state on the alluvial banks of the Nile and the Egyptians were the first to cultivate it in the basin of the Nile (12'th century BC). It was propagated then through North Africa to the Mediterranean, the Balkans, and India. It arrived then in the America at Brazil (1658), Dutch Guinea and at New Orleans before extending in the United States and going up to Philadelphia in 1781. Its scientific name is "Abelmoschus esculents" and also "Hibiscus esculents", it belongs to the family Malvaceae. It is a tropical plant, 15 which grows best in warmer climates. It"s ready to harvest in around 60 days when the blooms begin to open, and is slightly tough. They have to be picked about 4-5 days after flowering in the fall. Okra varies in shades of green and can be smooth or has ribbed surfaces. (Varmudy, 2010).

Area and production of okra in India is 452,000 ha. and 4,803,000 MT. in Nigeria 387,000 ha. and 1,039,000 MT. and in Sudan 21,926 ha. and 223,650 MT. Here the share of India is 67.1 per cent, followed by Nigeria at 15.4 per cent and Sudan at 9.3 per cent. (FAO, 2010). In India, okra is grown throughout except in the mountain regions. The major producers are West Bengal, Bihar, Orissa, Andhra Pradesh and Gujarat. As far as area under okra cultivation in India is concerned, Orissa has an area of 74 thousand ha, West Bengal has an area of 73.1 thousand ha under okra cultivation followed by Gujarat, Andhra Pradesh, Jharkhand and others states. In terms of okra production, it is 0.83 million tones in West Bengal, 0.65 million tones in Orissa and 0.43 million tonnes in Andhra Pradesh. The average productivity in India is 10.5 tones per hectare. The highest productivity is in Andhra Pradesh at 15 tones per hectare followed by Jharkhand at 14 tons per hectare. The total area under this crop has increased over the years.

We eat food for good growth of our body. The food we eat contains nourishing substances called nutrients. There are five major nutrients, namely carbohydrates, proteins, fats, minerals and vitamins. It has an average nutritive value of 3.21 gm, which is higher than tomato, pumpkin and ashgourd. It contains 27 gm of carbohydrates, 2.2 gm of proteins, 0.29 gm of fat, 90 mg of calcium, 50 mg of phosphorus, 15 mg of iron and 16 mg of vitamin C per 100 gm of edible portion. The seeds contain 18-20 per cent oil and 20-23 per cent crude protein. Soups and stews of okra are popular dishes in India. The seeds, when ripe are sometimes roasted and used 16 as a substitute for coffee. The roots and stems of okra are used for clarification of sugarcane juice before it is converted into jiggery and brown sugar. The crop is used in the paper industry and fiber is extracted from its stem. Okra is considered by many as a super-vegetable with a lot of nutrition and medicinal benefits. Fibre also helps in stabilizing blood sugar. The mucilage not only binds cholesterol but also the bile acid carrying toxins dumped into it by the liver. Its fiber absorbs water and helps to prevent constipation. In fact, its slippery characteristics, which people dislike, facilitates elimination of excess cholesterol and toxins from the body.

There is many medicinal importance of okra; (i) The tender fruit is boiled and administered in fevers, gastric ulcers, catarrh, inflammation of the mucous membrane, difficulty in urination and dysentery. (ii) It is also considered remedy for spermatorrhea (involuntary discharge of the semen), syphilis, gonorrhea, and other disorders of the genitals. (iii) The fruit is also reported to increase sexual potency. (iv) The unripe fruit is eaten for tuberculosis of the lungs. (v) The infusion of the seeds will induce perspiration etc.

Okra can be grown in a wide range of soils – sandy loams to clay loams, provided they are well drained and supplied with enough organic matter. Main Okra growing season is Kharif (rainy season) June-July. However, it can be grown in September-October, January-February and also in summer season, where assured irrigation facilities are available (www.indiaagronet.com). Out of 137.00 lakh hectares geographical area of Chhattisgarh, 43 per cent area comes under cultivation. On the basis of climate and topography the state is divided into three agro climatic zones i.e. Chhattisgarh plains, Northern hills and Bastar Plateau. Horticulture exports has helps the country to earn 14,000 crore tones in the year of 2011-2012. Indian horticulture has crossed of production all time of over 240 million tones in the year of 2011-2012.

Keeping this in view, the present research entitled "To study the knowledge level of okra growers with scientific production technology"

Materials and Methods

The study was conducted in purposively selected kannauj district of Uttar Pradesh. There are 8 community development blocks in this

KNOWLEDGE ABOUT FORMATION, IMPLEMENTATION AND FUNCTIONING OF DIFFERENT WOMEN SHGS IN KANPUR DEHAT DISTRICT (U.P.)

Shalu gautam[1], R.K. Doharey[2], and Prakash Singh[3]
1,2&3 Department of Extension Education, College of Agriculture, NDUA&T,Kumargani, Ayodhya(U.P.)-224229

Abstract

The study was conducted in Akbarpur block of Kanpur Dehat district selected purposively. A total number of 100 respondents of women SHG were selected purposively which were selected from 20 Villages randomly. The structured schedule was developed keeping in view the objectives and variables under study. The respondents were contacted personally for data collection. The analysis of data was done by using the percentage, mean, standard deviation, and correlation coefficient for drawing the inferences. The data revealed that the maximum number of women SHG members (62%) had medium level of knowledge about formation, implementation and functioning of different women SHG followed by low (20%), high (18%) respectively. It is evident from the values of correlation coefficient as appeared in that out of 17 variables. The 4 variables *viz.*, annual income, social participation, extension contact, awareness about of ICT tools were found to be significant and positively correlated with degree of knowledge about formation, implementation and functioning of different women SHG at 0.05% probability and one variable 'caste' was found to highly significant and negatively correlated with degree of knowledge about formation, implementation and functioning of different women SHG at 0.01% probability. The variables like education, family type, family size, housing pattern, scientific orientation, and accessibility to computer were found to be non-significant but positive correlated with degree of knowledge about formation, implementation and functioning of different women SHG. The variable like 'caste' was found highly significant and negatively correlated with degree of knowledge about formation, implementation and functioning of different women SHG. This led to conclusion that out of 17 variables 4 variables which were significant influenced the degree of knowledge about formation, implementation and functioning of different women SHG means that as the annual income, social participation, extension contact, awareness about of ICT tools, etc.

Key words: Knowledge about formation, implementation and functioning of different women SHGs.

Introduction

The Self-Help Groups (SHG) is a small voluntary association of poor people, preferably from the same socio-economic background. They come together for the purpose of solving their common Problems through self-help and mutual help. The SHG promotes small savings among its members and these savings are kept with a bank. This common fund is in the name of the SHG. The SHG is a group formed by the community which has specific number of members like 15 or 20. Usually, the number of members in one SHG does not exceed twenty. In such a group the poorest would come together for emergency, disaster, social reasons economic support to each other have ease of conversation, social interaction and economic interactions.

A self-help group is defined as a "self-governed, peer-controlled information group of people with similar socio-economic background and having a desire to collectively perform common purpose. The Self-help groups have been able to mobilize small savings either on weekly or monthly basis from persons who were not expected to have any savings. They have been able to effectively recycle the resources generated among the members for meeting the productive and emergent credit needs of members of the group.

The SHGs are novel and innovative organizational setup in India for the women upliftment and welfare. All women in India are given chance to join any one of SHGs for training and development, so as to be prospective entrepreneur and skilled worker. The SHGs are promoted by the Government as if women in India may not be resourceful enough to be entrepreneurs. When the SHGs arrange training facilities to carry out certain kind of work which are suitable for women in India, bank must arrange financial assistance to carry out manufacturing and trading activities, arranging marketing facilities while the Governments will procure the product of SHGs, arrange for enhancing the capacity of women in terms of leadership quality and arranging for the management of SHGs by themselves so as to have administrative capacity. As a social movement with government support SHGs become more or less a part and parcel of the society.

The Government has been implementing various programmes which support women programmes to take up new venture and start self-employment, which has been categorized under four heads.

Other enabling measures: Rashtriya Mahila Kosh (RMK), a national level mechanism to meet micro credit needs of poor and asset less women in the informal sector also known as the National Credit Fund for Women (NCFW). The total number of Self Help Groups (SHGs) promoted under National Rural Livelihoods Mission (NRLM) was 1864742 as on 31.03.2014. Their number increased to 2305513 as on 31.07.2015, recording a growth of 440771 SHGs as compared to 31.03.2014. In percentage terms, the progress made in the number of SHGs between 31.03.2014 and 31.07.2015 was 23.64%.

The SHGs have given a new lease of life to the women in villages for their social and economic empowerment. Economic development plays an important role in the development and growth of any society. The importance of promoting women to engage in economic activities is being increasingly realized in all developing countries which has two folds: of to empower the women by bringing them into the mainstream developing and improving their economic status and to provide new employment opportunities by way of income generation, self-employment and entrepreneurship to women for different socio-economic sector.

The constitution of SHGs is sometimes exclusively on particular social groups or a mix. The impact of SHGs on social harmony has also been mixed while it has been observed that the groups with mixed membership had group's leaders that came from a variety of the social groups. SHGs have impact on the community at large. There have been few instances of significant contributing to education, family planning, eradication of child labour and hygiene. The SHGs have helped their members and their communities by taking a leadership role in community development, hence SHG are perceived to be a guiding force for village. The loans that SHG members received are intended to improve their livelihood so that they can receive greater and steadier cash flows.

The concept of Self-help groups had its origin in the co-operative philosophy and the co-operators by and large, including the National Federations in the credit sector, could not think of any better SHG than a [illegible] could extend itself as SHG

[3]Assistant Professor, Department of Extension Education, UPAC, Varanasi, Uttar Pradesh

ABSTRACT

Mobile phones have reduced the gap among farmers and buyers, now farmers directly communicate with customers and get price of their products from market. Mobile phones have also provided new approach to farmers to get latest information from meteorological department for weather conditions before using pesticides in their farms. However, internet is also disseminating information regarding price and marketing of goods and farmers are receiving information within minutes from all over the world. Into consideration of the above fact the study was conducted to examine the knowledge level of farmers about using mobile phone in the Milkipur tehsil of Ayodhya district, Uttar Pradesh during the agricultural year 2015-16. Selection of the respondents had done by simple random sampling method and 25 respondents from each village had taken to make a total sample size of 250 from the list of ten purposively selected villages for collection of primary data.

Keywords: Knowledge, Mobile phone, Primary data, Purposively, Simple random sampling

INTRODUCTION

In the 21st century agriculture is one of the divers industry which are increasing rural income as well as long term stability of its natural resources. This can create different activities which will affect farmers, stakeholder, customers and government industries. Information and communication technologies have transferred most important information about agriculture in developing countries. These developing countries now are connected with developed nations and getting the latest information and technologies regarding weather, natural resources and other related information (Rao, 2007).

In August 1995, the Chief Minister of West Bengal, Shri Jyoti Basu ushered in the cell phone revolution in India by making the first call to Union Telecom Minister Sukhram. Sixteen years later 4th generation services were launched in Kolkata. In India, out of every hundred citizens there are ninety people with mobile phone. A report by Kantar IMRB ICUBE (2018) highlighted that the number of internet users is 566 million as of December 2018. The report also finds that 87 per cent of the total user base, or 493 million Indians, are defined as regular users. Of this, 293 million active internet users reside in urban India, while there are 200 million active users in rural India. Not surprisingly, 97 per cent of users access the internet on their mobile device. According to the report, digital adoption is now being propelled by rural India. It is estimated that users in rural India are expected to reach 290 million by the end of 2019.

There are several reasons why mobile phones are considered as particularly important for development. First, beyond basic connectivity, mobile phones offer benefits such as mobility and security to owners (Donner, 2006). Second, due to their unique characteristics, the mobile phone is an especially good leap frogger: it works using the radio spectrum, as such there is no need to rely on physical infrastructure such as roads and phone wires, and base-stations can be powered using their own generators in places where there is no electrical grid (Economist, 2008). Third, mobile phones only require basic literacy, and therefore are accessible to a large segment of the population. Fourth, mobiles enjoy some technical advantages that make them particularly attractive

ABSTRACT: Field demonstration is the elderly concept of Front-Line Demonstration. FL Devolved by the Indian Council of Agriculture Research with the beginning of the Technology operation on Oilseed Crops during mid-eighties. Field demonstrations carry out close regulation of scientists of National Agriculture Research System recognized as frontline demonstrations because technologies are demonstrated in front of farmer by the scientists before being fed into the major extension method of the State Department of Agriculture. Adoption level of the beneficiaries were medium to high even as non-beneficiaries were found small level of adoption are enhanced production practice of mustard crop, proper training and extension strategies to be followed maximum adoption of mustard crop in the research area. Major limitations are to improve the spread of area explicit and maintainability upgrading advancements. Decentralize specialized and dynamic power to the locale level. Make a more compelling and monetarily maintainable public expansion framework. Step up the privatization of certain innovation move exercises. This article is helpful in extension work for improving the yield, economics and income of the farmer with different ideas and methods discussed.

Keyword: Frontline Demonstration, KVK, Yield, economics, growth, management practices and India.

INTRODUCTION

The Krishi Vigyan Kendras were assigned different actions pertaining to evaluation, modification and expression of different novel technologies. This includes conduction of association of Frontline demonstration, estimation, training programmes and sophistication of different agriculture and related technologies during OFT. Extension activities and movement of Krishi Vigyan Kendras do significant movement for the farmers and useful in hole crop period. Krishi Vigyan Kendras are the base of all organizations who work for purpose of technology through refinement, evaluation and demonstration of confirmed technology under diverse "micro farming" situation in a region (Das, 2007). In the year 1991-92 Indian Government established a "Technology Mission on Pulses" to improve the pulse production and productivity through frontline demonstration. The mandate of the Krishi Vigyan Kendra (KVKs) are application of technology through refinement, demonstration and assessment of verified technologies under different "micro farming" situations in a region (Das, 2007).

Frontline demonstrations is show recently released crop protection and production technology and its running practice on the farmers field under diverse farming situation and agro-climatic regions. While demonstrating the technologies on farmer's field, the scientist are compulsory to study situation, factors and elements involving in higher crop production. Limitation of production and thereby create production data and feedback information. Frontline demonstrations were conduct in two adopted villages at pasture of 20 farmers within area of 0.4 hectare each. Moong crop was grown according to the package and practices of moong crop according field demonstration (Anonymous, 2017).

A. Additional activities to be conducted by KVKs

Abstract

The present study was undertaken to find out adoption of package practices, marketing, constraints, Socio economic status, integrated pest management and recommended of legumes production technology. It was found that the independent variables, education, family size, social participation, size of land holding, age, extension contact, farming situation, education, social participation and risk orientation exposure had positive and significant association with the adoption level of the respondents regarding chickpea production technology. Majority of the farmers (small, marginal and medium) had fallen in medium category adoption about recommended cultivation practices of leguminous crops. Maximum number of legume growers were experienced various constraints in adoption of IPM practices, most of the respondents' highlighted non-availability of bio-agents, non availability of inputs at proper time (herbicide, traps and bio-pesticides etc.).

Keywords: Knowledge, Adoption, Marketing, IPM, Constraints, Legumes Grower and Indian.

Introduction

India is the largest producer, importer and consumer of pulses in the world, accounting for 25% of global production, 15% trade and 27% consumption. Pulses are chief source of protein and integral part of vegetarian human diet. The per capita availability of pulses in India is @ 42 g per day against the recommended dose of pulses for adult male and female 60 g and 55 g per day respectively (Tiwari and Shivhare, 2016). A variety of pulses are being grown in India including Chickpea (40%), Pigeonpea (18%), Blackgram (11%), Greengram (9%), Lentil (8%), Field pea (5%) and others (9%) are grown on 22-24 million ha. of area, producing 13-15 Mt. of grain with an average productivity of 6-6.5 tons/ha (Kumar and Kumawat, 2019). Uttar Pradesh state has a total area of 577 thousand ha, production of 475.4 thousand tones and yield 824 kg/ha under chickpea cultivation (Anonymous, 2017).

Socio-economic features of the legume grower farmers

Socio economic status

Patodia (2002) concluded that 56.67% of the total respondents belonged to middle class status, 22.92% had lower class status and 20.41% respondents were in higher class status. Kumar *et al.* (2017) revealed that all the sampled farmers of Hamirpur district were using improved seed of pulses whereas fertilize was applied by all the sampled farmers of Chitrakut district. The plant protection measures used by all the selected farmers of Chitrakut, Jalaun and Mahoba districts. In Madhya Pradesh, about 90% selected farmers of Sagar and Tikamgarh district were using improved seed of pulses, application of DAP and pest management done by all the farmers.

Age

Patodia (2002) reveals that 66.67% of total respondent were in the middle age group of 31 to 50 years, 22.50% farmers were above 50 years, while 10.83% respondents were in 22 to 30 years age group. Jadav (2005) concluded that more than two third (76%) of the respondents were in middle and old age group.

Farming situation

Jadav (2005) concluded that the majority of the mango growers possessed medium to large size of farm holding and might have medium irrigation potentiality proportionate to their farm.

Factors influencing adoption level of farmers regarding organic farming in eastern UP

Arvind Pratap Singh, Prakash Singh, RK Doharey, RK Singh, Rishi Kumar Singh, Abhay Kumar Singh and Vikash Pandey

Abstract
This study was undertaken in three districts selected randomly from each Zone namely (1) North Eastern Plains Zone (2) Eastern Plains Zone (3) Vindhyan Zone in Eastern Uttar Pradesh. From each selected district, two blocks were selected randomly. Thereafter two villages from each block was selected randomly, thus make a total 12 villages. The majority of respondents were of middle aged and literate including formal and informal education. Highest number of the respondents (55.83%) was observed in the medium category (33 to 44) of materials possession. Majority of farmers (60.41%) had medium level of overall extent of awareness about organic farming practices. The variables like age, family size, material possession and economic motivation, were found positively correlated but not significant with adoption level regarding organic farming practices. The variables like education, caste, family type, housing pattern, land holding, occupation, income, social participation, extension contact, value orientation, risk orientation and attitude were found negatively correlated but not significant with adoption level regarding organic farming practices.

Keywords: block, proportionate, age, education, overall materials possession, organic farming practices, adoption, correlations etc

Introduction
The organic movement in India has its origin in the work of Howard who formulated and conceptualized most of the views which were later accepted by those people who became active in this movement. Organic farming is a production system which avoids, or largely excludes, the use of synthetic fertilizers, pesticides, growth regulators, and livestock feed additives.

The Indian government has initiated various promotional activities, such as setting up a National Institute of Organic Farming in Ghaziabad, Uttar Pradesh, in 2003, appointment of accreditation and certifying agencies for organic farm products, developing norms for certifying organic products and providing financial support to implement promotional activities for organic farming. The task force constituted by the Government of India has also recommended the initiation of post-graduate level courses in organic farming. One of steering committee constituted by Central Government under the chairmanship of Mr. M.S. Swaminathan, Chairman, farmer's commission, has suggested taking up organic farming as a challenging national task and to take up this as a trust area of the 10th Five Year Plan. The Ministry of Commerce launched the National Organic Program in April, 2002 and processed food products export.

"Organic farming is a production system that avoids or largely excludes the use of synthetically compounded fertilizer, pesticides, growth regulators and livestock feed additives. Organic farming systems rely to the maximum extent on crop rotations, crop residues, animal manures, legumes, green manures, off-farm organic wastes, and aspects of biological pest control to maintain soil productivity and tilt, to support plant nutrients and control insects, weeds and other pests". (Kanel, 2005) [2].

Methodology
The present study was conducted in six blocks of three districts namely Barabanki Basti, and Prayagraj of Uttar Pradesh. Each district selected two block and find out the different independent variables and their level of adoption of organic farming practices in organic farming. Those blocks namely Masauli, bani kodar, Haraiya, Vikram jot, Phulpur and Dhanupur was selected randomly having production area of agriculture.

Hence, the present study has been designed to explore the level of adoption of organic farming

Abstract

Now a days through social media people are easily connected to each other thus enhancing the knowledge sharing process, it shows that the usage of social media by the students and type of that use by respondents. Social media is becoming one of the most popular and most accessed media of communication these days, the world of extinct knowledge require researcher to share knowledge among them with the invention of social media it utilizes information and communication technologies to improve people to people connections. With the advancement of science and technology, the world has come close to each other. Today people don't have to wait for the dissemination process but the condition is such that every social media user has become a source of information on their own. The daily news and views to which the social media user comes across cover a wide range of topics. These topics or subjects are related to the happenings of our surrounding. The whatsapp was I[st] and facebook was II[nd] rank Instagram that it got III[rd] ranks.

Key words: whatsapp, Facebook, Twitter, Instagram, Students.

Introduction

Social media have been defined in a variety of ways. The definition of social media as a "platform to create profiles, make explicit and traverse relationships" by Boyd & Ellison, 2008. Social media is often described by example. Social networking sites, blogs, wikis, multimedia platforms, virtual game worlds and virtual social worlds SNS in the United States social networking market (com Score, 2011). Social media are interactive computer-mediated technologies that facilitate the creation or sharing of information, ideas, career interests and other forms of expression via and networks. Social media are technologies that facilitate social interaction, make possible collaboration, and enable deliberation across stakeholders". These technologies now include blogs, wikis, media (audios, photos, videos, texts) sharing tools, networking platforms (including Facebook) and virtual worlds, Social media has brought different people from the different geographical area on one platform on which they can share their feeling, ideas, emotions, information and much more (Bryer & Zavatarro, 2001). Social media, derived from the social software movement, are a collection of Internet websites, services, and practices that support collaboration, community building, participation, and sharing (Junco *et al.*, 2010).

Methodology

Acharya Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya in the district Ayodhya (U.P.), hence the study has been purposively confined in one of its university. The particulars of the district have been furnished here has under. The district Ayodhya, is situated at 26.50°N latitude and 81.4°E longitude. Its total geographical area is 2643 square kilometer. The density of population is 1054 per square kilometer. It has five tehsils namely Faizabad, Milkipur, Bikapur Sohaval, Rudouli and community development blooks namely Sohaval, Masodha, Purabazar, Mayabazar, Milkipur, Amaniganj, Bikapur, Tarun, Haringtonganj, Rudouli and Mawie At the second stage of sampling out of 11 communities development Blocks of Ayodhya district, the Milkipur development Block was selected purposively for this study because of the criteria that Acharya Narendra Deva University of Agriculture & technology, Kumarganj is situated in this Block. Community development block, Milkipur was established in 1962. This is a post stage block according to block settlement. The block has been divided into six village development officer's circle for carrying out the development activities. This block has 10 Nyan panchayats namely Inayat Nagar, Dubhiyara, Gaknia, Alipur khajuri, Kuchera, Tendha, Sari, kurawali, Sufedi and Milkipur and 67 gram panchayats and 113 villages which cover a total geographical area of 2169.45 square kilometers. The total population of the Block according to 2011 census was 158,938 (78,528 Male and 80410 female), among them 25,872 males and 8,926 female were literate.

Result and Discussion

ABSTRACT

The study was conducted in year 2018 to 2020 since the investigator is studying in N.D.U.A & T, Kumargunj, Ayodhya. So were done collect the required information from N.D.U.A & T, Ayodhya, C.S.A.U.A. & T, Kanpur, S.V.P. U.A &T, Meerut and Banda University of Agriculture &Technology, Banda. College of Agriculture from each university was taken for the study purpose. Selection of the respondents purposively was done by simple random sampling method from every agriculture college for each agricultural university in Uttar Pradesh. An it's of all the students studying in P.G. classes in all four agricultural universities were prepared and out of that 30% of the students were selected as sample for study purpose. The total sample size 657 respondents, about the 30% total post graduate students sample size 197respondents were selected randomly all four universities college. The respondents were contacted personally for data collection. The results of the study depicted that the maximum number of the respondents were found in various socio-economic profile characters like, age composition of 22 to 25 years (48.22%), General caste (32.99%), Unmarried respondents (24.36%), Nuclear/ single family system (75.63%), Family size (small up 5 members) (52.79%), Land holding as small (1-2 ha.) (57.36%), House hold materials (cots) (100.0%), Communication and media possession (mobile phone) (100.0%), Farm power (diesel engine) (77.15%), Agriculture implements (Khurpi) (100.0%), Social participation (no participation) (49.74%), Parent Occupation (agriculture main) (70.05%), Annual family income (medium 36001-150000) (49.74%), Housing pattern (pucca) (49.74%), respectively.

Keywords: *Socio-economic profile, Knowledge, Awareness*

INTRODUCTION

The word "media" is derived from the word medium, signifying mode or carrier. Media is intended to reach and address a large target group or audience. The word was first used in respect of books and newspapers that is print media but with the advent of technology, media now encompasses television, movies, radio and internet. In today's world, media becomes as essential as our daily needs.

Books (48.22%) preparation , Magazines (25.38%) farm management information, Mobiles/Cell phone/Android phone (48.22%) communication, Demonstration (43.14%) sowing new practice for student development, Film show (40.60%) transfer of new technology, Exhibition (41.62%) education, and Posters (43.14%) display of awareness in class room, respectively.
Key words: *Uses mass media pattern, collection of information and awareness etc.*

INTRODUCTION

The term media is derived from Medium, which means carrier or mode. Media denotes an item specifically designed to reach a large audience or viewers. The term was first used with the advent of newspapers and magazines. However, with the passage of time, the term broadened by the inventions of radio, TV, cinemas and Internet. In the world of today, media has become almost as necessary as food and clothing. It is true that media is playing an outstanding role in strengthening the society. Its duty is to inform, educate and entertain the people. It helps us to know current situation around the world. The media has a strong social and cultural impact upon society. Because of its inherent ability to reach large number of public, it is widely used to convey message to build public opinion and awareness. The role of media in education is evident today by the number of computer labs, television sets and libraries that have become part of curriculum in most schools today. Media comes in different forms and each form affects the way students learn and interpret information. Media has brought the world closer (globalization) so that now students from different universities in different parts of the world are connected through a mere internet connection. Amidst the information revolution m ass media has become such a massive part of our lives (2018) [1-3].

The success of agricultural development programmes in developing countries largely depends on the nature and extent of use of mass media in mobilization of people for development. The planners in developing countries realize that the development of agriculture could be hastened with the effective use of mass media. Radio,Television have been acclaimed to be the most effective media for diffusing the scientific knowledge to the masses. In a country like India, where literacy level is low, the choice of communication media is of vital importance. In this regard the television and radio are significant, as they transfer modern agricultural technology to literate and illiterate farmers alike even in interior areas,

Abstract

Social media has become ubiquitous and almost inescapable, revolutionizing the way students communicate, interact and socialize and has become an integral part of their social and cultural fabric, consequently, students are spending a substantial part their time on social media. Social media is becoming one of the most popular and most accessed media of communication these days. Social media has brought different people from the different geographical area on one platform on which they can share their feeling, ideas, emotions, and thoughts on the same platform. With the advancement of science and technology, the world has come close to each other. Today people don't have to wait for the dissemination process but the condition is such that every social media user has become a source of information on their own. The daily news and views to which the social media user comes across cover a wide range of topics. These topics or subjects are related to the happenings of our surrounding. People can like, show emotions through the list of emoticons or even comment accordingly. The social media act as an umbrella that constitutes a variety of interesting features that have our life very easier. Features of tagging friends, location sharing, photo and video uploads, message chatting, video calling, searching friends etc have made our life more engaging.

Key words: Social Media, Student, Information, Sources.

Introduction

Social media are technologies that facilitate social interaction, make possible collaboration and enable deliberation across stakeholders". These technologies now include blogs, wikis, media (Audios, photos, videos, texts) sharing tools, networking platforms (including Facebook) and virtual worlds (Bryer & Zavatarro, 2001). Social media has brought different people from the different geographical area on one platform on which they can share their feeling, ideas, emotions, information and much more. The Manifold social networking sites like Face book, WhatsApp, Instagram, Twitter, LinkedIn, Google and others open the door to share ideas, views and thoughts on the same platform. With the advancement of science and technology, the world has come close to each other. Today people don't have to wait for the dissemination process but the condition is such that every social media user has become a source of information on their own. The daily news and views to which the social media user comes across cover a wide range of topics. These topics or subjects are related to the happenings of our surrounding. People can like, show emotions through the list of emoticons or even comment accordingly. The social media act as an umbrella that constitutes a variety of interesting features that have our life very easier. Features of tagging friends, location sharing, photo and video uploads, message chatting, video calling, searching friends etc have made our life more engaging (NIPFP, 2016).

Methodology

Acharya Narendra Deva University of agriculture and technology,Kumarganj, Ayodhya in the district Ayodhya (U.P.), hence the study has been purposively confined in one of its university. The particulars of the district have been furnished here has under. The district Ayodhya, is situated at 26.50°N latitude and 81.4°E longitude. Its total geographical area is 2643 square kilometer. The density of population is 1054 per square kilometer. It has five tehsils namely Faizabad, Milkipur, Bikapur, Sohaval, Rudouli and community development blooks namely Sohaval, Masodha, Purabazar, Mayabazar, Milkipur, Amaniganj, Bikapur, Tarun, Haringtonganj, Rudouli and Mawie At the second stage of sampling out of 11 communities development Blocks in Ayodhya district, the Milkipur development Block was selected purposively for this study because of the criteria that Acharya Narendra Deva University of Agriculture & technology, Kumarganj is situated in this Block.

Community development block, Milkipur was established in 1962. This is a post stage block according to block settlement. The block has been divided into six village development officer's circle for carrying out the development activities. This block has 10 Nyan panchayats namely Inayat Nagar, Dobhiyara, Gukula, Alipur khajuri, kuchera, Tendha Sari, kurawan, Sidsid and Milkipur and 67 gram panchayats and 113 villages which cover a total geographical area of 2169.45 square kilometers. The total population of the Block

Current perceptive on canine cystic endometrial hyperplasia-pyometra syndrome-A review

Saurabh, Sushant Srivastava, Anand Kumar, Pushkar Sharma, RK Doharey, VK Singh and Vinay Kumar

DOI: https://doi.org/10.22271/chemi.2020.v8.i2c.9772

Abstract
Cystic endometrial hyperplasia-pyometra complex (CEH/P) is a life-threatening challenge in canine reproduction. Hormonal imbalances result in environmental and histological changes in the uterus leading to a predisposition to bacterial growth. Haematological analysis shows the total number of leucocytes is frequently elevated in cases of pyometra, although the degree is much less marked in cases of open cervix pyometra compared with closed cervix pyometra. Ovariohysterectomy is the treatment of choice for closed cervix or open cervix pyometra. If the condition is not life-threatening and the animal is enrolled in breeding programmed or particularly valuable or when the clinical situation precludes surgery, medical treatment may be considered.

Keywords: Uterus, cystic endometrial hyperplasia (CEH), hormones, canine pyometra, aglepristone

Introduction
During estrus cycle, the uterus of female dogs undergoes different morphological changes under the influence of progesterone and estrogen. Cystic endometrial hyperplasia is an abnormal response of non-castrated canine uterus under these ovarian hormones. Cystic endometrial hyperplasia and pyometra complex (CEH/P) represents a common life-threatening challenge in small animal reproduction (Pretzer, 2008; Melandri *et al.*, 2019) [37, 30]. Cystic endometrial hyperplasia (CEH)-pyometra syndrome is an acute or chronic, poly-systemic, diestrual disorder of non-castrated bitch characterized by hyperplasia of the endometrium and infiltration of inflammatory cells, which may be present in all layers of the uterus (Dow, 1957; Kennedy *et al.*, 1993) [9, 29]. However, during the animal's life, there is progressive hyperplasia, which ultimately results in the development of pathological lesions termed cystic endometrial hyperplasia several authors suggested that pyometra should be classified as CEH-pyometra complex because sub-acute endometritis later develops as CEH is the most important predisposing factor of pyometra (Sandholm *et al.*, 1975) [39]. Others suggest that CEH and pyometra should be classified separately based on differences in clinical and histopathological findings (Debosscher, *et al.*, 2001) [8]. It is common to see pyometra defined as the endometritis/cystic endometrial hyperplasia/pyometra complex (CEH/P) (Arora *et al.*, 2006) [3].

Pyometra can be defined as the pathological condition of uterus in which, there is an accumulation of purulent semisolid-liquid material inside the uterine lumen of intact bitches, generally during post progesterone dominant phase of the estrous cycle. Canine Pyometra can be classified based on the status of the cervix may be two types open-cervix and closed-cervix. Closed-cervix pyometra is a particularly more dangerous condition in comparison to open cervix because septicemia and toxemia may develop rapidly and left untreated can result in patient death. However closed-cervix pyometra needs surgical intervention to prevent its progression to sepsis and fatality in non-castrated bitch (Smith, 2006) [45].

Prevalence and History
Pyometra has consistently been shown to predominantly affect middle-aged to older-aged non castrated bitches, with mean age varying from 6.4 to 9.5 years (Dow, 1958; Ewald, 1961; Hardy 1974; Wheaton *et al.*, 1989; Sevelius *et al.*, 1990; Niskanen and Thrusfield, 1998; Egenvall *et al.*, 2001; Fukuda, 2001; Whitehead, 2008; Igna, 2011; Hagman *et al.*, 2011) [10, 14].

ABSTRACT

Horticulture sector has become one of the major drivers of growth in the agriculture sector and it share about 30 per cent among total agriculture output. Potato (*Solanum tuberosum* L.) is considered to be one of the most epochal horticultural crops in the world because of its most affordable and most accessible food, which provide copious health benefits. In Uttar Pradesh, Kannauj district is an abundant producer of the potato crop. The study was conducted in Jalalabad block of Kannauj district of Uttar Pradesh. A simple random sampling method was used to select 125 respondents out of total 1338 potato growers from the selected five villages. The study reveals that according to degree of seriousness of constraints the maximum number of respondents faced constraints like, the constraint under socio-psychological was found most important constraints, *i.e.* 'skilled farm workers are hardly available'. Under economical constraints, the most important constraints *i.e.* 'costly diesel charges, and 'corruption of credit sanctions. Under technological constraints, the most important constraints were 'non-availability of quality HYV seeds. Under transportation constraints, the most important, was 'indigenous transport-means *viz.*, bullock cart, dunlop, tonga take much time and causes more inconvenience in transporting the products. Under post harvest technological constraints, the most improvement were 'lack of space in house of potato farmers for storing the products. The suggestive measures to overcome the constraints in potato production technology as perceived by the respondents were "suitable approach for the safeguard of the crop against the animal (blue calf)". Most frequently opined remedial measures expressed by the respondents and field observation made by the investigator was ensuring the fencing of the farmers' farm as appropriately as possible

INTRODUCTION

Potato (*Solanum tuberosum* L.) popularly known as 'The king of vegetables', has emerged as fourth most important food crop in India after rice, wheat and maize. Indian vegetable basket is incomplete without Potato. Because, the dry matter, edible energy and edible protein content of potato makes it nutritionally superior vegetable as well as staple food not only in our country but also throughout the world. Potato contributes about 1.23 per cent to the gross production from agricultural and allied activities in India (Prasad, 2006). Potato is a very important cash crop in India and the country produced 45.34 mt of potato from 1.99 mha land with average productivity of 22.80 tones/ha during 2012-13 (NHB, 2013).

Uttar Pradesh is the largest potato producing state in the country and accounts for 32 per cent of total production. The state produces 14.43 mt of potato from an area of 0.60 mha with productivity of 23.9 tones/ha during 2012-2013 (NHB, 2013). This rapid growth under production (10.63 mt in 2008-09 to 14.43 mt in 2012-2013) of potato in Uttar Pradesh was possible through dissemination of the latest technology under real farming conditions. Potato cultivation has become highly commercialized in Uttar Pradesh, still there is a wide gap between current production and potential productivity. So efforts have to be made by researchers, policy makers and extension workers together to overcome these constraints. With the view to achieve a high level of production it is not enough to develop farm

Evaluation of the effect of different fungicides against *Phytophthora infestans* (Mont) de Bary *(In vitro)*

Vinay Kumar, Ramesh Singh, RK Doharey and Satendra Kumar

Abstract
Late blight of potato caused by *Phytophthora infestans* (Mont.) de Bary is one of the the most serious disease of potato. Several management practices have been adopted for so for to minimize the disease. Butin the present investigation based on Laboratory condition. The efficacy of six different fungicides tested on mycelial growth of the *Phytophthora infestans* (Mont.) de Bary that minimum radial growth with 0.75 mm in diameter was recorded at 300 ppm concentration which was followed by 200 ppm, and 100ppm and 50 ppm. However, nomycelial growth recorded at 400 ppm. As per concern of percent inhibition the highest with 100 % inhibition was recorded from 400 PPM concentration of Metalaxyl . Hence, the use of fungicides is the very effective method for management of plant disease and continuous use both systemic and even protective fungicides of fungicides may supressed growth of a develop strain of the *Phytophthora infestans* (Mont.) de Bary.

Keywords: Phytophthora, Late blight, Mycelium, Fungicides, Radial growth, ppm

Introduction
Potato (Solanumtubersom L) ranks third in importance as a food crop, following wheat and rice belonging to the family Solanaceae (Hawkes, 1989) [2]. It is considered as a good source of energy and proteins, sodium, potassium, thiamin, calcium, phosphorus, magnesium, vitamin B, folic acid and other vitamins. Late blight of potato caused by *Phytophthora infestans* (Mont.) de Bary is one of the most serious and destructive diseases of potato all over world, including India. The great Irish famine in 1845, due to late blight is one of the most dramatic episodes caused by a plant pathogen in human history (Khurana *et al*., 1998 [3]. Worldwide losses due to late blight of potato are estimated to exceed $5 billion annually and thus the pathogen is regarded as a threat to global food security. The disease caused yield losses ranging from 31-100%.The use of fungicides is the very effective method for management of plant disease. Several management practices have been adopted for so for to minimize the disease. But in the present investigation condition use of six different fungicides tested on mycelial growth of the *Phytophthora infestans* (Mont.) de Bary. In India, late blight pathogen attacked the potato crop in severe form wherever it is grown. However, it is comparatively more devastating in Himalayan and Nilgiri hills and causes severe crop losses. In Indo-Gangetic plains, depending upon prevailing weather conditions, the early appearance of late blight of potato may seriously damage the potato crop and causing heavy loss of potato growers.

Materials and Methods
The present investigations based on Glasshouse experiment was undertaken at Department of Plant Pathology, Chandra Shekhar Azad University of Agriculture and Technology Kanpur during crop season 2016-18. The procedure and techniques applied during the course of investigations were elucidated as below:

Isolation, purification, identification and maintenance of *Phytophthora infestans* (Mont) de Bary Collection of infected plant samples
Late blight infected leaves were collected from the potato field at Vegetable Research Farm, C. S. Azad University of Agriculture and Technology, Kanpur. Infected leaves with sporulation lesions were taken from the field and washed in sterilized water. The leaves were then placed in a humidity chamber with the leaf an axial side up. They were incubated at 18±1°C in BOD. until sporulation appeared. Small pieces of infected tissue along with healthy portion from the sporulating border were cut and placed under potato slices in empty sterilized Petri-plates. The Petri-plates were incubated at 18± 1°C for 10 days until there was a growth of abundant

Study the effect of integrated disease management approach on germination, plant height and yield of potato and on severity of late blight of potato *Phytophthora infestans* (Mont.) de Bary.

Vinay Kumar, Ramesh Singh, RK Doharey, Ramesh Chand, Sushant Srivastava and Rabindra Kumar

DOI: https://doi.org/10.22271/chemi.2020.v8.i2b.9501

Abstract
Late blight of potato caused by *Phytophthora infestans* (Mont.) de Bary is one of the most serious diseases of potato. Several management practices have been adopted so for to minimize the disease. But in present investigation based on laboratory and glass house condition revealed that soil application and tuber seed dressing with bioformulation provided good protection against late blight and also stimulate the germination. The data showed that the plant height of potato was maximum in treatments T1(Soil application of FYM @ 125gm/pot +mushroom waste with *T. harzianum* @ 5gm/gm+tuber treatment with *Azotobacter* @ 5%+foliar spray with Ridomil @ 0.25%) with the value of 44.9 cm at 30 days age of plant. Tuber treatment with bio agents stimulated the germination per cent of the tuber. The Maximum germination per cent was noted in case of T1(Soil application of FYM @ 125gm/pot+mushroom waste with *T. harzianum*@ 5gm/kg+tuber treatment with *Azotobacter*@5%+foliar spray with Ridomil @ 0.25%) Growth promoting effects of the soil amendment+ tuber treatment + foliar spray were also perceived. The fungicides and bio agents were found to increase the plant length over control. Foliar spray with the fungicides pathogenic inoculation protected the plants against infection resulting reduced disease severity. The minimum disease severity (10.66) was reported from treatments were given as treatment T1(Soil application of FYM 125gm/pot+ mushroom waste with *T. harzianum* 5gm/kg +tuber treatment with *Azotobacter* @5%+foliar spray Ridomil @ 0.25%) treated plants against 82.33% disease severity in case of control. The integrated effect o FYM+ mushroom waste as soil application bioformulation as tuber 51.67gm. and total weight of tuber 338.33gm. where trea tment was given as soil application of FYM @125gm/pot+ mushroom waste with *T. harzianum*@ 5gm/kg+tuber treatment with *T. harzianum* @5%+foliar spray with 665.02gm was recorded from treatment T1(Soil application of FYM 125gm/pot +mushroom waste *T. harzianum* @ 5gm/kg+tuber treatment with *Azotobacter*@ 5%+foliar spray with Ridomil @ 0.25%).

Keywords: Late blight, *Azotobacter*, mushroom waste, *Trichoderma*

Introduction
Potato can be used as a vegetable alone or in combination with other vegetables such as cabbage, cauliflower, tomato, brinjal, beans etc. It is also used in the preparation of chips, puffs and raw pulp. It is served in meals as well as snacks preparation. Thus, potato is important for small- hold farmers as well as a cash crop. The daily need of potato is increasing day by day resulting from increasing population growth of the world. Therefore, there is a demand for more production from per capital available land. Though, production of potato is increasing continuously but productivity rate per unit area of land is very low as per other countries of the world, which has the main reason of biotic factors caused by fungi, bacteria, virus, viroid and nematodes etc. Among them late blight of potato caused by *Phytophthora infestans* (Mont.) de Bary is one of the most serious and destructive diseases of potato all over world, including India. The great Irish famine in 1845, due to late blight is one of the most dramatic episodes caused by a plant pathogen in human history (Khurana *et al*., 1998) [1]. The Irish famine affected food production as well as economic and social aspect of communities (Large, 1940) [2]. The disease is also the major bottleneck in potato production in Ethiopia and other parts of the world (Goodwin *et al*. 1995) [3].

Awareness of farmers about hybrid rice production practices

Vikash Pandey, RK Doharey and NR Meena

Abstract
The present study was conducted in two districts of Eastern Uttar Pradesh. Namely district Azamgarh in Eastern Plain Zone North and Sonbhadra in Vindhyan Zone of Uttar Pradesh since there was more cultivated land. Keeping in view the highest and lowest area under hybrid rice in the block of the district. From selected blocks of Azamgarh district namely Thekma, Tarwa and Tahbarour. Separate lists of villages were prepared. From them four villages from each block will be selected randomly to draw the samples of farmers, with the consideration of highest acreage under hybrid rice. Four villages from each block were selected randomly to draw the samples of farmers, with the consideration of highest acreage under hybrid rice. From selected blocks of Sonbhadra District namely Chatra, Chopan, Duddhi. Separate lists of villages were prepared. From them four villages from each block will be selected randomly to draw the samples of farmers, with the consideration of highest acreage under hybrid rice. Four villages from each block were selected randomly to draw the samples of farmers, with the consideration of highest acreage under hybrid rice. A separate list of farmers was prepared for each selected village and arranged according to the category of farmers i.e. marginal, small, medium, and big farmers. Therefore, a total of 360 respondents were selected through random sampling techniques, 15 framers were selected from each village. The knowledge in the present context has been conceptualized as the amount of information about currently recommended practices is known to the farmers and the adoption would be operational the recommended technology is actually being utilized by the farmer on their fields. . Keeping in the view consequence of production practices of hybrid rice, the present study conducted on "Awareness of farmers about hybrid rice production practices". Present study pertaining to 2020-21. majority of farmers are aware from new production technology used in hybrid rice production 49.44 farmers having high(29and above) followed by medium (25-28) 28.33 per cent and low (up to 24) 22.22 pe cent, respectively are aware from new production technology at overall level. It also concluded that most of farmers are aware from what are the different types of hybrid rice farming.

Keywords: awareness, knowledge, random sampling technique, technology etc.

Introduction
The total agricultural exports from the country. Rice is the most essential and widely grown food crop in the world. Because of it provides national food security and generating employment and incomes for the low-income sectors of society, most of Asian governments regard hybrid rice as an intentional commodity. India was the major exporter of hybrid rice (10.14 million tones) in 2013-14 followed by Thailand, Vietnam and U. S. A. Hybrid rice occupies about 23 per cent of the gross cropped area as well as 35 per cent of the total area under food grains in the country. Hybrid rice is consider as the master crop of coastal India as well as in several regions of the eastern India during the summer monsoon rainy season mutually high temperature and heavy rainfall offers ideal circumstances for the cultivation of hybrid rice. Approximately the entire parts of India are appropriate for raising hybrid rice during the summer season. Consequently, hybrid rice is too raised even western Uttar Pradesh, Punjab and Haryana in low level areas such as waterlogged during the summer and monsoon rainy season. The need of machinery for hybrid rice cultivation arises due to drudgery, high production cost, low quality, low cropping intensity and Labor scarcity. Farm equipment are used in agricultural operations including immediate post-harvest activities with the objective of increasing the productivity of land and labor through relevance of operations, efficient use of inputs, perfection in quality of produce, safety issues and comfort to farmers, reduction in loss of produce and drudgery of farmer. Tractor mounted implements i.e. mould board ploughs, disc ploughs, cultivators and other crop- specific equipment are widely used for seed bed preparation. Seed drills and planters, both animals drawn and tractor mounted, become popular. The knowledge recognized as one of the most important component of human

To assess the knowledge extent of farmers which use of cell phone in Kanpur Dehat district of U.P.

Shalu Gautam, RK Doharey, NR Meena and Atul Kumar

Abstract
This study was conducted in Akbarpur, Maitha, Sarwankhera and Jhinjhak block of Kanpur Dehat district of Uttar Pradesh to know the study and importance of cell phone usages for empowerment of rural farmer's during the year 2020-21. A total number of 400 farmers were selected randomly from a list of 20 randomly selected villages. The structured schedule was developed keeping in view the objectives and variables under study. The respondents were contacted personally for data collection. The analysis of data was done by using the percentage, mean, standard deviation, and correlation coefficient for drawing the inferences. That the majority of the respondents (46.00) belonged to the categories of medium (25-56) for their overall knowledge about using cell phone, followed by 27.50 per cent respondents belonged from the category of low (up to 24) and only 26.50 per cent respondents belonged from the category of high (57 and above), respectively. Hence, it can be concluded that the overall knowledge level of the cell phone users about using cell phone was maximum medium category (25-56).

Keywords: knowledge, mean, standard deviation, correlation, cell phone, respondents

Introduction
A cellular phone is a telecommunication device that uses radio waves over a networked area (cells) and is served through a cell site or base station at a fixed location, enabling calls to transmit wirelessly over a wide range, to a fixed landline or via the Internet. In this networked system, the cellular phone is identified as a mobile system consisting of the equipment and SIM card that actually assigns the mobile telephone number.

A cellular phone is also known as a cell phone or mobile phone. It enables a user to communicate almost anywhere in the world. The cell phone was invented by Dr. Martin Cooper, along with his team of developers at Motorola.

The first cell phone weighed 2.4-pounds and was 9-inches long. Dr. Cooper also made the first cell phone call at Motorola on April 3, 1973.

India has 1,026.37 million active mobile users on 2G, 3G and 4G networks – in 2018, TRAI statistics report. Total mobile subscriber base including active and inactive users has reached 1,176 million in2018. The proportion of active subscribers was approximately 87.28 percent of the total wireless subscriber base.

Bharti Airtel has the maximum proportion (98.68 per cent) of its active wireless subscribers. Vodafone Idea has 93.33 percent active mobile phone customers on its network. Reliance Jio has 83.59 percent active customers on its 4G network. BSNL has 56.20 percent active mobile users in 2018.

Mobile customers in urban areas reached 647.52 million. India has 528.48 million mobile users in rural areas. Mobile phone density in India was 89.78 in 2018. Mobile service tele-density was 155.48 in urban areas and 59.15 in rural areas.

Information delivery system is the one of the main components for dissemination of knowledge or new technology. Information gap has been recognized as one of the important constraints in the overall agricultural development of the country. Indian agriculture had been on traditional lines till the first waves of green revolution in late 60s. The green revolution gave a sudden boost to the production and productivity of major cereals in the assured irrigated areas. Quick dissemination of technological information from the Agriculture Research System to the farmers in the fields and reporting farmers' feedback to the research system is one of the critical inputs in transfer of technology.

To increase the farm production, the farmers need to be informed on recent scientific farm innovations. Farm information and technology dissemination to the farmers provides opportunities for their self-development, improves existing knowledge, skills and enhances

Socio-economic, communication and psychological characteristics attributes of the hybrid rice growers

Vikash Pandey, RK Doharey and NR Meena

Abstract
The present study was conducted in two districts of Eastern Uttar Pradesh. Two districts *viz*. Azamgarh and Sonbhadra from Eastern regions of Uttar Pradesh were selected purposively. Therefore, three blocks *viz*. Thekma, Tarwa, Tahbarpur of Azamgarh district and Chatra, Chopan, Duddhi of Sonbhadra district were selected purposively. Separate lists of villages were prepared. From them four villages from each block will be selected randomly to draw the samples of farmers, with the consideration of highest acreage under hybrid rice. Four villages from each block were selected randomly to draw the samples of farmers, with the consideration of highest acreage under hybrid rice. Four villages from each block were selected randomly to draw the samples of farmers, with the consideration of highest acreage under hybrid rice. A separate list of farmers was prepared for each selected village and arranged according to the category of farmers i.e. marginal, small, medium, and big farmers. Therefore, a total of 360 respondents were selected through random sampling techniques, 15 framers were selected from each village. The suitable statistical tools/techniques were used for computing the data and inferences to be drawn. The present study carried out during the year 2020-2021. Hybrid rice is consider as the master crop of coastal India as well as in several regions of the eastern India during the summer monsoon rainy season mutually high temperature and heavy rainfall offers ideal circumstances for the cultivation of hybrid rice. Most of farmers are belonged to age group (35-55 years) 49.44per cent and majority of people belongs to general category. Majority of respondents educated, most of respondents have mixed house, majority of farmers depends on agriculture as a source of income, most of farmers having marginal farmers and their income falls under medium income. It also concluded that majority of respondents are belongs to nuclear family. It observed that 42.22 per cent of the respondents were participated as member of two organizations/office bearer followed by 37.77 per cent participated in one organization and 20.00 per cent respondents having No participation in any organization. Respondents were used cycle as means of transportation. Sent per cent members having cots and crockery in term of house hold material. It also evident from that sent per cent of the respondents having Kudal, kurpi found as source of agricultural material. Majority of respondents were used mobile phone 90.83 per cent for communication purpose.

Keywords: social participation, communication, statistical tools, sampling technique and respondents etc.

Introduction
Paddy (*Oryza sativa*) is one of the vital cereal crops of the world and forms the staple food for more than 50 per cent of population and is recognized as "king of cereals". The United Nations General Assembly, in a resolution confirmed the year of 2004 as the "International Year of Rice", which has tremendous significance to food security. It very eloquently upheld the need to enhance awareness about the role of rice in alleviating poverty and malnutrition. India stands first in area and second in total food production. Among the rice growing countries, India has the largest area under rice in the world (45.50 million ha) with a total production of 96.43 million tonnes during 2007-08 and it stood next only to China in the world with respect to production. Hybrid rice is consider as the master crop of coastal India as well as in several regions of the eastern India during the summer monsoon rainy season mutually high temperature and heavy rainfall offers ideal circumstances for the cultivation of hybrid rice. Approximately the entire parts of India are appropriate for raising hybrid rice during the summer season. Consequently, hybrid rice is too raised even western Uttar Pradesh, Punjab and Haryana in low level areas such as waterlogged during the summer and monsoon rainy season. Individual when he is confronted with a new situation. Rice is one such crop where is lot of scope incorporating the above said practices such as to harvest higher yields and to maintain soil productivity. Hence, in order to minimize the cost of production and maximize the productivity without affecting the environment, certain steps to be taken for rice cultivation, *viz*. integrated nutrient management, integrated pest management and water

To assess the impact of farmers through knowledge and adoption of crop insurance scheme

Atul Kumar, RK Doharey, SN Singh, NR Meena and Shalu Gautam

Abstract
A study conducted in titled "To assess the impact of farmers through knowledge and adoption of crop insurance Scheme". State U.P. and District Hardoi were selected purposively for present study because researcher is familiar with the area. Two blocks of Hardoi District namely Harpalpur and Sandi also selected purposively, separate lists of villages were prepared. From them ten villages from each block were selected randomly to draw the samples of farmers. A separate list of farmers was prepared for each selected village and arranged according to the category of farmers i.e. marginal, small, medium, and big farmers. Therefore, a total of 200 respondents were selected through random sampling techniques, 10 framers were selected from each village. A structured schedule was developed with the help of guide for specially this study through various resources like research paper and because of locality. The schedule was contained various details like independent and dependent variables. The data was collected by personal interview. Statistical framework for analysis of data to analyze the collected information, following statistical tools and methods were used for interpreting the data. Present study pertaining to 2020-21. Result found that 39.00 percent respondents have high knowledge about crop insurance scheme whereas 38.50 percent and 22.50 percent respondents have medium level and low level of knowledge about Crop Insurance Scheme respectively. Majority of respondents were coming into high level of knowledge category. The mean score of knowledge is 23.39 and Standard deviation was 4.31 with range from minimum 14 to maximum 37.

Keywords: Knowledge, schedule, statistical framework and statistical tool etc.

Introduction
In April 1985, the Comprehensive Crop Insurance Scheme was implemented which covered all the willing states and Union Territories. It was implemented in 17 states and 2 Union Territories up to kharif, 1990. The benefits of the crop insurance were extended to nearly 1.94 million farmers and covered 3.14 million hectares. However, the scheme covered mainly large farmers but small and marginal farmers could not get benefits of the scheme. The benefit of the Comprehensive Crop Insurance Scheme was availed mainly by farmers of Gujarat, Maharashtra, Andhra Pradesh and Madhya Pradesh. Their share in the claims was nearly 90 percent of total claims paid in the country. On the other hand, states, like Bihar, Assam and northeastern states lagged behind in availing the benefits of crop insurance and their share less than 1 percent of total claims paid in the country. In the year, 1999-2000 the Government of India in co-ordination with the General Insurance Corporation of India (GIC) introduced a new scheme namely, the National Agricultural Insurance Scheme (NAIS) from rabi, 1999-2000 season. India is an agrarian country with 58 percent of the population engaged in agriculture and allied activities for their livelihood and contributing about 14.1 percent of the country's GDP. Crop production is not merely an occupation, but means of livelihood for Indian farmers. Nearly 75 percent of the total Indian population and 89 percent of total population of Bihar live in rural areas where primary occupation is crop cultivation. Jawaharlal Nehru once said that "*Everything can wait but not Agriculture*".

Agriculture which is an important sector of economy is considered widely as an industry. It faces various types of natural hazards. Insurance is an important instrument to give protections under risky activities and that plays significant role in the agricultural production decision, chemical use decision, cultivation practices and cropping pattern decisions. In the advance market economy public agencies introduced all risk crop insurance policies to give protection to the agriculture sector. But in the less developed or developing country such mechanism does not exist because the farmers have the lowest risk bearing capacity. Though in the developing country the sharecropping is an important policy to give them safeguard from risk activity but

Relationship between independent variables with those of dependent variables of the cell phone usages farmers in Kanpur Dehat district of U.P.

Shalu Gautam, RK Doharey, NR Meena and Atul Kumar

Abstract
This study was conducted in Akbarpur, Maitha, Sarwankhera and Jhinjhak block of Kanpur Dehat district of Uttar Pradesh to know the study and importance of cell phone usages for empowerment of rural farmer's during the year 2020-21. A total number of 400 farmers were selected randomly from a list of 20 randomly selected villages. The structured schedule was developed keeping in view the objectives and variables under study. The respondents were contacted personally for data collection. The analysis of data was done by using the percentage, mean, standard deviation, and correlation coefficient for drawing the inferences. The study furnish that most of the independent variables were positively correlated and highly, moderately significant with the dependent variables i.e. knowledge and empowerment.

Keywords: variables, mean, standard deviation, correlation, cell phone, respondents

Introduction

A cellular phone is a telecommunication device that uses radio waves over a networked area (cells) and is served through a cell site or base station at a fixed location, enabling calls to transmit wirelessly over a wide range, to a fixed landline or via the Internet. In this networked system, the cellular phone is identified as a mobile system consisting of the equipment and SIM card that actually assigns the mobile telephone number.

A cellular phone is also known as a cell phone or mobile phone. It enables a user to communicate almost anywhere in the world. The cell phone was invented by Dr. Martin Cooper, along with his team of developers at Motorola.

The first cell phone weighed 2.4-pounds and was 9-inches long. Dr. Cooper also made the first cell phone call at Motorola on April 3, 1973.

India has 1,026.37 million active mobile users on 2G, 3G and 4G networks – in 2018, TRAI statistics report. Total mobile subscriber base including active and inactive users has reached 1,176 million in2018. The proportion of active subscribers was approximately 87.28 percent of the total wireless subscriber base.

Bharti Airtel has the maximum proportion (98.68 per cent) of its active wireless subscribers. Vodafone Idea has 93.33 percent active mobile phone customers on its network. Reliance Jio has 83.59 percent active customers on its 4G network. BSNL has 56.20 percent active mobile users in 2018.

Mobile customers in urban areas reached 647.52 million. India has 528.48 million mobile users in rural areas. Mobile phone density in India was 89.78 in 2018. Mobile service tele-density was 155.48 in urban areas and 59.15 in rural areas.

Information delivery system is the one of the main components for dissemination of knowledge or new technology. Information gap has been recognized as one of the important constraints in the overall agricultural development of the country. Indian agriculture had been on traditional lines till the first waves of green revolution in late 60s. The green revolution gave a sudden boost to the production and productivity of major cereals in the assured irrigated areas. Quick dissemination of technological information from the Agriculture Research System to the farmers in the fields and reporting farmers' feedback to the research system is one of the critical inputs in transfer of technology.

To increase the farm production, the farmers need to be informed on recent scientific farm innovations. Farm information and technology dissemination to the farmers provides opportunities for their self-development, improves existing knowledge, skills and enhances their capability. In this connection, Information and Communication technologies (ITCs) hold lot of promise to deliver agricultural knowledge to the farmers.

Social traits of rice growers in eastern region of Uttar Pradesh

Anuj Tiwari, NR Meena and RK Doharey

Abstract
Rice is principal food grain of India specially in eastern Uttar Pradesh. Rice (Oryza sativa) is one of the major staple food for the major population of the world. The present investigation was conducted with the objective to know the Social traits of rice growers. Six blocks of Ayodhya, Bakabanki and Sultanpur district were selected randomly. Two hundred forty respondents were selected from these twelve villages i.e. 20 respondents from each village. The study concluded that a maximum number of the respondents (67.08 per cent) were finding in the age group *i.e.* middle (37-51 years). The maximum *i.e.* 98.75 per cent of respondents were found to be literate, while 01.25 per cent were illiterate. The majority of the respondents were married (95.41 per cent) against it, (4.58 per cent) respondents were un-married. The maximum number of respondents (79.58 per cent) were large farmers. The maximum 67.50 per cent of the respondents were observed to have agriculture as their main occupation followed by 8.75 per cent service (govt.+ private), 7.91 per cent per cent caste-based occupation, 6.66 per cent Business, 6.25 per cent agro-based enterprise, 1.66 per cent orcharding, 1.25 per cent goat sheep rearing, and 0.83 per cent dairying respectively.

Keywords: rice growers, land holding, orcharding

Introduction
Rice is world's leading staple crop, cultivated over an area of about 155 million hectares with a production of about 596 million tons of paddy. It is second to wheat, in area and production aspect. It provides about 22 per cent of the world supply of calories and 17 per cent of the proteins. Maximum area under rice is in Asia. Among the rice growing countries India has the largest area (44.8 million hectares) followed by China and Indonesia. In respect of production India ranks second with 131 million tons of paddy next to China (200 million tons of paddy). In regards to average yield per hectares Egypt ranks first followed by USA. Average rice yield of India is only 2929 kg per hectare.

Agriculture is the main source of income for families in the state. It has 11.56 million hectare of cultivated area, constituting 70 per cent of the total geographical area. The irrigated area is over 13.43 million hectare. The small and marginal farmers jointly contribute 19.46 per cent of farming household in eastern region against that of 19.11 per cent of Uttar Pradesh.

Majority of the agriculture land is used to grow major cereal crops: rice & wheat. Rice is the major crop in Uttar Pradesh and is grown in about 5.90 Mha which comprises of 13.5 per cent of total rice in India. Uttar Pradesh has favorable and suitable climate, vast areas of fertile soils, sunshine and adequate water resources. The cropping intensity is 153 per cent. The state ranks 3rd in the country in production of rice. (Source: Annual report 2017-18, Department of Agriculture, cooperation and farmer's welfare. Govt. of India)

Methodology
The research was confined to Eastern region of Uttar Pradesh since there was more rice cultivated land. For maintaining the representativeness of the data three districts from Eastern region of Uttar Pradesh surrounding the university i.e. Ayodhya, Barabanki and Sultanpur were selected purposively. Another reason for selection of these districts was the easy accessibility of the investigator to reach that area, people and officials etc. these districts have always been considered to be most climatically suitable for rice cultivation.

The total number of blocks in Ayodhya district is 11 namely, Masodha, Sohawal, Bikapur, Milkipur, Maya Bazar, Pure Bazar, Haringtonganj, Amaniganj, Tarun, Mawai and Rudauli. Out of these, two blocks namely Masodha and Bikapur were selected randomly.

The total number of blocks in Barabanki district is 16 namely, Banki, Masauli, Dewa, Harakh,

ABSTRACT: Field demonstration is the elderly concept of Front-Line Demonstration. FL developed by the Indian Council of Agriculture Research with the beginning of the Technology operation on Oilseed Crops during mid-eighties. Field demonstrations carry out close regulation of scientists of National Agriculture Research System recognized as frontline demonstrations because technologies are demonstrated in front of farmer by the scientists before being fed into the major extension method of the State Department of Agriculture. Adoption level of the beneficiaries were medium to high even as non-beneficiaries were found small level of adoption are enhanced production practice of mustard crop, proper training and extension strategies to be followed maximum adoption of mustard crop in the research area.

Keyword: Frontline Demonstration, KVK, Yield, economics, growth, management practices and India.

INTRODUCTION

The Krishi Vigyan Kendras were assigned different actions pertaining to evaluation, modification and expression of different novel technologies. This includes conduction of association of Frontline demonstration, estimation, training programmes and sophistication of different agriculture and related technologies during OFT. Extension activities and movement of Krishi Vigyan Kendras do significant movement for the farmers and useful in hole crop period. Krishi Vigyan Kendras are the base of all organizations who work for purpose of technology through refinement, evaluation and demonstration of confirmed technology under diverse "micro farming" situation in a region (Das, 2007). In the year 1991-92 Indian Government established a "Technology Mission on Pulses" to improve the pulse production and productivity through frontline demonstration. The mandate of the Krishi Vigyan Kendra (KVKs) are application of technology through refinement, demonstration and assessment of verified technologies under different "micro farming" situations in a region (Das, 2007).

Frontline demonstrations is show recently released crop protection and production technology and its running practice on the farmers field under diverse farming situation and agro-climatic regions. While demonstrating the technologies on farmer's field, the scientist are compulsory to study situation, factors and elements involving in higher crop production, Limitation of production and thereby create production data and feedback information. Frontline demonstrations were conduct in two adopted villages at pasture of 20 farmers within area of 0.4 hectare each. Moong crop was grown according to the package and practices of moong crop according field demonstration (Anonymous, 2017).

Determinants of behavioural indicators of potato (*Solanum tuberosum*) growers in Kannauj district of Uttar Pradesh

ASHWANI KUMAR VERMA[1], R K DOHAREY[2], S K DUBEY[3]*, O P SINGH[4] and S N SINGH[2]

ICAR-Agricultural Technology Application Research Institute, Kanpur Uttar Pradesh 208 002, India

Received: 07 July 2020; Accepted: 31 August 2021

ABSTRACT

The present study was carried out to find out the factors that may affect the behavioural dimensions of potato farmers, viz. their knowledge and adoption level as well as their knowledge-adoption gap about scientific potato cultivation practices in Kannauj district of Uttar Pradesh during 2016–17. Multiple regression and stepwise regression analysis was done with selected independent variables to see the effect of independent variables on the selected indicators. The analysed data showed that at knowledge level out of 18 variables taken for analysis of regression, four variables, viz. housing pattern, occupation, material possession and formal extension contact were highly significant (P<0.01); five variables, viz. education, housing pattern, informal extension contact, scientific orientation and risk orientation were highly significant (P<0.01) for their adoption level; and at knowledge-adoption gap one variable i.e. education was highly significant (P<0.01). The R^2 value and F value of knowledge, adoption and knowledge adoption level were 0.59, 0.29, 0.33 and 8.63, 2.52 and 2.95 (P<0.01), respectively. The R^2 value of stepwise regression in knowledge, adoption and knowledge-adoption gap level was 0.54, 0.24 and 0.24.

Keywords: Adoption, Knowledge, Multiple regression, Potato

Potato (*Solanum tuberosum* L.) belongs to family Solanaceae, is well known as the king of vegetables and has emerged as the most important food crop of India. Despite higher retail price of potato, the sowing of tuber is set to shrink in Northern states as farmers prefer alternate crops including onion, garlic, sugarcane and other perishables during *rabi*. Introduction of potato crop is not only important for ensuring socio-economic upliftment of the local farmers but for warranting financial sustainability of crop husbandry also (Rana *et al.* 2017). In last few years, the gap between wholesale and retail price of potato has widened by two-three times. It has disappointed potato growers and many are shifting to other crops. Mostly big farmers who store their produce have incurred losses in potato business and many such farmers are shifting from cultivation of tuber. In the last three years, glut in potato production has caused unrest among farmers in North. The annual output has grown to 53 million tonnes (MT) in 2018–19 compared to 51 million tonnes in 2017–18 (Krar 2019). The increase in area of potato cultivation has squeezed margins for growers as well as traders in the region.

Uttar Pradesh is a major potato growing state in India followed by West Bengal and Bihar with the production of 10455.30, 7482.30 and 1720.20 thousand tonnes, respectively. It produced almost 13.1 MT of potato, thus contributing nearly 28.6% of total potato production in the country (Directorate of Economics and Statistics 2016). Kannauj district is the highest producer of potato followed by Farrukhabad and Agra with production of 9.43, 8.33 and 6.47 lakh metric tonnes with area being 34.6, 29.8 and 18.20 thousand hectares, respectively (Anonymous 2001–02). Therefore, considering the significance of potato in Kannauj district, the study was carried out to analyse the profile of potato farmers of the district and to identify the determinants which may affect their behavioural dimensions in terms of their level of knowledge, adoption and knowledge-adoption gap.

MATERIALS AND METHODS

The present study was carried out in Kannauj district of Uttar Pradesh during 2016–17, which was selected purposively due to its high grown area under potato crop. It is considered to be the most climatically suitable area for potato cultivation. Jalalabad block of Kannauj district with maximum area under potato cultivation was further selected purposively. Five villages, viz. Paraspur, Gadnapur, Mirpur, Purva, and Bisundhua were selected randomly and from each village, 25 farmers actively involved in cultivating potato were further selected randomly.

Factors influencing adoption level of farmers regarding organic farming in eastern UP

Arvind Pratap Singh, Prakash Singh, RK Doharey, RK Singh, Rishi Kumar Singh, Abhay Kumar Singh and Vikash Pandey

Abstract
This study was undertaken in three districts selected randomly from each Zone namely (1) North Eastern Plains Zone (2) Eastern Plains Zone (3) Vindhyan Zone in Eastern Uttar Pradesh. From each selected district, two blocks were selected randomly. Thereafter two villages from each block was selected randomly, thus make a total 12 villages. The majority of respondents were of middle aged and literate including formal and informal education. Highest number of the respondents (55.83%) was observed in the medium category (33 to 44) of materials possession. Majority of farmers (60.41%) had medium level of overall extent of awareness about organic farming practices. The variables like age, family size, material possession and economic motivation, were found positively correlated but not significant with adoption level regarding organic farming practices. The variables like education, caste, family type, housing pattern, land holding, occupation, income, social participation, extension contact, value orientation, risk orientation and attitude were found negatively correlated but not significant with adoption level regarding organic farming practices.

Keywords: block, proportionate, age, education, overall materials possession, organic farming practices, adoption, correlations etc

Introduction
The organic movement in India has its origin in the work of Howard who formulated and conceptualized most of the views which were later accepted by those people who became active in this movement. Organic farming is a production system which avoids, or largely excludes, the use of synthetic fertilizers, pesticides, growth regulators, and livestock feed additives.

The Indian government has initiated various promotional activities, such as setting up a National Institute of Organic Farming in Ghaziabad, Uttar Pradesh, in 2003, appointment of accreditation and certifying agencies for organic farm products, developing norms for certifying organic products and providing financial support to implement promotional activities for organic farming. The task force constituted by the Government of India has also recommended the initiation of post-graduate level courses in organic farming. One of steering committee constituted by Central Government under the chairmanship of Mr. M.S. Swaminathan, Chairman, farmer's commission, has suggested taking up organic farming as a challenging national task and to take up this as a trust area of the 10th Five Year Plan. The Ministry of Commerce launched the National Organic Program in April, 2002 and processed food products export.

"Organic farming is a production system that avoids or largely excludes the use of synthetically compounded fertilizer, pesticides, growth regulators and livestock feed additives. Organic farming systems rely to the maximum extent on crop rotations, crop residues, animal manures, legumes, green manures, off-farm organic wastes, and aspects of biological pest control to maintain soil productivity and tilt, to support plant nutrients and control insects, weeds and other pests". (Kanel, 2005) [2].

Methodology
The present study was conducted in six blocks of three districts namely Barabanki Basti, and Prayagraj of Uttar Pradesh. Each district selected two block and find out the different independent variables and their level of adoption of organic farming practices in organic farming. Those blocks namely Masauli, bani kodar, Haraiya, Vikram jot, Phulpur and Dhanupur was selected randomly having production area of agriculture.

Hence, the present study has been designed to explore the level of adoption of organic farming practices in Barabanki, Basti, and Prayagraj districts of Uttar Pradesh with specific objective.

ABSTRACT: Field demonstration is the elderly concept of Front-Line Demonstration. FL developed by the Indian Council of Agriculture Research with the beginning of the Technology operation on Oilseed Crops during mid-eighties. Field demonstrations carry out close regulation of scientists of National Agriculture Research System recognized as frontline demonstrations because technologies are demonstrated in front of farmer by the scientists before being fed into the major extension method of the State Department of Agriculture. Adoption level of the beneficiaries were medium to high even as non-beneficiaries were found small level of adoption are enhanced production practice of mustard crop, proper training and extension strategies to be followed maximum adoption of mustard crop in the research area.

Keyword: Frontline Demonstration, KVK, Yield, economics, growth, management practices and India.

INTRODUCTION

The Krishi Vigyan Kendras were assigned different actions pertaining to evaluation, modification and expression of different novel technologies. This includes conduction of association of Frontline demonstration, estimation, training programmes and sophistication of different agriculture and related technologies during OFT. Extension activities and movement of Krishi Vigyan Kendras do significant movement for the farmers and useful in hole crop period. Krishi Vigyan Kendras are the base of all organizations who work for purpose of technology through refinement, evaluation and demonstration of confirmed technology under diverse "micro farming" situation in a region (Das, 2007). In the year 1991-92 Indian Government established a "Technology Mission on Pulses" to improve the pulse production and productivity through frontline demonstration. The mandate of the Krishi Vigyan Kendra (KVKs) are application of technology through refinement, demonstration and assessment of verified technologies under different "micro farming" situations in a region (Das, 2007).

Frontline demonstrations is show recently released crop protection and production technology and its running practice on the farmers field under diverse farming situation and agro-climatic regions. While demonstrating the technologies on farmer's field, the scientist are compulsory to study situation, factors and elements involving in higher crop production, Limitation of production and thereby create production data and feedback information. Frontline demonstrations were conduct in two adopted villages at pasture of 20 farmers within area of 0.4 hectare each. Moong crop was grown according to the package and practices of moong crop according field demonstration (Anonymous, 2017).

ABSTRACT

India is an agrarian nation with 65.97 percent population belongs to rural area. The majority of the peasants in India are small and marginal, possessing less than two hectares of land. Integrated Farming System (IFS) witnessed fast development in the recent two decades when harvest and animal yields expanded, together with the worries about their financial and biophysical tradeoffs. It is basic to create procedures that empower satisfactory pay and business age, particularly for little and minimal ranchers who comprise more than 85 % of the cultivating community. Therefore, Integrated Farming frameworks can be demonstrated as reasonable methodology speaks to a suitable blend of homestead undertakings, viz. crop creation, agriculture, domestic animals, fishery, ranger service, poultry and goat in an explicit cultivating circumstance to address the issues of practical financial development of Indian cultivating communities. An integrated Farming system appears to be the conceivable answer for the nonstop increment of interest for nourishment and sustenance, salary solidness, and job upliftment, especially for little ranchers with limited resources.

Keywords: Integrated farming system, livestock, crop, apiculture, sericulture, sustainability.

INTRODUCTION

Farming has consistently been considered the inspiration of our nation. In India, 70 you look after the agricultural populace is occupied with horticulture and 80% of the populace live, legitimately or during a detour on salary conveyed from agribusiness. There are 115 million operational possessions within the nation and around 80 you're peripheral and small ranchers (Manjunatha*et al.*, 2014). To satisfy the elemental needs of the household including nourishment (oat, beats, oilseeds, milk, organic product, nectar, meat, so forth.), feed, grub, fiber, and then forth warrant a consideration about Integrated Farming System. Without a doubt, the larger a part of the ranchers is doing cultivating for a protracted back yet their

EFFECT OF INSECT POLLINATORS ON SEED YIELD ATTRIBUTING PARAMETERS OF PIGEON PEA CROP

R.K.Verma,RVSingh, Umesh Chandra,Ramveer,M.P.Gautam
Department of Entomology
N.D. University of Agriculture and Technology Kumarganj, Faizabad

Abstract

The present investigation entitled "Effect of insect pollinators on seed yield attributing parameters of pigeon pea crop" at Farm of Main Experiment Station of N.D.U.A.T, Kumarganj, Faizabad during *kharif* 2014-15. The result revealed that the maximum pod setting 171 pod/plant and 90.43 per cent seed setting were recorded in open-pollination followed by bee-pollination with 161 pod/plant and minimum pod setting 124.53 pod/plant and 76.96 per cent seed setting in self-pollination. The highest seed yield 19.60 q/ha which was 40.30% increased over on self-pollination was observed in Open-pollination followed by 18.33 q/ha seed yield in Bee-pollination and minimum in self-pollinated pollination with 13.97 q/ha.

Key word: pollinators, seed, pod , insect, flowers and pigeon pea,

Introduction

Predominantly pigeon pea flowers are self-fertilized with 20-40% cross-fertilization so it is known as often cross-pollinated crop. *Cajanus cajan* flowers have bright corollae and produce nectar and pollen. These traits suggest that *C. cajan* would be attractive and possibly bee pollinated by bees (Grewal et al., 1990; Saxena et al., 1990; Reddy et al., 2004 and Sarah et al.2010).

Globally, yields of insect-pollinated crops are often managed for greater pollination through the addition of honey bees (*Apis mellifera* L.) as an agricultural input. Therefore, the potential impact of wild pollinator decline on crop yields is largely unknown. Nor is it known whether increasing application of honey bees compensates for losses of wild pollinators. The effects of evenness on pollination services remain largely unknown, and the impact of wild insect loss on fruit set has not been evaluated globally for insect-pollinated crops.

Materials and Methods

Pigeon pea variety (Narendra Arhar -1) was sown in *kharif* 2014-15 season in the month of June (30-06-2015) and crop was harvested on 25-4-2016 at Main Experiment Station of Narendra Deva University of Agriculture and Technology Kumarganj, Faizabad. All the recommended agronomical practices were adapted to get a good crop in the field.

1. The pigeon pea (Narendra Arhar-1) harvested for sampling and recording the observations of the experiment. The following Seed yield attributing characters were worked out viz.;

(a) Number of pods per plant
(b) Per cent seed setting = No. of developed seed in pod ÷ No. of locals in pod × 100
(c) Weight of grain per plot ($6m^2$) and ha^{-1}.

Results and Discussion

Number of pods

The significant effect of insect pollinators on the pod formation was observed between different treatments. The highest pod formation 171.26 pods /plant was recorded in treatment T_2 (Open-pollination) which was higher as compared to pod formation in treatment T_3 (Bee-pollination) with 161.43 pods /plant and 124.53 pods /plant in treatment T_1 (Self-pollination.

The significantly maximum pod setting, 171pod/plant was recorded in open-pollination followed by 161 pod/plant in bee- pollination and minimum pod set 124 pods/plant was recorded from self-pollination. Pando et al. (2011) recorded *Chalicodoma cincta cincta* foraging resulted to a significant increase of the fruiting rate by 19.65%, as well as the number of pod/plant by 24.33%. Singh et al. (2013) recorded significantly positive effect of bee pollination on reproductive parameters in open pollinated plants i.e. pod setting, number of seeds and seed weight increased by 35.71, 39.14 and 32.88 per cent in cross-pollinated (unbagged) plant in comparison to self-pollinated (bagged) plant. Anonymous (2014-15) also found maximum pods setting in open- pollinated crop followed by bee-pollination and self-pollination.

2. Per cent seed setting:

A glance of data depicted in Table 1 revealed that there was significant effect of insect pollinators on the seed setting of pigeonpea crop between treatments. The maximum seed setting 90.43 per cent was recorded in treatment T_2 (Open pollination) which was significantly higher as compared to seed setting in treatment T_3 (Bee pollination) which was 87.52 per cent and 76.96 per cent in treatment T_1 (Self-pollination).

The significantly maximum seed setting, 90.43 per cent was recorded in open-pollination followed by 87.52 per cent in bee-pollination and minimum seed set 76.96 per cent was recorded from self-pollination. Fohouo et al. (2014) recorded the foraging activity of *X. olivacea* resulted in a significant increase in the Fruit by 22.26%, as well as the number of seeds/pod by 34.98% Placing *X. olivacea* nests close to *C. cajan* fields is recommended to increase seed setting in Cameroon. Rathi and Sihag (1993) recorded plots caged with *C. lanata* showed increases in seed numbers and weight compared with open-pollinated crops. Values for plots caged without bees were significantly reduced. Mazi et al. (2014) reported the fruiting rate, the number of seeds per fruit and the percentage of normal seeds of unprotected flowers in *C.cajan* were significantly higher than those of flowers protected from insects.

3. Average seed yield in q /ha:

The significant effect of insect pollinators on the seed yield was observed between treatments. The highest seed yield 19.60 q/ha was observed in treatment T_2 (Open-pollination) followed by 18.33 q/ha seed yield in treatment T_3 (Bee-pollination) and 13.97 q/ha in treatment T_1 (Self-pollination).

The significant effect of insect pollination on the seed yield was observed between treatments. The highest seed yield 19.60 q/ha was observed in treatment T_2 (Open-pollination) followed by 18.33 q/ha seed yield in treatment T_3 (Bee-pollination) and 13.97 q/ha in treatment T_1 (Self-pollination). This result is in close agreement with Brar et al. (1992) recorded pods/plant and seed yields were similar on plots caged with *A. mellifera* and those caged without bees, but pods/plant and seed yields values were 3 and 4 times greater, respectively, on open-pollinated plots. Anonymous (2014-15) also found maximum yield in open- pollination followed by bee-pollination and self-pollination.

Table-1 Effect of Insect Pollination on seed yield attributing parameters of pigeonpea crop

Treatment	Mean of Seed Yield attributing parameter				Increase over on SP in per cent
	No. of Pod per plant	Seed setting per cent	Kg/plot (6 m^2)	q/ha	
Self-Pollination (SP)	124.53	76.96	0.83	13.97	-
Open-Pollination (OP)	171.26	90.43	1.17	19.60	40.30
Bee-Pollination (BP)	161.43	87.52	1.09	18.33	31.20

Relative efficacy of newer insecticides against gram pod borer, *Helicoverpa armigera*

RK Yadav, U Chandra, Ram Veer, Amit Raj, CPN Gautam, Sachin Kumar and Gajendra Singh

Abstract
The experiment was conducted at Students' Instructional Farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad during Rabi season 2015-16. Studied on Emamectin benzoate 5 SG @ 11 g a.i./ha was found most effective insecticide (94.44%) to reduce the larval population, it was followed by flubendiamide 480 SC @ 30 g a.i./ha that gave 87.78 per cent reduction, which was at par with rynaxypyr 20SC @ 40 g a.i./ha (83.33%). Least effective treatment was Lufenuron 50EC @ 60 g a.i./ha. in which only 64.44 percent reduction in larval population was registered. Reduction in larval population computed from data recorded 14 days after spraying revealed that all the treatments were effective and significantly superior to control. Emamectin benzoate 5 SG @ 11 g a.i.//ha was found most effective that reduced 100.00 per cent larval population.
Emamectin benzoate 5 SG @ 11 g a.i.//ha treated plots gave maximum grain yield (18.00 q/ha), it was at par with flubendiamide 480 SC @ 30 a.i./ha and Rynaxypyr 20SC @ 40 g a.i./ha in which 17.00, 16.50 q/ha grain yield, respectively were recorded. Maximum cost- benefit ratio was obtained in plot treated with flubendiamide 480 SC @ 30 g a.i./ha (1:10.06) followed by emamectin benzoate 5 SG @ 11 g a.i.//ha (1:9.20). Lowest cost -benefit ratio (1:3.10) was found in Lufenuron 50 EC@ 60 g a.i./ha treated plot.

Keywords: Pod borer, management, cost benefit, treatments and insecticides

Introduction
Chickpea, *Cicer arietinum* L. belongs to family Papilionaceate is an important pulse crop grown in many parts of the world. It is an important source of protein in human diet and animal feed (Khoso, 1992) [2]. The split grain of chickpea is called dal which is an excellent source of high quality proteins, essential amino and fatty acids, fibres, minerals and vitamins.
The area under chickpea cultivation in India is about 9.51 m ha with production of 8.83 m tonnes and productivity 929 kg/ ha. The area under U.P. is 0.0604 m ha with production of about 0.0732 m tonnes with an average yield of 1212 kg/ha (Anonymous, 2013-14) [1].
The chickpea pod borer, *Helicoverpa armigera* is polyphagous in nature which causes damage to several crops such as pigeon-pea, groundnut, cotton, vegetables, pearl millets, sorghum, maize, sunflower etc.
The young larvae often feed upon the tender foliage before attacking the pods by causing heavy losses to crop and sometimes whole crop failed due to severe infestation (Lohar and Rahoo, 1993; Nizamani, 1998) [3, 4]. Damage potential of this pest is so great that an average infestation of single larva may destroy 30-40 pods per plant in chickpea. The extent of losses in chickpea by pod borer varies from region to region. On chickpea, the pest appears in late February and reaches its peak by the end of April. Since not much resistance is available in gram genotype against the pest, therefore, farmers are increasingly relying on synthetic insecticides to manage this pest on different crops.
The pest feeds voraciously from seedling stage to maturity and causes about 50 to 60 per cent damage to the chickpea pods (Khare and Ujagir, 1977) [5]. In India, losses caused by pod borer on chickpea and pigeon pea fields exceeded Rs. 12,000 million per year (Anonymous, 1996) [6].
To control this insect pest number of chemical insecticides is used injudiciously which resulted development of resistance in insect, secondary pest outbreaks, threat to their natural enemies and residual effect on environment. In order to develop pest management strategies of *H. armigera*, knowledge on the basic biology of this pest is required. Jadhav and Suryawanshi, (1998) [7] reported that the application of insecticides reduced the larval population of pod borer on chickpea crop to a considerable extent and hence increased the yield. Balasubramanian *et al* (2001) [8] reported that chlorpyrifos 20 EC was the most effective insecticide to control gram pod borer.

Population dynamics of pigeonpea pod fly (*Melanagromyza obtusa*) and their correlation with abiotic factors in pigeonpea

Sachin Kumar, Umesh Chandra, SK Yadav, Jyoti and Vinod Kumar

Abstract
The present investigations entitled "Population dynamics of pigeonpea pod fly (*Melanagromyza obtusa*) and their correlation with abiotic factors in Pigeonpea" was carried out at Students' Instructional Farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad during *Rabi*, 2017. The pest activity started with the initiation of pod formation and continued though at varying level, throughout the reproductive stage of the crop. The presence of maggots of *M. obtusa* was noticed for the first time in 5th standard week. The maximum maggot population (37 maggots /100 pods) were recorded during 9th SW and the highest pupal population of (21pupae /100 pods) were recorded in 12th SW. It is evident from data that during 2017-18, maggots population showed non-significant negative correlation with minimum temperature (-0.261) and maximum temperature (-0.243) while relative humidity showed non-significant positive correlation (0.529) and pupal population had non-significant positive correlation with minimum temperature (0.195) and maximum temperature (0.389) while relative humidity showed non-significant negative correlation (-0.196).

Keywords: Population dynamics, pigeonpea pod fly, *Melanagromyza obtusa*, correlation, abiotic factor and pigeonpea

1. Introduction

Pigeonpea [*Cajanus cajan* (L.) Millsp.] is also known as red gram or arhar or tur in vernacular, the most important delicious pulse of the entire country. After gram, pigeonpea is the second most important pulse crop of India, which contributes about 90 per cent of the world's pigeonpea production. Area under pigeonpea in India is about 53.87 lakh hectare with an annual production of 45.99 lakh tons and productivity of 854 kg/ha. Pod fly being an internal feeder, both the maggot and pupal stages are present inside the pods. The white maggots feed on the developing seed and pupate inside the pod. The pod fly infested pods do not show any external symptom of damage until the fully grown larvae chew the pod wall leaving a thin papery membrane intact known as window through which adults exit the pods and thus it becomes hard to manage the pest in time. Pod fly, *Melanagromyza obtusa* (Malloch) is a key pest of pigeonpea (*Cajanus cajan*) throughout South-east Asia. It attacks the crop from pod filling to pod maturity. The oviposition of pod fly takes place on the inner surface of the pod walls. Females deposit the eggs singly under the epidermis in the green pods and the larvae after hatching mines into the pods and feeds on the soft seed thus making it unfit for human consumption as well as seed purposes (Lal and Yadav, 1993) [7]. Pulse are important components of over daily dietary requirements as they are cheapest sources of protein, vitamin, energy and minerals, production of pulse increase at a much slower rate compare to cereal, oil seeds and other crops over the two decades. Just like other crops, include of red gram in cropping pattern repair soil health and soil fertility. It plays an important role in human diet and also improving soil fertility through the biological nitrogen fixation. Arhar is one of the most important pulse crop, to be cultivated in 25 countries of the world on 5.8 million ha with 4.4 million tons of production, whereas in Asia it is grown in 5.07 million ha and producing 3.07 million tons in 2011 (FAO, 2013) [4]. Pigeonpea is a most important *Kharif* pulse crop grown in India. Area under pigeonpea in India is about 53.87 lakh hectare with an annual production of 45.99 lakh tons and productivity of 854 kg/ha (Anonymous, 2017) [1]. Pod fly incidence was started from the second week of January (2.0 to 2.8%) and continues till harvest, with a peak of 15.6 per cent in the first and 13.7 per cent in the second year during the third week of January and the incidence showed significant negative correlation with the

Abstract
The survey of population dynamics of insect – pests in sugarcane crop with special reference to early shoot borer and top borer carried out during spring season at farmer's field in eastern U.P. Present investigation revealed that five insect- pests prevailed and infested sugarcane crop in these areas. They were shoot borers (*Chilo infuscatellus*), top borer (*Scirpophaga excerptalis*), leaf hopper (*Pyrilla perpusilla*), termites (*Odentotermes obesus*) and grass hopper (*Hieroglyphus spp.*). The maximum infestation (32.22%) of shoot borer was recorded on 20th Standerd week and the minimum infestation (3.33%) on 13th and 28th SW. The highest termite infestation (38.88%) was noticed on 20th SW, whereas the lowest (1.11%) on 12th and 28th SW. The maximum population (4.47 insects/plant) of grass hoppers was noticed from 31th SW and the minimum population (0.13 insects/ plant) on 42nd SW in the field. Sugarcane top borer caused maximum infestation (35.55%) on 32nd SW and minimum (1.11%) on 41st SW.
Keywords- Shoot borer, Top borer, infestation, leaf hoppers

Introduction

Sugarcane (*Saccharum officinarum* L.) is one of the major sugar-producing crop that contributes nearly 75 per cent to the total sugar pool at global level. It belongs to genus Saccharum and family Poacae. Molasses is an important by- product of sugar industry. It is used for production alcohol by the distilleries. India ranks first in sugarcane production in the world followed by Brazil. The area, production and productivity of sugarcane in India were 5.47 mha, 380 mt and 69.4 t/ha, respectively. Whereas in Uttar Pradesh, sugarcane is grown in about 2.28 mha area with 121.36 mt annual production and 53.23 t/ha productivity (Anonymous 2012).

Among the various constraints in sugarcane production, varieties, fertilizers, irrigation, insect- pests and the disease are prime importance. As many as 200 species of insect- pests have been reported on sugarcane crop (Jaipal and Singh, 2010), however, one dozen are recognized as major pests at various stages of crop growth. The shoot borer, Chilo infuscatellus Snellen and top borer, Scirpophaga excerptalis Walker are more serious pests in the early stage of the crop throughout the country. In Punjab, Haryana and northern Rajasthan the stalk borer, Chilo auricillius Dudgeon is raised as an important pest in recent years (Atwal and Dhaliwal, 2007).

Shoot borer has been reported as serious pest of sugarcane in which the early shoot borer, *Chilo infuscatellus* caused 30 to 75 per cent losses in early stage of the crop in sub-tropical region (Jaipal et al. 2010). The young larvae bore down the spindles by moving upward direction and destroyed the apical meristem. Consequently, the cut off spindle dries up and develops a conspicuous 'dead heart' that can be pulled out easily and emits rancid odour.

Top borer, *Scirpophaga excerptalis* has been considered as the most serious pest of sugarcane which caused 31.94% loss in early and 28.50% loss in mid to late maturing cultivars. It attacks the upper parts of the sugarcane plant. The caterpillars bore into the midrib of leaves and enter into the top portion of the plants (Madan and Singh, 2002).

Materials and Methods

Population dynamics of insect- pests:

Farmer fields were selected to record the population dynamics, Sugarcane crop was regularly monitored in the morning hours at weekly intervals to observe the population/infestation of various insect- pests from germination to harvest on 10 randomly selected plants at three locations in each in all the fields.

A. Borers:

i. **Shoot borers-**

Number of healthy and infested plant at shoot stage of the cane was recorded by observing the dead hearts and puncture holes on leaf sheath.

ii. **Top borer-**

The observations on incidence of top borer was recorded by observing the dead hearts, shoot holes, mined midrib leaves as well as bunchy top on sugarcane clumps.

B. **Root feeders**:

i. Termites-

Number of infested and healthy crop plants.

C. Sap Feedres:

i. Grass hopper-

Number of both nymphs and adults on the infested leaves.

ii. Leaf hopper-

Number of both nymphs and adults on upper, middle and lower leaves

Results and Discussion

Only five insects- pests were noticed on sugarcane crop during spring, season *viz.*, shoot borers (*Chilo infuscatellus*), termites (*Odentotermus obesus*), top borer (*Scirpophaga excerptalis*), leaf hopper (*Pyrilla perpusilla*) and grasshopper (*Hieroglyphus spp.*) at different growth stages of the crop.

The initiation of shoot borers infestation was noticed on 13th SW (3.33%) and continued up to the 27th SW. The maximum infestation (33.33%) was recorded on 20th SW, and minimum (3.33%) at 27th SW. The initiation of termite infestation was noticed on 13th SW (6.6%) and continued up to the 27th SW. The maximum infestation (43.33%) was recorded on 20th SW and minimum (3.33%) at 27th SW.

Initiation of top borer infestation was started on sugarcane in 25th SW and which was continued up to 41th SW, the maximum infestation (33.33%) was recorded on 32nd SW and minimum (3.33%) at 25th and 40th SW. Grasshopper population was noticed on 13th SW (0.30 insects/plant) and continued up to the 42nd SW. The maximum population (4.60 insects/plant) was noticed on 31th SW and minimum (0.20 insects/plant) at 42th SW.

Initiation of leaf hopper population was noticed on 22nd SW (0.40 insects/plant) and continued up to 41st SW. The maximum population (4.20 insects/plant) was recorded on 35th SW and minimum (0.30 insects/plant) at 41st SW. The results are in conformity with Madan and Chaudhary (1995) observations, who had noticed the population of leaf hopper from January to December with (25.5 insects/plant) highest population in the month September, while lowest (0.1 insects/plant) in March.

ABUNDANCE AND QUANTIFICATION OF THE POLLINATORS IN PIGEON PEA

R. K.Verma,RVSingh, Umesh Chandra,Ramveer,Gajendra Singh,C.P.N.Gautam
Department of Entomology, N.D. University of Agriculture and Technology Kumarganj, Faizabad

Abstract

The present investigation entitled "Abundance and Quantification of the pollinators in pigeon pea [*Cajanus cajan* (L.) Millsp.] through insect pollinators" at Farm of Main Experiment Station of N.D.U.A.T, Kumarganj, Faizabad during *kharif* 2014-15. The result revealed that the a number of insect pollinator *Apis dorsata, Apis mellifera and Trigona irridipennis* of honey bee species, house fly, butter fly, syrphid flies and moths were observed on pigeon pea flowers during the observation period i.e., 21 February to 2 March of the year, 2015. The insects of order-hymenoptera namely; *Apis dorsata, Apis mellifera, T. irridipennis* were the major floral visitors belonging to family Apidae. The insects among this apidae family, *Apis dorsata* and *A. mellifera* were the most frequent visitors. The abundance of insect pollinators were found maximum in afternoon (3.00-4.00 PM) with 44.9 pollinators /plant /5 min. The higher number of floral visitors in the evening can be attributed of favourable meteorological parameters of afternoon. However, *A. dorsata* showed its maximum visit on inflorescence in forenoon in respect to other pollinators.

Key word: pollinators, visitors, insect, pigeon pea, and flowers.

Introduction

Pigeon pea [*Cajanus cajan* (L.) Millsp], is a short-lived perennial crop of family Fabaceae and it is invariably cultivated as annual and often cross-pollinated (20-70%) crop. Pigeon pea is one of the major grain legume crops grown in the tropics and subtropics (Saxena et al., 2002). Most of the evidence points to India as the place where pigeon pea originated because of the presence of several wild relatives, the large diversity of the crop gene pool, ample linguistic evidence, a few archaeological remains and the wide usage in daily cuisine (Van der Maesen. 1990). *Cajanus cajan* offers many benefits to subsistence farmers as a food and cash crop and also ensures stable crop yields in times of drought (Nene and Sheila 1990).

Cajanus cajan flowers have bright corollae and produce nectar and pollen. These traits suggest that *C. cajan* would be attractive and possibly bee pollinated by bees (Grewal et al., 1990; Saxena et al., 1990; Reddy et al., 2004 and Sarah et al.2010).

Globally, yields of insect-pollinated crops are often managed for greater pollination through the addition of honey bees (*Apis mellifera* L.) as an agricultural input. Therefore, the potential impact of wild pollinator decline on crop yields is largely unknown. Nor is it known whether increasing application of honey bees compensates for losses of wild pollinators. The effects of evenness on pollination services remain largely unknown, and the impact of wild insect loss on fruit set has not been evaluated globally for insect-pollinated crops.

Materials and Methods

The field works of experiment was carried out at farm of Main Experiment Station of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) on the Faizabad Road at the distance of 42 km away from Faizabad district.

Quantification of Pollinators:

1.The visit of different pollinators and their number on flowers were recorded on randomly selected 10 plants for 5 minutes each in forenoon (9-10 AM) and afternoon (3-4 PM) for 10 days in open-pollination crop (OP).

2.Weather parameters also recorded particularly temperature, humidity, rainfalls and sunshine hour during observations of pollinators visit and their correlation with pollinators.

Results and Discussion

Pollinators' diversity on pigeon pea:

To quantify the insect pollinators, the regular visual observations of pollinators' number were recorded on inflorescence in open-pollinated plots (OP) of the Pigeonpea crop during flowering period (21 February to 2 March, 2015) at the Main Experiment Station, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad and presented in the Table-1. Several insect pollinators were found during observation period. The pollinators visited on the pigeonpea flowers were belonging to the orders Diptera, Hymenoptera and Lepidoptera. Among them the house fly (order: Diptera) were most dominating pollinators besides, honey bee (Hymenoptera).

Table-1: Diversity of insect pollinators on pigeonpea crop during blooming period at MES, Kumarganj, Faizabad, during 2015.

S. No.	Common name	Scientific name	Order	Family
1	Rock bee	*Apis dorsata* Fab.	Hymenoptera	Apidae

Effect of bee pollination, *Apis mellifera* L. on yield and quality parameters of Bael (*Aegle marmelos* Correa)

Satya Narayan Satapathy and Umesh Chandra

Abstract
The present experiment was conducted to mensurate the pollination effect of *Apis mellifera* L. on yield attributing characters i.e. fruits per panicle, its weight and TSS percentage of cultivar "Narendra Bael 9" at Main Experiment Station, Horticulture and Apiculture laboratory, Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.), India during 2014. The trees were laden with floral buds/panicles within 7-10 days of emergence of new leaves and reached in full bloom during the months of May-June when days were long and temperature was high. Bael is mostly cross pollinated fruit crop and pollination is carried out by various insect pollinators. The treatment applied were pollination by honey bee only, natural pollination with augmentation of honey bees, natural pollination and control (no pollination). Maximum average number of fruit panicle^{-1}, average fruit weight and average TSS percentage were 27.3, 2.05 kg and 41.3% in natural pollination with augmentation of honey bees while minimum 1.3, 1.8 kg and 35.7% were observed in control. Similarly an increase of 2000.00%, 8.46% and 15.68% over control and 47.56%, 6.22% and 5.08% over natural pollination was observed in average number of fruit panicle^{-1}, average fruit weight and average TSS percentage under the treatment natural pollination with augmentation of honey bees.

Keywords: Pollination, *Apis mellifera*, Bael fruit panicle^{-1}, fruit weight, TSS percentage

1. Introduction
Pollination is defined as the transfer of pollens from male portion of a flower to the female portion which is essential for the process of fertilization and production of fruits and/or seeds [1]. About 90% pollination is carried out by insects, 85% of which comprises the honeybees [2]. The nature and extent of pollination can vary between crops, ranging from increasing the quality and quantity of fruits or seeds and increase genetic diversity within crop species [3]. Inadequate pollination can result not only in reduced yield but also in delayed yield and a high percentage of inferior fruits [4]. The insects of family Apidae are the most reliable agents for pollination. Among members of Apidae family, honey bees are particularly important pollinators as they are capable of carrying pollens with which they feed their immature stages, and in the process, the plants visited by them are benefited [5]. Bees are active when flowers are most receptive. Collection of pollens by bees usually ends before noon but nectar collection continuous into late afternoon. Bees visit the fruit producing flowers more often than the male blossoms and stay on them longer [6].
Bael is mostly cross pollinated fruit crop and pollination is carried out by various insect pollinators like honeybees, hover fly, yellow wasp, carpenter bee, weevil, black ants, butterflies etc. [7] Emergence of new leaves commenced during the 2nd and 4th week of May and continued till July. The transfer of pollen requires some agents and animal pollinators such as honeybee, *Apis mellifera* L. play an important role for carried out the pollination process [3]. The present study was planned to determine the effect of pollinators including honeybee (*Apis mellifera* L.) on yield and quality parameter of bael.

2. Materials and Methods
The present study was carried out under saline sodic soil condition and experimental site is located at Main Experimental Station, Department of Horticulture, Narendra Deva University of Agriculture and Technology, Faizabad (U.P.) [26.47^0 N latitude, 82.12^0 E longitude and altitude of 113 metres from mean sea level] during 2014. A randomized block design (RBD) with four treatments and six replications was applied.

Screening of mungbean (*Vigna radiata* L.) germplasm against major sucking pest

Rohit Chauhan, AK Singh, Kamal Ravi Sharma and Amjad Ali

Abstract
A field experiment was conducted to screening the mungbean germplasm against sucking pests. The data revealed that the population of whitefly ranged from 3.66 to 23.30/cage. The maximum white fly population was recorded in genotype RMG-1092 (23.30 white fly/cage) followed by AKM 12-14 and GAM-5(13.66 whitefly/cage) and minimum (3.66 whitefly/cage) in genotype MDGVV-16. However, the population of jassid was ranged between 7.33 to 30.00/cage. The maximum jassid population was recorded in genotype VGG 10-008 (30.00 jassid/cage), followed by COGG-912 (28.00 jassid/cage) and minimum (7.33 jassid/cage) in genotype PUSA-1672. The population of thrips ranged from 3.80 to 8.80 per five plants. The maximum population of thrips was recorded in genotype IGKM 06-26-5(8.80 thrips/5 plants) followed by NKM 15-12 (8.70 thrips/5 plants). While the minimum population of thrips was observed in NBPGR-150 (3.80 thrips/5 plants).

Keywords: Mungbean, germplams, white fly, jassid, thrips.

Introduction

Pulses, the food legumes, have been grown by farmers since millennia providing nutritionally balanced food to the people of India [1] and many other countries in the world. *Vigna radiata* (L.) Wilczek [Synonyms: *Phaseolus radiatus* L. (1753), *Phaseolus aureus* Roxb. (1832)], often known as green gram/mungbean, is native to India and central Asia. It has been grown in these regions since prehistoric times [2] and as an important legume crop in India throughout the year. It is short day plant. An annual rainfall of 600-700 cm is sufficient for crop growth. Optimum temperature requirement is 28-30 ^{0}C. It is cultivated on a wide range of soils from sandy loams to black cotton soil. Optimum pH of soil for green gram is 6.5-7.5. It can tolerate soil salinity to some extent. Mungbean is third most important pulse crop of India after chickpea and pigeon pea. It is relished for easy digestibility as dal or split seeds and green pods are used as vegetables. The seeds are said to be a traditional source of cures for paralysis, rheumatism, coughs, fevers and liver ailments [3] Being an important short-duration *Kharif* grain legume, mungbean is grown extensively in major tropical and sub-tropical countries of the world. It is cultivated in India, Myanmar, Pakistan, Thailand, Sri Lanka, Indo-China, Indonesia and China. In India, it is cultivated in Andhra Pradesh, Orissa, Madhya Pradesh, Maharashtra, Bihar and Gujarat. In India, the area under mungbean was 3.83 mha. with production 1.60 million tonnes and productivity 418 kg/ha. In Uttar Pradesh, the area under mungbean was 51000 ha. with production 33000 tonnes and productivity 666 kg/ha [4].

It has been reported that sixteen species of insect-pests cause damage to mungbean *viz.*, legume pod borer (*Maruca vitrata*), gram pod borer (*Helicoverpa armigera*), white fly (*Bemisia tabaci*), jassid (*Amrasca biguttula biguttula*), thrips (*Megalurothrips distalis*), bihar hairy caterpillar (*Spilarctia obliqua*), tobacco caterpillar (*Spodoptera litura*), and stem fly (*Ophiomyia phaseoli*) [5]. Among sucking pests, whitefly *Bemisia tabaci* (Aleyrodidae: Homoptera) is a serious pest. Both nymphs and adults suck the sap from under surface of leaves which result in chlorotic spots and also pre-maturely dropping of leaves. It also leads to development of souty mould on leaves that interfere with photosynthetic activity [6]. It also acts as a vector of Mungbean Yellow Mosaic Virus (MYMV). Jassid, *Amrasca biguttula biguttula* (Cicadellidae: Homoptera) is an alarming pest throughout the crop growth. Nymphs and adults of jassid desap the leaves which results in a characteristic symptom known as "hopper burn". Thrips are small, slender insects that are less than 2 mm long. Pest status is moderate, widespread and regular. Crops are at greatest risk during flowering and pod set. Nymphs and adults feed on growing points and inside the flowers which can result in flower abortion and pod distortion.

Studies on correlation between populations of major insect-pests with abiotic factors

Gajendra Singh, AK Singh, SK Yadav, SK Giri and Kuldeep Verma

Abstract
The present investigation was conducted to study the occurrence of major insect-pests of Indian mustard (*Brassica juncea* L.) during Rabi, 2016-2017 at major insect-pests from germination to pre-harvest stage of the crop at three farmers 'fields. In the village Pithla, Shivnathpur and Jorium of Narendra University of Agriculture and Technology, Kumarganj Faizabad total of five insects namely mustard sawfly, mustard aphid, painted bug, cabbage butterfly and Coccinellids was found associated with mustard crop of these first were found as pests and the Coccinellids as the predator of aphids. The aphid population build up significant negative correlation with minimum temperature (-0.469*) and non-significant negative correlation with maximum temperature (-0.283) and sunshine hours (-0.098) while it showed significant positive correlation (0.079*) with RH.

Keywords: Indian mustard, correlation coefficient, insect-pests with weather parameters

Introduction
Oilseeds crop play an important role in agriculture economy of India. Constitutes the second largest agriculture product in the country next after food grains 47.80 lakh in country Area under mustard cultivation in India as 36.15million ha with production of 71.09 mt. Rapeseed-mustard oil production increased from1.94 million MT from 2014-15 to 2.11 million MT in 2015-16 European Union is expected to be top producer followed by China & Canada tonnes and the national productivity (Anonymous, 2016) [1].

Indian mustard is a major winter (*Rabi*) season oilseed crop grown mainly in Northern parts of India. Farmers generally start sowing during late October which continues till late November In Uttar Pradesh the crop was grown on 0.82 m ha with production of 0.90 MT and productivity of 1262 kg/ha (FAO, 2015) [5].

The crop starts flowering in the months of December to January and harvesting season start mainly from mid- February to April month. Mustard seed is the third biggest source of vegetable oil in the world after soybean oil and palm oil. It is the second largest source of protein meal in the world after soybean meal. Oil content in rapeseed & mustard varies from 33% to 46% and average oil recovery is around 32% to 38%. After oil extraction, the remaining part of the seed is used to produce rapeseed/mustard meal an important component of cattle and poultry feed. Being a winter crop, it requires a temperate climate to prosper.

A dozen of insect-pests have been found associated with the crop out of which mustard sawfly, mustard aphid are the important pests of rapeseed- mustard (Bakhetia and Sachan 1997, Bakhetia and Sekhon 1989) [2, 3]. The incidences of insect-pests cause lower production and productivity of mustard due to direct and indirect damage. The present study was under taken to the know association the different association of different insect population. To record the correlation between populations of major insect-pests with abiotic factors.

Materials and Methods
The mustard crop was regularly monitored for occurrence of major insect-pests from germination to pre-harvest stage of the crop at three farmers 'fields- In the village Pithla, Jorium and Shivnathpur. The occurrence of insect-pests was recorded on ten randomly selected from each field from weekly interval and are presented in (Table-1). The mode of observations for different insect-pests and natural enemies has been given below.

The population dynamics of budfly *Dasyneura lini* was experimented during rabi season 2012-13 at the Student's Instructional Farm of Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Faizabad (U.P.). The incidence of budfly was recorded on variety Neelum at weekly intervals from germination till the harvest of the crop. There were eight treatments, namely Imidacloprid 17.8 SL @ 0.005%, Nimbicidine 0.25%, NSKE 5%, Neem leaf extract 5%, Green chilli extract 0.5%, Garlic extract 5%, Tulsi leaf extract 5% and Control. While application of Imidacloprid (17.8 SL @ 0.005 %) was found most effective followed by Nimbicidine @ 0.25 %, NSKE @ 5 % was found as the least effective in controlling of bud fly infestation. On the basis of yield, the highest yield was obtained from Imidacloprid 17.8 SL @ 0.005 % (16.22 q ha^{-1}) followed by (14.29 q/ha^{-1}) with Nimbicidine @ 0.25 %. On the basis of overall performance of all the eight treatments Imidacloprid was isolated as the most effective treatment for the control of the linseed budfly.

Linseed budfly, population dynamics, Imidacloprid

Introduction

Linseed, (*Linum usitatissimum* Linn.) is one of the oldest oilseed crop known as poor man's crop in India. It has got special importance amongst oilseed crop in rabi and has also been called as 'Alsi', 'Tisi', 'Mosina' and 'Arise' in India. Among all the insect of linseed, budfly is the most important insect and it affect the pods of linseed very drastically leads to reduce the crop yield. The crop is cultivated commercially for flax in the world. In India, Linseed is globally cultivated for oil production, fibers and flax. Fibres are used for the manufacture of linen and the stem yields fibres of good quality having high strength and beauty. It is utilized in making the best quality hand kerchiefs, materials of suits and dresses, bedding, napery, hand towels and other decorative articles (Gill, 1987). Every part of the linseed is utilized commercially either directly or after processing. About 80 per cent of the oil goes

Pollination efficiency of different insects on Phalsa *Grewia subinaequalis* D.C

Avinash Udikeri and Umesh Chandra

Abstract
A field experiment was conducted to evaluate efficiency of different pollinators on Phalsa, *Grewia subinaequalis* D.C. a fruiting shrub at Faizabad (U.P) during 2015. The foraging activity started from April month. *Apis dorsata* found to visit more number of flowers (10.01) in a minute by spending very less time (2.27 sec) per flower.*A. mellifera, Halictus sp., Polistes olivaceus* and *Megachile sp.* found visiting 9.35, 6.27, 4.16 and 3.92 number of flowers in a minute and spent 2.82,6.55,7.89,7.31 seconds on flower respectively. *A. dorsata* appeared to be most efficient pollinator on Phalsa with pollination index of 85066 followed by *Apis mellifera.* Highest fruit setting (59.17%) was recorded in the bee pollinated plants followed by open pollinated plants under Kumarganj agro-ecological conditions.

Keywords: bees, foraging rate, pollination index, phalsa

1. Introduction
Phalsa *Grewia subinaequalis* D.C (Order malvales and family Tiliaceae) an indigenous to India and it is mentioned in vedic books. Shrub is known with different names in East and North India. Phalsa was grown naturally at low elevations in dry zone of island of Luzon. Area of Phalsa is very less in the present world, It is only cultivated for research purpose in some places like former Federal Experiment Station, Mayaguez, Puerto Rico, and the Agricultural Research and Education Center, Homestead, Florida (Morton 1987) [10]. It was introduced into Phillipines in 1914 from India and Presently it is cultivated commercially mainly in the Punjab and around Mumbai. Apart from India it is cultivated in Pakistan, Nepal, Bangladesh, Laos, Sri Lanka, Thailand, Philippines, Vietnam and experimental basis in some provinces of United States of America. It bears very hardy fruit, hence can be planted on marginal soils, where rest of the fruits crops cannot be grown. Its cultivation is more popular in peri-urban vicinity. Phalsa fruit is liked for its acidic taste, coloured squash, syrup and medicinal astringent, stomachic values. It decreases inflammation when unripe fruit is eaten and is also administered in respiratory, cardiac and blood disorders, as well as in fever. An infusion of the bark is given as a demulcent, febrifuge and treatment for diarrhea. The root bark is employed in treating rheumatism. The leaves are known to have antibiotic action. It attracts many insects as flower visitors and reported to be pollinated by them Singh *et al.* (2018) [12].
The present studies has been conducted using the various factors such as foraging rate, loose pollen grains sticking to the body, pollination index and fruit set percentage in order to learn about the pollination efficacy of different insects which has not been assessed so far in Phalsa. A better understanding of entomophily may help in better maintenance of Phalsa shrubs and to have better yields.

2. Materials and Methods
The experiments were carried in a well established two years old Phalsa plantation (cv. Dwarf variety) at Main Experimental Station, Department of Horticulture, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) Geographically, it is situated at 26.47^{0}N latitude, 82.12^{0}E longitude and altitude of 113 meters above mean sea level. The site is located in typical saline-alkaline belt of indo gangetic plains of eastern Uttar Pradesh. The experiment site was having sodic soils. The experiment was conducted in randomized block design. The number of plants selected for observation was ten. The number of treatments were 5 which were replicated 5 number of times.

Effect of bee pollination, *Apis mellifera* L. on yield and quality parameters of Bael (*Aegle marmelos* Correa)

Satya Narayan Satapathy and Umesh Chandra

Abstract
The present experiment was conducted to mensurate the pollination effect of *Apis mellifera* L. on yield attributing characters i.e. fruits per panicle, its weight and TSS percentage of cultivar "Narendra Bael 9" at Main Experiment Station, Horticulture and Apiculture laboratory, Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.), India during 2014. The trees were laden with floral buds/panicles within 7-10 days of emergence of new leaves and reached in full bloom during the months of May-June when days were long and temperature was high. Bael is mostly cross pollinated fruit crop and pollination is carried out by various insect pollinators. The treatment applied were pollination by honey bee only, natural pollination with augmentation of honey bees, natural pollination and control (no pollination). Maximum average number of fruit panicle^{-1}, average fruit weight and average TSS percentage were 27.3, 2.05 kg and 41.3% in natural pollination with augmentation of honey bees while minimum 1.3, 1.8 kg and 35.7% were observed in control. Similarly an increase of 2000.00%, 8.46% and 15.68% over control and 47.56%, 6.22% and 5.08% over natural pollination was observed in average number of fruit panicle^{-1}, average fruit weight and average TSS percentage under the treatment natural pollination with augmentation of honey bees.

Keywords: Pollination, *Apis mellifera*, Bael fruit panicle^{-1}, fruit weight, TSS percentage

1. Introduction
Pollination is defined as the transfer of pollens from male portion of a flower to the female portion which is essential for the process of fertilization and production of fruits and/or seeds [1]. About 90% pollination is carried out by insects, 85% of which comprises the honeybees [2]. The nature and extent of pollination can vary between crops, ranging from increasing the quality and quantity of fruits or seeds and increase genetic diversity within crop species [3]. Inadequate pollination can result not only in reduced yield but also in delayed yield and a high percentage of inferior fruits [4]. The insects of family Apidae are the most reliable agents for pollination. Among members of Apidae family, honey bees are particularly important pollinators as they are capable of carrying pollens with which they feed their immature stages, and in the process, the plants visited by them are benefited [5]. Bees are active when flowers are most receptive. Collection of pollens by bees usually ends before noon but nectar collection continuous into late afternoon. Bees visit the fruit producing flowers more often than the male blossoms and stay on them longer [6].
Bael is mostly cross pollinated fruit crop and pollination is carried out by various insect pollinators like honeybees, hover fly, yellow wasp, carpenter bee, weevil, black ants, butterflies etc. [7] Emergence of new leaves commenced during the 2nd and 4th week of May and continued till July. The transfer of pollen requires some agents and animal pollinators such as honeybee, *Apis mellifera* L. play an important role for carried out the pollination process [3]. The present study was planned to determine the effect of pollinators including honeybee (*Apis mellifera* L.) on yield and quality parameter of bael.

2. Materials and Methods
The present study was carried out under saline sodic soil condition and experimental site is located at Main Experimental Station, Department of Horticulture, Narendra Deva University of Agriculture and Technology, Faizabad (U.P.) [26.47^0 N latitude, 82.12^0 E longitude and altitude of 113 metres from mean sea level] during 2014. A randomized block design (RBD) with four treatments and six replications was applied.

Study the abundance of insect pollinators/visitors in rapeseed-mustard (*Brassica juncea* L.)

SK Giri, Umesh Chandra, Gajendra Singh, MP Gautam and Ramesh Jaiswal

Abstract
The present investigation entitled "Impact of honey bee (*Apis mellifera* L.) pollination in mustard (*Brassica campestris* var. *toria*) to the enhancement of seed yield" in randomized block design was recorded at Student Instructional Farm of N.D.U.A.T, Kumarganj, Faizabad during *Rabi* 2016-17. The result revealed that the insects of order-Hymenoptera namely; *Apis dorsata, Apis mellifera, T. irridipennis* were the major floral visitors belonging to family Apidae. The insects among this apidae family, *Apis dorsata* and *A. mellifera* were the most frequent visitors. The abundance of insect pollinators was found maximum in afternoon (3.00-4.00 PM) with 31.56 pollinators /plant/5 min. The higher number of floral visitors in the evening can be attributed of favorable meteorological parameters of afternoon. However, *A. dorsata* showed its maximum visit on flowers in afternoon with respect to other pollinators. The maximum pod setting 76.24 pod/plant and 83.50 percent s eed setting were recorded in open-pollination followed by bee-pollination with 71.20 pod/plant and 78.25 percent seed setting and minimum pod setting 69.12 pod/plant and 71.80 percent seed setting in self-pollination.

Keywords: Abundance, pollinators, visitors, rapeseed-mustard, *Brassica juncea. Apis dorsata, Apis mellifera and Trigona irridipennis*

1. Introduction
India is one of the largest rapeseed-mustard growing country in the world occupying the third position in the area and in production after China and Canada with 12% of the worlds total production. *Brassica juncea* is the second most important oilseed crop in the country after groundnut and accounts for nearly 30.7% of the total oilseed production in the country. At global level rapeseed-mustard is cultivated on 36.15 m ha with production of 71.09 mt. Rapeseed-mustard oil production increased from 1.94 million MT from 2014-15 to 2.11 million MT in 2015-16. European Union (EU) is expected to be the top producer followed by China and Canada in 2015-16. India may be the fourth largest producer. India's share in global production of mustard oil in 2015-16 may be around 9.0 percent. The US and China were the leading importing countries of mustard oil in the world. India was the 7th largest importing country in 2013-14. (Anonymous 2015) [5].

Indian mustard [*Brassica juncea* L. Czern & Coss.], which is cultivated throughout the world belongs to the family *Cruciferae* (*Brassicaceae*) under the genus Brassica, cultivated all over India and it is the major *rabi* oilseed crop of northern India. It has 38 to 42% oil & 24% protein. Honeybees provide pollination services to several cultivated and wild species, thereby, maintaining biological diversity. Bee poisoning or killing of bees from pesticides continues to be a serious problem for beekeepers. Most bee kill occurs when pesticides are applied or allowed to drift on to flowering crops or weeds. Most (99%) bee kills result from bees picking up the pesticides when foraging. The hazards of insecticidal application on flowering crops include direct mortality, fumigative effects, repellent effects and toxicity of the residues present on various floral parts and in nectar (Pal *et al*.-2015) [6].

2. Materials and Methods
An extensive research work was conducted in order to collect the information pertaining to different aspects of the present investigation entitled "Impact of honey bee (*Apis mellifera*) pollination in mustard (*Brassica campastris* var. *toria*) to enhancement of seed yield". The investigation was carried out during *Rabi*, 2016-17 at Student Instructional Farm, Narendra Deva University of Agriculture and Technology Kumarganj, Faizabad (U.P.) India.

A B S T R A C T

The present investigations entitled "Studies on population dynamics of *Helicoverpa armigera* (Hubner) on chickpea" was carried out at Students' Instructional Farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad during *Rabi,* 2016.All the treatments were found significantly superior over control, indoxacrb (14.5 SC) performed best among the treatments followed by Neem oil. The effectiveness of treatment determined in the terms of grain yield of chickpea obtained in different treatments revealed that the Indoxacarb @ 14.5SC, Neem seed oil @ 5ml and karanj oil @ 5ml were significantly superior over untreated control. Indoxacarb 14.5@ SC, gave maximum grain yield of chickpea in compared to other treatments as well as in managing the population of *H. armigera*. Besides Neem seed oil @ 5ml and karanj oil @ 5 ml were found the second and third most effective treatments respectively

Introduction

Gram (chick pea) is the crop of tropical, subtropical and temperate region and widely grown in Uttar Pradesh, Madhya Pradesh, Punjab, Rajasthan and Maharastra which is popularly used as a protein adjunct to starchy diets. Seeds are widely consumed as pulse and in the form of flour which is largely fed to the horse and eaten after roasting. Seeds of chick pea contain 17.1% proteins, 5.3% fats, 16.2% carbohydrates, 3.9 % fibres and 2.7% minerals. Moderate to high levels of resistance to cypermethrin and moderate resistance to endosulfan were recorded in field populations of *H. armigera*. The growing awareness of the hazards of pesticide use has created a worldwide interest in pest control agents of plant origin that are bioactive and yet ecologically safe. Hence, the present experiment was conducted to assess the performance of Neem Seed Kernel Extract (NSKE) along with safer new molecule Flubendiamide 39.35 SC as an effective combination of oviposition inhibitor and larvicidal effect for the management of *H. armigera* on chickpea.

Pod borer *Helicoverpa armigera* Hubner (Noctuidae: Lepidoptera) is one of the major pest of gram. The pest starts its attack at early stage and become severe during maturity stage of the crop. The pest accounts for 90-95% of total damage. A single larva of *H. armigera* can damage 25-30 pods of

Bio-efficacy of cyazypyr 10% OD, a new anthranilic diamide insecticide, against fruit and shoot borer on Brinjal

Phool Chand, SK Mandal, Umesh Chandra and Anil Kumar

Abstract
Leucinodes orbonalis Guenee (Pyraustidae: Lepidoptera) is the key pest of eggplant (also known as brinjal and aubergine). The yield loss due to this pest is to the extent of 70-92 percent. Five doses of cyazypyr 10% OD (60, 75, 90 and 105g a.i./ha in both the year 2011 and 2012) were sprayed every year for their efficacy along with fipronil 5% SC @ 60 g a.i./ha, Flubendiamide 40% SC @ 30g a.i./ ha and Profenofos 50% SC @ 500 g a.i./ ha as a standard check. In both the seasons 2011 and 2012, cyazypyr 10% OD @ 105 and 90g a.i./ha were superior to most of the other treatments in respect of percent shoot infestation. Cyazypyr @ 105g a.i./ha, however, was superior to its 90g a.i./ha dose after 10 days of 2nd and 4th spray. Flubendiamide 40% SC @ 30g a.i./ha, fipronil 5% SC@ 60g a.i./ha and profenofos 50% EC @ 500ga.i./ha were on a par among them in percent shoot damage in most of the observations. Flubendiamide, however, showed similar performance with cyazypyr 10% OD @ 90g a.i./ha in a few cases. Cyazypyr 10% OD @ 75 g and 60g a.i./ha were ineffective, and it is also safer to natural enemies.

Keywords: Brinjal, cyazypyr, *Leucinodes orbonalis* and natual enemies

Introduction
Brinjal (*Solanum melongena* L.) is one of the widely used vegetable crops by most of the people and is popular in many countries *viz.*, Central, South and South East Asia, some parts of Africa and Central America [4]. It is native of India and second largest brinjal producing country after China with 27.1% share. It is an important vegetable grown in all the seasons. Due to its nutritive value, consisting of minerals like iron, phosphorous, calcium and vitamins like A, B and C, unripe fruits are used primarily as a vegetable in the country. Hence, it is subjected to attack by a number of insect pests right from the nursery stage till harvesting [7]. Among the insect pests infesting brinjal, the major ones are shoot and fruit borer, *Leucinodes orbonalis* (Guen.), whitefly, *Bemicia tabaci* (Genn.), leafhopper, *Amrasca biguttula biguttula* (Ishida), and non insect pest, red spider mite, *Tetranychus macfurlanei*. Of these, L. *orbonalis* is considered the main constraint as it damages the crop throughout the year. This pest is reported from all brinjal growing areas of the world including Germany, Burma, USA, Srilanka and India. It is known to damage shoot and fruit of brinjal in all stages of its growth. The yield loss due to the pest is to the extent of 70-92 percent [1, 2, 5]. The infested fruits become unfit for consumption due to loss of quality and hence, lose their market value. Farmers largely follow the chemical method as it produces quick results. High-frequency application is the common scenario. However, these chemicals, in many cases, invited the problems of pesticide resistance, resurgence, secondary pest outbreak, environmental contamination, residual toxicity and toxicity to beneficial organisms and disturbance in homeostasis of natural populations. The new generation of pesticide molecules have been claimed to be effective as well as safer for non-target organisms [3, 6, 8, 9]. Therefore, the present study was conducted with an objective to evaluate the field efficacy of cyazypyr 10% OD against *L. orbonalis* in brinjal.

Materials and Methods
The experiment was conducted during the 2011 and 2012 in the University farm at Kalyani, West Bengal state of India. Brinjal 'Muktakeshi' was grown in plots measuring 5 m×5 m, at spacing of 1m x 0.75m with three replications during the period from mid- April to July, two years, following recommended package of practices.

Effect of bee pollination, *Apis mellifera* L. on yield and quality parameters of Bael (*Aegle marmelos* Correa)

Satya Narayan Satapathy and Umesh Chandra

Abstract
The present experiment was conducted to mensurate the pollination effect of *Apis mellifera* L. on yield attributing characters i.e. fruits per panicle, its weight and TSS percentage of cultivar "Narendra Bael 9" at Main Experiment Station, Horticulture and Apiculture laboratory, Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.), India during 2014. Bael is mostly cross pollinated fruit crop and pollination is carried out by various insect visitors. The 'NB 9' cultivars were laden with floral buds panicle^{-1} within 7-10 days 0f emergence of new leaves and reached to its full bloom during the moths of May- June, when days were long and temperature was so high. From the four treatments, i.e. pollination by honeybee only, natural pollination with augmentation of honey bees, natural pollination and control (no pollination), maximum average number of fruit panicle^{-1}, average fruit weight and average TSS percentage were 27.3, 2.05 kg and 41.3% in natural pollination with augmentation of honey bees while minimum 1.3, 1.8 kg and 35.7% were observed in control. Similarly an increase of 2000.00%, 8.46% and 15.68% over control and 47.56%, 6.22% and 5.08% over natural pollination was observed in average number of fruit panicle^{-1}, average fruit weight and average TSS percentage under the treatment natural pollination with augmentation of honey bees.

Keywords: Pollination, *Apis mellifera*, Bael fruit panicle^{-1}, fruit weight, TSS percentage

1. Introduction
Pollination is defined as the transfer of pollens from the male portion of a flower to the female portion which is essential for the process of fertilization and production of fruits and/or seeds [1]. About 90% pollination is carried out by insects, 85% of which comprises the honeybees [2].The nature and extent of pollination can vary between crops, ranging from increasing the quality and quantity of fruits or seeds and increase genetic diversity within crop species [3]. Inadequate pollination can result not only in reduced yield but also in delayed yield and a high percentage of inferior fruits [4]. The insects of family Apidae are the most reliable agents for pollination. Correlation between *Helicoverpa armigera* (Hubner) population and Weather factors in chickpea (*Cecer aratinum* L.)

MP Gautam, Umesh Chandra, SN Singh, Ramveer, Ramesh Jaiswal and SK Yadav

Abstract
The present investigations entitled "Studies on population dynamics and management of *Helicoverpa armigera* (Hubner) on chickpea using botanicals" was carried out at Students' Instructional Farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad during *Rabi*, 2016. revealed that *Helicoverpa armigera* population were noticed for the first time during 46th SW of 2016 and respective mean population were 0.33 larvae/plant. Mean population of *Helicoverpa armigera* showed non-significant negative correlation with minimum (-0.335) and maximum temperature (-0.220) and rainfall (-0.266) while RH showed non-significant with positive correlation (0.394).

Keywords: Gram, *Helicoverpa armigera*, Correlation and Weather Factor

1. Introduction

Chickpea (*Cicer arietinum* Linn. Leguminacae) is one of the most important *rabi* pulse crop of India. The world area of chickpea is estimated to be about 135.40 lakh ha^{-1} at global level with production and productivity of 131.02 lakh tonnes and 968 kg ha^{-1} respectively. In India, the area, production and productivity 59 mha, 77.03 million tonnes and 890 kg ha^{-1}, respectively (Annonymous 2016) [1].

Gram Pod borer *Helicoverpa armigera* is one of the major pest of gram. The pest starts its attack at early stage and become severe during maturity stage of the crop. The pest accounts for 90-95% of total damage. A single larva of *Helicoverpa armigera* can damage 25-30 pods of gram in its life time. It feeds on tender shoots and young pods. It makes holes in pods and insert its half body inside the pod to eat the developing seeds. The pod borers inflict heavy crop losses from seedling to maturity and the losses reach at its peak when the pods appear. The seed yield losses due to *Helicoverpa armigera* were 75-90% and in some places the losses were up to 100%. The yield loss in chickpea due to pod borer was reported as 10 to 60 per cent in normal weather conditions, while it was 50 to 100 per cent in favorable weather conditions, particularly in the state where frequent rain and cloudy weather is prevailing during the crop season. These losses can be reduced by the application of insecticides. In favorable conditions pod borer may cause 90-95 per cent of pod damage (Kumar *et al.*, 2017).

Helicoverpa armigera is a conundrum and one of the most dominant insect pests in agriculture, accounting for half of the total insecticides usage in India for protection of crops. The problem of this pest is magnified due to its direct attack on fruiting structures, voracious feeding habits, high mobility and fecundity, multivoltine nature, overlapping generations, nocturnal behavior etc., (Sarode, 1999) [7]. At the same time adequate ecological data is prerequisite for integrated pest management, which can therefore be enhanced after determining the seasonal abundance (Mathur *et al.*, 2003) [5]. There are many environmental factors which influence the insect pest populations (Lode and Sharma, 1993) [3]. Among them abiotic factors play a vital role in multiplication and distribution of insect pests.

Method and Material

To know the effect of abiotic variables on the population of *Helicoverpa armigera*, simple correlation analysis was carried out. The result of the analysis has been presented in (Table-2) and details have been given here as below:

Correlation observed between the *Helicoverpa armigera* population and abiotic parameters showed non-significant positive correlation with minimum and maximum temperature, relative humidity while rainfall had non-significant negative correlation.

Studies on correlation co-efficient of larval population of *Helicoverpa armigera* in reference to weather parameters

Anil Kumar, MK Tripathi, Umesh Chandra and Ram veer

Abstract
Chickpea, (*Cicer arietinum* L.) is an important pulse crop world-wide. There are many constraints in the production of the crop, of which pod borer, *Helicoverpa armigera* Hubner is the notorious one which causes both quantitative and qualitative loss. Therefore, an experiment was conducted during *Rabi* 2010-11 and 2011-12. The larval population was recorded at weekly interval from a vegetative stage to till maturity and meteorological data was collected from the department of meteorology during crop season The results of the investigation on larval population of pod borer (*Helicoverpa armigera* Hubner) in relation to abiotic factors revealed that the appearance from 46 standard week to till 14 standard week. The correlation co-efficient with the population of *H. armigera* was significantly positively correlated with minimum temperature (0.5463 during 2010-11 and 0.7998 during 2011-12) and maximum temperature (0.5202 during 2010-11 and 0.6339 during 2011-12) respectively. While relative humidity (-0.3536 during 2010-11 & -4191) and rainfall (-0.14966 during 2010-11 & 0.3343 during 2011-12) showed negative correlation.

Keywords: Pod borer, correlation, temperature, chickpea, R.H and rainfall

Introduction
Chickpea, (*Cicer arietinum* L.) is an important pulse crop in Bangladesh. There are many constraints in the production of the crop, of which pod borer, *Helicoverpa armigera* Hubner is the notorious one which causes both quantitative and qualitative loss. On an average, 30 – 40% pods were found to be damaged by this pest and an average of 400 kg/ha grain was lost by the borer (Rahman, 1990) [10]. In favourable condition, pod damage goes upto 90-95 percent (Shengal and Ujagir, 1990) [12]. Preference of insecticides depends on their easy availability and applicability, but their excessive and indiscriminate use has resulted in the development of insecticidal resistance in the pests and environmental pollution (Phokela *et al.*, 1990) [9].
Helicoverpa armigera Hubner (Lepidoptera: Noctuidae), the cotton bollworm, also known as the gram pod borer or the tomato fruit worm, is a polyphagous agricultural pest with a wide geographical distribution, recorded from Europe, Asia, Africa, Oceania, and recently South America. Larvae of *H. armigera* have been reported from over 67 host families, including Asteraceae, Fabaceae, Malvaceae, Poaceae and Solanaceae and this pest has caused losses to economically important crops such as cotton, legumes, sorghum, maize, tomato, soybean, ornamentalplants, and fruit trees (Krinski and Godoy, 2015) [6]. Marigold (Tagetes spp.) (Asterals: Asteraceae), a native of Mexico, is one of the most popular cut flowers in the world having the highest economic importance in the floriculture industry and comprises about 33 species (Adriana *et al.*, 2012) [1].
The area under floriculture production in India during the year 2015-2016 was estimated to be as 243 thousand hectares with a production of 2236 thousand metric tonnes (Anonymous, 2016) [2]. Among the various factors responsible for low yield of marigold in India, *H. armigera* is most important, which cause very heavy losses in yield. Excessive use of chemicals not only causes the economic restrain on farmers, but also produces the harmful side effects on the environments as well as mammals. The best way to overcome this situation is to destroy the pest at the initial stage of the life cycle (Chatar *et al.*, 2010) [3]. This is possible if timely prediction of the incidence of the pest can be made. Hence, an attempt was made to investigate the incidence of pod borer, *H. armigera* infesting marigold in relation to different abiotic factors.

Seasonal incidence of *Helicoverpa Armigera* on chickpea crop in Eastern region of Uttar Pradesh

Anil Kumar, MK Tripathi, Umesh Chandra and Ram Veer

Abstract
Helicoverpa armigera is a polyphagous insect pest commonly known as gram pod borer. Present experiments was conducted at the Agriculture Farm, De partment of Entomology, Tilak Dhari Post Graduate College, Jaunpur during *Rabi* 2010-11 and 2011-12. The observation were recorded both year randomly selected plants at weekly interval from vegetative to maturity stage. The highest mean larval populations 5.60 per square meter in the first year were observed during the 48th standard week and in the second year it is 6.2 per square meter were observed during the 11th standard weeks. However, lowest mean larval population 0.40 per square meter in the first year were observed during the 14th standard week and in second year it is 0.90 per square meter were observed during the 1st standard week.

Keywords: Pod borer, incidence, larvae and chickpea

Introduction
Chick pea (*Cicer arietinum* L.) commonly known as gram or Bengal gram, is an important pulse crop cultivated globally. Its play an important role in the vegetarian diet as a major source of protein. It is consumed as a green vegetable, dal, chhole, germinated breakfast food and powder to prepare sweets and many other relishing dishes. Its leaves are consumed both raw and cooked to take advantage of malic acid, citric acid, mineral matter and fiber, all of which are of medicinal value. The grain consists of 52-70% carbohydrates, 18-22.2% protein. Besides, it is a rich source of calcium, iron. Vitamin C (green stage) and'B_1'.
The crop occupies 8.74 million hectares with a production of 7.35 million tonnes and productivity with 8.41 q/ha in India (Anonymous, 2010) [1]. Madhya Pradesh, Uttar Pradesh, Rajasthan, Maharashtra, Gujarat, Andhra Pradesh, and Karnataka are the major chickpea producing states sharing over 95% area. Various factors responsible for low production and productivity of chick pea are poor genetic base, weeds, diseases and insect pests. Major insect-pests of chickpea are cutworm (*Agrotis ipsilon* Hufnagel), gram pod borer (*Helicoverpa armigera* Hubner), gram semilooper (*Autographa nigrisigna* Walker), aphid (*Aphis craccivora* Koch) and tur pod bug (*Clavigralla gibbosa* Spinola) (Sithanantham *et al*., 1984) [6].
Gram pod borer, *Helicoverpa armigera*, is considered as a notorious pest of chickpea. It also attacks pigeon pea, moong bean, lentil, soybean okra, maize, berseem, sunflower, sorghum, tobacco and tomato. Besides gram pod borer, it is also known as cotton bollworm, gram caterpillar, tomato fruit worm and tobacco bud worm. Pod borer is the most serious insect pest of Chickpea. Percent larval survival and pupation were the maximum on chickpea as compared to other host plants (Ullah *et al.* 2015) [7].
Gram pod borer, *Helicoverpa armigera* (Hubner) (Lepidoptera: Noctuidae), a global and polyphagous pest equipped with multivoltine, diapauses is magnified due to its attack on reproductive stages, primarily on fruiting bodies, highly mobile and nocturnal in nature spread quickly in wide areas, found to cause economic damage to several cultivated crops *viz*., chickpea, pigeonpea, tomato, chilli, okra, etc throughout the year in India and sub-continent. The pest lays eggs on chickpea seedlings at second and third leaf stage of crop in Orissa. Its larvae appeared on chickpea crop after 15 days of germination at Dharwad, Karnataka. Singh and Ali (2006) [4] reported *H. armigera* larvae found active throughout the chickpea crop period at Faizabad, Uttar Pradesh (Singh *et al.* 2015) [5].

Economics of botanicals and biopesticides especially in reference to management of *Helicoverpa armigera* in chickpea crop

Anil Kumar, MK Tripathi, Umesh Chandra and Ram veer

Abstract
The field experiment was carried out at the Agriculture Farm, Department of Entomology, Tilak Dhari Post Graduate College, Jaunpur during *Rabi* 2010-11 and 2011-12 with three replications and seven treatments of Biopesticides, against *Helicoverpa armigera*. The Biopesticides like NSKE, *Bacillus thuringiensis*, Neem leaf extract, Neem oil, Nimbicidine and nuclear polyhedrosis virus in reducing the infestation of gram pod borer, *Helicoverpa armigera* and providing a higher net return per rupee invested. The higher grain yield of 24.07 Q./ha and22.65 Q/ha was recorded with the application of NSKE @ 5 per cent /ha during both years. The most favourable cost benefit ratio was obtained from the plot treated with Neem leaf Extract @ 5 per cent 31.82 and 22.22 followed by Neem leaf Extract @ 5 per cent 31.82 and 22.22, Neem oil @ 2 per cent 22.59 and 20.94, NSKE @ 5 per cent 19.68 and 15.06, Nimbecidine @ 2 per cent 16.16 and 15.04, Ha NPV @ 450 LE/ ha 9.34 and 6.28, Bt.1 kg /ha 6.40 and 4.91 during both years.

Keywords: Podborer, biopesticide, NPV and chickpea

Introduction
Chickpea (*Cicer arietinum* L.) is grown widely in the world because the seeds are a rich source of protein for the rapidly increasing population. However, the production and productivity of chickpea have been experienced drastically because of biotic and abiotic stresses. In India, chickpea crop is mainly known for protein source, grown in tropical, subtropical and temperate regions. India ranks first among the chickpea growing nations in terms of production and cultivated area.

Biopesticides based on microbial and botanical products are efficacious and promising agents. Neem, *Azadirachta indica* A. Juss. is known to affect larvae of various lepidopteran and coleopteran pests. *Bacillus thuringiensis* (Bt) is a spore-forming, gram positive bacteria which produces proteinaceous crystal at the time of sporulation. These crystals have shown potential against lepidopteran, dipteran and coleopteran pests. In India, scientists have done extensive studies on evaluation of NPVs and developed technologies for successful application of indigenous NPV preparations to combat *H. armigera infesting* chickpea. The pod borer *Helicoverpa armigera* Hübner (Lepidoptera: Noctuidae) is among the most threatening plant pests, cosmopolitan in distribution and polyphagous in herbivorous nature (Wakil *et al.*, 2009a and 2009b) [9, 10]. The larvae of *H. armigera* feed on leaves and stems but, they prefer buds, inflorescences, fruits and pods, thus causing significant damage to both vegetative and reproductive plant parts (Moral Garcia, 2006) [7]. A total of 500 US million worth of soybean and cotton has been lost in Brazil by *H. armigera* where it has been introduced in the recent past (Czepak *et al.*, 2013) [2]. The *H. armigera* is the key production constraints in several crops including chickpea, pigeonpea, pea, lentil chilies, Sun flower, Tomato, to bacco and cotton crops. A viable and sustainable method for this polyphagous pest using the conventional approach of relying primarily on chemical pesticides has become increasingly costly now days, and resistance in several pest species, environmental impact, safety and accumulation of residues has been the primary cause of concern. Hence, there is an urgent need for the development of environment friendly management by adopting insect

Evaluate the pollination efficiency of different insect pollinators in mango (*Mangifera indica* L.) *var.* amrapali

Ajay Kumar Chauhan, Umesh Chandra and PK Gupta

Abstract
In the present resurch Amrapali var. of mango was taken to study the insect pollinators efficiency at main experimental station (MES) Horticulture & Apiculture laboratory NDUAT kumarganj Faizabad (U.P.) India during 2014. Pollination efficiency can be find out based on time spend (sec/flower), no. of flower visited by insects/min. & no. of loose pollen grains/foragers. Apis mellifera L. are the most efficient pollinators of mango flowers followed by Blue bottle fly & Apis dorsata under agro- ecological conditions of NDUA&T kumarganj Faizabad.

Keywords: Insect-pollinators, mango, forraging rate, forraging speed, pollen grains

Introduction

The flowering duration in mango is usually of short i.e. 2-3 weeks. The flowers of mango are polygamous and produce on terminal panicles varying in length from a few inches up to two feet. Each panicle carries from 200 to 300 up to more than 4000 flowers depending upon the variety and climatic conditions. Mango flowers are usually very tiny (6-8mm in diameter). The calyx is composed of 5 sepals and the corolla of 5 whitish to pinkish petals. All this inserted on a hemispherical disk. Mango trees bear two types of flowers: the hermaphrodite and the male flower. They are both of the same size and give the inflorescence a sweet smell. The pollen grains are oval or triangular or oblong shapes ranging from 20-35 micron. The nectar production was continuous and in small amounts on an average 0.045 micro liter/flower. Mango is mainly cross pollinated as 65% of the perfect flowers were never pollinated, indicating that wind is not an effective pollinating agent.

Material and methods: the pollination studies in mango variety Amrapali was carried out under sodic soil condition and experimental site is located at Main Experimental Station, Department of Horticulture, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) during 2014. The foraging rates of different type of insect visitors were recorded in the term of flowers visited /pollinators/minute. Foraging speed of bees will be recorded in terms of the time spent per flower (in seconds) by each species. The number of loose pollen grains will be collected from the body of insect visitors. Observe on an average 10 individuals of each insect species for counting the pollen grains.

Result and discussion: The average maximum foraging rate was token by *A. mellifera* (12.48 flowers / 5 min.), followed by Syrphid fly (12.13 flowers / 5 min.), Blue bottle fly (10.32 flowers / 5 min.), *T. irridipennis* (7.19 flowers / 5 min.) and *A. dorsata* (6.21 flowers / 5 min.) respectively. The average minimum foraging rate was recorded from *A. florea* (5.98 flowers / 5 min.). The average maximum foraging speed was recorded from blue bottle fly (9.37 Sec. / flower), followed by *A. dorsata* (11.39 Sec. / flower), Syrphid fly (12.68 Sec. / flower), *T. irridipennis* (13.37 Sec. / flower) and *A. florea* (13.88 Sec. / flower) respectively. The average minimum foraging speed was recorded from *A. mellifera* (14.62 Sec. / flower). The average no. of maximum loose pollen grains adhere to the body of *A. mellifera* (2000 pollen grains/bees), followed by *A. dorsata*, *A. florea*, *T. irridipennis* and Syrphid fly with 1353, 1137, 832 and 413 pollen grains/foragers respectively, and the average no. of minimum loose pollen grains was adhere to the body of Blue bottle fly (335 pollen grains/flies). On the basis of this finding *Aapis mellifera* L. was most efficient followed by blue bottle fly and *Apis florea* Fab. was least efficient pollinators.

Study on availability of bee flora and foraging activities of honey bee in Eastern Uttar Pradesh

Ramesh Jaiswal, Umesh Chandra, MP Gautam, SK Yadav, SK Giri and Ramveer

Abstract
The present investigation entitled "study on availability of bee flora and its foraging activities in eastern Uttar Pradesh", was carried out on the honeybee foraging activities were recorded on different agricultural and horticulture crops during *Rabi* season 2016-17. It was observed that the bee-flora consists of mostly, fruits and agriculture crops like spices, pulses, cereals, oil seed/yielding, fiber, and fodder crops etc. *Brassica rapa* were the major agricultural bee crops of the area with flowering period of three (3) and four (4) months respectively. These plants species served as the excellent sources of pollen and nectar in the study area. The result revealed that 10 crops were useful to honeybees, out of which 5 crops were agricultural crops like as Mustard, pigeon pea, gram, bakla etc. and 4 horticulture crops like as mango, lemon, guava, anola and the forest plant like as eucalyptus, which are well distributed and commonly found in the study area. The identified flora was further grouped into pollen, nectar and both pollen and nectar yielding plants out of 5 agricultural bee crops, three (3) plants were nectar yielding, one (1) pollen yielding and six (6) plants species were both pollen and nectar yielding

Keywords: Honeybee, *Apis mellifera,* bee flora and foraging activities etc.

1. Introduction
Flowers are the mainstay of the bee's life. From flowers,, they obtain pollen, the protein rich food used mostly to feed the carbohydrate fuel for their flight, foraging, hive activity and for rearing brood. The abundance of bee flora and their continuous availability is one of the major pre-requisites for successful beekeeping. This enables the beekeepers to exploit these sources to the maximum utilization by the bees. Every region has its floral dearth periods of short or long duration and it is essential to manage the honey bees and bee hives in the dearth period. As during this period, there is lack of availability of nectar and pollen in flora required for quantitative and qualitative production of honey.[1]. To overcome this problem. It is important to find out the suitable bee flora available in the locality to propagate and manage the plant species with a option of abundant nectar and or pollen to overcome the problem during the dearth period for commercial apiculture [4]. The present bee fauna dates back to Cretaceous period which is more that 70 mya. Bees are members of the kingdom Animalia, the phylum Arthropods, the class Insecta and the order Hymenoptera (from the Greek hymen, for membrane, and Petron, for wing) [2]. This order includes over 100,000 diverse species of bees, wasps, ants, and saw flies that have been identified and described. The most important characteristic of most members of this order for the understanding of layman is a "wasp waist" which is narrow area between the thorax and the abdomen. Of course, they also all have two pairs of wings, multi-segmented antennae and a few species have a piercing ovipositor [5].
The floral sources and its blooming period are the main indicators and tools for modem beekeeping in India. The bee plants are grouped into forest plants, horticultural /agricultural plants and pastures and hay fields [9]. In India, 50 million hectares of land is under bee dependent. Bee keeping (or) apiculture is the maintenance of honey bee colonies commonly in hives by humans. A bee keeper/ Apiarist keeps bees in order to gather honey bee wax to pollinate crops (or) to produce bees for sale to other beekeepers. Normally bee keepers use three types of hives for example traditional hives, top bar and langstroth hives. Newton's bee hive model normally adapted by the honey bee keepers [6, 7, 12].
The characteristics of *A. mellifera* combined with the high demand for Honey products put beekeeping as a key activity for ecosystem conservation and economic development, thus

Population dynamics of insect-pests of paddy and its correlation with weather parameters

Singh Devendra, Gupta PK, Chandra Umesh, Vikrant and Kumar Akshay

Abstract
This paper discusses the population dynamics of paddy and its correlation with weather parameters in Faizabad district of U.P. Occurrence and abundance of insect-pests of paddy on rice crop was monitored on rice variety Sarju-52 at Main Experimental Station of Narendra Deva University of Agriculture and Technology Kumarganj Faizabad (U.P.) during the season *kharif*, 2013. This investigation revealed that pest activity commenced from 35th Standard meteorological week (SMW) and continued to 49th SMW. Highest dead hearts (8%) of Yellow Stem Borer, *Scirpophaga incertulas* was found in the 38th SMW, the maximum population (2.40%) of Rice Hispa was recorded in the 36th SMW, the peak population of whorl maggot (2.50%) was estimated in the 42nd SMW. The highest population of the rice leaf folder and gundhi bug with 3.70% and 21.90% was found in the 40th and 43rd SMW, respectively. Yellow stem borer was positively correlated with sunshine hours and rice hispa with maximum temperature was found positively significant. The rice whorl maggot was positively non-significant with the maximum temperature, there were no negative correlations of rice leaf folder and rice gundhi bug was positively correlated with relative humidity.

Keywords: Rice leaf folder, *Scirpophaga incertulas,* minimum, maximum, temperature, correlation, pest, paddy, dead hearts, and population

1. Introduction
Rice, is the main staple food in India. Rice is mostly grown on the low-lying deltas of the Brahmaputra and Barak rivers. But its yield is greatly affected every year by various insect pests [3, 7]. Among the various insect pests of paddy, Rice hispa, *Dicladispa armigera* (Olivier) Yellow Stem Borer *Scirpophaga incertulas* (Walker), leaf folder, *Cnaphalocrosis mendinalis* (Guen), whorl maggot and rice gundhi bug *Leptocorisa accuta*. In the development of pest management strategies a detailed knowledge of the influence of abiotic factors on the pest insects is essential. Weather and climatic conditions are known to significantly affect the population dynamics of insect pests [9]. Knowledge of abiotic conditions, such as temperature, day length, rainfall and relative humidity can be used as important components in forecasting and predicting the severity of insect pest population [11]. Knowledge of insect-pests population dynamics is essential for developing sustainable crop protection strategies and for interpreting and forecasting the response of taxonomic groups to weathers patterns varying on a daily basis, seasonally, or as a long-term consequence of global climate change [6]. Information on population dynamics of insect-pests complex in relation to weather parameters under Faizabad conditions is lacking. Hence, considering the importance of insect-pests of rice an attempt has been made to study the population dynamics and its correlation with weather parameters.

2. Materials and Methods
For recording the population of insect-pests, the study was conducted at Main Experimental Station of Narendra Deva University of Agriculture and Technology Kumarganj, Faizabad-224229 (U.P.) during *kharif*, 2013. Total experimental plot size measured 10x10m. The seedlings were transplanted in the experimental plot with spacing 10 cm between plant to plant and 15 cm row to row. 21 days old seedlings of Sarju-52 rice variety were transplanted in IInd fortnight of July from the nursery sown 21 days ago, in experimental year. The normal cultural practices were performed throughout the growing season of the crop.
Method of Data Collection: Data collection was started after fifteen days of transplanting and subsequent at weekly intervals, using also sweeping method as per need. For insect-pests population, visuals counts of the numbers of insects/10 hills in plot were taken.

Abstract
An experiment was conducting during *kharif*, 2013 at Main Experimental Station of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad-224 229 (U.P.) to evaluate the efficacy of some insecticides at different doses against the yellow stem borer *scirpophaga incertulas* (Walker) in rice ecosystem. The application of insecticides was done after transplanting, when the pest population reached at their ETL (Economic threshold level). The result shows that among all the insecticides (treatments), profenofos 40 + cypermethrin 4 (44 EC) 880 gm a.i. was most effective against the yellow stem borer, *scirpophaga incertulas* (Walker) (1.25 per cent) followed by profenofos 40 + cypermethrin 4 (44 EC) 440 gm a.i. (1.75 per cent) and conversely protected the crop. The least efficacy of treatment was found in lambda cyhalothrin 5 EC (3.75 per cent) treated plots. All the treatments were found effective and significantly superior over the control.

Keywords: transplanting, pest, population, ETL, efficacy, insecticides, *scirpophaga incertulas*, profenofos, lambda cyhalothrin

1. Introduction
Rice (*Oryza sativa* L.) is one of the most important staple food crop of Asia and a primary stable diet of over half of the world population relying on rice as the major daily source of calories and protein [4]. Asia accounts for about 90% of the world's rice area and production. Among the rice growing countries, India has the largest area under rice in the world (about 44.6 mha) i.e. 28% of the world's area of production, and ranks second next to China. The share of India to the world's production is near about 22.1 percent [2]. Uttar Pradesh contributes 56.57 lakh ha area and 119.92 lakh ton production with productivity of 2.12 t/ha in comparison to Punjab with maximum productivity (3.82 t/ha) of rice in India [1]. Rice yield in south and south-east Asia fluctuate yearly and adverse only about 2 tonnes/ha or less. The two major factors responsible for poor yield are adverse weather (flood, drought, typhoons etc.) and pest epidemic. Present investigation on yellow stem borer *scirpophaga incertulas* (Walker) of paddy was conducted during *kharif*, 2013 at the main Experimental Station of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad-224 229 (U.P.) to estimate the effectiveness of insecticides against yellow stem borer. The rice plant is subjected to attack by more than 100 species of insects, 20 of them can cause economic damage. Together they infest all parts of the plant at all growth stages, and a few transmit viral diseases [5]. Ric e yellow stem borer (YSB), *Scirpophaga incertulas* (Walker) of national importance as their incidence has significant impact on rice yields across the diverse rice ecosystems.

2. Materials and Methods
The experiment was conducted during the kharif of 2013, at Main Experimental Station of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad-224 229 (U.P.) in a Randomized Block Design (RBD) with eight treatments and four replications in plot size measuring 11 x 5 sqm. The treatments were *viz*., Profenofos 40%+ Cypermethrin4% (44) EC @ 220 (g./ha.), Profenofos 40%+ Cypermethrin4% (44) EC @ 330 (g./ha.), Profenofos 40%+ Cypermethrin4% (44) EC @ 440 (g./ha.), Profenofos 40%+ Cypermethrin4% (44) EC @ 880 (g./ha.), Profenofos 50 EC, Cypermethrin 10EC and Lamda cyhalothrin 5 EC including an untreated or control against yellow stem borer *Scirpophaga incertulas* (Walker). The insecticides were applied as and when the pest population reached at their ETL (Economic threshold level) with their respective doses as mentioned in Table-1.

ABSTRACT

The present field experiment was conducted during kharif season of year 2013 and 2014 at Student Structional Form, N. D. University Of Agriculture and Technology. Kumarganj, Faizabad (U.P.) India to study the population dynamics of okra insect-pests and their natural enemies. The result revealed that major insect-pests and their natural enemies in Okra started from 2nd and 3rd week of August on 4-5 week-old plant-5 s and continued until fourth week of December on 25-week-old plant-5 s.. Investigations on Population dynamics of major insect-pests and their natural enemies on Okra revealed association of a total 12 arthropods with this crop. Among these seven viz- whitefly (*Bemisia tabaci*), jassid *Amrasca biguttula* (Dist.), Thrips *Thrips tabaci* (Lind.), Fruit borer *Helicoverpa armigera* (Hb.), okra shoot and fruit borer *Earias vittella* (Fabricius), aphid, *Aphis gossypii* (Glov.), and leaf hopper, *Amrasca devastans*. Five viz- lady bird beetle Coccinella septumpuntata and *Cheilomenes undecimpuntata* Linn.,) and predatory spider *Oxypus* spp. Green Lace wing *Chrysoperla Carnea* (Stephens) Mrid bug and Ants were recorded as natural enemies associated with this crop. The appearance of the major insect pests from 31th SW observed to 50 SW during *Kharif* 2013 and *Kharif* 2014 0.57 leaf hopper /plants at 30th SW during *Kharif* 2015 respectively.

Key words : *Whitefly, Jassid, Thrips, Fruit borer, Okra shoot and fruit borer Earias vittella aphid, and leaf hopper.*

The okra, *Abelmoschus esculentus* L. (Malvaceae) is an important vegetable of India and eaten by people with a great interest. The okra crop is infested by a number of insect pests like *Amrasca devastans, Earias vittella, Bemisia tabaci, Helicoverpa armigera, Acrocercops bifasciata, Thrips tabaci, Aphis gossypii, Podagrica, Anomisflava, Sylepta derogata, Haritalodes dervgata, Dysdercus koengii* and *Nezara viridula*. But *Amrasca devastans, E. vittela, H. armigera* and *B. tabaci*, are the notorious and major insect pests of okra (Dubey *et al.*, 1999; Basu, 1995; Lohar, 2001). Insect pest infestation not only reduce the growth but also transmit pathogenic diseases (Sheedi, 1980; Dhaliwal *et al.*, 1981). This challenging situation invites attention of entomologists to concentrate energies on integrated pest management (IPM) of okra and other crops (Huffaker and Carl, 1980; Dhaliwal *et al.*, 1981; Mahadevan and Chelliah, 1986; Dubey *et al.*, 1999; Kumawat *et al.*, 2000) Botanical insecticides (Neem oil or biosal and tobacco extracts), microbial control (Bacillusthuringiensis) and biological control agents (spider, ant, lady bird beetle, Orius, myrid bug, Laius, Chrysoperla, Trichogramma etc.) should be integrated for economic management of insect pests (Arora, *et al.*, 1996; Abro et al., 2004; Memon et al., 2004).

MATERIALS AND METHODS

The experiment was conducted at Student Structional Form, N. D. University Of Agriculture and Technology. Kumarganj, Faizabad (U.P.) India- 224229 by growing a popular variety 'Arka Anamika in the plot size 600m^2 following recommended practices during Kharif 2013 and 2014. Date of sowing- 12th July 2013 and 16th July 2014. The okra (cv. Arka Anamika) was sown in well prepared soil on ridges. The distance between row to row was 60 cm, and plant-5 to plant-5 45cm. The seed rate was 8 kg per acre. Observations were recorded on five randomly selected plant-5 s at weekly intervals starting with 14 days after sowing (DAS) till harvesting in terms of number of arthropods, per plant-5 using rectangular cage 45cm long, 30cm wide and 90cm high, according to the stage of crop at Student Structional Form, between 5-7 A.M. Larval population of shoot & fruit borer and fruit borer was recorded at weekly intervals on 5 randomly selected plant-5 s starting with 50 % flowering till harvest. The data of the treatments were recorded at weekly intervals. While recording the data, it was noted that the observations on insect pests and predators should be recorded early in the morning because of flying and moving of these creatures. The observations were recorded through tagging 5 plant-5 s selected at random in each treatment. The populations of sucking insect complex were recorded as per leaf, from five leaves by selecting one from top, 2 from middle and 2 from bottom portion of plant-5, while the population of chewing insect pests and predators were recorded as per plant-5. The pre-treatment observations were recorded before employing plant-5 protection tactics, while post-treatment observations were recorded 48 hours after application of the respective bio-rational pesticide. Weekly Meteorological data during crop was collected from Agro meteorological observatory N. D. University Agriculture

Studies on population dynamics of garm pod borer *Helicoverpa armigera* (Hubner) on chickpea (*Cicer arietinum* L.)

MP Gautam, Umesh Chandra, SK Yadav, Ramesh Jaiswal, SK Giri and Shesh Narain Singh

Abstract
The present investigations entitled "Studies on population dynamics of *Helicoverpa armigera* (Hubner) on chickpea" was carried out at Students' Instructional Farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad during *Rabi*, 2016. It is evident from the data that the *Helicoverpa armigera* population was started since the vegetative stage and continued up to maturity stage of the crop. Larvae were found on whole plant. Due to its attack, the leaflets become cup shaped and yellow at the edges. Heavy infestation whole plant become dried and finally defoliate at last.
Helicoverpa armigera population were noticed for the first time during 46th SW of 2016 and respective mean population were 0.33 larvae/plant.The lowest mean population *H. armigera* is 0.33larvae/plantwas recorded during 46nd and 47th SW at the minimum temperature of 11.8 °C, maximum temperature of 29 °C, relative humidity 67.4 and there were no rainfall. Whereas maximum mean population of *Helicoverpa armigera* population of 5.67 larvae/plant was recorded during 08 SW of 2017 at the minimum temperature of 11.1 °C, maximum temperature of 27.9 °C, relative humidity 63.9 and there were no rainfall.

Keywords: Gram, *Helicoverpa armigera* and population dynamics

Introduction
India ranks first in the production and consumption of chickpea (*Cicer arietinum* L.) in the world. Chickpea is a most important pulse crop of India which is mostly grown under dry land condition with heavy cloudy soil. It is a rich source of nutritional values in the diet of Indian people because of containing 21.5 per cent protein, 64.5 per cent carbohydrates and 4.5 per cent fat which is comparatively deficient in the cereals and oilseeds. Its green leaves and pods are used as green vegetables and germinated graiñs for breakfast and other delicious dishes by the people in their daily meals.
Gram pod borer, *Helicoverpa armigera*, is considered as a notorious pest of chickpea. It also attacks pigeon pea, moong bean, lentil, soybean okra, maize, berseem, sunflower, sorghum, tobacco and tomato. Besides gram pod borer, it is also known as cotton bollworm, gram caterpillar, tomato fruit worm and tobacco bud worm. Pod borer is the most serious insect pest of Chickpea. Percent larval survival and pupation were the maximum on chickpea as compared to other host plants.

Materials and Methods
The gram crop regularly was monitoring for occurrence of insect-pests from germination to pre-harvest stage of the crop at Students' Instructional Farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad. Insect pest population was recorded on 5 randomly selected plants at weekly interval in each plot after germination (Table-1). The mode of observation for *Helicoverpa armigera* are the ETL (3 eggs or 2 larvae/plant) regular weekly recording selected plat of gram pod borer population was done from 50% flowering till harvested in the experimental field.

Pollination efficiency of insect pollinators on *Aegle marmelos* Correa. At Kumarganj, Faizabad

SN Satapathy and Umesh Chandra

Abstract
In the present research the variety "Narendra Bael 9 (NB 9)" was taken to study the insect pollinator's abundance and their pollination efficiency at Main Experiment Station (26.47°N latitude, 82.12° E longitude and 113 meters altitude), Horticulture and Apiculture laboratory, Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.), India during 2014. The hymenopterans were the major floral visitors comprising of six species from four families *viz*., Xylocopidae, Apidae, Vespidae and Formicidae, followed by dipterans (One species from one family) *viz*., Syrphidae, Lepidoptera (three species from two families) *viz*., Pieridae and Arctiidae. The abundance of *Apis dorsata* was highest (7.90 bees/spike/5 minutes) followed by syrphid flies, *Eupeodes corolae* (3.45 visitors/spike/5 minutes) and *Apis mellifera* (1.20 bees/spike/5 minutes). Based on pollination index (Number of loose pollen grains sticking on the body of visitors × abundance), *A. dorsata* was found to be the most efficient pollinator of bael flowers followed by *Eupeodes corolae* and *A. mellifera* under agro-ecological conditions of Kumarganj, Faizabad (India).

Keywords: Abundance, pollinator, pollination efficiency, pollination index, pollen grain, bael

1. Introduction
Bael (*Aegle marmelos* C.) belongs to family rutaceae and it is known in India from pre-historic time [6]. In nature, only about 5 per cent of the flowers are self-pollinated and 95 per cent animal pollinated [5]. Bael is mostly cross pollinated fruit crop which has entomophilous flowers and pollination is carried out by various insect pollinators like honey bees (*Apis dorsata*, A. *mellifera*),hover flies, yellow wasp, carpenter bee, weevil, black ants, butterflies etc. [4]. Bees are the best among all pollinators. Butterflies are occasional pollinators, and do pollination of crops while feeding on nectar from one flower to another. Flies, hoverflies and wasps are effective pollinators because they visit flowers to feed upon nectar (or in some species pollen) for essential nutrients for egg maturation and extending their life-span [2]. Being a cross pollinated crop, its fruit set is expected to be affected by the insect visitors. The investigation was carried out on the pollination efficiency, which is defined as the proportion of pollinated flowers relative to those that experienced pollen removal.
The present studies were conducted with the objectives to know pollinators abundance and pollination efficiency of pollinator species.

2. Materials and Methods
The pollination studies in bael variety, "NB 9" was carried out under sodic soil condition and experimental site is located at Main Experimental Station, Department of Horticulture, Narendra Deva University of Agriculture and Technology, Faizabad (U.P.) [26.47^0 N latitude, 82.12^0 E longitude and altitude of 113 metres from mean sea level] during 2014.

2.1 Abundance of insect visitors: Abundance (number of visitors/ spike/5 minutes) of major pollinators was recorded from six randomly selected bael plants. These observations were recorded from 6:00 am to 6:00 pm at an interval of 3:00 hours. Observations were recorded for 7 days each after the initiation of 10% flowering in crop, at peak flowering and before the cessation of flowering in the crop.

2.2 Loose pollen grains sticking on the body of insects visitors: For estimating the number of loose pollen grains sticking to the body of major insect pollinator species, the insect pollinators were captured gently by forceps from the flowers to avoid shaking of body and the

The Wolf spider, *Pardosa psedonmulata* (Boes. & Strand) is probably the most important predator in rice fields in Asia. The diet of the wolf spider depends on type of insects that are available but leaf hoppers and plant hoppers are the major prey *Pardosa* feeds on both nymphs and adults and is considered to be a major regulator of brown plant hopper population. The first step in determining of the role of spiders in an agro- ecosystems is to identify the species present and determine their abundance and distributions. The biotic and abiotic factors of an environment often play an important role on the population buildup of spider. The experiment was carried out during Kharif session on rice variety Pant Dhan – 4 and NDR -359 at research field and on farmers field Sarjoo – 52, NDR -359, Pant Dhan – 4 and Sambha Mahsoori varieties was taken. The experiment was laid out and randomized in block designed with three replication plot size was assigned 7x25 m with border area of 1.5m between the replication. The transplanting was done in the first week of July both the year and observations were recorded with the help of hand net and quadrate methods at weekly interval starting at two weeks after transplanting and continue till maturity of crop. Also spider population data was recorded during off session, Main crop was harvested 6-7 cm above from the ground level and then given an irrigation after 20 days of harvesting. After four days of irrigation, area was applied and subsequent irrigation were also given as and when required and taken ratoon crop during off session. Observations on the hoppers and spiders population were recorded after 45 days of harvesting at weekly interval started from 45th to 18th meteorological week. Fourteen spider species was observed during studies viz., *Pardosa pesudoannulata* (Boes. & Str.), *Tetragnatha mandibulata* (Walk), *T. javana* (Thorell), *Hippasa holmerae* (Thorell), *Clubiona japonicola* (Boes. & Str.), *Araneus* spp., *Phidippus* spp. and *Neosconatheisi* (Walck). Amongst these *Pardosa pesudoannulata, Tetragnatha mandibulata* during kharif session and *Hippasa holerae, T. javana* and *Tetragnatha mandibulata* during off session were found dominant.

Introduction

Paddy (*Oryza sativa* L.) is one of the most important staple food crop of global importance. Rice helps to feeds almost half of the planet on a daily basis however at national level to feed the ever growing population and maintain our food security an additional two million tons of rice needs to be produced annually with less water, land and against a number of biotic and abiotic stresses that limits rice production.

ABSTRACT : Spray of Cartap hydrochloride 75SG @ 375 g.a.i./ha was found most effective and minimum dead hearts of 0.66 and 0.73 per cent and 0.26 & 0.24 per cent were respectively recorded on 7th and 15th day after Ist and IInd application and was at par with higher dose of Cartap hydrochloride @ 750 g.a.i./ha (with respective damage of 0.75 and 0.83 and 0.34 & 0.33 per cent) and Fipronil 5 SC @ 25 ml/ha (with respective damage of 0.91 & 1.05 per cent and 0.53 & 0.50 per cent) on the same dates after Ist and IInd applications. Minimum white ear incidence of 0.18 per cent and 0.20 per cent was recorded on 7th and 15th day of 3rd application in Cartap hydrochloride 75 SG @ 375 g a.i. ha^{-1} treated plots and was at par with Cartap hydrochloride 75 SG @ 750 g. a.i. ha^{-1} (0.25 & 0.26 per cent), Fipronil 5 SC @ 25 ml ha^{-1} (0.43 & 0.45 per cent) and Cartap hydrochloride 75 SG @ 318.75 g. a.i. ha^{-1} (0.44 & 0.46 per cent). The remaining treatments were found effective and significantly superior over untreated control.

Key words : Bio-efficacy, *Scirpophaga incertulus*, incidence, *Oryza sativa*.

INTRODUCTION

Rice (*Oryza sativa*) is world staple food for large proportion especially inside East Asia and Indonesia. In India rice is cultivated in 44.10 m ha with production of 131.3 mt and average productivity of 3.0 t/ha (Ferrer, 2011). Pasalu *et al* (2007) have reported yellow stem borer as a pest of national significance which cause significant yield loss across the rice eco-system. Alam *et al* (1992) estimated the maximum stem borer infestation of (20.79%) in deep water followed by low land (12.60%) and medium land (7.83%). Yellow stem borer is a major rice damaging species in Eastern part of India as well as in Uttar Pradesh, which cause low production of rice in fragile eco-systems (Senapati and Panda, 1999). Therefore, the present study was conducted to test the efficacy of certain insecticides against yellow rice stem borer.

MATERIALS AND METHODS

For evaluating the bio-efficacy of insecticides the experiments were conducted during *Kharif* 2010 at Students' Instructional Farm, NDUAT Campus, Kumarganj, Faizabad (U.P.) India. Thirty days old seedlings of rice variety 27P77 were transplanted in 2nd fortnight of July under Randomized Block Design in 5 x 4 m plot size with 5 replications. At the time of transplanting spacing of 20 cm between row to row and 15 cm between plant to plant was maintained. All agronomical practices were adopted to raise a good crop. Soluble granules of Cartap hydrochloride 75 SG were sprayed in the standing crop under sufficient moisture in field. Amount of insecticides *viz*. 4 doses of Cartap hydrochloride soluble granules, Cartap hydrochloride 50 per cent SP, Lambda cyhalothrin 2.5 EC and Fipronil 5 SC were measured and diluted separately in the required amount of water (based on the crop stage) and sprayed thoroughly with the help of foot sprayer. First application of the treatment was done at 30 days after transplanting (DAT) followed by the second and third applications on 45 & 60 DAT, respectively. The data on dead heart (DH) and white ears (WE) caused by yellow stem borer were recorded at one day before and 7 and 15 days after treatment. For calculating the per cent damage total numbers of tillers/ panicles and damaged tillers/panicles (DH/WE) were counted in quadrate on 12 randomly selected hills at three places in each plot. The data were converted into per cent (DH/WE) with the help of the following formulae:

$$\text{Dead hearts \%} = \frac{\text{Number of damaged tillers/12 hills}}{\text{Total number of tillers (healthy + damaged)/12 hills}} \times 100$$

$$\text{White ears} = \frac{\text{Number of damaged tillers/12 hills}}{\text{Total number of panicles (healthy + damaged)/12 hills}} \times 100$$

Arc sine values and Critical Difference were also calculated to test the significance of mean for the treatments difference at 5 per cent level probability.

Incidence and intensity of bark eating caterpillar, *Inderbella spp.* infesting aonla trees

Deepak Kumar, Umesh Chandra, Rishabh Mishra and Puneet Kumar

Abstract
The studies on. Incidence and intensity of bark. eating caterpillar, *Indarbela* sp. revealed that in Agronomy Research Farm of ANDUAT, the minimum incidence was recorded in 1st SMW (65.73%) and maximum incidence was racorded in 48 SMW (86.89%).The average minimum number of active holes per infested tree were recorded in 1st SMW(.66) and maximum number of active holes were recorded in 36 SMW(7.36). In Main Experiment Station Horticulture of ANDUAT, the minimum incidence was recorded in 1st SMW (55.5%) and maximum incidence was racorded in 39 SMW (83.85%). The average minimum number of active holes per infested tree were recorded in 1st SMW(.56) and maximum number of active holes were recorded in 36 SMW(6.55). In Akma Research farm of ANDUAT, the minimum incidence was recorded in 33 SMW (44.78%) and maximum incidence was racorded in 48 SMW (83.85%). The average minimum number of active holes per infested tree were recorded in 33 SMW(.45) and maximum number of active holes were recorded in 35 SMW(3.33).

Keywords: bark eating caterpillar, incidence, intensity, aonla

Introduction

Indian gooseberry, (*Emblica officinali*) earlier considered a minor commercial fruit crop is turning into a major one. It is recognised as the king of the arid fruits. Its belong to family Euphorbiaceae and is vernacularly known as amla and aura in Hindi; dharti and amlaki in Sanskrit; amla and amlaki in Bengali. It is native of Tropical South Asia particularly central and southern India (Moortan, 1960). Popularly also known as Aonla, amla, amrit phal is found attacked various number of insect-pests causing considerable damage. In India, the major insect-pests like shoot gall maker (*Betousa stylophora*), bark eating caterpillar (*Inderbela quardinatata*) recorded as key pests, Nowthose, pomegranate butter fly (*Virchola isocrates*),cow bug (*Tricentrus congestus*), leaf roller or leaf rolling caterpillar (*Gacillaria acidula*), hairy caterpillar (*Selepa celtis*), aphids (*Schoutedeni aemblica*) and termite (*Odentotermis obesus*) have been recorded as minor pests on this plant (Chaudhary et al., 2005).

Bark-eating caterpillar, *Indarbela sp.* (Metarbelidae: Lepidoptera), is a polyphagous pest feeding on the bark of fruit, forest and avenue trees. The bark eating caterpillar is widely distributed throughout the Indian subcontinent, including Bangladesh, Myanmar, Sri Lanka and Pakistan (Sharma and Kumar, 1986).

Genus *Indarbela* has 13 different species, out of which three viz. *I. quadrinotata* (Walker), *I. tetraonis* (Moore) and I. dea (Swinhoe) have are found to be economic importance (Verma and Khurana, 1978). To reported about 70 host plants of the bark eating caterpillar representing fruit, avenue and forest trees.

The caterpillar of bark eating caterpillar is nocturnal nature and eats on the bark under shelter of web and bores into the trunk and branches. It retreats into the tunnel during day and continues to bore it to about 15 to 25 cm in length. Only one caterpillar is found inside a tunnel. Its infestation is indicated by the presence of peculiar winding web, prepared out of excretory pellets and frass spun together with silk, generally near the forks or angles on the stem and branches. In case of severe infestation moment of sap are stopped and plant ceases to flush (Verma and Khurana, 1978), thereby affecting fruit production

Method and Material

Studies on "Incidence and Intensity of Bark Eating Caterpillar *Inderbella sp.* Infesting Aonla trees. Were carried out in the Department of Entomology, college of Agriculture, A.N.D.U.A.&T. Kumarganj Ayodhya (U.P.) and in different Aonla growing location of

Population dynamics of fruit flies in bitter gourd (*Momordica charantia* L.) and its relationship with weather factors

Dharm Beer, Umesh Chandra, Jai Kumar Yadav and Sameer Kumar Singh

Abstract
Bitter gourd (*Momordica charantia* L.) is one of the important cucurbitaceous vegetable grown in India. Among the cucurbits, it is considered a high-quality vegetable because of its nutritive value especially ascorbic acid and iron. The study was undertaken to investigate the population dynamics of *Bactrocera* spp. (Diptera: Tephritidae) round the year. Significant variation in occurrence of the pest was recorded during the period of investigation. First incidence of *Bactrocera* spp. was observed from 31st SM and continued upto 52nd SM in parapheromone Methyl Eugenol and Cuelure) traps. Peak incidence of the pest was recorded during 39th SM and 42nd SM with 135 fruit flies/trap/week. *B. zonata* and *B. dorsalis* incidence had significant positive correlation (r) of with minimum and maximum temperature (r = 0.563 and r = 0.564 respectively) during *Kharif* 2018. The *B. cucurbitae* traped had positive correlation with minimum (r = 0.752), maximum temperature (r = 0.788) and relative humidity during *Kharif* 2018. Findings of this study helps in understanding the population dynamics of fruits flies in bitter gourd and developing forewarning strategies to combact the pest in advance.

Keywords: Bitter gourd, fruit fly, incidence, cuelure, methyl eugenol

Introduction
Bitter gourd is an important cucurbitaceous vegetable grown in India. Each part of this crop has been reported useful having some specific medicinal value (Allwood and Drew, 1996) [1]. Fruit flies are important insect pests of fruits, vegetables and other ornamental plants (Bharathi *et al.*, 2004) [5]. Melon fruit fly, *Bactrocera cucurbitae* (Coq.) (Diptera: Tephritidae) is one of the main tropical fruit fly causing considerable damage in cucurbits. *B. cucurbitae* has been observed to infest a wide range of crops in the Cucurbitaceous family. Infestation by melon fruit fly in bitter gourd was reported from 41 to 89 per cent (Rabindranath and Pillai, 1986). Melon fruit fly infests 95 percent of bitter gourd fruits in Papua New Guinea, 90 per cent snake gourd and 60 to 87 per cent pumpkin fruits in Solomon Island while 31.27 per cent in India, respectively (Hollingsworth *et. al*., 1997; Singh *et. al*., 2000) [9, 10]. Yield loss varies from 30–100% (Nath and Bhusan 2006) [2]. It is very much difficult to manage the pest through the application of chemical pesticides due to their peculiar biological features.
Among the various, alternate strategies available for the management of fruit flies, the use of male attractant traps stands as the most outstanding alternative. Various parapheromones are known which are used against fruit flies. Monitoring of pest population round the year is one of the most important basic information in formulating Integrated Pest Management concept for sustainable agriculture. The Cuelure traps have been reported to attract *Bactrocera cucurbitae* males and this sex attractant is more effective than food lure (Pawar *et. al*., 1991, Liu and Lin, 1993; Zaman, 1995) [3, 8, 4]. Keeping in view, present investigation was undertaken to study the population dynamics of fruit flies and its relation with weather factors.

Materials and Method
The study was conducted at the Agricultural Research Farm of Acharya Narendra Dev University of Agriculture and Technology, Kumarganj Ayodhya, India (26.54°N, 81.93°E). The seasonal incidence of fruit flies was monitored at weekly intervals in the cropping season 2018–2019. Cuelure and methyl eugenol baited bottle traps were used for the monitoring of population. The traps used for monitoring fruit flies consisted of a one-litre plastic mineral water bottle (10 cm base diameter and 25 cm in height) with a screw lid.

ABSTRACT : A field investigation was conducted on the population dynamics of *Helicoverpa armigera* (Hübner) in chickpea during *Rabi* 2020-21. The results revealed that the infestation of gram pod borer started at 46th SMW with a mean population of 0.22 larvae/mrl and attained ETL at 48th SMW with 1.00 larvae/mrl. The peak appearance was recorded during 8th SMW with an average population of 8.80 larvae/mrl and it persisted up to 15th SMW with 0.40 larvae/mrl. The larvae population of H. armigera correlated with abiotic parameters and data revealed a negative non-significant correlation with maximum and minimum temperatures (r= -0.337 and r= -0.321, respectively), however, it showed a positive correlation with relative humidity in the morning which was non-significant and with evening relative humidity, it was significant (r= 0.296 and r = 0.496*, respectively) and there was no rainfall observed during the cropping season. Wind speed and sunshine hours also showed a positive non-significant correlation (r = 0.115 and r = 0.320) with the larval population.

Key words : Population dynamics, abiotic factors, gram pod borer, *Helicoverpa armigera*.

INTRODUCTION

The chickpea is the third most important crop after dry bean (*Phseolus vulgaris*) and pea (*Pisum sativum*). In India, chickpea is considered as King Pulses due to its high nutritional values and demand (Bhatt and Patel, 2001). It is a major supplement of protein (19g), calories 364 g), carbohydrate (61g), iron (34%), magnesium (28%) Vitamin B_6 (25%), vitamin C (6%) and contain various amino acids and medicinal properties (Anonymous, 2018) *i.e.* useful for stomach ailments, blood purifier and lowering of cholesterol (Bhargava, 2020). It has a high ability to fix more than 80 per cent atmospheric nitrogen in soil with help of symbiotic bacteria *Rhizobium* spp. (Baldev *et al*, 1998).

Globally, chickpea is grown about 10.70 million hectares with an average annual production of 9.00 metric tons. India leads the first rank in the area and production of chickpea. In India, chickpea occupies a 7.89-Million-hectare area and producing 7.06 Metric tons with 895 kg/ha productivity. Madhya Pradesh ranks highest in chickpea production (32.37%) followed by Rajasthan (19.46%), Maharashtra (15.82%), Andhra Pradesh (8.76%) and Uttar Pradesh (6.45%) these states contributing 82 per cent of the total production of the country. *Helicoverpa armigera* (Hübner) usually knows as gram pod borer, is one of the most important constraints of legume production. It has a wide host range due to its polyphagous nature and its feed on more than 250 crop species. The favourable weather conditions with frequent cloudy days during crop season that accounts for about 45 per cent to 95 per cent of damage caused by this pest (Sachan and Katti, 1994). Keeping these points in mind, above study was conducted to find the role of abiotic factors on the incidence of gram pod borer in chickpea.

MATERIALS AND METHODS

A field experiment was conducted at the Student's Instructional Farm (SIF), Acharya Narendra Deva University of Agriculture & Technology, Kumarganj, Ayodhya (U.P.) during *Rabi* 2020-21 on chickpea variety PUSA-262. The estimation of *H. armigera* larvae population was done under field condition in the plot size kept 10×10m with border 0.75m and row to row spacing kept 30cm and plant to plant spacing kept 10cm. Insecticides

ABSTRACT

Gram pod borer (Helicoverpa armigera) is a major insect pest of chickpea. The gram pod borer begins to infest at vegetative stage and later feeds on flowers and developing pods. A field investigation was conducted to evaluate the bioefficacy of certain new molecule insecticides against *Helicoverpa armigera* (Hübner) on chickpea during *Rabi* 2020-21 in randomized block design with three replications. The outcomes revealed that the application of Chlorantraniliprole 18.5% SC @ 25g a.i./ha and Cyantraniliprole 10.26% OD @ 60g a.i./ha were established to be most effective treatments and application of Fipronil 5% SC @ 50g a.i./ha was least effective in respect of reduction of *H. armigera* larval population. The maximum yield was recorded in Chlorantraniliprole 18.5% SC @ 25g a.i./ha (14.00 q/ha) followed by Cyantraniliprole 10.26% OD @ 60g a.i./ha (13.73 q/ha) and lowest yield was recorded from Novaluron 75g a.i./ha (10.15 q/ha) treated plot. The economics of different new molecule insecticides indicated that higher benefit cost ratio (BCR) was observed from Lambda Cyhalothrin 30g a.i./ha (7.86:1) followed by Emamectin benzoate 12g a.i/ha (6.75:1) and the lower BCR was recorded from Cyantraniliprole 60g a.i./ha (1.64:1) and Novaluron 75g a.i./ha (1.58:1). Chlorantraniliprole and Cyantraniliprole are newer group of insecticides, which are relatively safer and more effective against gram pod borer as comparison to conventional insecticides and can be used in successful management of this key pest of chickpea.

GALLEY PROOF

Introduction

Pulses are dry seeds of plants which belongs to Leguminosae family. Pulses are source of protein, amino acids and have other medicinal properties. Production and consumption of higher amount of pulses are the best way to overcome spread of protein malnutrition in world. In 2016, United Nations General Assembly (UNGA) celebrated as International Year of Pulses (IYP) to generate awareness in food security and several benefits of protein and also about sustainable foods production for small holder farmers (Anonymous, 2016). In India over dozens of pulse crops grown, however Chickpea (*Cicer arietinum* L.) is the third most important pulses crop after dry beans and field pea. It is commonly known as Bengal gram, chana or gram, originated from South Western Asia. It is an important *Rabi* pulse crop of India, and considered as 'King of Pulses' due to its nutritional values and high demand (Bhatt and Patel, 2001). Chickpea highly fix more than 80 per cent of atmospheric nitrogen in association with *Rhizobium* spp. India leads top rank in area and production of chickpea. In India, chickpea occupies 107.21 lakh hectare area and producing 9.02 million tons with 895

ABSTRACT

The present field experiment was conducted during kharif season of year 2013 and 2014 at Student Structional Form, N. D. University Of Agriculture and Technology. Kumarganj, Faizabad (U.P.) India to study the population dynamics of okra insect-pests and their natural enemies. The result revealed that major insect-pests and their natural enemies in Okra started from 2nd and 3rd week of August on 4-5 week-old plant-5 s and continued until fourth week of December on 25-week-old plant-5 s.. Investigations on Population dynamics of major insect-pests and their natural enemies on Okra revealed association of a total 12 arthropods with this crop. Among these seven viz- whitefly (*Bemisia tabaci*), jassid *Amrasca biguttula* (Dist.), Thrips *Thrips tabaci* (Lind.), Fruit borer *Helicoverpa armigera* (Hb.), okra shoot and fruit borer *Earias vittella* (Fabricius), aphid, *Aphis gossypii* (Glov.), and leaf hopper, *Amrasca devastans*. Five viz- lady bird beetle Coccinelia septumpuntata and *Cheilomenes undecimpuntata* Linn.,) and predatory spider *Oxypus* spp. Green Lace wing *Chrysoperla Carnea* (Stephens) Mrid bug and Ants were recorded as natural enemies associated with this crop. The appearance of the major insect pests from 31th SW observed to 50 SW during *Kharif* 2013 and *Kharif* 2014 0.57 leaf hopper /plants at 30th SW during *Kharif* 2015 respectively.

Key words : *Whitefly, Jassid, Thrips, Fruit borer, Okra shoot and fruit borer Earias vittella aphid, and leaf hopper.*

The okra, *Abelmoschus esculentus* L. (Malvaceae) is an important vegetable of India and eaten by people with a great interest. The okra crop is infested by a number of insect pests like *Amrasca devastans, Earias vittella, Bemisia tabaci, Helicoverpa armigera, Acrocercops bifasciata, Thrips tabaci, Aphis gossypii, Podagrica, Aniomisflava, Sylepta derogata, Haritalodes dervgata, Dysdercus koengii* and *Nezara viridula*. But *Amrasca devastans, E. vittela, H. armigera* and *B. tabaci*, are the notorious and major insect pests of okra (Dubey *et al.*, 1999; Basu, 1995; Lohar, 2001). Insect pest infestation not only reduce the growth but also transmit pathogenic diseases (Sheedi, 1980; Dhaliwal *et al.*, 1981). This challenging situation invites attention of entomologists to concentrate energies on integrated pest management (IPM) of okra and other crops (Huffaker and Carl, 1980; Dhaliwal *et al.*, 1981; Mahadevan and Chelliah, 1986; Dubey *et al.*, 1999; Kumawat *et al.*, 2000) Botanical insecticides (Neem oil or biosal and tobacco extracts), microbial control (Bacillusthuringiensis) and biological control agents (spider, ant, lady bird beetle, Orius, myrid bug, Laius, Chrysoperla, Trichogramma etc.) should be integrated for economic management of insect pests (Arora, *et al.*, 1996; Abro et al., 2004; Memon et al., 2004).

MATERIALS AND METHODS

The experiment was conducted at Student Structional Form, N. D. University Of Agriculture and Technology. Kumarganj, Faizabad (U.P.) India- 224229 by growing a popular variety 'Arka Anamika in the plot size 600m^2 following recommended practices during Kharif 2013 and 2014. Date of sowing- 12th July 2013 and 16th July 2014. The okra (cv. Arka Anamika) was sown in well prepared soil on ridges. The distance between row to row was 60 cm, and plant-5 to plant-5 45cm. The seed rate was 8 kg per acre. Observations were recorded on five randomly selected plant-5 s at weekly intervals starting with 14 days after sowing (DAS) till harvesting in terms of number of arthropods, per plant-5 using rectangular cage 45cm long, 30cm wide and 90cm high, according to the stage of crop at Student Structional Form, between 5-7 A.M. Larval population of shoot & fruit borer and fruit borer was recorded at weekly intervals on 5 randomly selected plant-5 s starting with 50 % flowering till harvest. The data of the treatments were recorded at weekly intervals. While recording the data, it was noted that the observations on insect pests and predators should be recorded early in the morning because of flying and moving of these creatures. The observations were recorded through tagging 5 plant-5 s selected at random in each treatment. The populations of sucking insect complex were recorded as per leaf, from five leaves by selecting one from top, 2 from middle and 2 from bottom portion of plant-5, while the population of chewing insect pests and predators were recorded as per plant-5. The pre-treatment observations were recorded before employing plant-5 protection tactics, while post-treatment observations were recorded 48 hours after application of the respective bio-rational pesticide. Weekly Meteorological data during crop was collected from Agro meteorological observatory N. D. University Agriculture

Efficacy of insecticides on yellow stem borer, *Scirpophaga incertulas* in rice crop

Singh Devendra, Gupta PK, Chandra Umesh, Vikrant and Kumar Akshay

Abstract
An experiment was conducting during *kharif*, 2013 at Main Experimental Station of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad-224 229 (U.P.) to evaluate the efficacy of some insecticides at different doses against the yellow stem borer *scirpophaga incertulas* (Walker) in rice ecosystem. The application of insecticides was done after transplanting, when the pest population reached at their ETL (Economic threshold level). The result shows that among all the insecticides (treatments), profenofos 40 + cypermethrin 4 (44 EC) 880 gm a.i. was most effective against the yellow stem borer, *scirpophaga incertulas* (Walker) (1.25 per cent) followed by profenofos 40 + cypermethrin 4 (44 EC) 440 gm a.i. (1.75 per cent) and conversely protected the crop. The least efficacy of treatment was found in lambda cyhalothrin 5 EC (3.75 per cent) treated plots. All the treatments were found effective and significantly superior over the control.

Keywords: transplanting, pest, population, ETL, efficacy, insecticides, *scirpophaga incertulas*, profenofos, lambda cyhalothrin

1. Introduction
Rice (*Oryza sativa* L.) is one of the most important staple food crop of Asia and a primary stable diet of over half of the world population relying on rice as the major daily source of calories and protein [4]. Asia accounts for about 90% of the world's rice area and production. Among the rice growing countries, India has the largest area under rice in the world (about 44.6 mha) i.e. 28% of the world's area of production, and ranks second next to China. The share of India to the world's production is near about 22.1 percent [2]. Uttar Pradesh contributes 56.57 lakh ha area and 119.92 lakh ton production with productivity of 2.12 t/ha in comparison to Punjab with maximum productivity (3.82 t/ha) of rice in India [1]. Rice yield in south and south-east Asia fluctuate yearly and adverse only about 2 tonnes/ha or less. The two major factors responsible for poor yield are adverse weather (flood, drought, typhoons etc.) and pest epidemic. Present investigation on yellow stem borer *scirpophaga incertulas* (Walker) of paddy was conducted during *kharif*, 2013 at the main Experimental Station of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad-224 229 (U.P.) to estimate the effectiveness of insecticides against yellow stem borer. The rice plant is subjected to attack by more than 100 species of insects, 20 of them can cause economic damage. Together they infest all parts of the plant at all growth stages, and a few transmit viral diseases [5]. Rice yellow stem borer (YSB), *Scirpophaga incertulas* (Walker) of national importance as their incidence has significant impact on rice yields across the diverse rice ecosystems.

2. Materials and Methods
The experiment was conducted during the kharif of 2013, at Main Experimental Station of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad-224 229 (U.P.) in a Randomized Block Design (RBD) with eight treatments and four replications in plot size measuring 11 x 5 sqm. The treatments were *viz.*, Profenofos 40%+ Cypermethrin4% (44) EC @ 220 (g./ha.), Profenofos 40%+ Cypermethrin4% (44) EC @ 330 (g./ha.), Profenofos 40%+ Cypermethrin4% (44) EC @ 440 (g./ha.), Profenofos 40%+ Cypermethrin4% (44) EC @ 880 (g./ha.), Profenofos 50 EC, Cypermethrin 10EC and Lamda cyhalothrin 5 EC including an untreated or control against yellow stem borer *Scirpophaga incertulas* (Walker). The insecticides were applied as and when the pest population reached at their ETL (Economic threshold level) with their respective doses as mentioned in Table-1.

EFFECT OF INSECT POLLINATORS ON SEED YIELD ATTRIBUTING PARAMETERS OF PIGEON PEA CROP

R.K.Verma,RVSingh, Umesh Chandra,Ramveer,M.P Gautam
Department of Entomology
N.D. University of Agriculture and Technology Kumarganj, Faizabad

Abstract

The present investigation entitled "Effect of insect pollinators on seed yield attributing parameters of pigeon pea crop" at Farm of Main Experiment Station of N.D.U.A.T, Kumarganj, Faizabad during *kharif* 2014-15. The result revealed that the maximum pod setting 171 pod/plant and 90.43 per cent seed setting were recorded in open-pollination followed by bee-pollination with 161 pod/plant and minimum pod setting 124.53 pod/plant and 76.96 per cent seed setting in self-pollination. The highest seed yield 19.60 q/ha which was 40.30% increased over on self-pollination was observed in Open-pollination followed by 18.33 q/ha seed yield in Bee-pollination and minimum in self-pollinated pollination with 13.97 q/ha.

Key word: pollinators, seed, pod , insect, flowers and pigeon pea,

Introduction

Predominantly pigeon pea flowers are self-fertilized with 20-40% cross-fertilization so it is known as often cross-pollinated crop. *Cajanus cajan* flowers have bright corollae and produce nectar and pollen. These traits suggest that *C. cajan* would be attractive and possibly bee pollinated by bees (Grewal et al., 1990; Saxena et al., 1990; Reddy et al., 2004 and Sarah et al.2010).

Globally, yields of insect-pollinated crops are often managed for greater pollination through the addition of honey bees (*Apis mellifera* L.) as an agricultural input. Therefore, the potential impact of wild pollinator decline on crop yields is largely unknown. Nor is it known whether increasing application of honey bees compensates for losses of wild pollinators. The effects of evenness on pollination services remain largely unknown, and the impact of wild insect loss on fruit set has not been evaluated globally for insect-pollinated crops.

Materials and Methods

Pigeon pea variety (Narendra Arhar -1) was sown in *kharif* 2014-15 season in the month of June (30-06-2015) and crop was harvested on 25-4-2016 at Main Experiment Station of Narendra Deva University of Agriculture and Technology Kumarganj, Faizabad. All the recommended agronomical practices were adapted to get a good crop in the field.

1. The pigeon pea (Narendra Arhar-1) harvested for sampling and recording the observations of the experiment. The following Seed yield attributing characters were worked out viz.;

(a) Number of pods per plant
(b) Per cent seed setting = No. of developed seed in pod ÷ No. of locals in pod × 100
(c) Weight of grain per plot ($6m^2$) and ha^{-1}.

Results and Discussion

Number of pods

The significant effect of insect pollinators on the pod formation was observed between different treatments. The highest pod formation 171.26 pods /plant was recorded in treatment T_2 (Open-pollination) which was higher as compared to pod formation in treatment T_3 (Bee-pollination) with 161.43 pods /plant and 124.53 pods /plant in treatment T_1 (Self-pollination.

The significantly maximum pod setting, 171pod/plant was recorded in open-pollination followed by 161 pod/plant in bee- pollination and minimum pod set 124 pods/plant was recorded from self-pollination. Pando et al. (2011) recorded *Chalicodoma cincta cincta* foraging resulted to a significant increase of the fruiting rate by 19.65%, as well as the number of pod/plant by 24.33%. Singh et al. (2013) recorded significantly positive effect of bee pollination on reproductive parameters in open pollinated plants i.e. pod setting, number of seeds and seed weight increased by 35.71, 39.14 and 32.88 per cent in cross-pollinated (unbagged) plant in comparison to self-pollinated (bagged) plant. Anonymous (2014-15) also found maximum pods setting in open- pollinated crop followed by bee-pollination and self-pollination.

2. Per cent seed setting:

A glance of data depicted in Table 1 revealed that there was significant effect of insect pollinators on the seed setting of pigeonpea crop between treatments. The maximum seed setting 90.43 per cent was recorded in treatment T_2 (Open pollination) which was significantly higher as compared to seed setting in treatment T_3 (Bee pollination) which was 87.52 per cent and 76.96 per cent in treatment T_1 (Self-pollination).

The significantly maximum seed setting, 90.43 per cent was recorded in open-pollination followed by 87.52 per cent in bee-pollination and minimum seed set 76.96 per cent was recorded from self-pollination. Fohouo et al. (2014) recorded the foraging activity of *X. olivacea* resulted in a significant increase in the Fruit by 22.26%, as well as the number of seeds/pod by 34.98% Placing *X. olivacea* nests close to *C. cajan* fields is recommended to increase seed setting in Cameroon. Rathi and Sihag (1993) recorded plots caged with *C. lanata* showed increases in seed numbers and weight compared with open-pollinated crops. Values for plots caged without bees were significantly reduced. Mazi et al. (2014) reported the fruiting rate, the number of seeds per fruit and the percentage of normal seeds of unprotected flowers in *C.cajan* were significantly higher than those of flowers protected from insects.

3. Average seed yield in q /ha:

The significant effect of insect pollinators on the seed yield was observed between treatments. The highest seed yield 19.60 q/ha was observed in treatment T_2 (Open-pollination) followed by 18.33 q/ha seed yield in treatment T_3 (Bee-pollination) and 13.97 q/ha in treatment T_1 (Self-pollination).

The significant effect of insect pollination on the seed yield was observed between treatments. The highest seed yield 19.60 q/ha was observed in treatment T_2 (Open-pollination) followed by 18.33 q/ha seed yield in treatment T_3 (Bee-pollination) and 13.97 q/ha in treatment T_1 (Self-pollination). This result is in close agreement with Brar et al. (1992) recorded pods/plant and seed yields were similar on plots caged with *A. mellifera* and those caged without bees, but pods/plant and seed yields values were 3 and 4 times greater, respectively, on open-pollinated plots. Anonymous (2014-15) also found maximum yield in open- pollination followed by bee-pollination and self-pollination.

Table-1 Effect of Insect Pollination on seed yield attributing parameters of pigeonpea crop

Treatment	Mean of Seed Yield attributing parameter				Increase over on SP in per cent
	No. of Pod per plant	Seed setting per cent	Kg/plot (6 m^2)	q/ha	
Self-Pollination (SP)	124.53	76.96	0.83	13.97	-
Open-Pollination (OP)	171.26	90.43	1.17	19.60	40.30
Bee-Pollination (BP)	161.43	87.52	1.09	18.33	31.20

Correlation between *Helicoverpa armigera* (Hubner) population and Weather factors in chickpea (*Cecer aratinum* L.)

MP Gautam, Umesh Chandra, SN Singh, Ramveer, Ramesh Jaiswal and SK Yadav

Abstract
The present investigations entitled "Studies on population dynamics and management of *Helicoverpa armigera* (Hubner) on chickpea using botanicals" was carried out at Students' Instructional Farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad during *Rabi*, 2016. revealed that *Helicoverpa armigera* population were noticed for the first time during 46th SW of 2016 and respective mean population were 0.33 larvae/plant. Mean population of *Helicoverpa armigera* showed non-significant negative correlation with minimum (-0.335) and maximum temperature (-0.220) and rainfall (-0.266) while RH showed non-significant with positive correlation (0.394).

Keywords: Gram, *Helicoverpa armigera*, Correlation and Weather Factor

1. Introduction

Chickpea (*Cicer arietinum* Linn. Leguminacae) is one of the most important *rabi* pulse crop of India. The world area of chickpea is estimated to be about 135.40 lakh ha^{-1} at global level with production and productivity of 131.02 lakh tonnes and 968 kg ha^{-1} respectively. In India, the area, production and productivity 59 mha, 77.03 million tonnes and 890 kg ha^{-1}, respectively (Annonymous 2016) [1].

Gram Pod borer *Helicoverpa armigera* is one of the major pest of gram. The pest starts its attack at early stage and become severe during maturity stage of the crop. The pest accounts for 90-95% of total damage. A single larva of *Helicoverpa armigera* can damage 25-30 pods of gram in its life time. It feeds on tender shoots and young pods. It makes holes in pods and insert its half body inside the pod to eat the developing seeds. The pod borers inflict heavy crop losses from seedling to maturity and the losses reach at its peak when the pods appear. The seed yield losses due to *Helicoverpa armigera* were 75-90% and in some places the losses were up to 100%. The yield loss in chickpea due to pod borer was reported as 10 to 60 per cent in normal weather conditions, while it was 50 to 100 per cent in favorable weather conditions, particularly in the state where frequent rain and cloudy weather is prevailing during the crop season. These losses can be reduced by the application of insecticides. In favorable conditions pod borer may cause 90-95 per cent of pod damage (Kumar *et al.*, 2017).

Helicoverpa armigera is a conundrum and one of the most dominant insect pests in agriculture, accounting for half of the total insecticides usage in India for protection of crops. The problem of this pest is magnified due to its direct attack on fruiting structures, voracious feeding habits, high mobility and fecundity, multivoltine nature, overlapping generations, nocturnal behavior etc., (Sarode, 1999) [7]. At the same time adequate ecological data is prerequisite for integrated pest management, which can therefore be enhanced after determining the seasonal abundance (Mathur *et al.*, 2003) [5]. There are many environmental factors which influence the insect pest populations (Lode and Sharma, 1993) [3]. Among them abiotic factors play a vital role in multiplication and distribution of insect pests.

Method and Material

To know the effect of abiotic variables on the population of *Helicoverpa armigera*, simple correlation analysis was carried out. The result of the analysis has been presented in (Table-2) and details have been given here as below:

Correlation observed between the *Helicoverpa armigera* population and abiotic parameters showed non-significant positive correlation with minimum and maximum temperature, relative humidity while rainfall had non-significant negative correlation.

Relative efficacy of newer insecticides against gram pod borer, *Helicoverpa armigera*

RK Yadav, U Chandra, Ram Veer, Amit Raj, CPN Gautam, Sachin Kumar and Gajendra Singh

Abstract
The experiment was conducted at Students' Instructional Farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad during Rabi season 2015-16. Studied on Emamectin benzoate 5 SG @ 11 g a.i./ha was found most effective insecticide (94.44%) to reduce the larval population, it was followed by flubendiamide 480 SC @ 30 g a.i./ha that gave 87.78 per cent reduction, which was at par with rynaxypyr 20SC @ 40 g a.i./ha (83.33%). Least effective treatment was Lufenuron 50EC @ 60 g a.i./ha. in which only 64.44 percent reduction in larval population was registered. Reduction in larval population computed from data recorded 14 days after spraying revealed that all the treatments were effective and significantly superior to control. Emamectin benzoate 5 SG @ 11 g a.i.//ha was found most effective that reduced 100.00 per cent larval population.
Emamectin benzoate 5 SG @ 11 g a.i.//ha treated plots gave maximum grain yield (18.00 q/ha), it was at par with flubendiamide 480 SC @ 30 a.i./ha and Rynaxypyr 20SC @ 40 g a.i./ha in which 17.00, 16.50 q/ha grain yield, respectively were recorded. Maximum cost- benefit ratio was obtained in plot treated with flubendiamide 480 SC @ 30 g a.i./ha (1:10.06) followed by emamectin benzoate 5 SG @ 11 g a.i.//ha (1:9.20). Lowest cost -benefit ratio (1:3.10) was found in Lufenuron 50 EC@ 60 g a.i./ha treated plot.

Keywords: Pod borer, management, cost benefit, treatments and insecticides

Introduction
Chickpea, *Cicer arietinum* L. belongs to family Papilionaceate is an important pulse crop grown in many parts of the world. It is an important source of protein in human diet and animal feed (Khoso, 1992) [2]. The split grain of chickpea is called dal which is an excellent source of high quality proteins, essential amino and fatty acids, fibres, minerals and vitamins.
The area under chickpea cultivation in India is about 9.51 m ha with production of 8.83 m tonnes and productivity 929 kg/ ha. The area under U.P. is 0.0604 m ha with production of about 0.0732 m tonnes with an average yield of 1212 kg/ha (Anonymous, 2013-14) [1].
The chickpea pod borer, *Helicoverpa armigera* is polyphagous in nature which causes damage to several crops such as pigeon-pea, groundnut, cotton, vegetables, pearl millets, sorghum, maize, sunflower etc.
The young larvae often feed upon the tender foliage before attacking the pods by causing heavy losses to crop and sometimes whole crop failed due to severe infestation (Lohar and Rahoo, 1993; Nizamani, 1998) [3, 4]. Damage potential of this pest is so great that an average infestation of single larva may destroy 30-40 pods per plant in chickpea. The extent of losses in chickpea by pod borer varies from region to region. On chickpea, the pest appears in late February and reaches its peak by the end of April. Since not much resistance is available in gram genotype against the pest, therefore, farmers are increasingly relying on synthetic insecticides to manage this pest on different crops.
The pest feeds voraciously from seedling stage to maturity and causes about 50 to 60 per cent damage to the chickpea pods (Khare and Ujagir, 1977) [5]. In India, losses caused by pod borer on chickpea and pigeon pea fields exceeded Rs. 12,000 million per year (Anonymous, 1996) [6].
To control this insect pest number of chemical insecticides is used injudiciously which resulted development of resistance in insect, secondary pest outbreaks, threat to their natural enemies and residual effect on environment. In order to develop pest management strategies of *H. armigera*, knowledge on the basic biology of this pest is required. Jadhav and Suryawanshi, (1998) [7] reported that the application of insecticides reduced the larval population of pod borer on chickpea crop to a considerable extent and hence increased the yield. Balasubramanian *et al* (2001) [8] reported that chlorpyrifos 20 EC was the most effective insecticide to control gram pod borer.

Study on availability of bee flora and foraging activities of honey bee in Eastern Uttar Pradesh

Ramesh Jaiswal, Umesh Chandra, MP Gautam, SK Yadav, SK Giri and Ramveer

Abstract
The present investigation entitled "study on availability of bee flora and its foraging activities in eastern Uttar Pradesh", was carried out on the honeybee foraging activities were recorded on different agricultural and horticulture crops during *Rabi* season 2016-17. It was observed that the bee-flora consists of mostly, fruits and agriculture crops like spices, pulses, cereals, oil seed/yielding, fiber, and fodder crops etc. *Brassica rapa* were the major agricultural bee crops of the area with flowering period of three (3) and four (4) months respectively. These plants species served as the excellent sources of pollen and nectar in the study area. The result revealed that 10 crops were useful to honeybees, out of which 5 crops were agricultural crops like as Mustard, pigeon pea, gram, bakla etc. and 4 horticulture crops like as mango, lemon, guava, anola and the forest plant like as eucalyptus, which are well distributed and commonly found in the study area. The identified flora was further grouped into pollen, nectar and both pollen and nectar yielding plants out of 5 agricultural bee crops, three (3) plants were nectar yielding, one (1) pollen yielding and six (6) plants species were both pollen and nectar yielding

Keywords: Honeybee, *Apis mellifera*, bee flora and foraging activities etc.

1. Introduction

Flowers are the mainstay of the bee's life. From flowers,, they obtain pollen, the protein rich food used mostly to feed the carbohydrate fuel for their flight, foraging, hive activity and for rearing brood. The abundance of bee flora and their continuous availability is one of the major pre-requisites for successful beekeeping. This enables the beekeepers to exploit these sources to the maximum utilization by the bees. Every region has its floral dearth periods of short or long duration and it is essential to manage the honey bees and bee hives in the dearth period. As during this period, there is lack of availability of nectar and pollen in flora required for quantitative and qualitative production of honey [1]. To overcome this problem. It is important to find out the suitable bee flora available in the locality to propagate and manage the plant species with a option of abundant nectar and or pollen to overcome the problem during the dearth period for commercial apiculture [4]. The present bee fauna dates back to Cretaceous period which is more that 70 mya. Bees are members of the kingdom Animalia, the phylum Arthropods, the class Insecta and the order Hymenoptera (from the Greek hymen, for membrane, and Petron, for wing) [2]. This order includes over 100,000 diverse species of bees, wasps, ants, and saw flies that have been identified and described. The most important characteristic of most members of this order for the understanding of layman is a "wasp waist" which is narrow area between the thorax and the abdomen. Of course, they also all have two pairs of wings, multi-segmented antennae and a few species have a piercing ovipositor [5].

The floral sources and its blooming period are the main indicators and tools for modem beekeeping in India. The bee plants are grouped into forest plants, horticultural /agricultural plants and pastures and hay fields [9]. In India, 50 million hectares of land is under bee dependent. Bee keeping (or) apiculture is the maintenance of honey bee colonies commonly in hives by humans. A bee keeper/ Apiarist keeps bees in order to gather honey bee wax to pollinate crops (or) to produce bees for sale to other beekeepers. Normally bee keepers use three types of hives for example traditional hives, top bar and langstroth hives. Newton's bee hive model normally adapted by the honey bee keepers [6, 7, 12].

The characteristics of *A. mellifera* combined with the high demand for Honey products put beekeeping as a key activity for ecosystem conservation and economic development, thus

SEASONAL INCIDENCE FLUCTUATION OF OKRA SHOOT AND FRUIT BORER AND THEIR NATURAL ENEMIES ON BHINDI (*ABELMOSCHUS ESCULENTUS* L.) IN RELATION TO ABIOTIC FACTORS

Umesh Chandra and Abhishek Kumar Chaudhary
Department of Entomology, N.D.U.A. & T., Kumarganj, Faizabad -224229

Abstract

The experiment was conducted during kharif season of year 2014 and 2015 at Student Instructional Form, N. D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) India to study the seasonal incidence fluctuation of okra shoot and fruit borer and their natural enemies on Bhindi. Incidence were recorded with three replication. The result revealed that shoot and fruit borer and their natural enemies in Okra observations started since 33th standard week at 5 week old plants until 50th standard week on maturity, the incidence of okra shoot and fruit borer *Earias vittella* (Fabricius), and their natural enemies lady bird beetle (*Coccinella septumpuntata* and *Cheilomenes undecimpuntata* Linn.,) and predatory spider (Oxypus spp.), Green Lace wing (*Chrysoperla Carnea* Stephens), Mrid bug and ants were recorded as natural enemies associated with this crop. The incidence of the okra shoot and fruit borer 0.41 larvae /plant from 33 th SW observed to 50 SW during Kharif 2014 and 0.34 *Earias vittella* larvae /plants at 32th SW during Kharif 2015 respectively.

Key words: *Earias vittella*, Bhindi, seasonal incidence.

Introduction

Okra (Abelmoschus esculentus L.) belongs to family Malvaceae or Mallow which is locally known as Bhendi and Lady's finger worldwide. It is very popular summer vegetable for home gardening while it is also grown commercially throughout the world especially in Indo Pakistan sub-continent. It is probably originated in Ethiopian region of Africa (Naheed et al., 2013). Okra [Abelmoschus esculentus (L.) Moench] is one of the important vegetable crops grown in India with an area of 532.70 thousand hectares with the production of 6346.40 thousand MT green fruits, whereas the productivity is 11.9 MT /ha. It is commercially grown in the state of Andhra Pradesh, West Bengal, Bihar, Gujarat, Maharashtra, Uttar Pradesh, Odisha, Jharkhand, Chhatishgarh Telangana, Karnataka, Haryana and Punjab etc. However, Uttar Pradesh is covering an area of 12.19 thousand hectare with a production of 148.64 thousand metric tonnes and productivity of 12.2 metric tonnes per hectare (Anonymous, 2015). Aphids and leafhoppers are important sucking pests which de-sap the plants, make them weak and reduce the yields to an extent of 54.04 per cent since incidence occurs during early stage (Choudhary and Dadheech, 1989), while, shoot and fruit borer severely attacks the tender fruits causing nearly 45 per cent direct yield loss in the production of quality fruits (Kumar et al ., 2003) Knowledge on seasonal incidence of different pests of okra at different growth stages of the crop and its relation with weather parameters will be of great help to plan appropriate management strategies of different insect pests. In order to reap maximum yields, it is imperative that the crop should be free from the infestation of pests

Materials and Methods

The experiment was conducted at Student Instructional Form, N. D. University of Agriculture and Technology. Kumarganj, Faizabad (U.P.) India- 224229 by growing a popular variety 'Arka Anamika in the each plot size 4x4 m2 following recommended practices during Kharif 2014 and 2015. Date of sowing- 12th July 2014 and 16th July 2015. The okra (cv. Arka Anamika) was sown in well prepared soil on ridges. The distance between row to row was 60 cm, and plant-5 to plant- 45cm. The seed rate was 8 kg per acre. Observations were recorded on five randomly selected plant-5 s at weekly intervals starting with 14 days after sowing (DAS) till harvesting in terms of number of arthropods, per plant-5 using rectangular cage 45cm long, 30cm wide and 90cm high, according to the stage of crop at Student Structional Form, between 5-7 A.M. Larval population of shoot & fruit borer was recorded at weekly intervals on 5 randomly selected plant-5 s starting with 50 % flowering till harvest. The data of the treatments were recorded at weekly intervals. While recording the data, it was noted that the observations on insect pests and predators should be recorded early in the morning because of flying and moving of these creatures. The observations were recorded through tagging 5 plant-5 s selected at random in each treatment. The populations of natural enemies were recorded as per leaf, from five leaves by selecting one from top, 2 from middle and 2 from bottom portion of plant-5, while the population of chewing insect pests and predators were recorded as per plant-5. Weekly Meteorological data during crop was collected from Agro meteorological observatory N. D. University Agriculture &Technology (Faizabad). Correlation between arthropod Population and abiotic factors was worked out.

Results and Discussion

Insect-pests population: Studies on Population dynamics of major insect-pests and their natural enemies on Okra with this crop in this area. The data presented in reveled that first appearance of Okra shoot and fruit borer (*Earias vittella*) was noticed in the 34th S.W. the larval population ranged from 0.30 to 2.07 larvae/plant of *Earias vittella* in 2014 and 0.43 to 2.04 in 32th in 2015 the maximum population of 2.07 larvae/plant of *Earias vittella* was found in the 41th S.W. during 2014 and 2.04 larvae/plant of *Earias vittella* in 41th in 2015.The data presented in reveled that the first appearance of Okra shoot and fruit borer *Earias insulana* was noticed in the 37th S.W. the larval population ranged from 0.33 to 3.29 larvae/plant of *Earias insulana* in 2014 and 0.14 to 3.93 in 32th in 2015 the maximum population of 3.29 larvae/plant of *Earias insulana* was found in the 37 th S.W. during 2014 and 3.93 larvae/plant of *Earias insulana* in 41th in 2015. Appearance of the the Natural enemies population: The first appearance of lady bird beetle in the 32th S.W. 2014 and 34th in 2015 beetle ranged from 0.33 to 5.35/plant-5 and 1.45 to 6.35 and the maximum population 5.34 was found in the 37th S.W. in 2014and 6.35 beetle /plant-5 in 38th SW in 2015 the first appearance of spider in the 31th S.W. 2014 and 2015 spider ranged from 0.45 to 5.12/plant-5 and 0.33 to 7.98 and the maximum population 5.34 was found in the 37th S.W. in 2014 and 6.35 beetle /plant-5 in 39th SW in 2015. The first appearance of ant in the 32 th S.W. 2014 and 33th in 2015 spider ranged from 0.33 to 3. 63 /plant-5 and 1.54 to 4. 58 and the maximum population 3. 63 was found in the 34th S.W. in 2014 and 4.58 spider /plant-5 in 34th SW in 2015. the first appearance of Green Lace wing in the 35th S.W. 2014 and 33th in 2015 spider ranged from 0.83 to 5.54/plant-5 and 1.25 to 6.51 and the maximum population 5.54 was found in the 38th S.W. in 2014 and 6.51 GLW /plant-5 in 39th SW in 2015. The first appearance of mirid bug in the 34th S.W. 2014 and 37th in 2015 ranged from 0.50 to 3.85/plant-5 and 0.76 to 4.25 and the maximum population 3.85 was found in the 38th S.W. in 2013 and 4.25 mirid bug /plant-5 in 42th SW in 2014. (Shobizai et. al., 2011 Chaudhary et al., 2017) have however reported association of twelve pests (Das et al., 2001) thirty one spp. and eleven and (Bindu et al,. 2003) twelve spp. of insect pests associated with this crop at its various growth stages. in the present study are in accordance with the finding of (Singh et al., 2015). To know the effect of abiotic variable simple correlation analysis was carried out the results of the analysis present in (Table-1&2) revealed that the Positive and significant correlation was observed between population of *E. vittella* with maximum temperature during *Kharif* 2014 and 2015, while positive and non-significant correlation was observed with minimum temperature during *Kharif* 2014 and 2015. However, during *Kharif* 2014 the

Pollination efficiency of insect pollinators on *Aegle marmelos* Correa. At Kumarganj, Faizabad

SN Satapathy and Umesh Chandra

Abstract
In the present research the variety "Narendra Bael 9 (NB 9)" was taken to study the insect pollinator's abundance and their pollination efficiency at Main Experiment Station (26.47°N latitude, 82.12° E longitude and 113 meters altitude), Horticulture and Apiculture laboratory, Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.), India during 2014. The hymenopterans were the major floral visitors comprising of six species from four families *viz*., Xylocopidae, Apidae, Vespidae and Formicidae, followed by dipterans (One species from one family) *viz*., Syrphidae, Lepidoptera (three species from two families) *viz*., Pieridae and Arctiidae. The abundance of *Apis dorsata* was highest (7.90 bees/spike/5 minutes) followed by syrphid flies, *Eupeodes corolae* (3.45 visitors/spike/5 minutes) and *Apis mellifera* (1.20 bees/spike/5 minutes). Based on pollination index (Number of loose pollen grains sticking on the body of visitors × abundance), *A. dorsata* was found to be the most efficient pollinator of bael flowers followed by *Eupeodes corolae* and *A. mellifera* under agro-ecological conditions of Kumarganj, Faizabad (India).

Keywords: Abundance, pollinator, pollination efficiency, pollination index, pollen grain, bael

1. Introduction
Bael (*Aegle marmelos* C.) belongs to family rutaceae and it is known in India from pre-historic time [6]. In nature, only about 5 per cent of the flowers are self-pollinated and 95 per cent animal pollinated [5]. Bael is mostly cross pollinated fruit crop which has entomophilous flowers and pollination is carried out by various insect pollinators like honey bees (*Apis dorsata*, A. *mellifera*),hover flies, yellow wasp, carpenter bee, weevil, black ants, butterflies etc. [4]. Bees are the best among all pollinators. Butterflies are occasional pollinators, and do pollination of crops while feeding on nectar from one flower to another. Flies, hoverflies and wasps are effective pollinators because they visit flowers to feed upon nectar (or in some species pollen) for essential nutrients for egg maturation and extending their life-span [2]. Being a cross pollinated crop, its fruit set is expected to be affected by the insect visitors. The investigation was carried out on the pollination efficiency, which is defined as the proportion of pollinated flowers relative to those that experienced pollen removal.
The present studies were conducted with the objectives to know pollinators abundance and pollination efficiency of pollinator species.

2. Materials and Methods
The pollination studies in bael variety, "NB 9" was carried out under sodic soil condition and experimental site is located at Main Experimental Station, Department of Horticulture, Narendra Deva University of Agriculture and Technology, Faizabad (U.P.) [26.47° N latitude, 82.12° E longitude and altitude of 113 metres from mean sea level] during 2014.

2.1 Abundance of insect visitors: Abundance (number of visitors/ spike/5 minutes) of major pollinators was recorded from six randomly selected bael plants. These observations were recorded from 6:00 am to 6:00 pm at an interval of 3:00 hours. Observations were recorded for 7 days each after the initiation of 10% flowering in crop, at peak flowering and before the cessation of flowering in the crop.

2.2 Loose pollen grains sticking on the body of insects visitors: For estimating the number of loose pollen grains sticking to the body of major insect pollinator species, the insect pollinators were captured gently by forceps from the flowers to avoid shaking of body and the

Abstract

The survey of population dynamics of insect – pests in sugarcane crop with special reference to early shoot borer and top borer carried out during spring season at farmer's field in eastern U.P. Present investigation revealed that five insect- pests prevailed and infested sugarcane crop in these areas. They were shoot borers (*Chilo infuscatellus*), top borer (*Scirpophaga excerptalis*), leaf hopper (*Pyrilla perpusilla*) termites (*Odentotermes obesus*) and grass hopper (*Hieroglyphus spp.*). The maximum infestation (32.22%) of shoot borer was recorded on 20th Standerd week and the minimum infestation (3.33%) on 13th and 28th SW. The highest termite infestation (38.88%) was noticed on 20th SW, whereas the lowest (1.11%) on 12th and 28th SW. The maximum population (4.47 insects/plant) of grass hoppers was noticed from 31st SW and the minimum population (0.13 insects/ plant) on 42nd SW in the field. Sugarcane top borer caused maximum infestation (35.55%) on 32nd SW and minimum (1.11%) on 41st SW.

Keywords- Shoot borer, Top borer, infestation, leaf hoppers

Introduction

Sugarcane (*Saccharum officinarum* L.) is one of the major sugar-producing crop that contributes nearly 75 per cent to the total sugar pool at global level. It belongs to genus Saccharum and family Poacae. Molasses is an important by- product of sugar industry. It is used for production alcohol by the distilleries. India ranks first in sugarcane production in the world followed by Brazil. The area, production and productivity of sugarcane in India were 5.47 mha, 380 mt and 69.4 t/ha, respectively. Whereas in Uttar Pradesh, sugarcane is grown in about 2.28 mha area with 121.36 mt annual production and 53.23 t/ha productivity (Anonymous 2012).

Among the various constraints in sugarcane production, varieties, fertilizers, irrigation, insect- pests and the disease are prime importance. As many as 200 species of insect- pests have been reported on sugarcane crop (Jaipal and Singh, 2010), however, one dozen are recognized as major pests at various stages of crop growth. The shoot borer, Chilo infuscatellus Snellen and top borer, Scirpophaga excerptalis Walker are more serious pests in the early stage of the crop throughout the country. In Punjab, Haryana and northern Rajasthan the stalk borer, Chilo auricillius Dudgeon is raised as an important pest in recent years (Atwal and Dhaliwal, 2007).

Shoot borer has been reported as serious pest of sugarcane in which the early shoot borer, *Chilo infuscatellus* caused 30 to 75 per cent losses in early stage of the crop in sub-tropical region (Jaipal et al. 2010). The young larvae bore down the spindles by moving upward direction and destroyed the apical meristem. Consequently, the cut off spindle dries up and develops a conspicuous 'dead heart' that can be pulled out easily and emits rancid odour.

Top borer, *Scirpophaga excerptalis* has been considered as the most serious pest of sugarcane which caused 31.94% loss in early and 28.50% loss in mid to late maturing cultivars. It attacks the upper parts of the sugarcane plant. The caterpillars bore into the midrib of leaves and enter into the top portion of the plants (Madan and Singh, 2002).

Materials and Methods

Population dynamics of insect- pests:

Farmer fields were selected to record the population dynamics, Farmer fields were regularly monitored in the morning hours at Sugarcane crop was regularly monitored in the morning hours at weekly intervals to observe the population/infestation of various insect- pests from germination to harvest on 10 randomly selected plants at three locations in each in all the fields.

A. **Borers:**

i. **Shoot borers-**

Number of healthy and infested plant at shoot stage of the cane was recorded by observing the dead hearts and puncture holes on leaf sheath.

i. **Top borer-**

The observations on incidence of top borer was recorded by observing the dead hearts, shoot holes, mined midrib leaves as well as bunchy top on sugarcane clumps.

B. **Root feeders**:

i. Termites-

Number of infested and healthy crop plants.

C. **Sap Feedres:**

i. Grass hopper-

Number of both nymphs and adults on the infested leaves.

ii. Leaf hopper-

Number of both nymphs and adults on upper, middle and lower leaves

Results and Discussion

Only five insects- pests were noticed on sugarcane crop during spring season *viz.*, shoot borers (*Chilo infuscatellus*), termites (*Odentotermes obesus*), top borer (*Scirpophaga excerptalis*), leaf hopper (*Pyrilla perpusilla*) and grasshopper (*Hieroglyphus spp.*) at different growth stages of the crop.

The initiation of shoot borers infestation was noticed on 13th SW (3.33%) and continued up to the 27th SW. The maximum infestation (33.33%) was recorded on 20th SW, and minimum (3.33%) at 27th SW. The initiation of termite infestation was noticed on 13th SW (6.6%) and continued up to the 27th SW. The maximum infestation (43.33%) was recorded on 20th SW and minimum (3.33%) at 27th SW.

Initiation of top borer infestation was started on sugarcane in 25th SW and which was continued up to 41th SW, the maximum infestation (33.33%) was recorded on 32nd SW and minimum (3.33%) at 25th and 40th SW. Grasshopper population was noticed on 13th SW (0.30 insects/plant) and continued up to the 42nd SW. The maximum population (4.60 insects/plant) was noticed on 31th SW and minimum (0.20 insects/plant) at 42th SW.

Initiation of leaf hopper population was noticed on 22nd SW (0.40 insects/plant) and continued up to 41st SW. The maximum population (4.20 insects/plant) was recorded on 35th SW and minimum (0.30 insects/plant) at 41st SW. The results are in conformity with Madan and Chaudhary (1995) observations, who had noticed the population of leaf hopper from January to December with (25.5 insects/plant) highest population in the month September, while lowest (0.1 insects/plant) in March.

The population dynamics of budfly *Dasyneura lini* was experimented during rabi season 2012-13 at the Student's Instructional Farm of Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Faizabad (U.P.). The incidence of budfly was recorded on variety Neelum at weekly intervals from germination till the harvest of the crop. There were eight treatments, namely Imidacloprid 17.8 SL @ 0.005%, Nimbicidine 0.25%, NSKE 5%, Neem leaf extract 5%, Green chilli extract 0.5%, Garlic extract 5%, Tulsi leaf extract 5% and Control. While application of Imidacloprid (17.8 SL @ 0.005 %) was found most effective followed by Nimbicidine @ 0.25 %, NSKE @ 5 % was found as the least effective in controlling of bud fly infestation. On the basis of yield, the highest yield was obtained from Imidacloprid 17.8 SL @ 0.005 % (16.22 q ha^{-1}) followed by (14.29 q/ha^{-1}) with Nimbicidine @ 0.25 %. On the basis of overall performance of all the eight treatments Imidacloprid was isolated as the most effective treatment for the control of the linseed budfly.

Introduction

Linseed, (*Linum usitatissimum* Linn.) is one of the oldest oilseed crop known as poor man's crop in India. It has got special importance amongst oilseed crop in rabi and has also been called as 'Alsi', 'Tisi', 'Mosina' and 'Arise' in India. Among all the insect of linseed, budfly is the most important insect and it affect the pods of linseed very drastically leads to reduce the crop yield. The crop is cultivated commercially for flax in the world. In India, Linseed is globally cultivated for oil production, fibers and flax. Fibres are used for the manufacture of linen and the stem yields fibres ,of good quality having high strength and beauty. It is utilized in making the best quality hand kerchiefs, materials of suits and dresses, bedding, napery, hand towels and other decorative articles (Gill, 1987). Every part of the linseed is utilized commercially either directly or after processing. About 80 per cent of the oil goes

ABSTRACT

The present investigations entitled "Studies on population dynamics of *Helicoverpa armigera* (Hubner) on chickpea" was carried out at Students' Instructional Farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad during *Rabi*, 2016.All the treatments were found significantly superior over control, indoxacrb (14.5 SC) performed best among the treatments followed by Neem oil. The effectiveness of treatment determined in the terms of grain yield of chickpea obtained in different treatments revealed that the Indoxacarb @ 14.5SC, Neem seed oil @ 5ml and karanj oil @ 5ml were significantly superior over untreated control. Indoxacarb 14.5@ SC, gave maximum grain yield of chickpea in compared to other treatments as well as in managing the population of *H. armigera*. Besides Neem seed oil @ 5ml and karanj oil @ 5 ml were found the second and third most effective treatments respectively

Introduction

Gram (chick pea) is the crop of tropical, subtropical and temperate region and widely grown in Uttar Pradesh, Madhya Pradesh, Punjab, Rajasthan and Maharastra which is popularly used as a protein adjunct to starchy diets. Seeds are widely consumed as pulse and in the form of flour which is largely fed to the horse and eaten after roasting. Seeds of chick pea contain 17.1% proteins, 5.3% fats, 16.2% carbohydrates, 3.9 % fibres and 2.7% minerals. Moderate to high levels of resistance to cypermethrin and moderate resistance to endosulfan were recorded in field populations of *H. armigera*. The growing awareness of the hazards of pesticide use has created a worldwide interest in pest control agents of plant origin that are bioactive and yet ecologically safe. Hence, the present experiment was conducted to assess the performance of Neem Seed Kernel Extract (NSKE) along with safer new molecule Flubendiamide 39.35 SC as an effective combination of oviposition inhibitor and larvicidal effect for the management of *H. armigera* on chickpea.

Pod borer *Helicoverpa armigera* Hubner (Noctuidae: Lepidoptera) is one of the major pest of gram. The pest starts its attack at early stage and become severe during maturity stage of the crop. The pest accounts for 90-95% of total damage. A single larva of *H. armigera* can damage 25-30 pods of

Pollination efficiency of different insects on Phalsa *Grewia subinaequalis* D.C

Avinash Udikeri and Umesh Chandra

Abstract
A field experiment was conducted to evaluate efficiency of different pollinators on Phalsa, *Grewia subinaequalis* D.C. a fruiting shrub at Faizabad (U.P) during 2015. The foraging activity started from April month. *Apis dorsata* found to visit more number of flowers (10.01) in a minute by spending very less time (2.27 sec) per flower. *A. mellifera, Halictus sp., Polistes olivaceus* and *Megachile sp.* found visiting 9.35, 6.27, 4.16 and 3.92 number of flowers in a minute and spent 2.82,6.55,7.89,7.31 seconds on flower respectively. *A. dorsata* appeared to be most efficient pollinator on Phalsa with pollination index of 85066 followed by *Apis mellifera*. Highest fruit setting (59.17%) was recorded in the bee pollinated plants followed by open pollinated plants under Kumarganj agro-ecological conditions.

Keywords: bees, foraging rate, pollination index, phalsa

1. Introduction
Phalsa *Grewia subinaequalis* D.C (Order malvales and family Tiliaceae) an indigenous to India and it is mentioned in vedic books. Shrub is known with different names in East and North India. Phalsa was grown naturally at low elevations in dry zone of island of Luzon. Area of Phalsa is very less in the present world, It is only cultivated for research purpose in some places like former Federal Experiment Station, Mayaguez, Puerto Rico, and the Agricultural Research and Education Center, Homestead, Florida (Morton 1987) [10]. It was introduced into Phillipines in 1914 from India and Presently it is cultivated commercially mainly in the Punjab and around Mumbai. Apart from India it is cultivated in Pakistan, Nepal, Bangladesh, Laos, Sri Lanka, Thailand, Philippines, Vietnam and experimental basis in some provinces of United States of America. It bears very hardy fruit, hence can be planted on marginal soils, where rest of the fruits crops cannot be grown. Its cultivation is more popular in peri-urban vicinity. Phalsa fruit is liked for its acidic taste, coloured squash, syrup and medicinal astringent, stomachic values. It decreases inflammation when unripe fruit is eaten and is also administered in respiratory, cardiac and blood disorders, as well as in fever. An infusion of the bark is given as a demulcent, febrifuge and treatment for diarrhea. The root bark is employed in treating rheumatism. The leaves are known to have antibiotic action. It attracts many insects as flower visitors and reported to be pollinated by them Singh *et al.* (2018) [12].
The present studies has been conducted using the various factors such as foraging rate, loose pollen grains sticking to the body, pollination index and fruit set percentage in order to learn about the pollination efficacy of different insects which has not been assessed so far in Phalsa. A better understanding of entomophily may help in better maintenance of Phalsa shrubs and to have better yields.

2. Materials and Methods
The experiments were carried in a well established two years old Phalsa plantation (cv. Dwarf variety) at Main Experimental Station, Department of Horticulture, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) Geographically, it is situated at 26.47^0 N latitude, 82.12^0 E longitude and altitude of 113 meters above mean sea level. The site is located in typical saline-alkaline belt of indo gangetic plains of eastern Uttar Pradesh. The experiment site was having sodic soils. The experiment was conducted in randomized block design. The number of plants selected for observation was ten. The number of treatments were 5 which were replicated 5 number of times.

Effect of bee pollination, *Apis mellifera* L. on yield and quality parameters of Bael (*Aegle marmelos* Correa)

Satya Narayan Satapathy and Umesh Chandra

Abstract
The present experiment was conducted to mensurate the pollination effect of *Apis mellifera* L. on yield attributing characters i.e. fruits per panicle, its weight and TSS percentage of cultivar "Narendra Bael 9" at Main Experiment Station, Horticulture and Apiculture laboratory, Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.), India during 2014. The trees were laden with floral buds/panicles within 7-10 days of emergence of new leaves and reached in full bloom during the months of May-June when days were long and temperature was high. Bael is mostly cross pollinated fruit crop and pollination is carried out by various insect pollinators. The treatment applied were pollination by honey bee only, natural pollination with augmentation of honey bees, natural pollination and control (no pollination). Maximum average number of fruit panicle^{-1}, average fruit weight and average TSS percentage were 27.3, 2.05 kg and 41.3% in natural pollination with augmentation of honey bees while minimum 1.3, 1.8 kg and 35.7% were observed in control. Similarly an increase of 2000.00%, 8.46% and 15.68% over control and 47.56%, 6.22% and 5.08% over natural pollination was observed in average number of fruit panicle^{-1}, average fruit weight and average TSS percentage under the treatment natural pollination with augmentation of honey bees.

Keywords: Pollination, *Apis mellifera*, Bael fruit panicle^{-1}, fruit weight, TSS percentage

1. Introduction

Pollination is defined as the transfer of pollens from male portion of a flower to the female portion which is essential for the process of fertilization and production of fruits and/or seeds [1]. About 90% pollination is carried out by insects, 85% of which comprises the honeybees [2]. The nature and extent of pollination can vary between crops, ranging from increasing the quality and quantity of fruits or seeds and increase genetic diversity within crop species [3]. Inadequate pollination can result not only in reduced yield but also in delayed yield and a high percentage of inferior fruits [4]. The insects of family Apidae are the most reliable agents for pollination. Among members of Apidae family, honey bees are particularly important pollinators as they are capable of carrying pollens with which they feed their immature stages, and in the process, the plants visited by them are benefited [5]. Bees are active when flowers are most receptive. Collection of pollens by bees usually ends before noon but nectar collection continuous into late afternoon. Bees visit the fruit producing flowers more often than the male blossoms and stay on them longer [6].

Bael is mostly cross pollinated fruit crop and pollination is carried out by various insect pollinators like honeybees, hover fly, yellow wasp, carpenter bee, weevil, black ants, butterflies etc. [7] Emergence of new leaves commenced during the 2nd and 4th week of May and continued till July. The transfer of pollen requires some agents and animal pollinators such as honeybee, *Apis mellifera* L. play an important role for carried out the pollination process [3]. The present study was planned to determine the effect of pollinators including honeybee (*Apis mellifera* L.) on yield and quality parameter of bael.

2. Materials and Methods

The present study was carried out under saline sodic soil condition and experimental site is located at Main Experimental Station, Department of Horticulture, Narendra Deva University of Agriculture and Technology, Faizabad (U.P.) [26.47^0 N latitude, 82.12^0 E longitude and altitude of 113 metres from mean sea level] during 2014. A randomized block design (RBD) with four treatments and six replications was applied.

Population dynamics of pigeonpea pod fly (*Melanagromyza obtusa*) and their correlation with abiotic factors in pigeonpea

Sachin Kumar, Umesh Chandra, SK Yadav, Jyoti and Vinod Kumar

Abstract
The present investigations entitled "Population dynamics of pigeonpea pod fly (*Melanagromyza obtusa*) and their correlation with abiotic factors in Pigeonpea" was carried out at Students' Instructional Farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad during *Rabi*, 2017. The pest activity started with the initiation of pod formation and continued though at varying level, throughout the reproductive stage of the crop. The presence of maggots of *M. obtusa* was noticed for the first time in 5th standard week. The maximum maggot population (37 maggots /100 pods) were recorded during 9th SW and the highest pupal population of (21pupae /100 pods) were recorded in 12th SW. It is evident from data that during 2017-18, maggots population showed non-significant negative correlation with minimum temperature (-0.261) and maximum temperature (-0.243) while relative humidity showed non-significant positive correlation (0.529) and pupal population had non-significant positive correlation with minimum temperature (0.195) and maximum temperature (0.389) while relative humidity showed non-significant negative correlation (-0.196).

Keywords: Population dynamics, pigeonpea pod fly, *Melanagromyza obtusa*, correlation, abiotic factor and pigeonpea

1. Introduction
Pigeonpea [*Cajanus cajan* (L.) Millsp.] is also known as red gram or arhar or tur in vernacular, the most important delicious pulse of the entire country. After gram, pigeonpea is the second most important pulse crop of India, which contributes about 90 per cent of the world's pigeonpea production. Area under pigeonpea in India is about 53.87 lakh hectare with an annual production of 45.99 lakh tons and productivity of 854 kg/ha. Pod fly being an internal feeder, both the maggot and pupal stages are present inside the pods. The white maggots feed on the developing seed and pupate inside the pod. The pod fly infested pods do not show any external symptom of damage until the fully grown larvae chew the pod wall leaving a thin papery membrane intact known as window through which adults exit the pods and thus it becomes hard to manage the pest in time. Pod fly, *Melanagromyza obtusa* (Malloch) is a key pest of pigeonpea (*Cajanus cajan*) throughout South-east Asia. It attacks the crop from pod filling to pod maturity. The oviposition of pod fly takes place on the inner surface of the pod walls. Females deposit the eggs singly under the epidermis in the green pods and the larvae after hatching mines into the pods and feeds on the soft seed thus making it unfit for human consumption as well as seed purposes (Lal and Yadav, 1993) [7]. Pulse are important components of over daily dietary requirements as they are cheapest sources of protein, vitamin, energy and minerals, production of pulse increase at a much slower rate compare to cereal, oil seeds and other crops over the two decades. Just like other crops, include of red gram in cropping pattern repair soil health and soil fertility. It plays an important role in human diet and also improving soil fertility through the biological nitrogen fixation. Arhar is one of the most important pulse crop, to be cultivated in 25 countries of the world on 5.8 million ha with 4.4 million tons of production, whereas in Asia it is grown in 5.07 million ha and producing 3.07 million tons in 2011 (FAO, 2013) [4]. Pigeonpea is a most important *Kharif* pulse crop grown in India. Area under pigeonpea in India is about 53.87 lakh hectare with an annual production of 45.99 lakh tons and productivity of 854 kg/ha (Anonymous, 2017) [1]. Pod fly incidence was started from the second week of January (2.0 to 2.8%) and continues till harvest, with a peak of 15.6 per cent in the first and 13.7 per cent in the second year during the third week of January and the incidence showed significant negative correlation with the

ABSTRACT

A trial was conducted to know the seasonal population dynamics of whitefly, *Bemisia tabaci* in okra (Arka Abhay) and their relation to weather parameters during kharif (2014 and 2015) seasons viz., The population of adults whitefly were and evening vapour pressure (r= 0.52 and r= 0.65), and evaporation (r= 0.53) whereas, negative correlation was expressed with morning RH% during kharif 2014. Similarly during the kharif season (2015) of okra the maximum and minimum temperature (r= 0.0451 and r= 0.040) morning whitefly population while, morning RH% was exhibited negative. Overall results revealed that weather parameters like temperature, RH%, sunshine and rainfall were played limiting factors for the buildup of whitefly population in okra agro-ecosystem.

Okra (*Abelmoschus esculentus* L.) belongs to family Malvaceae or Mallow, which is locally known as Bhendi and Lady's finger worldwide. It is very popular summer vegetable for home gardening while it is also grown commercially throughout the world especially in Indo-Pakistan sub-continent. It is probably originated in Ethiopian region of Africa (Naheed *et al.*, 2013). Okra is a widely cultivated vegetable crop within tropical and subtropical regions, for its immature pods which are consumed either fresh or after processing Duzyaman . The immature pods are consumed as boiled vegetables. It is also dried and used as soup thickeners or in stews (Yadev Dhanker 2009). The green fruits are rich sources of vitamins, calcium, potassium and other minerals. Despite the nutritional value of this important vegetable crop, its optimum yields (2-3 tons/ha) and quality have not been attained in the tropical countries partly because of a continued water shortage and other climatic limitations. Okra plant require relatively average temperatures and unable to tolerate low and high temperature for long time. Okra is a high water crop which has notable drought tolerance.

METHODS AND MATERIALS

Experimental layout : The experiment was conducted at the Student Structional Form Narendra Deva Agriculture University Kumarganj Faizabad UP) during 2015 and 2016. The experiment was laid out in Randomized Complete Block Design (RCBD). Each treatment measured 4 x 4 m^2. There were seven rows in each treatment and each row had 15 plants. Plant to plant and row to row distance was kept 60 cm and 45 cm, respectively. A buffer zone of 60 cm wide was kept between adjacent treatments to isolate them from one another. Uniform cultural practices including ploughing, irrigation, fertilizer and weeding were followed in each treatment.

Population dynamics of whiteflies : The pest population observation was recorded at 7 days interval, after sowing. The population dynamics was determined by correlating weather parameter incidence of okra insect- pests. Five lines of each Incidence plot were sown and observations were recorded on the insect-pests incidence at weekly interval right from after sowing till to the harvesting of the crop on five randomly selected plants for the sucking pests and predators, while borers incidence was recorded on ten randomly selected plants. The observation on sucking pest viz., whitefly was recorded on three leaves per plant, i.e. one upper, one middle and one lower leaf, while for fruit and shoot borer, whole plants were observed for number of infested shoots in the early crop growth stage and in later crop growth stage infested buds/fruits were taken into account. The number of larvae and adults of predators were recorded from these randomly selected five plants, (Patel *et al.* 2012).

Statistical analysis : The data recorded for each parameter was analyzed statistically by using Statistix 8.1 Software and means were separated by using Fisher Protected Least Significance Difference Test at 5% level of significance

RESULTS AND DISCUSSION

The results (Figure-1) showed that, the incidence of white fly population has no infestation in the month of August and September. The incidence of white fly commenced from fourth week after sowing that is, second week of September with an average population level of 0.50 in

ABSTRACT

The present field experiment was conducted during kharif season of year 2013 and 2014 at Student Structional Form, N. D. University Of Agriculture and Technology. Kumarganj, Faizabad (U.P.) India to study the population dynamics of okra insect-pests and their natural enemies. The result revealed that major insect-pests and their natural enemies in Okra started from 2nd and 3rd week of August on 4-5 week-old plant-5 s and continued until fourth week of December on 25-week-old plant-5 s.. Investigations on Population dynamics of major insect-pests and their natural enemies on Okra revealed association of a total 12 arthropods with this crop. Among these seven viz- whitefly (*Bemisia tabaci*), jassid *Amrasca biguttula* (Dist.), Thrips *Thrips tabaci* (Lind.), Fruit borer *Helicoverpa armigera* (Hb.), okra shoot and fruit borer *Earias vittella* (Fabricius), aphid, *Aphis gossypii* (Glov.), and leaf hopper, *Amrasca devastans*. Five viz- lady bird beetle Coccinella septumpuntata and *Cheilomenes undecimpuntata* Linn.,) and predatory spider *Oxypus* spp. Green Lace wing *Chrysoperla Carnea* (Stephens) Mrid bug and Ants were recorded as natural enemies associated with this crop. The appearance of the major insect pests from 31th SW observed to 50 SW during *Kharif* 2013 and *Kharif* 2014 0.57 leaf hopper /plants at 30th SW during *Kharif* 2015 respectively.

Key words : *Whitefly, Jassid, Thrips, Fruit borer, Okra shoot and fruit borer Earias vittella aphid, and leaf hopper.*

The okra, *Abelmoschus esculentus* L. (Malvaceae) is an important vegetable of India and eaten by people with a great interest. The okra crop is infested by a number of insect pests like *Amrasca devastans, Earias vittella, Bemisia tabaci, Helicoverpa armigera, Acrocercops bifasciata, Thrips tabaci, Aphis gossypii, Podagrica, Anomisflava, Sylepta derogata, Haritalodes dervgata, Dysdercus koengii* and *Nezara viridula*. But *Amrasca devastans, E. vittela, H. armigera* and *B. tabaci*, are the notorious and major insect pests of okra (Dubey *et al.*, 1999; Basu, 1995; Lohar, 2001). Insect pest infestation not only reduce the growth but also transmit pathogenic diseases (Sheedi, 1980; Dhaliwal *et al.*, 1981). This challenging situation invites attention of entomologists to concentrate energies on integrated pest management (IPM) of okra and other crops (Huffaker and Carl, 1980; Dhaliwal *et al.*, 1981; Mahadevan and Chelliah, 1986; Dubey *et al.*, 1999; Kumawat *et al.*, 2000) Botanical insecticides (Neem oil or biosal and tobacco extracts), microbial control (Bacillusthuringiensis) and biological control agents (spider, ant, lady bird beetle, Orius, myrid bug, Laius, Chrysoperla, Trichogramma etc.) should be integrated for economic management of insect pests (Arora, *et al.*, 1996; Abro et al., 2004; Memon et al., 2004).

MATERIALS AND METHODS

The experiment was conducted at Student Structional Form, N. D. University Of Agriculture and Technology. Kumarganj, Faizabad (U.P.) India- 224229 by growing a popular variety 'Arka Anamika in the plot size 600m² following recommended practices during Kharif 2013 and 2014. Date of sowing- 12th July 2013 and 16th July 2014. The okra (cv. Arka Anamika) was sown in well prepared soil on ridges. The distance between row to row was 60 cm, and plant-5 to plant-5 45cm. The seed rate was 8 kg per acre. Observations were recorded on five randomly selected plant-5 s at weekly intervals starting with 14 days after sowing (DAS) till harvesting in terms of number of arthropods, per plant-5 using rectangular cage 45cm long, 30cm wide and 90cm high, according to the stage of crop at Student Structional Form, between 5-7 A.M. Larval population of shoot & fruit borer and fruit borer was recorded at weekly intervals on 5 randomly selected plant-5 s starting with 50 % flowering till harvest. The data of the treatments were recorded at weekly intervals. While recording the data, it was noted that the observations on insect pests and predators should be recorded early in the morning because of flying and moving of these creatures. The observations were recorded through tagging 5 plant-5 s selected at random in each treatment. The populations of sucking insect complex were recorded as per leaf, from five leaves by selecting one from top, 2 from middle and 2 from bottom portion of plant-5, while the population of chewing insect pests and predators were recorded as per plant-5. The pre-treatment observations were recorded before employing plant-5 protection tactics, while post-treatment observations were recorded 48 hours after application of the respective bio-rational pesticide. Weekly Meteorological data during crop was collected from Agro meteorological observatory N. D. University Agriculture

ABSTRACTS

Okra (*Abelmoschus esculentus*) is cultivated throughout the year but *summer* and *kharif* are the favorable season for its cultivation. The major insect of shoot and fruit borer (*Earias vittella* Fabricius) is a major pest of okra effect direct loss in marketable fruit. Present investigation is being undertaken to evulateBio-rational insecticide and chemical insecticidematerial in the management of okra shoot and fruit borer (*Earias vittella* Fabricius) in research form of were carried out during the *Kharif* 2015-16seasons at Students' Instructional Farm, N.D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) The biorational insecticide are use to reduce the shoot and fruit damage like neem oil 2%, NSKE 5%, Garlic leaf extract 2%, Spinosad 45 SC120 gai.,Bt + Spinosad0.75kg + 0.6 g a i., *Bacillus thuringiensis*1.5 kg/ha, *Beavaria bassiana*, and Emamactin Benzoate12 g a iper ha. The highest suppression of shoot infestation was Emamactin Benzoate 2.91, NSKE 4.67, neem oil 5.85 Spinosad 5.74,Bt + Spinosad 6.12, *Bacillus thuringiensis* 7.05 *Beavaria bassiana* 6.87,and lowest, followed by Kranj oil 8.25, Zinger Extract9.93, garlic extract 14.20 compared to untreated control 8.14. The highest suppression of fruit infestation was Spinosad 5.16, Emamactin Benzoate 5.32, , Bt + Spinosad 9.26, *Bacillus thuringiensis* 14.15, neem oil 20.20, *Beavaria bassiana* 21.20, NSKE 20.34,and lowest, followed by Kranj oil 28.68, Zinger Extract 34.70, garlic extract 36.74 compared to untreated control 39.16.

Key words : *Earias vittella, Abelmoschus esculentus, biorational insecticide.*

Okra (*Abelmoschus esculentus* (L.) Monech is a importantsummer vegetable crop grown all over India. It is generally knownas Lady's finger. Among various factors responsible for poor yieldof okra in India, infestation of insect-pests is of prime importanceOkra crop is infested by many insect pests but *Amarasca devastance, Earias vitella, Bemisia tabaci, Helicoverpa armigera* are the majorpest of okra. *Earias vittella* (Fab.) is widely distributed and causes 8.4–73.2% infestation on fruit of okra depending on the season (Kumar and Urs, 1998). The avoidable loss in yield and fruit damagedue to this pest has been estimated from 36-90% (Mishra *et al.*, 2002). In controlling pest population by chemical insecticide theremay be a threat to develop pest resistance, secondary outbreak,phytotoxicity, harmful effect on beneficial organisms, residues infruits and health hazards to consumers. Today newer safer moleculeslike insect growth regulators (IGR's), synthetic pyrethroids, chitinsynthesis inhibitors, oxadiazanes etc. and insecticides based onnatural products are commercially available in the market. Theincreasing concern for environmental safety and global demand pesticide residue free food have evolved keen interest andnecessitated a deep insight into the issue of safer products in pestmanagement. Unraveling of this information will enable us in carefulmanipulation of insecticides in the management of *E. vittella*.

MATERIALS AND METHODS

The present investigation was conducted at theStudent Structional Form, N.D. University Of Agriculture and Technology. Kumarganj, Faizabad (U.P.) India- 224229 by growing a popular variety 'Arka Anamika in the plot size 600m^2 following recommended practices during Kharif 2015. Date of sowing- 12th July 2015. For studying seasonal incidence of *E. vittella* plot size of 3 x 5 m2 were prepared at the five different places in the research farm and for studying the Bioefficacy of some indigenous products and spinosad in the management shoot and fruit borer (*Earias vittella* Fabricius) in Faizabad. The randomized block design (RBD) with 3 replications and 10 treatments in plots of 4 x 4 m^2 size were prepared and two seeds were dibbled per hill at 5cm depth with 60 cm row to row spacing and 45 cm plant to plant spacing was maintained. Arka Anamikaokra variety was sown during *kharif* 22th July, 2015 by following practices, After 10 days of sowing, thinning and gap filling was done to maintain one plant per hill. Recommended fertilizers were applied @ NPK 50:25:25 kg/ha and 20 ton FYM per hectares. Full dose of P & K and half dose of N were applied as basal in the drills before sowing the seed and rest of the nitrogen was top dressed in two equal splits at 21 and 41 days after germination. All cultural practices were carried out as per recommendationNeem oil 2%, NSKE 5%, Garlic leaf extract 2%, Spinosad 45 SC 120 g a i., Bt + Spinosad 0.75kg + 0.6 g a i., *Bacillus thuringiensis* 1.5 kg/ha.

INTRODUCTION

A number of inorganic elements are essential for the growth, production and reproduction of animals [1]. In addition, mineral requirements are also influenced by age, parity, stage of pregnancy and stage of lactation. The inorganic elements are classified according to their requirements in animal body. Those required in greater quantities are referred as macrominerals (calcium, phosphorus, sodium, chloride, potassium, magnesium and sulfur). Macrominerals required in large amount each day and their concentration in diet is expressed as percentage of diet or in grams per kilogram of diet. Macrominerals has role in different physiological functions. Other elements required in much smaller amounts are referred as trace minerals (microminerals) i.e. copper, cobalt, iodine, iron, manganese, molybdenum, selenium, zinc, chromium and fluorine. Their concentration in diet is expressed as parts per million (ppm), which is equivalent to milligram per kilogram of diet or in some cases as parts per billion (ppb), which is equivalent to microgram per kilogram of diet. Adequate quantity of minerals are utmost important for proper functioning of various physiological functions in animals. Deficiency and excess both have detrimental effects on production and reproduction; thus significantly affecting the economics of animal husbandry.

Role of Various Macro Minerals in Animal Reproduction

Calcium (Ca): Calcium is an essential component of skeleton and plays a pivotal role in maintaining homeostasis of vertebrates [2]. The maximum portion of calcium present in the bone as hydroxyapatite (99%) and small fractions present in the cell membrane or endoplasmic reticulum (0.9%), extracellular fluid or serum (0.1%) and in cytosol (0.00002%) [3]. Extracellular calcium exist in three forms i.e. ionized (50%), complexes to anions (5%) such as citrate, bicarbonate, phosphate, or lactate and protein bound (45%). Ionized calcium involved in array of physiological processes such as muscular

EFFECT OF A-TOCOPHEROL ACETATE AND ZINC SUPPLEMENTATION ON LEPTIN HORMONE DURING DRY PERIOD AND EARLY LACTATION IN CROSS BRED COWS

Pankaj Kumar Maurya*, Anjali Aggarwal[1], Pramod Kumar and P.K. Choudhary
College of Veterinary Sci. & A.H., N.D. University of Agriculture & Technology, Kumarganj, Faizabad (UP)
[1]Dairy Cattle Physiology Division, National Dairy Research Institute, Karnal-132001 (Haryana)

Abstract

The study was conducted to investigate the effect of α-tocopherol acetate and zinc supplementation on Leptin Hormone during dry period and early lactation in cross bred cows. Twenty pregnant Karan Fries cows were selected on the basis of their body weight, BCS and parity: ten cows were kept in control group and other ten cows in treatment group which were supplemented with 1000 IU α-tocopherol acetate and 60 ppm zinc per day per cow. Blood samples were collected on the days -60, -45, -30, -15, -7, 0, +7, +15, +30, +45, +60 with respect to expected date of calving. Plasma was analyzed for Leptin hormone. Body condition score of all the experimental animals was recorded on the day of blood collection. At parturition, BCS decreased significantly ($P<0.01$) in control group than treatment group. The plasma concentration of leptin was decreased at parturition and the level was significantly ($P<0.001$) higher in treatment group as compared to control group (3.66 vs. 2.55 ng/ml). Plasma NEFA was significantly ($P<0.001$) lower in treatment group as compared to control group. The results of this study indicated that supplementation of α-tocopherol acetate and zinc have beneficial effects in changing Leptin hormone level in this way that improves body condition and metabolic status of the animals.

Keywords: *Leptin, Body Condition Score, Energy Metabolites, α-tocopherol acetate, Zinc*

Introduction

Leptin is a 16 kDa protein hormone and it is synthesized by white adipose tissue. Leptin is involved in regulation of feed intake, energy balance, immunity and reproduction (Houseknecht *et al.*, 2000; Ahima and Flier, 2003). After parturition, dairy cows suffer from an intense energy deficit caused by the onset of copious milk secretion and an inadequate increase in voluntary food intake which contributes to a decline in plasma leptin. This decline mirrors that of plasma insulin but is reciprocal to the profile of plasma growth hormone (GH), suggesting that both hormones may regulate plasma leptin in periparturient dairy cows (Block *et al.*, 2001). Energy deficit of early lactation reduces leptin synthesis in white adipose tissue (WAT), and suggest roles for insulin, GH and metabolic fuels in mediating this effect of energy balance (Block *et al.*, 2001). A concomitant suppression of immune functions and metabolic disorders during early lactation are related to decreased fertility (Butler and Smith, 1989). This may partly be due to decrease in blood concentrations of vitamins A & E and Zn (Meglia *et al.*, 2001, Chandra, 2009). To meet the nutritional demands of milk synthesis during early lactation, dairy cows need to mobilize body reserves causing negative energy balance until nutrient intake covers the demands.

Material and methods

Experimental design

The study was conducted at the Cattle Yard of National Dairy Research Institute, Karnal, Haryana (India). For the present study 20 Karan Fries (KF) peripartum cows were selected from the herd of National Dairy Research Institute, Karnal, 10 cows kept in Control group and other 10 cows in Treatment group. The cows in the control group were supplemented with no vitamins, and in the treatment group, they were given 1,000 IU of α-tocopherol acetate and 60 ppm zinc per cow per day from 60 days prepartum to 60 days postpartum over and above the normal feeding schedule at dairy farm of NDRI.

Blood sampling

Blood samples (10 ml/cow) were collected in the morning (6:00 AM) before feeding in sterile heparinised vacutainer tubes (BD VacutainerTM, UK) from jugular vein puncture, posing minimum disturbance to animal, on the days -60, -45, -30, -15, -7, 0, +7, +15, +30, +45 and +60 with respect to expected date of calving. Day '0' represented the day of calving. Blood samples were brought to the laboratory in the icebox soon after collection and centrifuged at 3000 rpm at 4°C for 20 min to separate the plasma. Plasma samples were stored at -20°C until analysis of Leptin hormone. Body condition score (BCS) of all the experimental animals was recorded on the day of blood collection using a scale of 1 to 5.

Sample analysis

Blood sample was analyzed for plasma leptin and NEFA. Plasma Leptin was determined by "Bovine Leptin ELISA Quantitation kit" from Cusabio Biotech Co., Ltd. The copper soap solvent extraction method modified by Shipe et al. (1980) was adopted for the estimation of plasma NEFA.

Statistical analysis

Statistical analysis of data was carried out to find the mean ± SE. Two way ANOVA was done to find significant difference between groups and days of experiment and their interaction by using SYSTAT 3.1 (2004) software. The correlations among the various parameters were also calculated (Snedecor and Cochran, 1994).

Results and Discussion

Leptin

The mean±SE of plasma leptin concentration of control cows was 6.06±0.10 ng/ml 60 days before calving and on the day of calving it decreased to 2.55±0.31ng/ml. Further, in treatment group the plasma leptin concentration was 6.19±0.11ng/ml 60 days before calving and on the day of calving it decreased to 3.66±0.11ng/ml. In present study decrease in the plasma leptin concentration of control and treatment group cows was 57.92% and 40.87% respectively from 60 days before calving to the day of calving. This decrease was more significant ($P<0.01$) from 30 days before calving to the day of calving in control group than treatment group. After parturition it's level remained low up to 30 days then started increasing up to 60 days of lactation.

In present study there was found a positive correlation between leptin with BCS and insulin and a negative correlation was found between leptin with NEFA in control and treatment group of cows around parturition. The plasma concentration of leptin was positively correlated with plasma concentrations of insulin and negatively correlated with plasma concentrations of growth hormone, cortisol and non-esterified fatty acids (Block *et al.*, 2001; Chelikani *et al.*, 2008). Sauerwein *et al.* (2004) investigated that in ruminants the decline in plasma leptin levels towards parturition is probably caused by the decline in adiposity and insulin concentrations. In ruminants and other animals, leptin is synthesized in proportion to the overall degree of adiposity and acts on the central nervous system to reduce voluntary feed intake (Ehrhardt *et al.*, 2000). Leptin, mainly produced in adipose tissue, inhibits feed intake and down-regulates adipose tissue deposition. Block *et al.* (2001) showed that leptin is negatively correlated with the amount of nonesterified fatty acids, which reflects the amount of fat mobilization. From early to mid pregnancy circulating leptin levels increased and remained elevated until late pregnancy in cattle (Liefers *et al.*, 2003; Villalobos *et al.*, 2007).

ABSTRACT

Forty two (42) apparently healthy, non-pregnant, non-lactating Chhotanagpuri ewe, having body weight ranging between 14.11±0.09 to 15.38±0.06 Kg were selected and selected ewes were isolated from rams 2 months prior to melatonin administration. The selected animals were allocated randomly into seven groups viz. Group-I [Normal control], Group-II [Long day (LD) control], Group-III [LD + Melatonin administration orally (3mg/day)], Group-IV [(LD + Melatonin administration subcutaneously (1mg/day)], Group-V [Short Day (SD) control], Group-VI [SD + Melatonin administration orally (3mg/day)] and Group-VII [SD + Melatonin administration subcutaneously (1mg/day)] comprising six animals in each group. Rams were then introduced into each group after completion of exogenous administration of melatonin. Blood sample without anticoagulant in vials was collected from each animal day before the start of experiment and there after every month up to fifth month. After administration of melatonin, serum glucose was decreased in group- III, IV, VI and VII in comparison to group-I, although this decrease was not statistically significant. An increasing trend of serum glucose was observed in all groups from third to fourth month. Total protein at first month was significantly ($P<0.05$) higher in group VI in comparison to 0 day. After administration of melatonin, total serum protein concentration was significantly ($P<0.05$) decreased in group VI in comparison to first month and continued up to third month. At fifth month, total serum protein was significantly ($P<0.05$) lower in group III, IV and VI in comparison to 0 day and first month.

Introduction

Sheep husbandry is backbone of rural economy in India. The Chhotanagpuri sheep is the only recognized breed of sheep found in Jharkhand with a few numbers in Bihar and West Bengal. This breed is maintained solely for mutton production. They produce coarse wool of poor quality. This is being utilized for carpet manufacturing. Sheep

Introduction

Short days enhance immune function in individuals with robust reproductive responses to photoperiod. Total splenic lymphocyte number, and macrophage counts were significantly higher in hamsters exposed to short days, as compared to animals exposed to long photoperiods (Brainard *et al.*, 1988). Photoperiodic influences on lymphocyte number and total white blood cell count have been reported for deer mice (Blom *et al.*, 1994); short day (LD 8:16) mice possessed more white blood cells than animals maintained in long day lengths (LD 16:8). Importantly, all laboratory studies of photoperiodic effects on immune function have reported enhanced immune function in short day lengths (Nelson and Demas, 1996). Although many field studies support this hypothesis, with data suggesting enhanced immune function and decreased disease prevalence during the winter as compared to the summer, a substantial number of studies have reported the opposite pattern of results (Nelson and Demas, 1996); i.e., reduced immune function is coincident with the short days of winter. These conflicting results can be resolved by considering additional environmental factors, not usually manipulated in laboratory studies. For example, winter-associated stressors (e.g., restricted food and low ambient temperatures) appear to counteract short day enhancement of immune function in the lab.

Exogenous administration of melatonin increased the lymphocyte percentage in Broiler chicks (Abozahra *et al.*, 1998), Rats (Anwar *et al.*, 1998), and Squirrels (Rai *et al.*, 2009). Rai and Haldar (2003) reported daily subcutaneous injection of melatonin at 17:30 to 18:00 hr significantly increased the lymphocyte count of blood in adult male squirrels, while pinealectomy decrease percent lymphocyte count in peripheral blood and bone marrow. The precise mechanism responsible for this melatonin induced increase in lymphocyte percentage is not clear. However, several mechanisms may be involved in this respect. Haldar *et al.* (2006) accessed the effect of melatonin on immune parameters in a seasonally breeding animal, the Indian palm squirrel F. pennant and bird P. asiatica during reproductive phases in vivo as well as in vitro. Melatonin treated squirrels and birds showed an increase in percent lymphocyte count (% LC) and percent stimulation pinealectomy in squirrels. Melatonin administration recovered all the decreased immune parameters to the control level (Rai and Haldar, 2003). MEL supplementation also enhanced all immune parameters in both in vivo and in vitro, suggesting that the immune system was sensitive during the reproductively active phase to MEL when peripheral melatonin level was low and the role of melatonin could be important for the maintenance of the immune status of seasonal breeders.

As reported by Etim *et al.* (2014[a]) immune status is a function of leucocytes, lymphocytes and Neutrophils. Lymphocytes are known to play key roles in immune defense system of both man and animals (Etim et al., 2014[b]). The objective of this experiment was to determine Lymphocyte percent count in Chhotanagpuri sheep after exogenous administration of melatonin following different photoperiods.

Materials and Methods

The present study was conducted in Department of veterinary physiology, College of veterinary science and A.H., Birsa Agricultural University, Kanke, Ranchi-6, Jharkhand located at 23.36°N latitude and 85.33°E longitude with an altitude of 651 m above mean sea level. Design of experiment was approved by the Institutional Animal Ethics Committee vide letter no.-139/528/RVC/IAEC. Forty two (42) apparently healthy, non-pregnant, non-lactating Chhotanagpuri ewes, having body weight ranging between 14.11±0.09 to 15.38±0.06 Kg reared under uniform managemental husbandry practices were selected. Selected ewes were isolated from rams prior to melatonin administration. The selected animals were allocated randomly into seven groups (viz. group-I to group-VII) comprising six animals in each group. Group-I [Normal control]:- The animals in this group were exposed to normal variation in day length. Group-II [Long day (LD) control]:- In this group in addition to natural sun light, artificial light was provided to animal for maintaining 16-18 hours of light every day for the period of one month and considered as long day control. Group-III [LD + Melatonin administration orally (3mg/day)]:- In this group in addition to natural sun light, artificial light was provided for maintaining 16-18 hours of light every day for the period of one month and after that 3 mg melatonin was administered orally for one month to each animal. Group-IV [(LD + Melatonin administration subcutaneously (1mg/day)]:- In this group in addition to natural sun light, artificial light was provided for maintaining 16-18 hours of light every day for the period of one month and after that 1 mg melatonin was administered subcutaneously for one month to each animal. Group-V [Short Day (SD) control]:- Animals in this group were provided only 8 hours natural day light and were then kept in a light-proof shed for 16 hours exposure in dark every day for the period of one month. This group served as short day control. Group-VI [SD + Melatonin administration orally (3mg/day)]:- Animals in this group were provided only 8 hours natural day light and were then kept in a light-proof shed for 16 hours exposure in dark every day for the period of one month and after that 3 mg melatonin was administered orally for one month to each animal. Group-VII [SD + Melatonin administration subcutaneously (1mg/day)]:- Animals in this group were provided only 8 hours natural day light and then were kept in a light-proof shed for 16 hours exposure in dark every day for the period

Comparative studies on urinary system of Aseel and Rhode Island Red (RIR) breeds of poultry

Mukesh Kumar, Gaurav Panday, KN Singh, SS Sanger, PK Chaudhary and Pramod Kumar

Abstract
The present comparative study was conducted to evaluate the urinary system of Aseel and Rhode Island Red (RIR) breeds of poultry and experiments was done on 24 apparently healthy birds of Aseel and RIR breeds of poultry which were divided into grower and adult groups. Each kidney was divided into cranial, middle and caudal divisions by the grooves present on the ventral surface. In RIR grower as well as in adults, weight, volume and maximum width of kidney to body weight was more in RIR grower than Aseel. While, in adult birds it was more in Aseel than RIR. The ureter had two parts, renal and pelvic. Highly significant difference was observed in the weight, length and volume of both the ureters of an RIR grower than Aseel.

Keywords: Aseel, RIR, Gross morphology, Urinary system

Introduction
Avian urinary system has consisted of the kidney and ureter only. Kidneys play an important role in maintaining homeostasis. The ureter is an important organ, which carries urine to the cloaca. There was no literature available on the gross studies of the urinary system of this breed. The present work was undertaken to study the comparative gross morphology of the urinary system of Aseel and RIR breeds of poultry.

Materials and Methods
The experiment was done on 24 apparently healthy birds of 2 groups of RIR and Aseel breeds of poultry irrespective of sex. The birds were divided into grower and adult (group I and II) respectively. Both the groups had 12 birds, 6 birds of each breed. After taking the body weight, birds of the specified age group were sacrificed by cutting jugular vein and common carotid artery. Kidney and ureter were collected and their length and width were recorded by using Vernier caliper, weight was taken with the help of electronic monopan balance whereas, volume was taken with the help of the water displacement method. The data were statistically analyzed by using analysis of independent mean "T" test as per Snedecor and Cocharan (1994) [2].

Results and Discussion
Kidney: The colour of the kidneys was reddish brown. The right and left kidneys were retroperitoneal and present symmetrically in a depression on ventral surface of synsacrum and renal fossa of ilium. Depression on the synsacrum was extended upto the distal third. The cranial margin of each kidney was extended immediately caudal to the lungs between the sixth and seventh thoracic vertebrae. These extended upto the rostral third of gizzard in grower birds while, in adult birds upto the distal third of gizzard. On the surface of the kidney small projections were seen in all three divisions. This might be the external surface of the renal lobule.

The dorsal surface of the kidney had the impression of lumbosacral mass, which extended from the medial border to the middle of the kidney. The impressions were shallow in grower birds that an adult bird in both breeds. Each kidney was divided into cranial, middle and caudal divisions by the grooves present on the ventral surface. The groove was shallow and directed caudo-laterally from median plane. However, (Nubipour *et al.* 2009) [1] started that the groove was transverse. External iliac artery was present in the groove between the cranial and middle division. Groove containing ischiatic artery seprated the middle and caudal division of the kidney.

In both breeds and age groups, the shape of the kidney was similar. The cranial division was oval elongated, middle division was slender and caudal division was irregular.

COMPARATIVE EFFECTS OF CEFTIOFUR SODIUM, GENTAMICIN SULFATE AND *Zingiber officinale* ON HEMATOLOGICAL PARAMETERS OF ENDOMETRITIC BUFFALOES (*Bubalus bubalis*)

Pushkar Sharma[1], Sushant Shrivastava[2], Vijay Gautam[1], Rajesh Kumar[2*], Pramod Kumar[3] and Saurabh[1]

Abstract
The present study aimed to investigate the comparative therapeutic efficacy of Ceftiofur sodium, Gentamicin sulfate and Zingiber officinale extract on hematological parameters of endometritic buffaloes. The endometritic affected animals were randomly allotted to five groups namely Groups CB, C, G, CF and GG comprising of ten animals in each group. Haemoglobin, PCV, TLC, DLC and ESR values were analysed at 0, 15th day and 30th day in each group. Haematological profile was differed significantly between cyclic and endometritic buffaloes. The findings indicated blood indices helps in diagnosis of clinical endometritis in buffaloes.
Keywords– *Endometritis, Ceftiofur sodium, Gentamicin sulphate, Zingiber officinale.*

Introduction

Endometritis is inflammation of the endometrial lining of the uterus and formation of mucopurulent secretion. It is a major cause of repeat breeder syndrome of bovines. Unlike metritis, it does not affect the general health. Therefore it has a major economic impact by poor conception rate, increasing calving interval, reduction in calf crop, increased cost of treatment decrease milk yield and increase cull rate. The most common initiating cause of endometritis is non-specific, opportunist pathogens that contaminate the uterus during the pericalving period, dystocia, retained foetal membranes (RFM), caesarian section, contamination of uterus at the time of A.I., induced parturition, still birth, twins, ovarian inactivity, cystic ovaries, unhygienic calving environment, concurrent disease and nutrition - fatty liver disease and hypocalcaemia are reported to increase endometritis rates, natural insemination infected with venereal disease, etc (Noakes *et al.*, 2002). Opportunistic pathogens are not able to colonize in the genital tract during normal circumstances due to several protective mechanisms, viz., anatomical and functional barriers, specific and nonspecific immune responses (Foldi *et al.*, 2006). Blood is a crucial importance for maintain of physiological equilibrium in the body. Normal levels of vital haematological constituents are of most importance for maintaining functional integrity of the reproductive system. Any change in haematological parameters may adversely affect the reproductive efficiency of livestock. Haematological indices are useful in diagnosing various pathological and metabolic disorders, which can adversely affect the production and reproductive performance of buffaloes.

Materials and methods

In these study mainly two commonly used antibiotics ceftiofur sodium and gentamicin sulphate and one herb extract, *Zingiber officinale* were selected for treatment of endometritic buffaloes. The cases of Instructional Dairy Farm Complex, Teaching Veterinary Clinical Complex, Veterinary hospitals lying adjacent to Kumarganj, Faizabad, and cattle colonies near Buddeyshwaran, lucknow (U.P) India were selected for study purpose. *Zingiber officinale* extract was prepared in Soxhlet apparatus as per standard method and then concentrated in vacuum rotary evaporator at 40^0 C for ethanol removal. One gram concentrated extract was mixed in double distilled water in floor shaker water bath used for intrauterine therapy.

The buffaloes were categorized into five groups for the present study, viz., Normal cycling healthy estrus buffaloes (**CB**), No treatment is given, recommended for sexual rest (**C**), 10ml (40mg/ml) Gentamicin sulfate (dissolved in 40 ml of distilled water) intrauterine daily for three days(**G**), 500mg Ceftiour Sodium (dissolved in 50 ml of distilled water) intrauterine daily for three days.(**CF**), One gram Extract of *Zingiber officinale* (dissolved in 50 ml of distilled water) intrauterine daily for three days (**GG**). Blood Sample was collected three times (0, 15th and 30th day) during the whole experimental period. Approximately 5 ml of blood was collected aseptically from the jugular vein of each experimental animal in sterilized disposable syringe (16 gauge needle). All haematological values obtained were subjected suitable statistical methods (Snedecor and Cochral, 1989).

Results and Discussion

In the present research work, blood indices such as Hb, PCV, TEC, TLC and DLC were estimated to investigate any possible correlation in between endometritis and hematological profile of buffaloes.

Hemoglobin (Hb)

The overall mean hemoglobin in pretreated, 15th, 30th day post treated and in regular cyclic buffaloes were given in the table 3.1. and column chart 3.1. Hemoglobin levels were increased significantly ($P<0.05$) in gentamicin (G) and ceftiofur (CF) after 30th day post treatment. Pateria and Rawal (1990) and Pateria *et al.*, (1992) also observed significant increase ($p<0.05$) in haemoglobin level after treatment in buffaloes which were affected with metritis and endometritis. The decrease in haemoglobin level of affected buffaloes is probably due to disintegration of erythrocytes and/ or effect of some haemolytic type of microbes and their endotoxins on the blood cells and haemopoietic system. Similar results were obtained by Dhoble and Gupta (1981), Jaini *et al.*, (1995), Ahmad *et al.*, (2003), Rathour *et al.*, (2005) and Narnaware and Sirothia (2010) in buffaloes. The mean Hb levels in responded animals was lower at the time of treatment and increased significantly ($p<0.01$) after 21 days in next estrus. Pradhan *et al.*, (1995) reported that lower level of Hb values which may be representing some systemic derangement due to deficiency of certain trace minerals which in turn depressed the physiology of reproduction. The low level of Hb indicated long term protein deficiency and influences tissue oxygenation of reproductive tract which in turn affects the cyclicity (Ramakrishna, 1997). Lack of sufficient quantities of Hb in blood is responsible for reduced oxygen transport to the vital tissues, it causes reduced oxidation of nutrients, which in turn affect the whole cellular metabolism in gonadal cells which is metabolically more active. (Sabasthin *et al.*, (2012) reported that decrease in the Hb value in the animal could be the cause of repeat breeding. The trend of variation in PCV was found to be similar to be the value of Hb and ESR in both cattle & buffaloes. Similar finding was also reported by Anthony *et al.*, (2012) and Verma (2015).

Packed Cell Volume (PCV)

The mean value of PCV in regular cyclic buffaloes group (CB) was observed as 30.89±0.31% PCV values were reported as 29.22±0.27, 28.69±0.28 & 9.21±0.22 per cent in untreated control, 29.05±0.36, 29.75±0.52 & 29.75±0.52 per cent in gentamicin, 28.18±0.29, 30.54±0.46 & 31.07±0.40 per cent in ceftiofur (CF) groups and 29.03±0.42, 29.63±0.45 & 30.19±0.25 percentage in *Zingiber officinale* extract at 0, 15th and 30th day post treatment, respectively (Table No. 3.1 and column chart 3.2). Significant ($p<0.01$) increase in PCV was observed in all the treatments at 30th day post treatment. This indicates that the mean PCV increases after treatment by using any biological modifier which reduces the infection. The present

Abstract

The study was conducted to investigate effect of vitamin E and zinc on cortisol hormone during peripartum period in Karan Fries cows. Sixteen pregnant Karan Fries (KF) cows were selected from the herd of National Dairy Research Institute (NDRI) Karnal, on the basis of their body weight, BCS and parity. Eight cows were kept in control group and other eight cows in treatment group which were supplemented with 1000 IU vitamin E and 60 ppm zinc per day per cow. Blood samples were collected on the days -60, -45, -30, -15, -7, 0, +7, +15, +30, +45, +60 with respect to expected date of calving. Plasma was analyzed for Cortisol hormone. Body weight and Body condition score (BCS) of all the experimental animals were recorded on the day of blood collection. Plasma cortisol was significantly (P<0.001) lower in treatment group as compared to control group (2.98 vs. 3.10 ng/ml). There was a steady increase in the body weight of control and treatment cows towards parturition and was found a significant (P<0.001) difference between the control and treatment groups. The body condition score of control and treatment groups decreased by 33.05% and 17.76% respectively after calving. This showed that the control group cows lost significantly (P<0.001) more body condition as compared to treatment group cows. The results of this study indicated that supplementation of vitamin E and zinc have beneficial effects in changing cortisol level in this way that improves body condition and decreases the effect of parturition stress in the animals.

Keywords: Cortisol, Body Condition Score, Energy Metabolites, Peripartum period, Vitamin E, Zinc

Introduction

Cortisol is a steroid hormone that helps the body respond to stress. It is also called the stress hormone. It is released in response to stress and low blood glucose concentration. It is the principal glucocorticoid during the reproduction and lactation of cows [1]. Adrenal secretion of cortisol is modulated by a complex negative feedback mechanism involving the central nervous system, hypothalamus, pituitary and adrenals [2]. The synergistic action of endogenous cortisol along with other hormones has been found to be critical for parturition and initiation of lactation in domestic animals [3]. At term the corticosteroid concentration rises in the plasma of peripartum cows [4, 5,6]. Plasma total cortisol level increased from 2.13 ng/ml to 2.62 ng/ml till one day prepartum and increased to 6.08 ng/ml at parturition in crossbred cows. The level decline from 3.42 ng/ml on 1 day postpartum to 2.49 ng/ml at 3 day postpartum [6]. In Murrah buffaloes level of cortisol was found 1.46 ng/ml at 30 day prepartum which increased to 3.78 ng/ml at parturition and decline to 1.89 ng/ml at 3 day postpartum[2].

Cortisol concentrations have been used as a physiological marker of stress. During heat acclimation there is reduction of plasma cortisol that helps in reduction of heat production of animals[7]. An initial increase in cortisol occurs due to acute heat stress followed by a decline after prolonged exposure in cows. The animals adjust physiologically to elevated heat loads by decreasing adrenal corticoid output [7]. Cortisol concentrations have been found lower in high producing cows at day 30 than at day 90 or in nonlactating cows due to reduced pulse amplitude. Low cortisol concentrations likely participate in the enhanced production observed in high producing cows [8]. Heat exposure at temperature above 40°C has been found to raise the cortisol level to almost double the pre-exposure levels [9]. Similar results were also found by others in hot-dry, hot-humid and winter seasons in crossbred cows (4.17, 4.35 and 2.09 ng/ml respectively) [10].

Materials and Methods

Experimental design

The study was conducted at the Cattle Yard of National Dairy Research Institute, Karnal, Haryana (India). Karnal is situated on an altitude of 250 meter above mean sea level, latitude and longitude position being 29°42" N and 79°54" E respectively. The maximum ambient temperature in summer goes up to 45°C and minimum temperature in winter comes down to 0°C with a diurnal variation in the order of 15-20°C. For the present study 16 Karan Fries (KF) peripartum cows were selected from the herd of National Dairy Research Institute, Karnal, 8 cows kept in Control group and other 8 cows in Treatment group. The cows in the control group were supplemented with no vitamins, and in the treatment group, they were given 1,000 IU of vitamin E and 60 ppm zinc per cow per day from 60 days prepartum to 60 days postpartum. Animals were maintained in open area with asbestos roof in the sides of the open area, where the animals were offered feed. The open area had brick floor. The animals were free to move inside the controlled open area. All the animals were fed as per the standard feeding practices followed at the NDRI farm.

Blood sampling

Blood samples (10 ml/cow) were collected in the morning (6:00 AM) before feeding in sterile heparinised vacutainer tubes (BD VacutainerTM, UK) from jugular vein puncture, posing minimum disturbance to animal, on the days -60, -45, -30, -15, -7, 0, +7, +15, +30, +45 and +60 with respect to expected date of calving. Day '0' represented the day of calving. Blood samples were brought to the laboratory in the icebox soon after collection and centrifuged at 1,200×g at 4°C for 20 min to separate the plasma. Plasma samples were stored at -20°C until analysis of Cortisol.

Sample analysis

Blood sample was analyzed for cortisol. Plasma Cortisol was determined by "Cortisol EIA kit" from Cayman Chemical Company, Ann Arbour, USA. Body weight and Body condition score (BCS) of all the experimental animals was recorded on the day of blood collection using a scale of 1 to 5.

Statistical analysis

Statistical analysis of data was carried out to find the mean ± SE. Two-way ANOVA was done to find significant difference between groups and days of experiment and their interaction by using SYSTAT 3.1 (2004) software.

Results and Discussion

Cortisol

The mean±SE of plasma cortisol concentration of control cows was 2.87±0.09 ng/ml 60 days before calving and on the day of calving it increased to 3.24±0.07 ng/ml. Further, in treatment group the plasma cortisol concentration was 2.78±0.03 ng/ml 60 days before calving and on the day of calving it increased to 3.10±0.03 ng/ml. In present study, the overall mean±SEM of plasma cortisol concentration was found significantly (P<0.001, Table 2) lower in treatment group as compared to control group. Plasma levels of cortisol varied between 2.3-3.5 ng/ml during pre and postpartum in Holstein cows [11]. After 7 days of calving it's level started decreasing up to 60 day of lactation.

A review: heat stress in cow and buffaloes in India

Pramod Kumar, Rishikant, Rabindra Kumar, KN Singh and Mukesh Kumar

Abstract
India is a tropical climatic country in which heat stress is an important disadvantageous factor that reduces the production performance of cattle and buffalo and conduces to significant decrease in milk yields in dairy cows and buffalo and some metabolically disorders. The objective of this review is to known the heat stress metabolism, its causing factors and its preventative methods for increase the production performance through manage mental and nutritional procedures.

Keywords: Tropical, Heat, Temperature, Conduction, Convection, Radiation, Evaporation, Panting, Sweating, Moisture

Introduction
Climatic conditions of India are such that the hot and humid season is relatively long, there is intense radiant energy for an extended period, and there is generally the presence of high relative humidity. Thus, heat stress is chronic in nature especially for animal, there is often little relief from the heat during the evening hours, and intense bursts of combined heat and humidity further depress performance of animal. Lactating dairy cattle and buffaloes create a large quantity of metabolic heat and accumulate additional heat from radiant energy (West, 2003) [20]. Heat production and accumulation, coupled with compromised cooling capability because of environmental conditions, causes heat strain in the cattle and buffaloes to increase to the point that body temperature rises, intake declines and ultimately the cow's productivity declines.

Heat stress is caused by a combination of climatic factors like air temperature, humidity, solar radiation, wind velocity etc. A common time for experience adverse effects of high temperatures is during transport (Fiore *et al*, 2009) [6]. Transport is a multi affected stressor that can create or exacerbate existing heat loads. Handling of animal, increases body temperature. Animal are adversely affected any time the ambient temperature is more than their thermoneutral zone, which ranges about 25°C. Because that heat stress conduces to some disadvantageous affect on livestock, many researchers work about heat stress in animal.

Thermoneutral zone
The Thermoneutral Zone (TNZ) is defined as. "the range of ambient temperature within which metabolic rate is at a minimum, and within which temperature regulation is achieved by non evaporative physical processes alone" (Bligh & Johnson, 1973) [3]. The lower critical ambient temperature range point and the upper critical ambient temperature point indicate the limits of the TNZ. The ambient temperature below, which the rate of heat production of a resting homeotherm increases to maintain thermal balance, is the lower critical temperature (LCT). The upper critical temperature (UCT) may be defined as the ambient temperature when the: (a) metabolic rate increases; (b) evaporative heat loss increases; or (c) tissue thermal insulation is minimal (Silanikove, 2000) [14]. Below and above these temperature limits heat production is increased. The width of the thermoneutral zone will vary depending on age, species and breed, level of nutrition, previous state of temperature acclimation or acclimatization, level of productivity, housing conditions, insulation, and behavior etc (Yousef, 1985b) [22]. In order to more clearly define the TNZ (Silanikove, 2000) [14] suggested that the subdivision of the TNZ into a zone of thermal well-being is most suitable to describe the relation between an animal and its environment. Figure 1, illustrate this concept.

Micrometry of renal corpuscles and renal tubules in *Marwari* Sheep (*Ovis aries*)

Krishna Nand Singh, Sanjeev Joshi, Rakesh Mathur, Mukesh Kumar and Pramod Kumar

Abstract

The microscopic studies of Renal tubules of 6 *Marwari* sheep showed that there was no significant difference between juxtamedullary renal corpuscles and cortical corpuscles. The glomeruli in the cortical region had an average transverse diameter of 109.35±2.85 microns and average vertical diameter of 84.41±2.18 microns. The average transverse diameter of juxtamedullary glomeruli was 128.55±2.18 microns and average vertical diameter was 94.7±1.72 microns. The average diameter of PCT, DCT, collecting duct, thick and thin segment of loop of Henle was 49.91±2.02, 39.14±1.82, 42.80±0.99, 32.85±1.11, and 19.50±0.76 micron respectively.

Keywords: *Marwari* sheep, Micrometry, Renal corpuscles, loop of Henle

Introduction

Marwari sheep constitutes a major portion of the sheep population in western part of Rajasthan which has 14.31 million sheep (about 40%) and plays an important role in the economy of arid and semi-arid tract. Low rainfall and scanty vegetation are common in the western part of Rajasthan and the conditions become oppressive when extreme environmental conditions bring about the adaptive changes in organs necessary for physiological adjustments in these extreme ambient conditions. In mammals the kidneys are compound tubular glands and the chief excretory organs of the body. They have a major role in the maintenance of fluid and electrolyte balance and in control of the blood pressure.

Materials and Methods

The diameter of various parts of uriniferous tubule was measured from random samples seen under light microscope in high power (400X). The Micrometry of Renal tubules across various areas were recorded by using occular micrometer after calculating calibration with stage micrometer to record the observations on mean diameters of various parts of nephron and collecting duct.

Results and discussion

The Renal Corpuscles

Renal corpuscles in the cortical region (Fig.1) had an average transverse diameter of 134.79±5.47 microns and average vertical diameter was 98.99±3.83 microns. The average transverse diameter of juxtamedullary renal corpuscles was 158.63±2.94 microns and average vertical diameter 109.42±3.44 microns. The glomeruli in the cortical region had an average transverse diameter of 109.35±2.85 microns and average vertical diameter of 84.41±2.18 microns. The average transverse diameter of juxtamedullary glomeruli was 128.55±2.18 microns and average vertical diameter was 94.7±1.72 microns (Table 1).

The Proximal Convoluted Tubule

The diameter of the proximal convoluted tubule varied from 39.4 to 67.9 microns, with an average of 49.91±2.02 microns (Table 2). It was similar to the findings of Trautmann and Fiebiger (1957) [4] who stated that the diameter of proximal convoluted tubule ranged from 45 to 60 microns in domestic animals. Yadava and Calhoun (1958) [5] recorded an average diameter of proximal convoluted tubule to be 56, 50, 45 and 45 microns for horse, ox, sheep, and goat respectively. Whereas Ommer and Mariappa (1970) [3] reported in Indian buffalo that an average diameter was 47.4 microns with a range of 40.7 to 64.7 microns and Beniwal (1995) [1] reported in camel that an average diameter was 76.63 microns with a range of 43.98 to 117.28 micron.

INTEGRATION BETWEEN THE THERMAL STRESS INDEX (TGWB) AND THE LIVESTOCK STRAIN INDEX (LSI) AS A GUIDELINE FOR DAIRY FARMING IN TROPICAL CLIMATE

Abstract

A new thermal stress index (TGWB Index), based on Air temperature (Tdb), globe temperature (Tg) and wet bulb (Twb) temperature suggests as a potential substitute for the temperature humidity index (THI) for cattle in tropical climate. This new stress index, found to have a high correlation to THI, is constructed from fast reading meteorological response sensors (Tdb, Twb, and Tg) that take only a few seconds to reach equilibrium. Furthermore, the TGWB Index is the first stress index using direct measurements of solar radiation and is calculated as follows:
TGWB Index = 0.78 (Tg + Twb) + 35.8
The recently suggested Livestock Strain Index (LSI) is capable of indicating physiological strain and analyzing milk production of cattle. The LSI is constructed from rectal temperature (Tre) and respiratory frequency rate (Rf) as follows:
$LSI = 5\ (Tre_{obs.} - Tre_{min.}).\ (Tre_{max.} - Tre_{min})^{-1} + 5\ (Rf_{obs.} - Rf_{min.}).\ (Rf_{max.} - Rf_{min.})^{-1}$
Where Tre_{obs} and Rf_{obs} are the observed measurements Tre_{max} and Tre_{min}, and Rf_{max} and Rf_{min} are maximum and minimum simultaneous measurements taken at any time. The LSI is scaled from 0-10, whereby each variable LSI_{Tre} or LSI_{Rf} which represent the cardiovascular and the thermoregulation systems respectively. The purpose of this study was to develop guidelines based on TGWB Index and LSI for dairy cattle for combat to heat stress. In order to integrate LSI and TGWB Index, we decided to use both the LSI_{Rf} and LSI_{Tre} component, which represents the respiratory frequency rate and the strain reflected by the cardiovascular system. Furthermore, LSI_{Rf} and LSI_{Tre} are easier to measure, are easier to implement and simplifies the integration with TGWB Index. Concomitantly, it also categorizes the strain between 0-5, the higher the value, the higher the strain.

Key words: Tropical climate, Thermal stress, Indices, Solar Radiation, LSI, TGWB Index

Introduction

The incidence of heat stress as measured by the frequency of days with THI greater than 80 has increased significantly over the 40-year period on record. This is due to both changes in the temperature variables used and also the incidence of drought as drought years appear to be also associated with high stress frequency.

In hot climates, high ambient temperatures, humidity, wind speed, and high direct and indirect solar radiation are the main environmental stress factors that impose strain on animals (Finch, 1985, Silanikove, 2000). Heat stress indices range from simple measurements of ambient air temperature to indices that try to provide a weighted estimation of all environmental factors involved. Keeping the fact that heat stress is caused by multiple environmental or thermal factors, it is often misleading to use ambient temperature alone as the indicator of heat stress. Different heat stress indices have been proposed that indicate level of thermal stress. Thom suggested a Temperature-Humidity Index (THI) based on dry bulb and wet bulb thermometers. The Temperature Humidity Index (THI) has been widely used as a heat stress index in beef and dairy (cattle & buffaloes) industries (Stokka *et al.*, 1996: West, 1999; Mader *et al.*, 2002). Following a list of temperature humidity indices:

$THI\ 1 = (0.15 \times T_{db} + 0.85 \times Twb) \times 1.8 + 32$
(Bianca, 1962),

$THI\ 2 = (0.35 \times T_{db} + 0.65 \times Twb) \times 1.8 + 32$
(Bianca, 1962),

$THI\ 3 = [0.4 \times (T_{db} + Twb) \times 1.8 + 32 + 15$
(Thom, 1959),

$THI\ 4 = (0.55 \times T_{db} + 0.2 \times Tpo) \times 1.8 + 32 + 17.5$
(National Research Council, 1971),

$THI\ 5 = (1.8 \times T_{db} + 32) - (0.55 - 0.0055 \times RH) \times (1.8 \times T_{db} - 26) = 0.81 \times T_{db} + 0.143 \times RH) + 0.0099 \times RH \times T_{db} + 46.3$
(National Research Council, 1971),

$THI\ 6 = (T_{db} + Twb) \times 0.72 + 40.6$
(National Research Council, 1971),

$THI\ 7 = (T_{db} + 0.36 \times Tpo) + 41.2$
(Yousef, 1985a),

The above indices have been used to calculate stress for each combination of environmental variables corresponding to the measurements made in the animals, in order to assure that each animal response was associated to a given environmental condition. The index THI1 is used to monitor discomfort of temperature and humidity in humans. The THI2 and THI7 have been empirically determined for cattle exposed to heat stress conditions in climatic chambers. How these indices from controlled environments relate to field conditions? With diurnal fluctuation of environmental variables remain unanswered (Bohmanova *et al.*, 2007). The index THI3 is used to monitor the degree of discomfort in humans. The THI5 represents cattle heat stress index, designed to indicate level of heat stress of outdoors cattle (West, 2003); and THI6 has been developed by the United State Weather Bureau to describe discomfort in humans.

THI values of 70 or less are considered comfortable, 75 to 78 stressful, and values greater than 78 because extreme distress and animals are unable to maintain normal body temperature (Silanikove, 2000). The THI fails to reflect the contributions of other environmental factors, such as airflow and thermal radiation.

As noted before, the index has gained immense popularity over the years. The temperature humidity index (THI) is in use in temperate climatic condition for cattle. The Temperature Humidity Index (THI) has been widely used as a heat stress index in beef and dairy industries (Stokka *et al.*, 1996: West, 1999; Mader *et al.*, 2002). It is important to note the correlation of temperature humidity index (THI) to physiological responses was only partially tested and was based mainly on the correlation between the number of heat stress cases of dairy animal and the heat load as calculated by the THI. I have inroduced my new thermal stress index (TGWB) based on Air temperature (Tdb), globe temperature (Tg) and wet bulb (Twb) temperature as follows:

TGWB Index = 0.78 (Tg + Twb) + 35.8

This newly developed index was validated by using large databases and was found to be highly correlated to the temperature humidity index (THI). TGWB Index differs from other indices that have been suggested in the past for two main reasons. First, new thermal stress index (TGWB) based on Air temperature (Tdb), globe temperature (Tg) and wet bulb (Twb) temperature, aside from using temperature

Abstract

Arsenic in drinking water is the major cause of arsenic toxicity. Most of the reports highlighted chronic Arsenic toxicity in animals is increasing. In contrast inorganic arsenic compounds are well known as animal and human carcinogens, based on sufficient evidence in carcinogenicity in animals. From health point of view gastrointestinal effects, anaemia, peripheral neuropathy, skin lesions, hyper pigmentation, liver and kidney damage in animals and humans are common findings in arsenicosis. Inorganic exposure in animals by the inhalation has been shown to be strongly associated with lung cancer, while ingestion of inorganic arsenic in animals has been linked to a form of skin cancer and also to bladder, liver and lung cancer. A socio-toxicological survey was conducted in order to find out arsenic prone area in Faizabad district. Survey report showing Arsenic contamination in water, soil and poultry meat of Faizabad district (73% Veterinary/human hospitals/farmers informed about the contamination) as depicted in table no.1. This helps in the selection of centers. After survey and collection, samples were analyzed in laboratory. 80 samples each of water, soil and poultry meat collected from different locations of Faizabad districts were analyzed for detection of arsenic level. Arsenic contents of samples were detected by Hydride Generation Atomic Absorption Spectrophotometer (HG-AAS). The average arsenic contents of water, soil and poultry meat of different areas are 0.00550±0.00304 µg/g, 5.5500±2.9810 µg/g and 0.17924±0.05247µg/g respectively.Correlation analysis showed a significant positive correlation between drinking water, soil and poultry meat (Correlation coefficient $r=0.623$, $p<0.01$) and correlation was also found positive at (Correlation coefficient $r=0.497$, $p<0.05$). On the basis of above observation and results this can be concluded that periodical survey, study and monitoring of level of arsenic in water, soil & poultry meat is essential.

Keywords: Arsenic,Hydride Generation Atomic Absorption Spectrophotometer (HG-AAS).

Introduction

Arsenic is a widespread pollutant in various regions of the world (Flora *et al.*, 2005). Weathering of rocks converts arsenic sulfides to arsenic trioxide, which enters the arsenic cycle as dust or by dissolution in rain, rivers, or groundwater (Mandal and Suzuki, 2002). The occurrence of high concentrations of arsenic in groundwater used for drinking purpose has been recognized as a major public health concern in several parts of the world. Arsenic has been found to accumulate in the plant tissues and results in reduction in their biomass (Drlickova *et al.*, 2013).

The World Health Organization (WHO, 2007) permissible limit for arsenic is 0.01mg/l for drinking water and FAO permissible limit is 0.10mg/l for irrigation water (Bhattacharya *et al.*, 2009; Ahsan and Del Valls, 2011), whereas the concentrations of arsenic in non-contaminated soils range from 0.1to10mg/kg (Kabata-Pendias and Pendias, 1992). The immediate and long-term impact of using arsenic contaminated water for irrigating paddy soils is a burning concern as arsenic can transfer from water to soil and several studies have proven this phenomenon. It is seen that the total exposure of arsenic to humans and animals is the sum total of exposures from the diet, drinking water, direct ingestion of soil and dust, inhalation and percutaneous absorption (WHO, 2000; Hopenhayn, 2006). The areas across the Gangetic plains in India and Nepal also recently reported as the area affected from Arsenic (Maharjan *et al.*, 2005). Drinking water is the primary and main route of exposure to arsenic. Maximum Permissible Limit(MPL) is the standard concentration of arsenic in drinking water which is not hazardous, is set by the US EPA at 10µg/l (EPA, 2001) and the value for concentration of arsenic in drinking water is recommended by the WHO is also 10µg/l (WHO, 1992). In West Bengal (India), the arsenic concentration in drinking water is about 60 to 3700µg/l and about 40 million people are affected from it (Acharyya, 2002). In middle Ganga plain, Bihar, 206 tube wells (95% of total) were analyzed for arsenic content and showed that 56.8% tube wells have exceeded arsenic concentration of 50µg/l and 19.9% have more than 300µg/l (Chakraborti *et al.*, 2003; Acharyya *et al.*, 1999). Arsenic may be present in the organic or inorganic form (Ahmed, 2003). Of the inorganic forms, arsenite (trivalent) and arsenate (pentavalent) are the two most prevalent and potential dangerous forms, while organic form of organoarsenicals is also important (Dopp *et al.*, 2004; Sharaf *et al.*, 2013).

Himalayan Mountain and Tibet plateau are considered as the biggest source of arsenic contamination in the Gangetic region and this contamination is evidently becoming life threatening in almost every year (Chakraborti *et al.*, 2009). Geographically Uttar Pradesh is situated in the northern region of India and border of Nepal and comes under upper and middle gangetic plain. The river Ganga and Ghaghara are two major river flows from northeast to southeast. Arsenic was introduced as a contaminant in Ballia district of U.P. for the first time in 2003 (Yasunori *et al.*, 2012). Status of Arsenic Contamination in Eastern U.P.: In U.P. Jal Nigam and UNICEF combinedly reported and identified in 18 districts. Arsenic above the 10 ppb limit for drinking and Arsenic according to WHO limit was found in 31 districts (Chaurasia *et al.*, 2015; WSSO U.P. 2011). Times of India also reported "Ground water arsenic contamination of Uttar Pradesh exceeds to the value of BIS (Bureau of Indian Standards) permissible limit of 0.01 mg/liter across 31 districts of the state.

Pandey *et al.* (2015) reported alarming situation and highly contaminated districts are Bahraich, Ballia and Lakhimpur Kheri among than Ambedkar Nagar, Bareli, Basti, Bijnaor, Chaudauli, Faizabad, Ghazipur, Gorakhpur, Meerut, Sant Ravidar Nagar, Shahjahanpur, Siddarth Nagar, Sitapur, Unnao and Kanpur (Yasunori *et al.*, 2012).

Materials and Methods

This study was designed to **identify the** different **arsenic prone** locations in Faizabad district **of eastern Uttar Pradesh.** The major objectives were: –

Abstract
Now a day due to various side effects of allopathic medicine, scientists of pharmaceutical industries and research centers have been engaged to explore the pharmacological properties of herbal plants. The present review explains the pharmacological properties of *Boerhavia diffusa* plant. This plant commonly known as punarnava, is herb of family Nyctaginaceae. *B. diffusa* known to have medicinal properties and used as Ayurvedic medicine in India. Battery of phytochemicals like alkaloids, flavonoids, rotenoids and phytosterols has been found in the plant which are responsible for its various pharmacological properties such as analgesic, anti-*inflammatory*, diuretic, hepatoprotective, immunomodulator and nephroprotective, antiulcer and antihistaminic etc. Moreover, several new phytochemicals are discovered which again validate its medicinal importance. This review presents the evidence-based pharmacological properties of *B. diffusa*. In conclusion *B. diffusa* contain many bioactive phytochemicals that may be use as prophylactic as well as for cure of various ailments of human and animals.

Keywords: *Boerhavia diffusa,* bioactive phytochemicals, pharmacological properties, hepatoprotective and Immunomodulator

Introduction
Boerhavia diffusa, a perennial herb with stout root stock and many procumbent branches, flowers pale rose coloured, small, short-stalked; fruits highly viscid and one-seeded with many vernacular names viz. Punarnava, Raktapunarnava, Shothaghni, Kathillaka, Kshudra, Varshabhu, Raktapushpa, Varshaketu amd Shilatika in India. The genus *Boerhavia* (often spelled as Boerhaavia) was named in honor of Hermann Boerhaave (1668–1738), an eighteenth century Dutch botanist, humanist and physician at the University of Leiden, while the species got the name from typical diffuse branching. The botanical name of the plant is often written in the literature as *Boerhaavia diffusa* (Hiruma-Lima *et al*., 2000) [33], but Linnaeus Latinized Boerhaave's name to Boerhavius and adopted the spelling *Boerhavia diffusa*, which is the correct spelling to be used (Spellenberg, 2004) [75].
Punarnava is a very important medicinal herb of Ayurveda. Its name is derived from two words, *Punar* (= once again /regaining/restoring) and *Nava* (=new, renew or young), so the literal meaning of the name is, one which becomes new or young again. This name signifies the rejuvenating property of Punarnava. It is a Rasayan herb of Ayurveda which renews the body or restores youth.

RESEARCH ARTICLE

Impact of Different Therapeutic Protocols on Blood Biochemical Markers and Fertility in Anestrus Sahiwal Cows

Safayat Husain[1], Rajesh Kumar[1]*, Bhoopendra Singh[1], Sushant Srivastava[1], Rabindra Kumar[1], Pramod Kumar[2], Nilufar Haque[3]

Abstract

Bovine anestrus syndrome is a multifactorial disorder of the reproductive system. The problem is severe in suburban and rural areas of the country. The present study was aimed to evaluate the effect of different therapy on biochemical parameters and fertility response in 24 anestrus Sahiwal cows. Anestrus cows were randomly divided into four equal groups of six animals each, and were subjected with Lugol's iodine 2%, cervical painting with per rectal massage of genitalia thrice on alternate day (G1, n=6), XXX herbal bolus 1 bid for 2 days, repeated on day 11 & 12 later in non-respondents (G2, n=6), and modified ovsynch protocol which consisted of 100 mg hydroxy progesterone caproate injected daily s/c for 6 days followed by inj. GPG (G3, n=6), while one group was kept as untreated control (G4, n=6). Blood samples were collected thrice from all cows, *i.e.*, pretreatment day-0 (S1); post-treatment at induced estrus/AI (S2) and day 21 post-AI (S3), for estimation of serum progesterone and biochemical constituents. In general, except progesterone, the mean values of serum glucose, total cholesterol, total protein, albumin, calcium and phosphorus were significantly ($p<0.05$) lower at d-0 than the corresponding values at induced estrus and day 21 post-AI in treatment groups G1, G2 and G3; whereas, the periodic values did not differ significantly in control group G4. The estrus induction response was 100% in all treated cows with comparable conception rates among different therapeutic protocols (83.33, 66.66 & 83.33 %) as against nil response in control group G4. The results suggest that bovine anestrus syndrome can be managed well with comparatively low-cost Lugol's iodine and herbal therapeutics.

Introduction

Bovine anestrus syndrome is a multifactorial disorder of the reproductive system, characterized by the absence of estrus either due to lack of estrus or failure of its detection. The problem is severe in suburban and rural areas of the country. Wide variation in the incidence of anestrus has been reported in cattle and buffalo across the country (Butani *et al.*, 2008 and Ashoo *et al.*, 2020). The clinical syndrome can be diagnosed using anamnesis, ovarian palpation, progesterone estimation, and ultrasonography; being multifactorial, it can be treated according to their cause; however, there is no single panacea to correct it. Many non-hormonal and hormonal drugs have been tried and tested to treat anestrus syndrome (Kumar et al., 2011; Dhami et al., 2015; Kumar *et al.*, 2020; Kumar *et al.*, 2021). Among herbal therapeutics, various types of tropical plants are used traditionally to augment reproductive performance. Some plants contain secondary metabolites which are effective in inducing estrus in post-partum anestrus cows. The hormonal drugs being costly cannot always be affordable under field conditions. Thus, the present study was aimed to assess comparative efficacy of Lugol's iodine, XXX bolus (herbal heat inducer) and modified ovsynch protocol on fertility response in post-partum anestrus cows and its effect on blood biochemical profile.

Materials and Methods

The study was carried out under farm conditions during the year 2019-20 in the semi-urban areas of Ayodhya district in UP, India. The experimental protocol was approved by Institutional Animal Ethics Committee of the College. At preliminary stage, 34 cows were selected on the basis of history, breeding records and per-rectal examination. The

A B S T R A C T

The study was conducted to investigate the effect of α-tocopherol acetate and zinc on milk composition in Karan Fries cows. Twenty pregnant Karan Fries cows were selected two months before expected date of calving. The experimental animals were randomly divided in to two groups namely control group (ten cows) and treatment group (ten cows). Treatment group cows were supplemented with α-tocopherol acetate @ 1000 IU/day/cow and zinc @ 60 ppm/day/cow. Milk fat % was lower in treatment group than control group but the overall fat in treatment group was found significantly higher than control group (4.47±0.20 vs. 3.95±0.27, P<0.01). The overall mean milk protein % was found 3.08±0.04 vs. 3.05±0.11, milk lactose % 4.47±0.08 vs. 4.48±0.10 and SNF % 8.17±0.15 vs. 8.15±0.17 in control group and treatment group, respectively which showed that there was no significant difference between the groups. The overall mean (±SEM) of somatic cell count of milk was found significantly lower (P<0.001) in treatment group than control group. The results of this study indicated that supplementations of antioxidants like α-tocopherol acetate and zinc have beneficial effects in improving quality of milk.

Introduction

For good quality dairy products there is need to know the quality aspects of milk produced. Since the diet is the fastest way to modify the milk production and quality in animals, even if the relations between the feeding and milk composition are quite complex. Trace elements, along with vitamins and minerals, are essential nutrients for cellular metabolism. They are critical components of almost every aspect of how a body grows, develops, functions and reproduces. Vitamin E is crucially involved in immune system function, such that supplementation with supranutritional levels of the vitamin E, results in improved immune responses and milk production (Chawla and Kaur, 2005; Baldi, 2005; Baldi *et al.*, 2008; Chandra and Aggarwal, 2009). There was significant decrease of somatic cell count (SCC) in milk at 15 days of lactation (0.29×10^6 vs. 0.86×10^6) in cows supplemented with 1000 IU vitamin E / day during dry period (Kaur *et al.*, 2002). The somatic cell count is internationally recognized as a parameter for assessing the milk quality and udder health. The present

Effect of Exogenous Melatonin and Different Photoperiods on Differential Leucocyte Count in Chhotanagpuri Ewe

Pankaj K. Choudhary[1]*, Ajay K. Ishwar[2], Pramod Kumar[1], Pankaj K. Maurya[1], Mukesh Kumar[3], Rajesh Kumar[4], Debasish Niyogi[5]

Abstract

Forty-two healthy, non-pregnant, non-lactating Chhotanagpuri ewe, having body weight ranging from 14.11 ± 0.09 to 15.38 ± 0.06 kg, were selected and isolated from rams 2 months before melatonin administration. The selected animals were allocated randomly into seven groups each of 6 animals, *viz.*, Group-I [Normal control], Group-II [Long day (LD) control], Group-III [LD + melatonin administration 3 mg/day orally], Group-IV [(LD + melatonin administration s/c @ 1 mg/day], Group-V [Short day (SD) control], Group-VI [SD + melatonin administration 3 mg/day orally] and Group-VII [SD + melatonin administration s/c @ 1 mg/day]. Rams were then introduced into each group after completion of exogenous administration of melatonin for one month. Blood samples without anticoagulant were collected from each animal a day before the experiment and then every month till the fifth month. Among different periods, lymphocyte % in the third and fourth months of the experiment was significantly ($p < 0.05$) lower in all groups (group-I to VII) in comparison to 0 days, first, and second months. In the fifth month, lymphocyte % was significantly ($p < 0.05$) higher in group III, IV, VI, and VII compared to the third and fourth months of the experiment. Neutrophil % in the third and fourth months of the experiment was significantly ($p < 0.05$) higher in all groups in comparison to 0 days, first, and second months. In the fifth month, neutrophil % was significantly ($p < 0.05$) lower in group III and VI than in the third and fourth months. Monocyte % was significantly ($p < 0.05$) higher in group III and IV than group VII at first month. In the third month, monocyte % was significantly ($p < 0.05$) higher in group IV and VI than in group I and group II.

Ind J Vet Sci and Biotech (2021): 10.21887/ijvsbt.17.2.00

Introduction

The major functions of the white blood cells and their differentials are to fight infections, defend the body by phagocytosis against invasion by foreign organisms, and produce or at least transport and distribute antibodies in immune response (Etim, 2015). Thus, animals with low white blood cells are exposed to a high risk of infection. In contrast, those with high counts are capable of generating antibodies in the process of phagocytosis and have a high degree of resistance to disease (Soetan *et al.*, 2013) and enhancing adaptability to local environment and disease prevalent conditions (Isaac *et al.*, 2013). According to Etim *et al.* (2014) immune status is a function of leucocytes, lymphocytes, and neutrophils. Lymphocytes are known to play critical roles in the immune defense system of both men and animals (Etim *et al.*, 2014[b]).

Melatonin signaling is necessary for photoperiodic adjustment in immune responses; it is difficult to parse the direct differential effects of melatonin on immune cells from indirect modulatory actions on other neuroendocrine axes, including the systems that control gonadal and adrenal steroids. However, the hypothesis that melatonin acts on immune function via downstream hormonal effects has not been born out, as gonadectomy and steroid replacement has minimal effect on photoperiodic plasticity in the immune system (Prendergast *et al.*, 2005).

Exogenous melatonin administration increased the total leucocytic count and lymphocyte percentage in squirrels (Rai

Effect of *Withania somnifera* on Monocrotophos toxicity in commercial Poultry

Rishi Kant, RP Diwakar and Pramod Kumar

Abstract
The present study was conducted to investigate the protective efficacy of aqueous extracts of root and leaves of *W.somnifera* (Ashwagandha) against monocrtophos toxicity in broilers. Seventy two day old broiler chicks, were divided randomly and equally into six groups viz. Group I (Untreated Control), group II(MCP Control), *W. somnifera* root extract was given daily@ 100 and 300(mg/kg b.wt., orally) to group III and IV respectively in drinking water, *W. somnifera* leaf extract was given daily@ 100 and 300(mg/kg b.wt., orally)to group V and VI respectively in drinking water. On 21 day group II,III, IV, V andVI were administered single oral dose of MCP @ 1.34mg/Kg b.wt.($1/5^{th}$ of LD_{50}). There was no significant difference in haematological parameters in any of the experimental groups of birds after 1 day of single monocrotophos treatment except TEC which was significantly reduced in group II in comparison to group I birds. After 7 days there was a significant ($P<0.05$) decrease in the values of Hb, TEC and % lymphocytes in group II birds in comparison to group I birds. After 7 days *W. somnifera* root and leaf extract could not change the altered value of Hb to normal in groups III to VI, however leaf extract increased the depleted values of TEC and of % lymphocytes in group V and VI.
Monocrotophos significantly increased the activities of ALT, AST and ALP after 1 day of monocrotophos exposure in group II in comparison to group I birds. *W. somnifera* root and leaf extract significantly decreased ($P<0.05$) the values of these enzymes in the birds of group III to VI. In addition to that, root extract also reduced the value of serum creatinine, total protein and albumin in group IV in comparison to group II. Other parameters like globulin level, A:G ratio and activity of LDH remain unchanged. After 7 days of monocrotophos treatment activities of ALT, LDH and creatinine level were increased significantly in group II as compared to group I birds. The AST and ALP activities were unaltered in group II as compared to group I birds. Root and leaf extract showed their potential by decreasing the activity of ALT significantly in group III to VI birds in comparison to group II. However, the extract could not ameliorate the toxic effect of monocrotophos on LDH activity and creatinine level. The other biochemical parameters were unaltered.

Keywords: Monocrotophos, Ashwagandha (*Withania somnifera*) root and leaf extract

1. Introduction
Monocrotophos is an organic ester of phosphorus, which has the ability to inhibit the AChE. It is widely used to control insects and pests of rice and other crops and ectoparasiticide in animal husbandry practices (WHO 1993) [16]. Exposure of poultry to monocrotophos causes health consequences to poultry culminating in great economic loss, while also posing a potential threat to public health due to presence of pesticide residue in poultry meat (Pal and Kushwah, 1998, 2000) [8, 9]. Chronic exposure of chicks to small amount of organophosphates leads to deleterious effects on metabolism and immune system of birds (Garg *et al.* 2004) [2, 3]. Pharmacological screening of *W. somnifera* reveals that it is used as a tonic, stimulant, alterative, aphrodisiac, diuretic and abortifacient. Prolonged medication with *W. somnifera* caused a positive effect on weight, feed consumption, general resistance, liver weight and antistress effects in men and animals (Rao *et al.*, 1999, Archana and Namasivyam, 1999) [10, 1]. The present study was conducted to investigate the protective efficacy of aqueous extracts of root and leaves extract of *W. somnifera* in poultry exposed to monocrotophos.

Materials and Methods
Preparation of root and leaves extracts
After collection the plant materials were shade dried and powdered. The powders were further processed for aqueous extraction. The powder was soaked in distilled water for 24h with intermittent stirring at 40 °Cwith the help of magnetic stirrer. The infusions were filtered through muslin cloth and centrifuged at 400g for 15 minutes to get the supernatant. The filtrates were dried with the help of incubator with fan and lypholizer (37 °C) to get the final extracts.

GROSS AND HISTOLOGICAL STUDIES OF THE URETER IN *MARWARI* SHEEP (*Ovis aries*)

Krishna Nand Singh[1], Sanjeev Joshi [2], Rakesh Mathur[2], Mukesh Kumar[1], Pramod Kumar[1], S.S. Sengar[1] K. K. Tripathi[1] and Rakesh Gupta[3]

1. Asstt. Professor, C. V. Sc & A.H., N.D.U.A & T., Kumarganj- Faizabad (U.P.)
2. Department of Veterinary Anatomy and Histology, CVAS, Bikaner.
3. P.G. scholar Department of Veterinary Pathology, C. V. Sc & A.H., N.D.U.A & T.

Abstract

The present study was conducted on ureters of 15 *Marwari* sheep of either sex between the ages of 1.5 -2 years. It was a long and thin muscular tube begins from renal pelvis at the hilus and passes backward along medial border of kidney. In the Histological structure ureter was composed of tunica mucosa of transitional epithelium. The mucosa was thrown on to longitudinal folds giving the lumen a stellate appearance. Lamina propria is wide which was composed of fibroelastic connective tissue with many bundles of coarse collagen fibres. The tunica muscularis was consisted of inner longitudinal, middle circular, and outer longitudinal layers of smooth muscles. The outer layer tunica adventitia is continuous with fibroelastic connective tissue which contain blood vessels and nerve endings.

Key words: Ureter, Stellate Lumen, transitional epithelium, smooth muscle fiber.

Introduction

Marwari sheep constitutes a major portion of the sheep population in western part of Rajasthan which has 14.31 million sheep (about 40%) and plays an important role in the economy of arid and semi-arid tract. Low rainfall and scanty vegetation are common in the western part of Rajasthan and the conditions become oppressive when extreme environmental conditions bring about the adaptive changes in organs necessary for physiological adjustments in these extreme ambient conditions. The present investigation has been planned to study the gross and histological structure of the ureter to justify its importance and essentiality in the body. In mammals the ureters are the chief excretory ducts of the body.

Materials and Methods

The Gross study was conducted on 15 apparently healthy adult *Marwari* Sheep (*Ovis aries*) of either sex. The Ureters from the freshly slaughtered animals were procured from Municipal slaughterhouse, Bikaner.

For the histological examination the small pieces of tissues (2 mm size) were collected from 12 ureters (6 right and 6 left). From each, the tissues were collected from different anatomical regions to explore regional differences if any. The tissues were preserved in 10% formal saline for 48 hrs, Bouin's fluid for 12 hrs, and Zenker's fluid for 18 hrs (Singh, U.B. and Sulochana, S. 1996). Fixed tissue was latter washed in running tap water for 6-10 hours followed by dehydration in ascending grade of alcohol, clearing, embedding in paraffin wax of melting point of 58-60℃, preparation of blocks, section cutting (5-6 µm thick), and mounting of section on albuminized slides, drying of sections and finally stained with the histological stains (Luna, L.G. 1968). to demonstrate different histological structures of ureters.

Results and Discussion

Each kidney was connected to the urinary bladder by a ureter. It was a long and thin muscular tube begins from the renal pelvis at the hilus and passes backward along medial border ofthe kidney. It passes ferther caudally and enters in tothe pelvic cavity. It inclines inward and downward and open in to the bladder at the caudodorsal aspect. Similar findings were also reported by Konig and Liebich (2006) and Dyce *et al* (2010) in domestic animals.

In the histological structure the ureter of Marwari sheep was composed of tunica mucosa of transitional epithelium. The mucosa was thrown on to longitudinal folds giving the lumen a stellate appearance (Dellmann HD, 1993). Lamina propria is wide which was composed of fibroelastic connective tissue with many bundles of coarse collagen fibres which was dense towards the epithelium and loose towards the muscularis mucosa. The tunica muscularis was consisted of inner longitudinal, middle circular, and outer longitudinal layers of smooth muscles (Fig1. and Fig 2.). The outer layer, the tunica adventitia is continuous with fibroelastic connective tissue which contain blood vessels and nerve endings. Similar findings were also reported by Doaa Zaghloul *et al* in Camel, Woldemeskel *et al.* (1998) in sows and Konig and Liebich (2006) and Dyce *et al* (2010) in domestic animals. Whereas A.R. Sreeranjini *et al* (2010) found that the sub mucosa of intra renal ureteric branches and ureter in Japanese quail contained collagen, elastic and reticular fibers. Tunica muscularis of ureter contained few elastic fibers among smooth muscle fibers. Tunica adventitia was comprised of loose connective tissue containing collagen and elastic fibers.

Management of traumatic proptosis in a pug: A case study

Sandeep Yadav, Vibha Yadav, RP Diwakar and Pramod Kumar

Abstract
A three years old male pug dog, weigh 10 kg was presented to Jai Pet Care Clinic Raebareli, Uttar Pradesh for treatment with unilateral traumatic proptosis. All clinical parameters were normal. Physical examination revealed partial prolapse of right eye globe with severe periorbital edema, haemorrhage, absence of menace and presence of miosis. Therapeutic management done by administration of triflupromazine @4mg/kg I/M for sedation, dexamethasone and gentamicine 0.2ml each in combination injected through intra palpebral route, which was repeated on 5th day. Animal was also given intramuscular injection of gentamicin @5mg/kg, dexamethasone @0.125mg/kg, vitamine B complex 2.0 ml and chlorpheniramine maleate @0.5mg/kg only once for 5 consecutive days. Eye drop of moxifloxacine and dexamethasone 4 times a day for instillation, chloramphenicol ointment 4 times a day for local application and enrofloxacin @5mg/kg orally once for 7 days were used. Animal recovered successfully after 7 days of regular treatment. Vision was assessed by simple vision testing using junction box, after 15 days of recovery and found normal.

Keywords: Pug, proptosis, therapeutic management

Introduction
Proptosis is forward displacement of globe which occur secondary to any blunt trauma to head [7]. Proptosis typically occurs in dogs following trauma to the face or head. Certain breeds of dog are more prone to eye proptosis than others because of their differences in facial conformation. The most common cause of proptosis in small breed dogs is a fight with a larger dog. During trauma, the globe is luxated from the orbit, and eyelid spasms prevent its retraction. Secondary orbital hemorrhage and swelling displace the globe further from the orbit following corneo-conjunctival drying and malacia [3]. Prognosis depends on pupil size and reflexes, duration of exposure, other globe or orbital damage, breed and other systemic trauma. Approximately 40–60% of dogs, but very few cats, recover vision. Traumatic proptosis can occur in any breed and in both dogs and cats. Only 20-40% of dogs that have the reattachment of the eyeball regain their vision.

Case history and observations
A three year old male pug of 10 kg weight was presented at Jai Pet Care Clinic Raebareli, Utter Pradesh with unilateral traumatic proptosis having recent history of blunt head trauma by hitting head against the wall. Clinical examination revealed partial prolapse of right eye globe (fig.-1) through the pulpebral fissure with severe periorbital edema (fig.-2), haemorrhage without fracture of skull. There was absence of menace and presence of miosis. Corneal examination revealed concurrent finding of pigmentary vascular keratitis. All clinical parameters of the pug were normal.

In vivo evaluation of bio agents, botanical and fungicides against *Fusarium oxysporum* f. sp. *basilica*

Rajendra Prasad, S.K. Pandey, Subhash Chandra, Neeraj Kumar Rajvanshi and Divya Singh

Abstract
The Holy Basil (*Ocimum sanctum* Linn.) commonly known as Tulsi, is an aromatic perennial plant, belongs to the family Liliaceae. It is native to Indian subcontinent and wide spread as a cultivated plant throughout the south-east Asian tropics. Holy Basil is widely grown in India for medicinal as well as religious purposes. For the management of wilt disease of Holy Basil (*Ocimum sanctum*) the experimental finding depicted in Table no.3 reveal that among 6 treatment which include three bio-agent T_1 *Trichoderma viride*, T_2 *Trichoderma harzianum* and T_3 *Pseudomonas fluorescence* and one botanicals T_4 Neem leaves and two chemicals T_5 Tebuconazole and T_6 Mancozeb. The most effective was Tebuconazole 250 EC @ 0.1% with percent disease control and percent disease intensité, (68.20) and (19.67) respectively. And Mancozeb 75WP @ 0.1%. With PDC and PDI (62.54) and (23.17), respectively where as the bio-agent *Trichoderma viride* Talc based formulation was prepared.cfu-1×10^9/gm and dissolved @ 10gm in 1.0 lit. Distilled water) with PDC and PDI (45.41) and (33.75), respectively. *Trichoderma harzianum* (Talc based formulation was prepared.cfu-1×10^9/gm and dissolved @ 10gm in 1.0 lit. distilled water) with PDC and PDI (37.02) and (38.94) respectively and *Pseudomonas fluorescence* @ 4 gm/kg seed with PDC and PDI (27.76) and (44.62) respectively. and Neem leaves @ 5% with PDC and PDI (16.98) and (51.53).The used fongicide and bio pesticide significantly reduce the wilt of *Ocimum sanctus*.

Keywords: Tulsi, *Pseudomonas fluorescence,* Tebuconazole

Introduction
The Holy Basil (*Ocimum sanctum* Linn.) commonly known as Tulsi, is an aromatic perennial plant, belongs to the family Liliaceae. It is native to Indian subcontinent and wide spread as a cultivated plant throughout the south-east Asian tropics. Holy Basil is widely grown in India for medicinal as well as religious purposes. There are many species of Basil such as *Ocimum sanctum* L.(Tulsi), *Ocimum gratissimum* (Ram Tulsi), *Ocimum canum Sims* (Dulal Tulsi), *Ocimum basilicum* (Ban Tulsi), *Ocimum kilimandscharicum Gureke (*Camphor Basil*) and Ocimum americanum* Linn *(*Hoary Basil) among them holy Basil *(Ocimum sanctum)* has been well known for its therapeutic potential (Prakash and Gupta, 2005) [2].The chemical constituents present in *Ocimum sanctum* are Oleanolic acid, Ursolic acid, Rosmarinic acid, Eugenol, Carvacrol, Linalool and β-caryophyllene, β-elemene (Kothari *et al*.2004) [1] In several ancient system of medicine including Ayurveda, Greek Roman, Siddha and Unanni, *Ocimum sanctum* has vast number of therapeutic applications such as in cardiopathy,

Pigeon pea (*Cajanus cajan* L.) is widely adaptable to wide variety of climate and is one of the important legume crops of tropics and subtropics. It played a major role in nutritional security for the people taking cereal based diet. Beside their dietary value and nitrogen fixing ability, pulses also play an important role in sustaining intensive agriculture by improving physical, chemical and biological properties of soil and are considered excellent crop for diversification of cereal based cropping system.

Wilt disease caused by *Fusarium udum* Butler, is the most destructive soil and seed born disease of pigeon pea in India leading to heavy production losses. The *F. udum* is host specific to pigeon pea (Patel *et al*., 2011) and can survive in soil under wilted plant stubble for a long period. The best way of wilt management is by growing resistant varieties. For developing resistant varieties, resistant source are the basic requirement. Therefore, the present investigation was undertaken.

Seeds of 58 germplasm of Pigeon pea were obtained from the Department of Genetics and Plant Breeding, N.D.U.A.&T., Ayodhya and ICAR-IIPR, Kanpur. The germplasms were screened under sick plot technique. The plots (sick soil) showed over 90% wilt incidence in susceptible cultivar Bahar of Pigeon pea was used as test variety. After germination, observations were recorded regularly up to 60 days for the appearance of wilt symptoms and severity. The disease was recorded using 1-9 scale for the wilt disease.

Fifty eight germplasms of Pigeon pea were screened for their reaction to *Fusarium udum* in sick plot. It is evident (Table 1) that out of 58, 6 germplasms *viz*.; AKT 201030, IPA 96, IPAF, IPA 204, JSA 59 and WRGE 18 were found resistant, attributing to the higher concentration of phenol as observed by Haldar and Srinivasan (2007), 5 moderately resistant, 10 tolerant, 16 moderately susceptible and 21 germplasm were highly

Table 1. Performance of Pigeon pea genotypes against *Fusarium udum* under field condition (Sick plot technique)

Reaction (Rating scale)	Name of the genotypes
Resistant (1)	AKT201030, IPA96, IPAF, IPA204, JSA59, WRGE18.
Moderately resistant (3)	IPA9F, IPA204, ICP8863, WRGE18, BDN2.
Tolerant (5)	IPA13F, AL1573, H2001-4, HDM04-1, UPAS120, GRG206, JKM197, PT02-9, IPA2F, IPA4F.
Moderately susceptible (7)	IPA12F, WRG123, JKM206, JKM208, PT02-5, PT25-6, AL1514, AL1571, PA325, PT05-37, WPB205, AKT222560, ASI106, JKM209, NDA05-1, WRGE42.
Highly susceptible (9)	IPA11F, IPA14F, IPA15F, IPA34, IPA234, JSA28, PA322, PT01-27, BAHAR, PUSA2006-2, SKN205, WRGE56, CORG990015, PT05-36, IPA1F, IPA3F, IPA5F, IPA5-2, IPA5-3, IPA6F, IPA7F.

Field evaluation of pigeonpea (*Cajanus cajan*) genotypes against fusarium wilt to disease resistance

Subhash Chandra, Neeraj Kumar Rajvanshi, Popin Kumar and Mukesh Kumar

Abstract
The pigeonpea germplasms/genotypes were evaluated to identify the sources of resistance to Fusarium wilt disease. The *F. udum* is host specific to pigeonpea and can survive in soil under wilted plant stubble for a long period. The best way of wilt management is by growing resistant varieties. Out of 54 screened genotypes, twenty one genotypes *viz.* BDN2001-6, BRG2-7, CORG2004-01, CORG990013, H2000-37, H2000-47, IPC7119, IPC8863, IPA14F, JKM186, JKM197, JKM204, JKM205, JKM209, KAWR11, KAWR91, NTL30, PT02-25, PT02-5, PT11-39, and PUSA2005-1 were found resistant, 15 moderately resistant, 13 tolerant, 4 moderately susceptible and 1 genotype were highly susceptible against fusarium wilt. The most susceptible variety Bahar showed 80 per cent wilting.

Keywords: Pigeonpea, *Fusarium,* germplasm, resistant

Introduction
Pigeonpea [*Cajanus cajan* (L.) Millsp.], also referred to as red gram or *arhar,* is a perennial shrub, with its centre of origin located in India. It is an important grain legume crop predominantly grown in the Indian subcontinent as an important source of dietary protein. In India, production of Pigeonpea was 42.54 Lac tones on area of 44.31 Lac ha with yield of 960 kg/ha (Anonymous, 2018) [1]. It is also cultivated in other parts of the world, including sub-Saharan Africa, Latin America, the Caribbean and South-East Asia. Its cultivation is increasing in semi-arid areas because of the crop's ability to thrive under prolonged drought and in degraded lands (Upadhyaya *et al*., 2012) [11]. The crop is mainly grown as annual using cultivars with different durations to maturity: 90 days (Short), 120 days (Medium) and 180 days (Long). It is cultivated as a perennial crop in several regions of India. The shift of pigeonpea cultivation from the traditional *kharif* season to pre *rabi* September sowing in north Bihar has not only shown an increased production potential of this important pulse crop but have also opened altogether a new possibilities in land use pattern of the rain fed areas of Bihar and adjoining states. Fresh pods are consumed as a vegetable; dried mature grains are used for cooking or in processing. Among the several factors responsible for reduction yield and quality deterioration of pigeonpea in India, diseases occupy a vital place. Among the diseases, wilt disease caused by *Fusarium udum* Butler, is the most destructive soil and seed born disease of pigeonpea in India leading to heavy production losses. The disease since been reported from Bangladesh, Ghana, Grenanda, Indonesia, Kenya, Malawi, Mauritius, Tanzania, Thialand, Trinida, Uganda and Zambia. In India it is the most serious problem all over the Pigeonpea growing states especially in U.P., M.P., Bihar and Maharashtra. In the epiphytotic conditions, disease incidence was recorded 15-25 per cent in general and up to 50 per cent (Butler, 1910) [2]. In Bihar and Uttar Pradesh, 5-10 per cent losses in standing crop are common feature every year (Singh, 2006) [10].

Materials and Methods
Seeds of fifty four genotypes of Pigeonpea were obtained from the Department of Genetics and Plant Breeding, N.D. University of Agriculture and Technology, Kumarganj, Ayodhya (U.P.) and IIPR, Kanpur. The genotypes were screened under artificial conditions (Sick plot technique) using the methods described by Nene *et al*., (1982) [5].

Screening of mungbean [*Vigna radiate* (L.) Wilczek] genotypes for resistance against mungbean yellow mosaic virus (MYMV) under field condition

Subhash Chandra, Neeraj Kumar Rajvanshi, Popin Kumar, Mukesh Kumar and MP Chauhan

Abstract
Mungbean (*Vigna radiata* L.) is also known as mung, moong, mungo. In India it is third most important pulse crop after chickpea and pigeonpea. Mungbean is an important short duration grain legume which is grown in different parts of the country, for grain and green manuring. It is an outstanding source of easily digestible proteins with low flatulence, which balances the staple rice diet in Asia. Mungbean yellow mosaic disease (MYMD) caused by whitefly (*Bemisia tabaci*) transmitted mungbean yellow mosaic virus (MYMV) is an important constraint of mungbean in India. Use of resistant genotypes is the best method of avoiding the occurrence of the disease. Keeping this point in view, out of fifty two genotypes of mungbean were tested for the resistance against MYMV during *Kharif* 2015 in field condition. The per cent disease incidence (PDI) of MYMV among 52 mungbean genotypes was worked out up to ninth week after sowing and it varied from 0 to 79.68 %. Out of fifty two mungbean genotypes, five were found resistance, eight were moderately resistant, seventeen genotypes were recorded moderately susceptible and twenty two genotypes were noticed susceptible. Five genotypes namely, PM 10-18, PUSA 1371, BM 2012-09, DGGV-2 and MH 810 found resistant during present investigation which can be used for the development of mapping population for the development of MYMV resistant varieties.

Keywords: mungbean, genotypes, resistance and yellow mosaic virus

Introduction
Mungbean (*Vigna radiata* L.) is also known as green gram, green bean, moong, mash bean, golden gram and green soy (Saminathan 2013) [10]. In India, the name green gram is more commonly used than mungbean (Chatterjee and Randhawa, 1952) [2]. It is third most important pulse crop of India after chickpea and pigeonpea. Mungbean can grow in all three seasons in India, *viz*., *Kharif* (July- Oct), *Rabi* (Sept- Dec) and summer (March- June). It is grown under rainfed condition during *Kharif* and on residual moisture during *Rabi* in eastern and southern part of the country. However, *Kharif* season crop occupies maximum area of its cultivation. Intercropping with sorghum, pearl-millet, maize, cotton, castor, pigeonpea etc., are popular. India alone contributes 54% of world production and covers 65% of the world acreage (Singh, 2011) [11]. It is grown in intercropping, catch cropping and relay cropping systems because of its short duration (less than 60 days). In India, mungbean is grown in an area of 4.32 m ha with production of 2.17 m tones and productivity of 502 kg/ha. Important mungbean growing states are Rajasthan, Maharashtra, Karnataka, Andhra Pradesh, Odisha, Bihar, Tamil Nadu, Madhya Pradesh and Uttar Pradesh (Anon, 2018) [1]. The standard worldwide yield of mungbean is very low (389 kg/ha) and its production has not increased over the year. The main reason for low yield is the susceptibility of the crop to insects, weeds and diseases caused by fungus, virus, nematodes and bacteria. Among these, the viruses are the most important group of plant pathogens affecting the production of the crop. They cause severe diseases and economic losses in mungbean and reducing seed yield and quality (Kang *et al*., 2005) [3]. Twelve viral diseases are reported on mungbean crop *viz*., Mungbean yellow mosaic virus (MYMV) disease, Bean yellow mosaic virus (BYMV) disease, Southern bean mosaic virus (SBMV) disease, Leaf crinkle virus (LCV) disease, Mungbean mosaic virus (MMV) disease, Cowpea aphid-borne virus (CABV) disease, Cucumber yellow mosaic virus (CMV) disease, Alfalfa

Evaluation of mungbean [*Vigna radiate* (L.) Wilczek] genotypes for resistance against web blight

Subhash Chandra, Neeraj Kumar Rajvanshi, MP Chauhan and Mukesh Kumar

Abstract
Web blight (*Rhizoctonia solani*) of mungbean is a very destructive disease caused by fungus *Rhizoctonia solani*. In India, mungbean crop suffers a great loss due to this disease.Use of resistant genotypes is the best method of avoiding the occurrence of the disease. Keeping this point in view, fifty two genotypes of mungbean were tested for the resistance against web blight in field condition. Out of fifty two genotypes of mungbean were carried out under field condition of natural infection, where twenty nine genotypes *viz*.; BM 2012-09, Palampur 93/kulu-4, LGC 574, NUL 516, T-44, SGC 20, SML 1082 (SC), IPM 312-19, IGKM 06-42, VG 10-008, MH 921, ML 2412, PUSA 571, RMG 1082, PUSA 1472, ML 2410, ML 2333, COGG-912, KM 2348, AKM 12-17, IPM 312-20, GM 11-02, KM 2241, ML 818, HUM-1, CO6, LGG 460, IPM 02-3 and GM 04-02 were found resistant, five genotypes were recorded moderately resistant, thirteen genotypes were noticed moderately susceptible, four genotypes *viz*.; NVL 825, DUG 5, VBN 4, RMG 1028 were recorded susceptible. Only one genotype K-851was found highly susceptible.

Keywords: Evaluation, mungbean, web blight, *Vigna radiate*

Introduction
Mungbean (*Vigna radiata*) belongs to fabaceae family along with good sources of protein, carbohydrates and vitamins for mankind all over the world. Mungbean (*Vigna radiata* L.) is also known as mung, moong, mungo. In India, the name greengram is more commonly used than mungbean (Chatterjee and Randhawa, 1952) [3]. It is third most important pulse crop of India after chickpea and pigeonpea. Mungbean can grow in all three seasons in India, *viz*., *Kharif* (July- Oct), *Rabi* (Sept- Dec) and summer (March- June). It is grown under rainfed condition during *Kharif* and on residual moisture during *Rabi* in eastern and southern part of the country. However, *Kharif* season crop occupies maximum area of its cultivation. Intercropping with sorghum, pearl-millet, maize, cotton, castor, pigeonpea etc., are popular. India alone contributes 54% of world production and covers 65% of the world acreage (Singh, 2011) [10]. It is grown in intercropping, catch cropping and relay cropping systems because of its short duration (less than 60 days). It is grown in intercropping, catch cropping and relay cropping systems because of its short duration (less than 60 days). In India, mungbean is grown in an area of 4.32 m ha with production of 2.17 m tones and productivity of 502 kg/ha. Important mungbean growing states are Rajasthan, Maharashtra, Karnataka, Andhra Pradesh, Odisha, Bihar, Tamil Nadu, Madhya Pradesh and Uttar Pradesh (Anon, 2018) [1].

Mungbean has been considered as "poor men's protein". It contains 26% protein, 51% carbohydrate, 4% minerals, 3% vitamins and 10% moisture (Khan, 1981) [7]. The standard worldwide yield of mungbean is very low (389kg/ha) and its production has not increased over the year. The main reason for low yield is the susceptibility of the crop to insects, weeds and diseases caused by fungus, virus and bacteria. Among these, the viruses are the most important group of plant pathogens affecting the production of the crop. They cause severe diseases and economic losses in mungbean and reducing seed yield and quality (Kang *et al.*, 2005) [6]. The crop is infected by a large number of pathogens consisting of (virus, bacteria, fungi and nematodes) which significantly contribute to poor yields. Among the diseases, Yellow mosaic, Web blight, Bacterial blight, Leaf crinkle, Powdery mildew, Cercospora leaf spot, Anthracnose and Macrophomina bight are important in different parts of the country which reducing the yield of mungbean heavily. Previously web blight was considered as minor disease.

Reaction of urdbean (*Vigna mungo*) genotypes against *Cercospora* leaf spot (CLS)

Subhash Chandra, Neeraj Kumar Rajvanshi, Popin Kumar, RM Tripathi and MP Chauhan

Abstract
The present investigation aimed to identify resistance in urdbean (Vigna mungo) against *Cercospora* leaf spot (CLS) in a field condition. The trial was conducted at Genetics and Plant Breeding Farm of Narendra Dev University of Agriculture and Technology, Kumarganj, Ayodhya. Forty six urdbean genotypes were screened in the summer season of the year of 2015- 2016. The severity of was recorded following 0-9 scale. The urdbean genotypes evaluated were grouped into different categories based on disease reaction. The present results indicated that genotype IPU 11-2, PU 10-23, KU 96-7, Pant U 19, TU 94-2, VBG 09-005, KPU 524-65, NIRB-004, DKU 11, Vamban 7, NDUK 13-6, CO 5, KUG 725, PU 10-16, NUL 7, Pant U 30, WBU 108, NIRB-003, Shekhar 3, NDUK 15-9, TU 67, VBG 12-062, RMG 353, IU 05-1, VBG 11-053, IPM 94-1, RUG 55 and TU 22 were resistant to CLS, 6 genotypes *viz.*; AKU 11-15, K 851, KU 96-3, LBG 645, NIRB-002, COBG 11-03 were exhibited moderately resistant, 05 genotypes *viz.*; LBG 623, MU 46, MU 44, KU 14-1, DBG 11 were showed moderately susceptible, 06 genotypes *viz.*; RUG 59, IPU 2-43, Pant U 31, KUG 479, IPU 13-1, KPU 129-104 were susceptible and only one genotype was highly susceptible. None of these genotypes was found free from infection. The urdbean genotypes which were found resistant the could be the choice for resistance against CLS.

Keywords: urdbean, *Cercospora*, *Vigna mungo*, CLS

Introduction
Pulses represent one of the most important foods that have been extensively used to cover basic protein and energy needs in day today life. Pulses have unique property of maintaining and restoring soil fertility through biological nitrogen fixation as well as covering and improving physical properties of soil by virtue of their deep root system. Urdbean or Blackgram (*Vigna mungo* L.) Hepper is the most important pulse crop of the *'vigna'* group. It is considered to have been domesticated in India from its wild ancestral form (*V. mungo* var. *Silvestris* Lukoki, Marechal & Otoul). Center of genetic diversity is found in India (Zeven and de Wet. 1982) [7]. It is an important crop of India and extensively grown over a wide range of agroclimatic zones of the country.

In India, urdbean occupies 4.50 m ha area, production 2.83 mt and productivity 628 kg/ha (Anonymous, 2018) [1]. Highest productivity of urdbean is reported from West Bengal followed by Andhra Pradesh and Uttar Pradesh. Urdbean is prone to several fungal diseases, among which *Cercospora* leaf spot (CLS) caused by *Cercospora* canescens. Eills and Mortin is one of the most important fungal disease of urdbean causing heavy yield losses particularly in Uttar Pradesh and Uttarakhand states. Disease is also reported from other states *viz.*, Punjab, Haryana, Bihar, Rajasthan, West Bengal, Himachal Pradesh and Jammu & Kashmir (Saksena and Dwivedi, 1973) [6]. Previously *Cercospora* leaf spot was considered as minor disease. Due to change in cropping system and introduction of yellow mosaic resistant varieties it is becoming an important fungal disease and constraint in production of this crop. Resistance is fundamental attributes of all living systems. Host plant resistance (HPR) is the most efficient and ecofriendly means of management. For exploitation of HPR, reliable field and controlled environment screening techniques are essential. Therefore, the present investigation was undertaken with an objective to identify the sources of resistance in different genotypes of urdbean against *Cercospora* leaf spot.

Histometrical Changes in the Thyroid Gland of Chabro Chicken Reared during Summer and Winter Seasons

Amit Singh Vishen[1], Varsha Gupta, S.P. Singh, Abhinov Verma, Rakesh Kumar Gupta, Hemant Kumar, K.N. Singh, Mukesh Kumar

10.18805/IJAR.B-4176

ABSTRACT

Background: Chabro is a strain of poultry birds especially designed for backyard farming and is more adoptive to climatic variations in the tropics. The thyroid gland plays an important role in controlling basal metabolic rate. The histoarchitectural changes of the gland in association with seasonal changes has not been studied so far in Chabro. The present study describes the season related variations in the histometry of thyroid gland.

Methods: Micrometrical studies were conducted on thyroid gland of eight to ten weeks old 24 apparently healthy Chabro chickens procured from Poultry Farm, DUVASU, Mathura after approval of CPCSEA. For this study the chickens were divided into two groups consist of 12 chickens in each group reared in summer and winter seasons.

Result: Histologically, the thyroid gland was composed of stroma and parenchyma. The capsule had outer thick adipose and inner thin fibrous layers. The follicles were filled with colloid produced by the follicular cells. The percentage of small follicles was more followed by medium and large follicles. The follicles were lined by simple squamous epithelium in summer and cuboidal epithelial cells in winter. All micrometrical parameters, amount of reticular fibers, percentage of large and active follicles were higher in winter.

Key words: Chabro chicken, Histology, Histometry, Season, Thyroid gland.

INTRODUCTION

Backyard poultry farming is being promoted for sustainability of poultry production and upliftment of socio-economic condition of Indian farm-ers. Different central government agencies have developed several strains of poultry birds for backyard farming, Chabro is one of them. Chabro chicken was developed by Central Poultry Development Organization (CPDO) by crossing Barred Plymouth Rock with Red Cornish especially for the farmers of our country owing to more adoptive to climatic fluctuations and acclimatizes to the entire climatic zone. Thyroid is a bilobed structure situated on either side of trachea. It is the only gland in the body of both mammals and birds that stores hormone in its inactive form. The substance of the gland consists of roughly spherical thyroid follicles. The thyroid gland is a unique endocrine gland which plays an important role in controlling pre and post natal growth and differentiation of many organ systems. The work has been conducted in the thyroid gland of different birds in relation to season variation by different scientists. The present study describes the season related variations in the histology and micrometry of thyroid gland in Chabro chicken. This study forms a basis for correlating the possible functions of the thyroid gland in relation to growth and diagnosis of deficiency syndrome.

MATERIALS AND METHODS

The present study was conducted on thyroid gland of eight weeks old 24 apparently healthy Chabro chickens procured from poultry farm of Veterinary College, Mathura in summer and winter seasons in 2018. For histological observations, small pieces of the thyroid gland were collected and fixed in 10% neutral buffered formalin. Fixed tissues were processed by routine paraffin embedding technique (Luna, 1968) and 6µ paraffin sections were procured. Following staining procedures were performed to record histological observations:

1) Haematoxylin and Eosin stain (Luna, 1968) :
   For the study of general histo- architecture of thyroid gland.
2) Masson's trichrome stain (Luna, 1968) :
   For the study of collagen fibers.

Histological studies on the liver of Marwari Goat (*Capra hircus*)

Mahesh Kumar Bamniya, Rakesh Mathur, Sanjeev Joshi, KN Singh, Mukesh Kumar, Amit Vishen and S Gharu

Abstract
The histological studies were conducted on the liver of 15 Marwari goats. Histologically, the whole liver was invested by peritoneum, except where it was reflected as ligaments and where it adheres to the diaphragm. Underlying it, the liver covered by connective tissue covering called as glisson's capsule. It was composed of collagenous and reticular fibers and few smooth muscles. The reticular fibers formed the stroma. The hepatic lobules were made up of central vein, portal area and one cell thick cords, which were not delineated by connective tissue. The sinusoidals were narrow and somewhat cylindrical. These were lined by continuous endothelial cells resting on basal lamina. Kupffer cells were present attached to the endothelial cells. There were numerous mucous glands present in the mucosa of hepatic, cystic and common bile ducts. The centrilobular and the periportal hepatocyte were rich in the glycogen content.

Keywords: Histology. Marwari goat and Liver

Introduction
Marwari goat (*Capra hircus*) is a domestic animal distributed in the Marwar region of Rajasthan, comprising of Pali, Jodhpur, Jalore, Barmer, Bikaner, Nagaur, and Jaisalmer districts. The goat (*Capra hircus*), is one of the most important animal and the goat husbandry has been playing an important role in the economy of our country with special reference to milk, meat, manure and hide production. The Present study has been planned to justify the functional importance and essentially of the liver, the largest single organ. The resemblance of the structure of liver throughout the animal kingdom, from fishes up to higher vertebrates, encourages the interest to get factual structural details of that colossal gland. Important functions performed by the liver are secretion of bile, excretion of waste product, storage of glycogen and vitamins (Vit. A, D and B), synthesis of fibrinogen, prothrombin, albumin, globulin etc., phagocytosis of foreign particles, detoxification, intermediate metabolism of carbohydrates, proteins and fats and haemopoiesis in embryo. Liver plays an important role in digestion process of these nutrient matter and energy production. An understanding of the structure of liver is vital to the interpretation of these processes.

Materials and Methods
The present study was conducted on 15 apparently healthy adult Marwari Goat (*Capra hircus*) of either sex. The liver from the freshly slaughtered animals were procured from Municipal slaughter house, Bikaner. For the histological examination the small pieces of tissues (2mm size) were collected from 15 livers. From each liver, the tissues were collected from thirteen fixed anatomical regions to explore regional differences if any. The tissues were preserved in 10% formal saline for 48 hrs. Fixed tissue were later washed in running tap water for 6-10 hours followed by dehydration in ascending grade of alcohol, clearing, embedding in paraffin wax of melting point of 58-60 °C, preparation of blocks, section cutting (5-6 µm thick), and mounting of section on albuminized slides, drying of sections and finally stained with the following routine and special histological stains to demonstrate different components of liver.

Results and Discussion
The capsule and stroma
In present histological study the liver of Marwari goat was covered by outer peritoneal and the inner connective tissue covering. Similar findings were reported by (Leeson and Leeson, 1981) [6] and (Dellmann and Brown, 1981) [4] in domestic animals, (Pareek, 2000) [10] in sheep and

Abstract

The present study was conducted in the department of anatomy, histology and embryology, Faculty of Veterinary and animal sciences, West Bengal university of animal fishery science Kolkatta. Total 15 specimens of adult black bengal goat where collected from different slaughter house of kolkatta. After slaughter of animal the samples where collected and brought to the departrmental laboratory for details study. Female genital system comprised of ovaries, fallopian tube, horn of uterus, vagina and vestibules. There were two ovaries and each of them was found to be an oval shape pale in colour organ situated in the corresponding abdominal cavity behind the kidneys and supported by the broad ligament named utero-ovarianligament. The vagina was placed along the middle floor of pelvic cavity. Vagina, vestibule and vulva exhibited usual character of other small domesticated animal. Broad ligament was attached to the lesser curvature of horn. All the above mentioned findings may be utilized by the physiologist, embryo-tranfer technologist, animal breeder and other related workers for the development of the goatery husbandry.

Key words: Histology, female genitalia, Black Bengal goat.

Introduction

Goat is the first domesticated animal for food purpose. Domestication of goat took place about 10,000 year ago in the mountains of west Asia. Goat is small, sturdy and easily adaptable animal and is the species of food animal having widest distribution over the glob the animal husbandry practice is mainly dependent upon the reproductive performances of the species consumed because highly variable structural differences are encountered particularly in the female reproductive systems among the domestic animals. It is therefore become matters of prime importance to study the structural organization of the female genitalia of a particular species.

Goat belong to the family of bovidae, genera Capra and species hircus. Scientific name of goat is Capra hircus. In India, goatery is the best suitable for barren, waste land and hilly areas where partially natural vegetation is available. The poor farmers give priority on goats keeping due to less maintinace cost as compare to cattle and buffalo. Goat is a poor man's cow because of their immense contribution to the poor people's economy.

Since goat meat has no religious bar in all sections of society, also goat meat has less fat which is desirable feather liked by man. Goat meat has ready market due to heavy demand. So the reproduction is outcome of a coordinated series of physiological phenomenon in male and the female goat. For reproduction of animal the details knowledge of gross anatomical disposition and histomorpholical organization on varies components of female genitalia of Black Bengal goat is required. The female reproductive system includes two ovaries, two uterine tubes (fallopian tubes or oviduct), uterus, vagina and vulva the oviduct has three part isthmus, ampulla and infundibulum. The uteres consist of two horns and a body and cervix. The vagina extends from uterus to vulva. Vulva consist of two labia, vestibules, clitoris. The ovum is expelled from the ovary and received by the infundibulum and carried to the uterine tube where fertilization normally occurs. The result of this investigation will certainly be a useful tool to the animal physiologist and breeders for better understanding and functional aspects of all these organs in this animal under normal as well as altered physiological condition.

Materials and Methods

The present study was conducted in the department of anatomy, histology and embryology, Faculty of Veterinary and animal sciences, West Bengal university of animal fishery science Kolkatta.

(A) Collection of specimen

Total 15 specimens of adult black bengal goat where collected from different slaughter house of kolkatta. After slaughter of animal the samples where collected and brought to the departrmental laboratory for details study.

(B) Processing of tissue for histological study

For histological slide preparation different parts of female genitalia of black Bengal goat were collected in small pieces (4-6 mm thick). The small pieces were kept in 10% neutral buffered Formalin. Small tissues of ovary, fallopian tube , uterus and vagina were taken from the sample of specimen. The specimens after fixation for 24 hours were washed under a water for 12 hours. Then tissues were passed ascending grades of alcohol(1hour each) for dehydration. Afterward the tissues were kept in half an hour of absolute alcohol and cedar wood oil for 7 days. Tissues were taken out and kept in small cubicle an xylene for10 minutes for removing of cedar wood oil. The tissues were kept in melting paraffin at the temperature 58° to 60°C. The tissues were changed into three melting paraffin in a paraffin bath for two hour each for three changes. Afterwards blocks were prepared in paraffin by standard procedure. Thin sections (5µ)were cut into with the help of rotary microtome. The sections were deparaffinised in Xylene and stained with haematoxylin an eosin as per routine method. Harris Haematoxylin (1900) was used in the staining procedure. Photomicrographs were made under light microscope in various magnifications of the luminal surface of horn, stereoscopic microscope was used.

The different parts of genitalia were measured, data were recorded and analyzed by standard statistical method.

Results and Discussion

Histomorphological organisation of various tissues of all the different components of female genitalia of Black Bengal goat have been studied in this investigation. The result have been presented under the following headings.

Ovary:

The ovaries represented the two distinct zone, outer cortex and inner medulla. The ovary was covered by the germinal epithelium. Ovarian follicles in various stages of development were found in the cortical zone, could be seen some large follicles with or without ovum.

Mature graffian follicle clearly identified in the histological slide. The blood vessels, nerves and lymphatics were found. These findings are in agreement with the Bacha et al(2000), Banks et al (1981), Dallmann et al (1998), Banerjee (1998), Frandson et al (1992) who have stated that ovary had outer cortex and inner medulla. In the cortical portion ovary contained more number of ovarian follicles. In the medullary portion there was loose connective tissue, nerve fibres and lymphatics.

Fallopian Tube:

ABSTRACT

A study conducted on the kidneys of *Marwari* sheep of either sex between the ages of 1-2 years. The morphological studies was done on the kidneys of 24 sheep and revealed that right kidney was slightly longer than the left and there was no significant difference observed between the weight, width, thickness, circumference and volume of right and left kidneys. Both the kidneys were bean shaped smooth and reddish brown in color. The renal crest or common papilla formed by the fusion of six to twelve pyramids.

Introduction

~~Ashwagandha [*Withania somnifera* (L.) Dunal] is an important medicinal plant of India belonging to Solanaceae. A native of Mediterranean region in North Africa, it is also found in Madhya Pradesh, Punjab, Himachal Pradesh, Western Uttar Pradesh and Himalayas.~~

~~It is cultivated in an area of about 4000 ha in India (Farooqui and Sreeramu, 2001). In Madhya Pradesh, it is cultivated in Neemuch, Chhindwara, Mandsaur, Seoni, Katni, Shahdol, Dewas, Dindori, Hoshangabad and Jabalpur districts. Roots are excellent for preparing medicines. Diseased leaves exhibited decrease in sugars (20%) and chlorophyll (26.5%) whereas; increase was noticed for proline (25%), free amino acids (3%) and proteins (74.3%).~~

~~The leaf blight of Ashwagandha caused by *A. alternata* revealed that a little information is available more particularly on disease prediction module in Madhya Pradesh leading to its management. Therefore, an attempt was being made for its management through fungicides, organic manure and biofertilzers.~~

Materials and Methods

The present study was conducted on 17 to 22 kg body weight bearing fifty apparently healthy adult Marwari sheep (*Ovis aries*) of either sex, 7-12 months old age. The livers were procured from the freshly slaughtered animals at Municipal slaughter house, Bikaner. The measurment for various physical parameters like weight, length,

Abstract

The present study was conducted on ureters of 15 *Marwari* sheep of either sex between the ages of 1.5 -2 years. It was a long and thin muscular tube begins from renal pelvis at the hilus and passes backward along medial border of kidney. In the Histological structure ureter was composed of tunica mucosa of transitional epithelium. The mucosa was thrown on to longitudinal folds giving the lumen a stellate appearance. Lamina propria is wide which was composed of fibroelastic connective tissue with many bundles of coarse collagen fibres. The tunica muscularis was consisted of inner longitudinal, middle circular, and outer longitudinal layers of smooth muscles. The outer layer tunica adventitia is continuous with fibroelastic connective tissue which contain blood vessels and nerve endings.

Key words: Ureter, Stellate Lumen, transitional epithelium, smooth muscle fiber.

Introduction

Marwari sheep constitutes a major portion of the sheep population in western part of Rajasthan which has 14.31 million sheep (about 40%) and plays an important role in the economy of arid and semi-arid tract. Low rainfall and scanty vegetation are common in the western part of Rajasthan and the conditions become oppressive when extreme environmental conditions bring about the adaptive changes in organs necessary for physiological adjustments in these extreme ambient conditions. The present investigation has been planned to study the gross and histological structure of the ureter to justify its importance and essentiality in the body. In mammals the ureters are the chief excretory ducts of the body.

Materials and Methods

The Gross study was conducted on 15 apparently healthy adult *Marwari* Sheep (*Ovis aries*) of either sex. The Ureters from the freshly slaughtered animals were procured from Municipal slaughterhouse, Bikaner.

For the histological examination the small pieces of tissues (2 mm size) were collected from 12 ureters (6 right and 6 left). From each, the tissues were collected from different anatomical regions to explore regional differences if any. The tissues were preserved in 10% formal saline for 48 hrs, Bouin's fluid for 12 hrs, and Zenker's fluid for 18 hrs (Singh, U.B. and Sulochana, S. 1996). Fixed tissue was latter washed in running tap water for 6-10 hours followed by dehydration in ascending grade of alcohol, clearing, embedding in paraffin wax of melting point of 58-60°C, preparation of blocks, section cutting (5-6 µm thick), and mounting of section on albuminized slides, drying of sections and finally stained with the histological stains (Luna, L.G. 1968). to demonstrate different histological structures of ureters.

Results and Discussion

Each kidney was connected to the urinary bladder by a ureter. It was a long and thin muscular tube begins from the renal pelvis at the hilus and passes backward along medial border ofthe kidney. It passes further caudally and enters in tothe pelvic cavity. It inclines inward and downward and open in to the bladder at the caudodorsal aspect. Similar findings were also reported by Konig and Liebich (2006) and Dyce *et al* (2010) in domestic animals.

In the histological structure the ureter of Marwari sheep was composed of tunica mucosa of transitional epithelium. The mucosa was thrown on to longitudinal folds giving the lumen a stellate appearance (Dellmann HD, 1993). Lamina propria is wide which was composed of fibroelastic connective tissue with many bundles of coarse collagen fibres which was dense towards the epithelium and loose towards the muscularis mucosa. The tunica muscularis was consisted of inner longitudinal, middle circular, and outer longitudinal layers of smooth muscles (Fig1. and Fig 2.). The outer layer, the tunica adventitia is continuous with fibroelastic connective tissue which contain blood vessels and nerve endings. Similar findings were also reported by Doaa Zaghloul *et al* in Camel, Woldemeskel *et al* (1998) in sows and Konig and Liebich (2006) and Dyce *et al* (2010) in domestic animals. Whereas A.R. Sreeranjini *et al* (2010) found that the sub mucosa of intra renal ureteric branches and ureter in Japanese quail contains collagen, elastic and reticular fibers. Tunica muscularis of ureter contained few elastic fibers among smooth muscle fibers. Tunica adventitia was comprised of loose connective tissue containing collagen and elastic fibers.

A B S T R A C T

A study conducted on the renal arteries of 12 *Marwari* sheep of either sex between the ages of 1.5 -2 years. Each renal arteries emanated laterally from the abdominal aorta at the level of the third lumbar vertebra. Each of them were divided into the lobar branches before reaching the hilus. Which gave 4-8 interlobar branches which ended into arcuate and interlobular arteries. The sub endothelial layer of renal artery was irregularly oriented. The inner elastic membrane showed corrugations. The middle layer consisted thick layer of smooth muscle cells. The outer layer consisted of irregular elastic and collagen fibres along with longitudinally arranged bundles of smooth muscle fibres.

Introduction

Marwari sheep constitutes a major portion of the sheep population in western part of Rajasthan which has 14.31 million sheep (about 40%) and plays an important role in the economy of arid and semi-arid tract. Low rainfall and scanty vegetation are common in the western part of Rajasthan and the conditions become oppressive when extreme environmental conditions bring about the adaptive changes in organs necessary for physiological adjustments in these extreme ambient conditions.

The present investigation has been planned to study the gross and histological structure of the kidney to justify its importance and essentiality in the body. In mammals the kidneys are the chief excretory organs of the body. They have a major role in the maintenance of fluid and electrolyte balance and in control of the blood pressure. The kidneys also produce and release a humoral agent (erythropoietin) in to the blood stream which affects the blood formation. This suggests that the organ has an extraordinary complex structure.

Materials and Methods

The study was conducted on the renal arteries of 12 *Marwari* sheep of either sex between the ages of 1.5 -2 years. The kidney with renal arteries from the freshly slaughtered animals were procured from

Abstract
The microscopic studies of Renal tubules of 6 *Marwari* sheep showed that there was no significant difference between juxtamedullary renal corpuscles and cortical corpuscles. The glomeruli in the cortical region had an average transverse diameter of 109.35±2.85 microns and average vertical diameter of 84.41±2.18 microns. The average transverse diameter of juxtamedullary glomeruli was 128.55±2.18 microns and average vertical diameter was 94.7±1.72 microns. The average diameter of PCT, DCT, collecting duct, thick and thin segment of loop of Henle was 49.91±2.02, 39.14±1.82, 42.80±0.99, 32.85±1.11, and 19.50±0.76 micron respectively.

Keywords: *Marwari* sheep, Micrometry, Renal corpuscles, loop of Henle

Introduction
Marwari sheep constitutes a major portion of the sheep population in western part of Rajasthan which has 14.31 million sheep (about 40%) and plays an important role in the economy of arid and semi-arid tract. Low rainfall and scanty vegetation are common in the western part of Rajasthan and the conditions become oppressive when extreme environmental conditions bring about the adaptive changes in organs necessary for physiological adjustments in these extreme ambient conditions. In mammals the kidneys are compound tubular glands and the chief excretory organs of the body. They have a major role in the maintenance of fluid and electrolyte balance and in control of the blood pressure.

Materials and Methods
The diameter of various parts of uriniferous tubule was measured from random samples seen under light microscope in high power (400X). The Micrometry of Renal tubules across various areas were recorded by using occular micrometer after calculating calibration with stage micrometer to record the observations on mean diameters of various parts of nephron and collecting duct.

Results and discussion
The Renal Corpuscles
Renal corpuscles in the cortical region (Fig.1) had an average transverse diameter of 134.79±5.47 microns and average vertical diameter was 98.99±3.83 microns. The average transverse diameter of juxtamedullary renal corpuscles was 158.63±2.94 microns and average vertical diameter 109.42±3.44 microns. The glomeruli in the cortical region had an average transverse diameter of 109.35±2.85 microns and average vertical diameter of 84.41±2.18 microns. The average transverse diameter of juxtamedullary glomeruli was 128.55±2.18 microns and average vertical diameter was 94.7±1.72 microns (Table 1).

The Proximal Convoluted Tubule
The diameter of the proximal convoluted tubule varied from 39.4 to 67.9 microns, with an average of 49.91±2.02 microns (Table 2). It was similar to the findings of Trautmann and Fiebiger (1957) [4] who stated that the diameter of proximal convoluted tubule ranged from 40 to 60 microns in domestic animals. Yadava and Calhoun (1958) [5] recorded an average diameter of proximal convoluted tubule to be 56, 50, 45 and 45 microns for horse, ox, sheep and goat respectively. Whereas Ommer and Mariappa (1970) [3] reported in Indian buffalo the an average diameter was 47.4 microns with a range of 40.7 to 64.7 microns and Beniwal (1995) [1] reported in camel that an average diameter was 76.63 microns with a range of 43.9 to 117.28 micron.

ABSTRACT

The experiment was conducted on stocking density of commercial broiler chicks reared in winter season under the existing climatic condition of Jharkhand. A total of 640-day-old chicks were housed at stocking densities of 0.50 sq.ft/bird, 0.75 sq.ft/bird, 1.0 sq.ft/bird and 1.25 sq.ft/bird. The result show the heaviest body weight of day-old-chicks was found to be 43.20 g in winter season. At 6th week of age the final body weight was 2589.50 g in winter season. The highest body weight was recorded as 2410.0 g on stocking density 1.0 sq.ft/bird. Stocking densities were found to be significant in the age group of 2nd and 6th weeks. Male birds were heavier (2524.42 g) than female birds (2122.40 g) at the end of sixth week. The average weekly feed consumption at 6th week of age in the birds was 1102.50 g in winter season. Seasonal effect was found to be significant up to 4th week of age. Feed consumption was recorded 1005.25 g, 912.38 g, 1006.50 g and 1006.50 g in the birds reared at the floor spaces of 0.50 sq.ft/bird, 0.75 sq.ft/bird, 1.0 sq.ft/bird and 1.25 sq.ft/bird, respectively. Significant effect (P<0.01) of winter of season on body weight gain was observed during 4th and 5th week of age. Body weight gain was recorded maximum at stocking density of 1.0 sq.ft/bird i.e. 654.25 g. Average feed conversion ratio was 1.69 (0.5 sq.ft/bird),1.52 (0.75 sq.ft/bird),1.53 (1.0 sq.ft/bird) and 1.57 (1.25 sq.ft/bird) at 6th week of age. It was apparent from the study that floor space allotted to chick during the early period was influential on rate of growth.

Key words: *Growth, density, season, feed conversion ratio*

Received 01.10.2017 Revised 21.10.2017 Accepted 29.10.2017

INTRODUCTION

In broiler production, floor space per chicken or stocking density is very important welfare factor which directly and indirectly influences and determines the level of growth of chicken. Growth in broilers is directly governed by amount of feed consumed and floor space per bird (1). Poultry producers tend to increase at the number of birds per unit of space to reduce housing, equipment and labour cost per unit of space and thereby to produce more kg of broiler per area. However, income per bird often decreases primarily due to reduction of growth rate, increased proportion of down graded carcass and greater risk of health related problems. Therefore, profitability increases with stocking density up to critical point. Although it is nearly impossible to prevent or eliminate all consequences of stocking density, a better understanding of what accurs as we increases the number of birds per unit area of floor space, however, will help to increase our awareness of potential problems and giving us the opportunity to take appropriate preventive measures. Therefore, the following study highlights necessity of space in order to express genetic potential and make the best use of feed by the broiler birds.

MATERIALS AND METHODS

Day-old-chicks of commercial strain (ven cob 400) were reared in winter season under standard management condition for 6 weeks on deep litter system under existing agro-climate condition of

Pork sandwich spread incorporated with different ingredients like honey, vitamin –C and nisin was stored and studied for the attainment of its maximum shelf life at the frozen storage. A highly significant ($P \leq 0.01$) difference for the appearance, flavor, juiciness, texture, spread ability, adhesion ability and overall acceptability. Although, the score was in decreasing trend on 45th day, even though the scale of score was rated between 'good' to 'very good' by the panelists. The remarkable acceptability for the pork sandwich spread was given by the panelists even on 45th day of storage. Total Plate Count (TPC) and Psychrophilic count on 45th day of storage were found to be 2.85 log cfu/g and 2.13 log cfu/g respectively. The Coliform, Yeast and Mould were not detected throughout the experimental period in the treated sample and it was found safe for consumption.

Spread, shelf life, TPC, Psychrophilic, log cfu/ g

Introduction

Meat as a food item is well accepted globally and do vary in its form for consumption. Meat has been identified, often wrongly, as a food having a high fat content and an undesirable balance of fatty acids. Meat consumption in India particularly varies according to its state, religion, consumption pattern and above all the taste. In fact lean meat is very low in fat (20-50 g/kg), pork and poultry have a favorable balance between polyunsaturated and saturated fatty acids (P:S) and grazing ruminants produce muscle with a desirable n-6:n-3 polyunsaturated fatty acid ratio. Storage of meat often leads to the development of abnormal odors and tastes and loss of colour. Chemical composition and biological characteristics make meat an excellent environment for microbial growth. Many factors influence the growth rate and activity of the microorganisms, including temperature, atmosphere, pH, salt concentration and product composition. The spoilage rate was related to initial pH, fat content etc. regardless of the origin of the meat (Blixit and Borch, 2002). Meat spread is a convenience product and constitutes meat, fat and other ingredients. Many such parallel products are available in the market but are not the meat based. Hence in the present study the product was incorporated with certain ingredients (honey, vitamin-C and nisin) having functional properties to improve the product quality and storage

Abstract: *Zea mays the third most important cereal crop in India but the Performance of maize is effected by the depth of sowing. A Pot experiment is conducted in Addanki, Prakasam (Dist) Andhra Pradesh with 3 different treatments Organic Inorganic and Absolute control. From overall results we observed that Organic treatment is better than other treatments because it shows better performance in all parameters like germination%, plant height, no of leaves etc and even it was observed that the tassels they emerged first in organic treatment only.*

Keywords : Maize, organic, chemical fertilizers and sustainability

I. INTRODUCTION

Maize (*Zea mays*) is a cereal grain belongs to Poaceae family crop also known as queen of cereal due to diverse uses. In India it is cultivated in most of the states throughout all the season. India ranks 3rd in maize after Rice and Wheat crop, It is staple human food, feed for livestock, for fermentation and many industrial uses. It is having abundant starch (65%). There are two types of milling. Wet milling produces industrial starch like sweeteners, also produces various modified maize starch for paper lamination, textile wrap, sizing and laundry finishing. Dry milled products are animal feed, brewing, breakfast cereals, other food. In India, dry milling is the predominant process for flour and animal feed, fermentation and distilling industries and composite flours. In the new millennium, it is an alternate crop to rice and wheat. About 35% production is consumed by human, 25% poultry and cattle 15% food processing calorically (higher perceived sweetness) other than sugarcane or sugar beet.

The major maize growing states are Karnataka, Maharashtra, Madhya Pradesh, Tamilnadu, Telangana, Bihar and Andhra Pradesh. Karnataka is the largest producer with 1.29million hectares area under cultivation and 3.55 million tons production followed by Maharashtra with 1.16million hectares area under cultivation and 3.54 million tons of production. (Directorate of Economics and statistics, DAC&FW) .Maize is grown in different types of climates but performs well in hot regions with annual rainfall of 60cm. It can grow in all types of soils but loamy sandy to clay loamy soils with abundant organic matter are preferred. The pH of 6.5-7.5 is preferred. In India maize is mostly used for poultry (47%) followed by direct consumption (20%). The average yield of maize is about 3 tonnes per hectare which is far less than that of 5 tonnes per hectare in countries like USA, China.

The average yield of maize in India is less due to many biotic and abiotic factors like weeds, pests, climate and soil conditions out of which proper sowing depth is one and most important for proper germination and yield. Therefore proper depth of sowing is to be determined and maintained to maximize the growth and yield.

II. MATERIALS AND METHODOLOGY

Experiment location -The pot experiment conducted in the kharif season of year 2020 (during the time of covid-19) at Addanki location to find the result under different climatic conditions. The location of the experiment are:-Addanki, Prakasam(dist) the latitude of Addanki is 15.8107° N, longitude is 79.9724° E Soil : the soils in Addanki (A.P) vary from black to sandy loam soils. Annual rainfall of 906mm and the average temperature is 28.5°c and semi arid region. Before sowing the seeds we have given Basal dosages of urea, NPK and FYM (farm yard manure). while top dressing we have given same Basal dosages of urea, NPK and FYM (farm yard manure) to the soils for better growth. The irrigation is given for every two days and Data were collected on 10 ,20,30,40,50 days after sowing .Growth parameters like Plant height, No. of Leaves, Leaf length, Leaf width were collected.

[4]Department of Agricultural Economics, College of Agriculture, Kotwa, Azamgarh (U.P.), India.
[5]Department of Agricultural Economics, College of Agriculture, Kotwa, Azamgarh (U.P.), India.

Abstract

The main objective of the present study was to analysis the economics and benefit cost ratio of Brinjal in two villages of Ghazipur district of Uttar Pradesh, India. It was found that the farmers of all selected randomly groups has been taken the crop on their field through a good advance package of practices, therefore their yield and net return in all size groups increased respectively in time. The study concludes yield and net return should be increased in future if they go through a good farm plans along with better crop management systems.

Key Words: Village, Farmers, Yield, Income, Farm plans.

Introduction

Brinjal (*Solanum melongena* L.) is warm season crop its plant not with stand frost the main sowing season being during July-August for a good yield 20-25 tons of FYM per hectare incorporated into the soil at the time of field preparation. It is necessary to maintain an even moisture supply in the soil; over watering is as harmful as insufficient irrigation. In this crop, phomopsis wilt is the most important fungal disease and is seed borne. Hot water treatment of the Seed helps to reduce the incidence of the disease. Little leaf is caused by mycoplasma and can be partially controlled with antibiotics. Brinjal is prone to attack by many damages caused by insects, pests, fungus, bacteria and viruses Purohit ML and Khatri AK (1973). Brinjal productions area consistently and extensively damaged by brinjal fruit and shoot borer and other fruit borer insects reported by Kuppu Swamy and Balasubramanian (1980). To reduce pest linked damage in brinjal as well as to protect the environment from adverse effect of pesticides, as an insect resistance management strategy Ghosh *et al.*, (2003). In India brinjal is the major source of profitable income for farmers because of local demand and it is a perennial crop so that fruit can be harvested throughout the year. A large number of brinjal varieties and hybrids are grown by small, medium, large size of farmers throughout the year.

Materials and Methods

The present study was conducted in two randomly selected villages namely Jaitpur (Block-Sador) and secondly Gaura (Block-Sadat) in Ghazipur district of Uttar Pradesh, India with farmers Scientist Collaborations in demonstrated groups small, medium and large size while selected randomly seven farmers from each groups Narendra hybrid Baigan-1 has been suggested seed rate 500-600 gram per hectare during field preparations 25 tons of FYM allowed to the soil planting distance line to line 60-75 cm and plant to plant are 45-60 cm. was proposed. Crop was taken on the field during July-August Season N:P:K:@ 100:50:25 Kg/hectare for better quality and better yield advised. All the advance package of practices has been specify for timely whenever needed. Survey method has been used to collect the data and tabular analysis was being used. Family schedule has been used to collect the data from the selected farmers according to their size of holdings, family size, area of the productionand income of the crop etc.The economic has been calculated at their current price rates.

Introduction

i also called 'red pepper' is an important cash ndia and is grown for its pungent fruits, which both green and ripe (the latter in the dried form) pungency to the final. As a condiment, it has indispensable in every Indian home. It is also dicinally, and in chutneys and pickles. Capsicum. are herbaceous or semi woody annuals or y high rainfall during its growth is harmful. igation and good manuring, excellent crops can in sandy and light alluvial loam as well as in red ils. As a garden crop, it is sometimes allowed to a stand-over crop for one or two seasons. The ughed and harrowed 3 or 4 times to obtain a . Recommended dose of FYM is better for good d better qualities. The Chilli is generally ted, through direct sowing. Foliar spray of Zinc not increase the yield and quality of the crop f Vadhvela (1967). The combined spray of Zinc, d iron through soil or its foliar Spray is better for ding. Suryanarayana and Hariprasad (1985) that these micronutrients increased the green Chillies. Rosman and Rosman (1993) give details hillies inther second edition. Seeds taken from well matured fruits selected for the purpose are mixed with ashes and shown evenly in well-manured nursery beads. The nursery treatment and other recommended practices had been taken at the time of their requirements.

Materials and Methods

The present study was conducted on the field in Ghazipur district of Uttar Pradesh, India in randomly selected two villages namely Bishunpura (Block-Karanda) and Secondly Gajipatpur (Block-Bornc) through farmers-scientist collaborations ranging small, medium and large size farmers groups. Seven farmers from each groups has been selected randomly. Pusa Sadabahar Chilli Variety has been offered for the demonstrations. Allowed 1 Kg. seed for a hectare to maintain line to line distance about 50 Cm. and plant to plant distance 45 Cm. The crop has been taken on the field on the field during August-September. All the package of practices has been introduced to the farmers for their better yield and qualities regarding time to time applications. All the information has been collected through survey method and tabular analysis was being used. Family schedule has been used to collect the data regarding family size, area of the crop, expenditure and net income. Emphasis has been given on cultural operation irrigation and other recommended practices for the upliftment of the crop.

Microbial fertilizers: Their potential impact on environment sustainability and ecosystem services

Mikhil Milton, Dr. Dipti Bisarya, Vinai Kumar, AK Singh and Chandra Mohan Mehta

DOI: https://doi.org/10.22271/chemi.2020.v8.i6sg.11120

Abstract
Microbial fertilizers have been used by farmers in agriculture for more than a century starting from rhizobia inoculants to a more recent Plant Growth Promoting rhizobacteria (PGPR) for increasing the nitrogen fixation and synthesis of plant hormones. Biofertilizers consists of microorganism that improves the nutrient content of the soil and enhances their availability to the crops. Pant nutrients represent the most crucial component of sustainable agriculture. At present, soil management approaches are largely dependent on chemical-based inorganic fertilizers which have posed a serious threat to human health and the ecosystem. Even though the usage of various chemical fertilizers and pesticides has provided high yield and consequently, population growth over the last century. The environment can no longer tolerate these practices as it has sustained significant damage such as loss of soil quality, atmospheric pollution, high eutrophication, and groundwater contamination. Thus maintaining food security along with environmental sustainability has become a massive challenge. However, the adoption of bio fertilizers represents a dependable and eco-friendly solution. Biofertilizers being organic in nature holds a vast expectation in fulfilling nutrient requirements, soil and water quality thus providing a low-cost approach compared to synthetic fertilizers in managing crop yield without causing much harm to the environment. Biofertilizers are becoming an irreplaceable component in Integrated Nutrient Management in order to achieve sustainability in agriculture. This review paper brings to light the potential effects of biofertilizers on ecosystem services and environmental sustainability.

Keywords: Microbial fertilizers, rhizobia inoculants, PGPR, ecosystem, eutrophication, pesticides

Introduction
Soil nutrients are critical for continuous growth and efficient production of crops thereby meeting the demands of the ever-increasing population with healthy food. India needs 280 MT of food grains to meet the requirement of the population (Singh *et al.*, 2016)[39]. Fertilizers are the main source of nutrients and hence agriculture is completely relied on fertilizers for increasing the yield of the crops. Fertilizers include synthetic, organic, or biofertilizers and their characteristics are different and each may possess a different ability to improve the yield of the crops (Chen, 2016) [6]. Chemical fertilizers are widely used to fulfill the nutrient requirement of the crops as they provide rapid results by providing nutrients over a short period of time. The nutrients are provided in high concentration which results in accelerated growth but causes a massive toll on the environment polluting both land and water by the deposition of harmful chemicals (Mahdi *et al.*, 2010) [41]. This practice became much prominent after the green revolution in India. Green revolution bought about a great change in the Indian agriculture scenario with the usage of high-yielding varieties, nutrient management (synthetic and organic fertilizers), and agriculture chemicals including pesticides, fungicides, and herbicides. These practices made India sufficient during the time of post-independence (Dotaniya *et al.*, 2014) [17]. Extensive usage of chemical fertilizers adversely affected the soil health reducing soil productivity. Increased ratios of fertilizers application i.e. 61:7:19:2:1 and 61:4:18.7:1 were practiced in Punjab and Haryana instead of the appropriate ratio of 4:2:1 (NAAS, 2014). This leads to a decrease in the yield and multi-nutrient deficiency in crops. Biofertilizers are considered to be among the most promising means to improve the productivity of the crop in an environment-friendly manner. Microbes present in biofertilizers consist of growth-promoting characteristics which play a pivotal role in optimizing various

Abstract: In the country, large numbers of flowers are grown in different parts based on soil and climate. There are also depending on likings and preferences of the people for a specific type of flower or flowers such as temple garlands, decorative garlands or orchids. Important flowers are rose, marigold, chrysanthemum, jasmine, lily tuberose, aster, zinnia, carnation, gladiolus, gaillardia etc. Flowers are tender and hence highly perishable. They are generally used in fresh form but they have very short shelf life. This poses great problems in their marketing, particularly long distance marketing. In this review paper, we have observed channels of marketing flowers and duly highlight the cost of marketing, problems and profit in this business. In the conclusion, we have also demanded the well organised marketing system for the improvement of marketing of flowers in the country.

Introduction

Flowers are very intimately associated with most social and religious activities in the country. In social life, flowers are offered to welcome, to felicitate and to greet friends or relatives and guests in functions. Flowers are needed in all the religious ceremonies and functions including marriages. Garlands and big wreaths are offered on dead bodies of martyrs, very important persons, and national heroes as a mark of respect and gratitude for their work and sacrifice. Flower is a token of love and tenderness. They are most wanted because of they are colourful and fragrant. Flowers are also used for extracting essential oils, which are used in perfumes. Many flowers have medicinal values and hence are used in Ayurveda. Therefore, flowers of different kinds are always in demand and there is need of understanding and improving marketing of flowers in India as well as world [1-10].

Marketing channels

Flower cultivation is concentrated in the hinder-land of big cities like Mumbai, Pune, Bangalore, Mysore, Chennai, Calcutta, Delhi etc., But with the development of quick transport facilities and refrigerated or insulated vehicle, flowers are transported to distant markets including exports. For successful marketing of flowers, well-developed markets and well-organised marketing system is necessary [11-20].

In the case of rose flower mostly following marketing channels were involved:

Channel I - Producer → Commission agent → Retailer → Consumer

Channel II - Producer → Retailer → Consumer

Channel III –Producer → Consumer

Since metro and cities as like Delhi, Mumbai, Chennai, Kolkata etc. is a big market, therefore more than 50 % flower were sold through channel I and remaining were sold through Channels II and Channels III. Thus, the local market area was less spread. Marketing costs, margins and producer's share in consumer's rupee were more in marketing channel II in comparison to marketing channel I for roses sold after marketing garlands. There was increase in value of roses when sold in the form of garlands.

In the case of orchids, mostly following marketing channels were involved:

Channel – I – Producer → Local buyer → Consumer

Channel – II – Producer → Wholesaler → Retailer → Consumer

The Cost of marketing worked out to nominal per spike. In this transport cost was the major followed by packing. Marketing Orchids in the distant markets was more remunerative.

In the case of Gladiolus mainly two marketing channels were found:

Channel- I – Producer → Wholesaler → Retailer → Consumer

Channel- II – Producer → Contractor → Retailer → Consumer

Channel – I was more important, produce passing through this channel than channel – II produce passing through it. This showed that it is more remunerative to sell flowers in the market where the forces of demand and supply are clearer and price determination is competitive and open or transparent.

In the case of Jasmine popular marketing channel was

Producer – Trader-cum-Commission agent – Retailer – Consumer' found.

In the case of marigold marketing channels were identified

Channel – I – Producer → Commission agent → Retailer → Consumer

Channel – II – Producer → Retailer → Consumer

Channel – III – Producer → Consumer

The flowers were sold in two ways

(i)In Loose form

(ii)In the form of garlands

Comparative studies on urinary system of Aseel and Rhode Island Red (RIR) breeds of poultry

Mukesh Kumar, Gaurav Panday, KN Singh, SS Sanger, PK Chaudhary and Pramod Kumar

Abstract
The present comparative study was conducted to evaluate the urinary system of Aseel and Rhode Island Red (RIR) breeds of poultry and experiments was done on 24 apparently healthy birds of Aseel and RIR breeds of poultry which were divided into grower and adult groups. Each kidney was divided into cranial, middle and caudal divisions by the grooves present on the ventral surface. In RIR grower as well as in adults, weight, volume and maximum width of kidney to body weight was more in RIR grower than Aseel. While, in adult birds it was more in Aseel than RIR. The ureter had two parts, renal and pelvic. Highly significant difference was observed in the weight, length and volume of both the ureters of an RIR grower than Aseel.

Keywords: Aseel, RIR, Gross morphology, Urinary system

Introduction
Avian urinary system has consisted of the kidney and ureter only. Kidneys play an important role in maintaining homeostasis. The ureter is an important organ, which carries urine to the cloaca. There was no literature available on the gross studies of the urinary system of this breed. The present work was undertaken to study the comparative gross morphology of the urinary system of Aseel and RIR breeds of poultry.

Materials and Methods
The experiment was done on 24 apparently healthy birds of 2 groups of RIR and Aseel breeds of poultry irrespective of sex. The birds were divided into grower and adult (group I and II) respectively. Both the groups had 12 birds, 6 birds of each breed. After taking the body weight, birds of the specified age group were sacrificed by cutting jugular vein and common carotid artery. Kidney and ureter were collected and their length and width were recorded by using Vernier caliper, weight was taken with the help of electronic monopan balance whereas, volume was taken with the help of the water displacement method. The data were statistically analyzed by using analysis of independent mean "T" test as per Snedecor and Cocharan (1994) [2].

Results and Discussion
Kidney: The colour of the kidneys was reddish brown. The right and left kidneys were retroperitoneal and present symmetrically in a depression on ventral surface of synsacrum and renal fossa of ilium. Depression on the synsacrum was extended upto the distal third. The cranial margin of each kidney was extended immediately caudal to the lungs between the sixth and seventh thoracic vertebrae. These extended upto the rostral third of gizzard in grower birds while, in adult birds upto the distal third of gizzard. On the surface of the kidney small projections were seen in all three divisions. This might be the external surface of the renal lobule.

The dorsal surface of the kidney had the impression of lumbosacral mass, which extended from the medial border to the middle of the kidney. The impressions were shallow in grower birds that an adult bird in both breeds. Each kidney was divided into cranial, middle and caudal divisions by the grooves present on the ventral surface. The groove was shallow and directed caudo-laterally from median plane. However, (Nubipour *et al.* 2009) [1] started that the groove was transverse. External iliac artery was present in the groove between the cranial and middle division. Groove containing ischiatic artery seprated the middle and caudal division of the kidney.

In both breeds and age groups, the shape of the kidney was similar. The cranial division was oval elongated, middle division was slender and caudal division was irregular.

Abstract
Now a day due to various side effects of allopathic medicine, scientists of pharmaceutical industries and research centers have been engaged to explore the pharmacological properties of herbal plants. The present review explains the pharmacological properties of *Boerhavia diffusa* plant. This plant commonly known as punarnava, is herb of family Nyctaginaceae. *B. diffusa* known to have medicinal properties and used as Ayurvedic medicine in India. Battery of phytochemicals like alkaloids, flavonoids, rotenoids and phytosterols has been found in the plant which are responsible for its various pharmacological properties such as analgesic, anti-*inflammatory*, diuretic, hepatoprotective, immunomodulator and nephroprotective, antiulcer and antihistaminic etc. Moreover, several new phytochemicals are discovered which again validate its medicinal importance. This review presents the evidence-based pharmacological properties of *B. diffusa*. In conclusion *B. diffusa* contain many bioactive phytochemicals that may be use as prophylactic as well as for cure of various ailments of human and animals.

Keywords: *Boerhavia diffusa,* bioactive phytochemicals, pharmacological properties, hepatoprotective and Immunomodulator

Introduction
Boerhavia diffusa, a perennial herb with stout root stock and many procumbent branches, flowers pale rose coloured, small, short-stalked; fruits highly viscid and one-seeded with many vernacular names viz. Punarnava, Raktapunarnava, Shothaghni, Kathillaka, Kshudra, Varshabhu, Raktapushpa, Varshaketu amd Shilatika in India. The genus *Boerhavia* (often spelled as Boerhaavia) was named in honor of Hermann Boerhaave (1668–1738), an eighteenth century Dutch botanist, humanist and physician at the University of Leiden, while the species got the name from typical diffuse branching. The botanical name of the plant is often written in the literature as *Boerhaavia diffusa* (Hiruma-Lima *et al*., 2000) [33], but Linnaeus Latinized Boerhaave's name to Boerhavius and adopted the spelling *Boerhavia diffusa*, which is the correct spelling to be used (Spellenberg, 2004) [75].
Punarnava is a very important medicinal herb of Ayurveda. Its name is derived from two words, *Punar* (= once again /regaining/restoring) and *Nava* (=new, renew or young), so the literal meaning of the name is, one which becomes new or young again. This name signifies the rejuvenating property of Punarnava. It is a Rasayan herb of Ayurveda which renews the body or restores youth.

RESEARCH ARTICLE

Impact of Different Therapeutic Protocols on Blood Biochemical Markers and Fertility in Anestrus Sahiwal Cows

Safayat Husain[1], Rajesh Kumar[1]*, Bhoopendra Singh[1], Sushant Srivastava[1], Rabindra Kumar[1], Pramod Kumar[2], Nilufar Haque[3]

Abstract

Bovine anestrus syndrome is a multifactorial disorder of the reproductive system. The problem is severe in suburban and rural areas of the country. The present study was aimed to evaluate the effect of different therapy on biochemical parameters and fertility response in 24 anestrus Sahiwal cows. Anestrus cows were randomly divided into four equal groups of six animals each, and were subjected with Lugol's iodine 2%, cervical painting with per rectal massage of genitalia thrice on alternate day (G1, n=6), XXX herbal bolus 1 bid for 2 days, repeated on day 11 & 12 later in non-respondents (G2, n=6), and modified ovsynch protocol which consisted of 100 mg hydroxy progesterone caproate injected daily s/c for 6 days followed by inj. GPG (G3, n=6), while one group was kept as untreated control (G4, n=6). Blood samples were collected thrice from all cows, *i.e.*, pretreatment day-0 (S1); post-treatment at induced estrus/AI (S2) and day 21 post-AI (S3), for estimation of serum progesterone and biochemical constituents. In general, except progesterone, the mean values of serum glucose, total cholesterol, total protein, albumin, calcium and phosphorus were significantly ($p<0.05$) lower at d-0 than the corresponding values at induced estrus and day 21 post-AI in treatment groups G1, G2 and G3; whereas, the periodic values did not differ significantly in control group G4. The estrus induction response was 100% in all treated cows with comparable conception rates among different therapeutic protocols (83.33, 66.66 & 83.33 %) as against nil response in control group G4. The results suggest that bovine anestrus syndrome can be managed well with comparatively low-cost Lugol's iodine and herbal therapeutics.

Ind J Vet Sci and Biotech (2021): 10.21887/ijvsbt.17.4.11

Introduction

Bovine anestrus syndrome is a multifactorial disorder of the reproductive system, characterized by the absence of estrus either due to lack of estrus or failure of its detection. The problem is severe in suburban and rural areas of the country. Wide variation in the incidence of anestrus has been reported in cattle and buffalo across the country (Butani *et al.*, 2008 and Ashoo *et al.*, 2020). The clinical syndrome can be diagnosed using anamnesis, ovarian palpation, progesterone estimation, and ultrasonography; being multifactorial, it can be treated according to their cause; however, there is no single panacea to correct it. Many non-hormonal and hormonal drugs have been tried and tested to treat anestrus syndrome (Kumar et al., 2011; Dhami et al., 2015; Kumar *et al.*, 2020; Kumar *et al.*, 2021). Among herbal therapeutics, various types of tropical plants are used traditionally to augment reproductive performance. Some plants contain secondary metabolites which are effective in inducing estrus in post-partum anestrus cows. The hormonal drugs being costly cannot always be affordable under field conditions. Thus, the present study was aimed to assess comparative efficacy of Lugol's iodine, XXX bolus (herbal heat inducer) and modified ovsynch protocol on fertility response in post-partum anestrus cows and its effect on blood biochemical profile.

Materials and Methods

The study was carried out under farm conditions during the year 2019-20 in the semi-urban areas of Ayodhya district in UP, India. The experimental protocol was approved by Institutional Animal Ethics Committee of the College. At preliminary stage, 34 cows were selected on the basis of history, breeding records and per-rectal examination. The

Micrometry of renal corpuscles and renal tubules in *Marwari* Sheep (*Ovis aries*)

Krishna Nand Singh, Sanjeev Joshi, Rakesh Mathur, Mukesh Kumar and Pramod Kumar

Abstract

The microscopic studies of Renal tubules of 6 *Marwari* sheep showed that there was no significant difference between juxtamedullary renal corpuscles and cortical corpuscles. The glomeruli in the cortical region had an average transverse diameter of 109.35±2.85 microns and average vertical diameter of 84.41±2.18 microns. The average transverse diameter of juxtamedullary glomeruli was 128.55±2.18 microns and average vertical diameter was 94.7±1.72 microns. The average diameter of PCT, DCT, collecting duct, thick and thin segment of loop of Henle was 49.91±2.02, 39.14±1.82, 42.80±0.99, 32.85±1.11, and 19.50±0.76 micron respectively.

Keywords: *Marwari* sheep, Micrometry, Renal corpuscles, loop of Henle

Introduction

Marwari sheep constitutes a major portion of the sheep population in western part of Rajasthan which has 14.31 million sheep (about 40%) and plays an important role in the economy of arid and semi-arid tract. Low rainfall and scanty vegetation are common in the western part of Rajasthan and the conditions become oppressive when extreme environmental conditions bring about the adaptive changes in organs necessary for physiological adjustments in these extreme ambient conditions. In mammals the kidneys are compound tubular glands and the chief excretory organs of the body. They have a major role in the maintenance of fluid and electrolyte balance and in control of the blood pressure.

Materials and Methods

The diameter of various parts of uriniferous tubule was measured from random samples seen under light microscope in high power (400X). The Micrometry of Renal tubules across various areas were recorded by using occular micrometer after calculating calibration with stage micrometer to record the observations on mean diameters of various parts of nephron and collecting duct.

Results and discussion

The Renal Corpuscles

Renal corpuscles in the cortical region (Fig.1) had an average transverse diameter of 134.79±5.47 microns and average vertical diameter was 98.99±3.83 microns. The average transverse diameter of juxtamedullary renal corpuscles was 158.63±2.94 microns and average vertical diameter 109.42±3.44 microns. The glomeruli in the cortical region had an average transverse diameter of 109.35±2.85 microns and average vertical diameter of 84.41±2.18 microns. The average transverse diameter of juxtamedullary glomeruli was 128.55±2.18 microns and average vertical diameter was 94.7±1.72 microns (Table 1).

The Proximal Convoluted Tubule

The diameter of the proximal convoluted tubule varied from 39.4 to 67.9 microns, with an average of 49.91±2.02 microns (Table 2). It was similar to the findings of Trautmann and Fiebiger (1957) [4] who stated that the diameter of proximal convoluted tubule ranged from 45 to 60 microns in domestic animals. Yadava and Calhoun (1958) [5] recorded an average diameter of proximal convoluted tubule to be 56, 50, 45 and 45 microns for horse, ox, sheep, and goat respectively. Whereas Ommer and Mariappa (1970) [3] reported in Indian buffalo that an average diameter was 47.4 microns with a range of 40.7 to 64.7 microns and Beniwal (1995) [1] reported in camel that an average diameter was 76.63 microns with a range of 43.98 to 117.28 micron.

Abstract

The study was conducted to investigate effect of vitamin E and zinc on cortisol hormone during peripartum period in Karan Fries cows. Sixteen pregnant Karan Fries (KF) cows were selected from the herd of National Dairy Research Institute (NDRI) Karnal, on the basis of their body weight, BCS and parity. Eight cows were kept in control group and other eight cows in treatment group which were supplemented with 1000 IU vitamin E and 60 ppm zinc per day per cow. Blood samples were collected on the days -60, -45, -30, -15, -7, 0, +7, +15, +30, +45, +60 with respect to expected date of calving. Plasma was analyzed for Cortisol hormone. Body weight and Body condition score (BCS) of all the experimental animals were recorded on the day of blood collection. Plasma cortisol was significantly ($P<0.001$) lower in treatment group as compared to control group (2.98 vs. 3.10 ng/ml). There was a steady increase in the body weight of control and treatment cows towards parturition and was found a significant ($P<0.001$) difference between the control and treatment groups. The body condition score of control and treatment groups decreased by 33.05% and 17.76% respectively after calving. This showed that the control group cows lost significantly ($P<0.001$) more body condition as compared to treatment group cows. The results of this study indicated that supplementation of vitamin E and zinc have beneficial effects in changing cortisol level in this way that improves body condition and decreases the effect of parturition stress in the animals.

Keywords: Cortisol, Body Condition Score, Energy Metabolites, Peripartum period, Vitamin E, Zinc

Introduction

Cortisol is a steroid hormone that helps the body respond to stress. It is also called the stress hormone. It is released in response to stress and low blood glucose concentration. It is the principal glucocorticoid during the reproduction and lactation of cows [1]. Adrenal secretion of cortisol is modulated by a complex negative feedback mechanism involving the central nervous system, hypothalamus, pituitary and adrenals [2]. The synergistic action of endogenous cortisol along with other hormones has been found to be critical for parturition and initiation of lactation in domestic animals [3]. At term the corticosteroid concentration rises in the plasma of peripartum cows [4, 5a]. Plasma total cortisol level increased from 2.13 ng/ml to 2.62 ng/ml till one day prepartum and increased to 6.08 ng/ml at parturition in crossbred cows. The level decline from 3.42 ng/ml on 1 day postpartum to 2.49 ng/ml at 3 day postpartum [6]. In Murrah buffaloes level of cortisol was found 1.46 ng/ml at 30 day prepartum which increased to 3.78 ng/ml at parturition and decline to 1.89 ng/ml at 3 day postpartum[2].

Cortisol concentrations have been used as a physiological marker of stress. During heat acclimation there is reduction of plasma cortisol that helps in reduction of heat production of animals[7]. An initial increase in cortisol occurs due to acute heat stress followed by a decline after prolonged exposure in cows. The animals adjust physiologically to elevated heat loads by decreasing adrenal corticoid output [7]. Cortisol concentrations have been found lower in high producing cows at day 30 than at day 90 or in nonlactating cows due to reduced pulse amplitude. Low cortisol concentrations likely participate in the enhanced production observed in high producing cows [8]. Heat exposure at temperature above 40°C has been found to raise the cortisol level to almost double the pre-exposure levels [9]. Similar results were also found by others in hot-dry, hot-humid and winter seasons in crossbred cows (4.17, 4.35 and 2.09 ng/ml respectively) [10].

Materials and Methods

Experimental design

The study was conducted at the Cattle Yard of National Dairy Research Institute, Karnal, Haryana (India). Karnal is situated on an altitude of 250 meter above mean sea level, latitude and longitude position being 29°42" N and 79°54" E respectively. The maximum ambient temperature in summer goes up to 45°C and minimum temperature in winter comes down to 0°C with a diurnal variation in the order of 15-20°C. For the present study 16 Karan Fries (KF) peripartum cows were selected from the herd of National Dairy Research Institute, Karnal, 8 cows kept in Control group and other 8 cows in Treatment group. The cows in the control group were supplemented with no vitamins, and in the treatment group, they were given 1,000 IU of vitamin E and 60 ppm zinc per cow per day from 60 days prepartum to 60 days postpartum. Animals were maintained in open area with asbestos roof in the sides of the open area, where the animals were offered feed. The open area had brick floor. The animals were free to move inside the controlled open area. All the animals were fed as per the standard feeding practices followed at the NDRI farm.

Blood sampling

Blood samples (10 ml/cow) were collected in the morning (6:00 AM) before feeding in sterile heparinised vacutainer tubes (BD VacutainerTM, UK) from jugular vein puncture, posing minimum disturbance to animal, on the days -60, -45, -30, -15, -7, 0, +7, +15, +30, +45 and +60 with respect to expected date of calving. Day '0' represented the day of calving. Blood samples were brought to the laboratory in the icebox soon after collection and centrifuged at 1,200×g at 4°C for 20 min to separate the plasma. Plasma samples were stored at -20°C until analysis of Cortisol.

Sample analysis

Blood sample was analyzed for cortisol. Plasma Cortisol was determined by "Cortisol EIA kit" from Cayman Chemical Company, Ann Arbour, USA. Body weight and Body condition score (BCS) of all the experimental animals was recorded on the day of blood collection using a scale of 1 to 5.

Statistical analysis

Statistical analysis of data was carried out to find the mean ± SE. Two-way ANOVA was done to find significant difference between groups and days of experiment and their interaction by using SYSTAT 3.1 (2004) software.

Results and Discussion

Cortisol

The mean±SE of plasma cortisol concentration of control cows was 2.87±0.09 ng/ml 60 days before calving and on the day of calving it increased to 3.24±0.07 ng/ml. Further, in treatment group the plasma cortisol concentration was 2.78±0.03 ng/ml 60 days before calving and on the day of calving it increased to 3.10±0.03 ng/ml. In present study, the overall mean±SEM of plasma cortisol concentration was found significantly ($P<0.001$, Table 2) lower in treatment group as compared to control group. Plasma levels of cortisol varied between 2.3-3.5 ng/ml during pre and postpartum in Holstein cows [11]. After 7 days of calving it's level started decreasing up to 60 day of lactation.

ADOPTION LEVEL OF POULTRY FARMERS REGARDING THE SCIENTIFIC BROILER FARMING PRACTICES IN EASTERN PLAIN ZONE OF UTTAR PRADESH

Mustak Ahmad[1], H.C.Verma*[2], R.K. Singh[3], Puspendra Kumar Singh[4] and Vijayendra Verma[1]

Abstract:

The present study was conducted in eastern plain zone (Faizabad and Ambedker nagar district) of Uttar Pradesh. Faizabad and Ambedkar Nagar district of Uttar Pradesh were selected purposively which has maximum poultry farmers. Data was collected by pre-structured interview schedule, from each district there was two blocks are also selected purposively which has maximum numbers of poultry farmers. From each selected block 24 poultry farmers were selected by applying simple random sampling technique. Total 96 poultry farmers were selected for the study. Those poultry farmers were selected which has minimum 500 flock size. Majority of the Poultry farmers (41.67 %) had the medium adoption level regarding scientific broiler farming practices (6-8), followed by whereas 40.63 percent in low level (<6) of adoption and 17.71 percent high level (>8) of adoption respectively about housing, brooding, feeding and health care management.

Keywords: *Adoption level, broiler farming, housing, brooding, feeding and health care management.*

Introduction:

Rogers (2003) defined adoption as a decision to make full use of an innovation as the best course of action available. In the present study, adoption refers to the extent to which selected scientific broiler farming practices are used by a broiler farmer completely and partially at his farm. It is estimated that in India 90 percent of the poultry in the Southern region, 80 per cent in the Western region, and 70 per cent in the Eastern region and 10 per cent in the Northern region were under a vertically integrated system (Rajan 2006). The Indian poultry sector with 7.3 per cent growth in poultry population, has witnessed one of the fastest annual growth of about 8 per cent in eggs and 10 per cent in meat production, over the last decade (2003-2013) amongst all animal based sectors (CARI vision 2050). The high growth has placed India at 3rd position in egg production after China and USA with a production of 75 billion eggs and 5th position in chicken meat after USA, China, Brazil and Mexico (Kornel, 2008) with a production of 3.7 million metric tons of chicken meat. Poultry farming plays an effective role in improving the economic status of the rural people by increasing their income besides providing nutritious food through meat. According to 19th livestock census 2012, there are 18.66 million poultry birds in Uttar Pradesh of which, 7.24 million are farm poultry. Among the farm poultry, broilers constitute 6.6 millions.

Material And Methodes:

The present study was conducted in eastern plain zone (Faizabad and Ambedker nagar district) of Uttar Pradesh, from each district there was two blocks are also selected purposively which has maximum numbers of poultry farmers. From each selected block 24 poultry farmers were selected by applying simple random sampling technique. Total 96 poultry farmers were selected for the study. Those poultry farmers were selected which has the minimum 500 flocks size of broiler farming at the time of investigation. The primary data was collected by personal interview method using a structured interview schedule. The collected data were tabulated, scored and analyzed in the light of the objective.

To find the adoption level of scientific broiler farming practices among poultry farmers.

Result And Discusion:

Table 1.1: Different adoption level scientific broiler farming practices of poultry farmers according to their existing practices (N=96)

Abstract:

The present study was conducted in eastern plain zone (Faizabad and Ambedker nagar district) of Uttar Pradesh. Faizabad and Ambedkar Nagar district of Uttar Pradesh were selected purposively which has maximum poultry farmers. Data was collected by pre-structured interview schedule, from each district there was two blocks are also selected purposively which has maximum numbers of poultry farmers. From each selected block 24 poultry farmers were selected by applying simple random sampling technique. Total 96 poultry farmers were selected for the study. Those poultry farmers were selected which has minimum 500 flock size. Majority of the Poultry farmers (41.67 %) had the medium adoption level regarding scientific broiler farming practices (6-8), followed by whereas 40.63 percent in low level (<6) of adoption and 17.71 percent high level (>8) of adoption respectively about housing, brooding, feeding and health care management.

Keywords: *Adoption level, broiler farming, housing, brooding, feeding and health care management.*

Introduction:

Rogers (2003) defined adoption as a decision to make full use of an innovation as the best course of action available. In the present study, adoption refers to the extent to which selected scientific broiler farming practices are used by a broiler farmer completely and partially at his farm. It is estimated that in India 90 percent of the poultry in the Southern region, 80 per cent in the Western region, and 70 per cent in the Eastern region and 10 per cent in the Northern region were under a vertically integrated system (Rajan 2006). The Indian poultry sector with 7.3 per cent growth in poultry population, has witnessed one of the fastest annual growth of about 8 per cent in eggs and 10 per cent in meat production, over the last decade (2003-2013) amongst all animal based sectors (CARI vision 2050). The high growth has placed India at 3rd position in egg production after China and USA with a production of 75 billion eggs and 5th position in chicken meat after USA, China, Brazil and Mexico (Kornel, 2008) with a production of 3.7 million metric tons of chicken meat. Poultry farming plays an effective role in improving the economic status of the rural people by increasing their income besides providing nutritious food through meat. According to 19th livestock census 2012, there are 18.66 million poultry birds in Uttar Pradesh of which, 7.24 million are farm poultry. Among the farm poultry, broilers constitute 6.6 millions.

Material And Methodes:

The present study was conducted in eastern plain zone (Faizabad and Ambedker nagar district) of Uttar Pradesh, from each district there was two blocks are also selected purposively which has maximum numbers of poultry farmers. From each selected block 24 poultry farmers were selected by applying simple random sampling technique. Total 96 poultry farmers were selected for the study. Those poultry farmers were selected which has the minimum 500 flocks size of broiler farming at the time of investigation. The primary data was collected by personal interview method using a structured interview schedule. The collected data were tabulated, scored and analyzed in the light of the objective.

To find the adoption level of scientific broiler farming practices among poultry farmers.

Result And Discusion:

ABSTRACT: The present study was carried by M.VSc student of Department of Veterinary & A.H. Extension Education, ANDUAT, Kumarganj, and Ayodhya out in Sultanpur district of Uttar Pradesh is an attempt to analyze the relationship of status of dairy farmers with their awareness regarding hygiene management practices. The information were composed with the help of pre design question schedule by contacting the sample dairy farmers personally the help of local leader in the research areaby random sampling method, for selection of district and block purposively due to the researcher is well equated about the work the socio-cultural status of the district which help in quick rapport building that is essential for authentic data collection .The information were generated from 120 dairy farmers from four blocks i.e. Kurebhar, Kurwar, Dhanpatganj, Baldirai selected for data collection, three villages from each randomly selected block were randomly selected with lottery method by preparing the list of the village where sufficient number of dairy farmers was available. Overall finding reported that the majority 35.83 percent of the dairy farmers were having medium, 32.50 Low and 31.67 high hygiene management practices like cleaning of housing & cleaning of floor, washing of animals, use of disinfection in animal shed, washing of animal udder at the time of milking, washing of hand at the time of milking, Clean milk production followed by dairy farmers in the study area.

Keywords: Awareness, Hygiene Management, Dairy farmer.

INTRODUCTION

Clean milk can be defined as milk produced from healthy mulch animal possessing normal flavor, devoid of dirt, and filth containing permissible limit of bacteria, and essentially free from adulterants, pathogens, various toxins, abnormal residues, pollutants, and metabolites.

The clean milk production (CMP) involves cleanliness at different phases of handling animals, processing, and transporting of milk and milk products. Stringent quality control and hygienic measures are required at a dairy farm level to maintain the milk quality. The milk quality is determined by aspects of composition and hygiene of milk. There are mainly four factors to be considered in CMP practices: Animal hygiene, milking hygiene, equipment hygiene, and processing hygiene. Contaminated milk deteriorates quickly and is a cause for health concerns. One of the major causes of illness in various countries is the transmission of diseases through food. Zoonosis is diseases and infections that are naturally transmitted between vertebrate animals and humans. Zoonosis constitutes 61% of all known infectious diseases. It may also be noted that of the 175 diseases considered to be emerging, 75% are zoonotic. We came out with that women play a significant role in livestock farming with a better performance rate

THERAPEUTIC MANAGEMENT OF OVERT PSEUDOPREGNANCY IN A BITCH: A CASE REPORT

Abstract

Pseudopregnancy is an exaggerated physiological response experienced by any non-pregnant puberal bitch (unbred or have infertile mating) completing the luteal portion of an estrous cycle. Prolactin hormone play a central role in pathophysiology of pseudopregnancy. Pseudopregnancy may ensue due to increased concentration of prolactin or increased sensitivity to prolactin induced by a more rapid than normal decline of progesterone levels in the late luteal phase (Concannon and Lein, 1989). Pseudopregnancy is easy to diagnose and easy to treat with prolactin suppression therapy i.e. dopamine agonists. Ovariectomy is the only permanent preventive measure (Johnston, 1980; Jochle et al., 1989) if bitches are not intended for breeding.

Keywords: Bitch, pseudo-pregnancy, patho-physiology, sex steroids, prolactin and dopamine agonist.

Introduction

Term pseudopregnancy was first used by Ancel and Bouin (1911) abnormally long luteal phase of estrous cycle in rabbit. As for as bitch is concern pseudopregnancy is an exaggerated physiological response experienced by any non-pregnant puberal bitch(unbred or have infertile mating) completing the luteal portion of an estrous cycle. The term pseudopregnancy does not distinguish clinical condition (overt or clinical pseudopregnancy) from covert or physiological pseudopregnancy. However, the term pseudopregnacy signify clinical or overt pseudpregnancy unless mentioned otherwise.

Prolactin hormone play a central role in pathophysiology of pseudopregnancy. Pseudopregnancy may ensue due to increased concentration of prolactin or increased sensitivity to prolactin induced by a more rapid than normal decline of progesterone levels in the late luteal phase (Concannon and Lein, 1989). Syndrome usually begins after 6-20 weeks after estrus and exhibit the behavioral signs such as restlessness, nesting, aggression, licking of abdomen and mothering inaninmate object. Moreover, mammary development or hypertrophy (Concannon and Lein, 1986) which is more pronounced in caudal pair of mammary gland although entire chain of gland may be involved and lactation is often encouraged by self-nursing or by adaptation of unrelated neonates (Razzaque *et al*., 2008). On the other hand, Johnston (1980) reported other symptom such as vomiting, anorexia, polyurea, polydypsia and polyphagia. Usually syndrome is self-limiting and signs cease after 2-4 weeks unless complicated by occurrence of mastitis and mammary dermatitis which is unlikely (Razzaque *et al*., 2008).

The diagnosis of the syndrome is easy and can be made on the basis of history, abdominal palpation, and ultrasonography. Traditionally, sex steroids (estrogen, progesterone, and androgens) use to treat pseudopregnancy, which is in high doses either suppress pituitary prolactin or decrease sensitivity to prolactin (Allen, 1986; Arbeiter *etal*., 1988; Feldman and Nelson,1987; Jochle,1987; Voith, 1980; Johnston, 1980); But side effects of sex steroids outweigh its therapeutic use (Gobello *et al*., 2001). At present, inspite of sex steroid therapy, prolactin- suppression therapy by dopamine agonist or antiprolactin is treatment of choice. Ergot alkaloids (bromocriptin and cabergolin), a dopamine agonist, causes inhibition of prolactin secretion. This inhibition can be modulated indirectly by serotonin, which suppresses dopamine release and increases prolactin (Thorner *et al*., 1998). The most common ergot compounds used clinically to inhibit prolactin secretion are the dopamine agonists bromocriptine and cabergoline. Another ergot alkaloid, is a serotonin antagonist, and thus has a dopaminergic effect and thus reduces prolactin secretion when administered at high doses (Janssens, 1986; Jochle *et al*., 1989; Hammon *et al*., 1981). Ovariectomy is the only permanent preventive measure (Johnston, 1980; Jochle *et al*., 1989) if bitches are not intended for breeding.

Materials and Methods

Case history

The rottweiler bitch, four-year-old and fifty-kilogram body weight was presented at Jai Pet Care, private clinic at Raebareli with the history of maternal behavior like nesting and affection to inanimate objects, inappetance, licking of genitalia, yellow to redish white vaginal discharge oozing of milk from teat along with hypertrophy of mammary gland for 6 month.

Clinical Examination and Diagnosis

The bitch was dull and depressed with red yellow discharge from vagina. Blood test reveals that lower hemoglobin, higher TLC, SGOT, SGPT, and serum alkaline phosphatase as 11.8 g per cent, 16200/cmm, 378.7 U/L, 355.46 U/L, and 492.9 U/L respectively. On the basis of history, clinical observation and blood test, the case was diagnosed as pseudopregnancy and treated with tab cabergolin @ 5 µg per kg, orally, inj. Neohepatex 2 ml, im; inj. Conciplex 2ml,im; inj. Ceftiofur sodium 250mg, im for seven days afterward tab Bactrim DS 1, BD, PO; syp. Liv 52 ,5ml, OD, PO. For ten days.

Results and Discussion

The bitch was completely recovered approximately after three weeks. In this case antiprolactin therapy namely cabergolin given at recommended dose rate causes cessation of luteatrophic action of prolacti as a result luteolysis ensue. High TLC was suggestive of uterine infectin which was managed by antibiotic ceftiofur sodium. Moreover, high SGOT.SGPT and serum alkaline phosphatase was indicating compromised liver function. To cope up this Liv 52, neohepatex and conciplex was given accordingly. Thus, the conclusion was made that the clinical pseudopregnancy can be well managed by above mentioned therapeutic agents.

Milk composition, Somatic cell count, Transition period, α-tocopherol acetate, Zinc

A B S T R A C T

The study was conducted to investigate the effect of α-tocopherol acetate and zinc on milk composition in Karan Fries cows. Twenty pregnant Karan Fries cows were selected two months before expected date of calving. The experimental animals were randomly divided in to two groups namely control group (ten cows) and treatment group (ten cows). Treatment group cows were supplemented with α-tocopherol acetate @ 1000 IU/day/cow and zinc @ 60 ppm/day/cow. Milk fat % was lower in treatment group than control group but the overall fat in treatment group was found significantly higher than control group (4.47±0.20 vs. 3.95±0.27, P<0.01). The overall mean milk protein % was found 3.08±0.04 vs. 3.05±0.11, milk lactose % 4.47±0.08 vs. 4.48±0.10 and SNF % 8.17±0.15 vs. 8.15±0.17 in control group and treatment group, respectively which showed that there was no significant difference between the groups. The overall mean (±SEM) of somatic cell count of milk was found significantly lower (P<0.001) in treatment group than control group. The results of this study indicated that supplementations of antioxidants like α-tocopherol acetate and zinc have beneficial effects in improving quality of milk.

Introduction

For good quality dairy products there is need to know the quality aspects of milk produced. Since the diet is the fastest way to modify the milk production and quality in animals, even if the relations between the feeding and milk composition are quite complex. Trace elements, along with vitamins and minerals, are essential nutrients for cellular metabolism. They are critical components of almost every aspect of how a body grows, develops, functions and reproduces. Vitamin E is crucially involved in immune system function, such that supplementation with supranutritional levels of the vitamin E, results in improved immune responses and milk production (Chawla and Kaur, 2005; Baldi, 2005; Baldi *et al.*, 2008; Chandra and Aggarwal, 2009). There was significant decrease of somatic cell count (SCC) in milk at 15 days of lactation (0.29×10^6 vs. 0.86×10^6) in cows supplemented with 1000 IU vitamin E / day during dry period (Kaur *et al.*, 2002). The somatic cell count is internationally recognized as a parameter for assessing the milk quality and udder health. The present

COMPARATIVE EFFECTS OF CEFTIOFUR SODIUM, GENTAMICIN SULFATE AND *Zingiber officinale* ON HEMATOLOGICAL PARAMETERS OF ENDOMETRITIC BUFFALOES (*Bubalus bubalis*)

Pushkar Sharma[1], Sushant Shrivastava[2], Vijay Gautam[1], Rajesh Kumar[2*], Pramod Kumar[3] and Saurabh[1]

Abstract
The present study aimed to investigate the comparative therapeutic efficacy of Ceftiofur sodium, Gentamicin sulfate and Zingiber officinale extract on hematological parameters of endometritic buffaloes. The endometritic affected animals were randomly allotted to five groups namely Groups CB, C, G, CF and GG comprising of ten animals in each group. Haemoglobin, PCV, TLC, DLC and ESR values were analysed at 0, 15th day and 30th day in each group. Haematological profile was differed significantly between cyclic and endometritic buffaloes. The findings indicated blood indices helps in diagnosis of clinical endometritis in buffaloes.
Keywords– *Endometritis, Ceftiofur sodium, Gentamicin sulphate, Zingiber officinale.*

Introduction

Endometritis is inflammation of the endometrial lining of the uterus and formation of mucopurulent secretion. It is a major cause of repeat breeder syndrome of bovines. Unlike metritis, it does not affect the general health. Therefore it has a major economic impact by poor conception rate, increasing calving interval, reduction in calf crop, increased cost of treatment decrease milk yield and increase cull rate. The most common initiating cause of endometritis is non-specific, opportunist pathogens that contaminate the uterus during the pericalving period, dystocia, retained foetal membranes (RFM), caesarian section, contamination of uterus at the time of A.I., induced parturition, still birth, twins, ovarian inactivity, cystic ovaries, unhygienic calving environment, concurrent disease and nutrition - fatty liver disease and hypocalcaemia are reported to increase endometritis rates, natural insemination infected with venereal disease, etc (Noakes *et al.*, 2002). Opportunistic pathogens are not able to colonize in the genital tract during normal circumstances due to several protective mechanisms, viz., anatomical and functional barriers, specific and nonspecific immune responses (Foldi *et al.*, 2006). Blood is a crucial importance for maintain of physiological equilibrium in the body. Normal levels of vital haematological constituents are of most importance for maintaining functional integrity of the reproductive system. Any change in haematological parameters may adversely affect the reproductive efficiency of livestock. Haematological indices are useful in diagnosing various pathological and metabolic disorders, which can adversely affect the production and reproductive performance of buffaloes.

Materials and methods

In these study mainly two commonly used antibiotics ceftiofur sodium and gentamicin sulphate and one herb extract, *Zingiber officinale* were selected for treatment of endometritic buffaloes. The cases of Instructional Dairy Farm Complex, Teaching Veterinary Clinical Complex, Veterinary hospitals lying adjacent to Kumarganj, Faizabad, and cattle colonies near Buddeyshwaran, lucknow (U.P) India were selected for study purpose. *Zingiber officinale* extract was prepared in Soxhlet apparatus as per standard method and then concentrated in vacuum rotary evaporator at 40^0 C for ethanol removal. One gram concentrated extract was mixed in double distilled water in floor shaker water bath used for intrauterine therapy.

The buffaloes were categorized into five groups for the present study, viz., Normal cycling healthy estrus buffaloes (**CB**), No treatment is given, recommended for sexual rest (**C**), 10ml (40mg/ml) Gentamicin sulfate (dissolved in 40 ml of distilled water) intrauterine daily for three days(**G**), 500mg Ceftiour Sodium (dissolved in 50 ml of distilled water) intrauterine daily for three days.(**CF**), One gram Extract of *Zingiber officinale* (dissolved in 50 ml of distilled water) intrauterine daily for three days (**GG**). Blood Sample was collected three times (0, 15th and 30th day) during the whole experimental period. Approximately 5 ml of blood was collected aseptically from the jugular vein of each experimental animal in sterilized disposable syringe (16 gauge needle). All haematological values obtained were subjected suitable statistical methods (Snedecor and Cochral, 1989).

Results and Discussion

In the present research work, blood indices such as Hb, PCV, TEC, TLC and DLC were estimated to investigate any possible correlation in between endometritis and hematological profile of buffaloes.

Hemoglobin (Hb)

The overall mean hemoglobin in pretreated, 15th, 30th day post treated and in regular cyclic buffaloes were given in the table 3.1. and column chart 3.1. Hemoglobin levels were increased significantly ($P<0.05$) in gentamicin (G) and ceftiofur (CF) after 30th day post treatment. Pateria and Rawal (1990) and Pateria *et al.*, (1992) also observed significant increase ($p<0.05$) in haemoglobin level after treatment in buffaloes which were affected with metritis and endometritis. The decrease in haemoglobin level of affected buffaloes is probably due to disintegration of erythrocytes and/ or effect of some haemolytic type of microbes and their endotoxins on the blood cells and haemopoietic system. Similar results were obtained by Dhoble and Gupta (1981), Jaini *et al.*, (1995), Ahmad *et al.*, (2003), Rathour *et al.*, (2005) and Narnaware and Sirothia (2010) in buffaloes. The mean Hb levels in responded animals was lower at the time of treatment and increased significantly ($p<0.01$) after 21 days in next estrus. Pradhan *et al.*, (1995) reported that lower level of Hb values which may be representing some systemic derangement due to deficiency of certain trace minerals which in turn depressed the physiology of reproduction. The low level of Hb indicated long term protein deficiency and influences tissue oxygenation of reproductive tract which in turn affects the cyclicity (Ramakrishna, 1997). Lack of sufficient quantities of Hb in blood is responsible for reduced oxygen transport to the vital tissues, it causes reduced oxidation of nutrients, which in turn affect the whole cellular metabolism in gonadal cells which is metabolically more active. (Sabasthin *et al.*, (2012) reported that decrease in the Hb value in the animal could be the cause of repeat breeding. The trend of variation in PCV was found to be similar to be the value of Hb and ESR in both cattle & buffaloes. Similar finding was also reported by Anthony *et al.*, (2012) and Verma (2015).

Packed Cell Volume (PCV)

The mean value of PCV in regular cyclic buffaloes group (CB) was observed as 30.89±0.31% PCV values were reported as 29.22±0.27, 28.69±0.28 & 9.21±0.22 per cent in untreated control, 29.05±0.36, 29.75±0.52 & 29.75±0.52 per cent in gentamicin, 28.18±0.29, 30.54±0.46 & 31.07±0.40 per cent in ceftiofur (CF) groups and 29.03±0.42, 29.63±0.45 & 30.19±0.25 percentage in *Zingiber officinale* extract at 0, 15th and 30th day post treatment, respectively (Table No. 3.1 and column chart 3.2). Significant ($p<0.01$) increase in PCV was observed in all the treatments at 30th day post treatment. This indicates that the mean PCV increases after treatment by using any biological modifier which reduces the infection. The present

Influence of Different Therapy on Hematological Markers and Fertility Response in Anestrus Sahiwal Cows

Safayat Husain[1], Rajesh Kumar[1]*, Bhoopendra Singh[1], Sushant Srivastava[1], Rabindra Kumar[1], Pramod Kumar[2], Ashish Srivastava[3]

Abstract

The study was designed to evaluate influence of different therapy on hematological markers, resumption of ovarian cyclicity and conception rate in 24 anestrus Sahiwal cows, which were randomly and equally allocated to four groups as G1, G2, G3 and G4. Lugols iodine (2%, cervical painting with per rectal massage of genitalia thrice on alternate day) XXX herbal bolus (1 bid for 2 days, repeated on day 11 & 12 later in non-respondents) and modified ovsynch protocol (progesterone 100 mg s/c once a day for 6 days followed by GPG) was administered in G1, G2 and G3, respectively, while G4 kept as untreated control. All these animals were dewormed with bolus fenbendazole 3 g plus ivermectin 100 mg, once and supplemented with mineral mixture 30 g/day for 21 days before above therapies. Blood samples were collected thrice, *i.e.*, on day 0, day of induced estrus/AI and day 21 post-AI (day 0, 21 and 63 in non-respondents) for hematological analysis. In general, hemogram and leucogram did not vary significantly within and among different groups, except neutrophil and lymphocyte. Cent per cent estrus induction response was observed in treatment group G1, G2 and G3, however, none of the cows resumed cyclicity in untreated control group G4. The treatment to estrus induction interval was 9.17±2.34, 8.33±2.36 and 16±0.00 days; treatment to fertile estrus interval was 33.6±8.40, 42.0±8.57 and 29.4±5.14 days and overall conception rate was 83.33, 66.66 and 83.33 % in group G1, G2 and G3, respectively, while nil in untreated anestrus cows.

Introduction

Bovine anestrus syndrome is a most common single cause of infertility in dairy cattle that leads to huge economic losses in terms of prolonged calving interval, reduced calf crop and shorter productive life. Malnutrition is the most common cause of true anestrus featured by absence of estrus cyclicity with small smooth inactive ovaries. Bovine anestrus syndrome is a multifactorial disorder of the reproductive cycle which is characterized by absence of estrus signs manifested either due to lack of expression of estrus or failure of its detection. It can be normal physiological (pregnancy, lactation and in early postpartum period) or pathological (metritis, fetal resorption/PCL, pyometra, maceration and mummification). Many non-hormonal and hormonal drugs have been used to treat anestrus (Kumar *et al.*, 2011; Dhami *et al.*, 2015; Dhami *et al.*, 2019; Kumar *et al.*, 2020[a]). Among herbal therapeutics, various type of tropical plants are used traditionally to augment the reproductive performance. Some plants contain secondary metabolites which are effective in inducing estrus in postpartum anestrus cows (Pugashetti *et al.*, 2009). Deficiency of minerals is also an important cause of anestrus in animals (Kumar *et al.*, 2020[b]). This study was therefore designed to assess influence of different treatment protocols on hematological markers as well as on fertility response in true anestrus Sahiwal cows.

Effect of Exogenous Melatonin and Different Photoperiods on Differential Leucocyte Count in Chhotanagpuri Ewe

Pankaj K. Choudhary[1]*, Ajay K. Ishwar[2], Pramod Kumar[1], Pankaj K. Maurya[1], Mukesh Kumar[3], Rajesh Kumar[4], Debasish Niyogi[5]

Abstract

Forty-two healthy, non-pregnant, non-lactating Chhotanagpuri ewe, having body weight ranging from 14.11 ± 0.09 to 15.38 ± 0.06 kg, were selected and isolated from rams 2 months before melatonin administration. The selected animals were allocated randomly into seven groups each of 6 animals, *viz.*, Group-I [Normal control], Group-II [Long day (LD) control], Group-III [LD + melatonin administration 3 mg/day orally], Group-IV [(LD + melatonin administration s/c @ 1 mg/day], Group-V [Short day (SD) control], Group-VI [SD + melatonin administration 3 mg/day orally] and Group-VII [SD + melatonin administration s/c @ 1 mg/day]. Rams were then introduced into each group after completion of exogenous administration of melatonin for one month. Blood samples without anticoagulant were collected from each animal a day before the experiment and then every month till the fifth month. Among different periods, lymphocyte % in the third and fourth months of the experiment was significantly ($p < 0.05$) lower in all groups (group-I to VII) in comparison to 0 days, first, and second months. In the fifth month, lymphocyte % was significantly ($p < 0.05$) higher in group III, IV, VI, and VII compared to the third and fourth months of the experiment. Neutrophil % in the third and fourth months of the experiment was significantly ($p < 0.05$) higher in all groups in comparison to 0 days, first, and second months. In the fifth month, neutrophil % was significantly ($p < 0.05$) lower in group III and VI than in the third and fourth months. Monocyte % was significantly ($p < 0.05$) higher in group III and IV than group VII at first month. In the third month, monocyte % was significantly ($p < 0.05$) higher in group IV and VI than in group I and group II.

Introduction

The major functions of the white blood cells and their differentials are to fight infections, defend the body by phagocytosis against invasion by foreign organisms, and produce or at least transport and distribute antibodies in immune response (Etim, 2015). Thus, animals with low white blood cells are exposed to a high risk of infection. In contrast, those with high counts are capable of generating antibodies in the process of phagocytosis and have a high degree of resistance to disease (Soetan *et al.*, 2013) and enhancing adaptability to local environment and disease prevalent conditions (Isaac *et al.*, 2013). According to Etim *et al.* (2014) immune status is a function of leucocytes, lymphocytes, and neutrophils. Lymphocytes are known to play critical roles in the immune defense system of both men and animals (Etim *et al.*, 2014[b]).

Melatonin signaling is necessary for photoperiodic adjustment in immune responses; it is difficult to parse the direct differential effects of melatonin on immune cells from indirect modulatory actions on other neuroendocrine axes, including the systems that control gonadal and adrenal steroids. However, the hypothesis that melatonin acts on immune function via downstream hormonal effects has not been born out, as gonadectomy and steroid replacement has minimal effect on photoperiodic plasticity in the immune system (Prendergast *et al.*, 2005).

Exogenous melatonin administration increased the total leucocytic count and lymphocyte percentage in squirrels (Rai

A review: heat stress in cow and buffaloes in India

Pramod Kumar, Rishikant, Rabindra Kumar, KN Singh and Mukesh Kumar

Abstract
India is a tropical climatic country in which heat stress is an important disadvantageous factor that reduces the production performance of cattle and buffalo and conduces to significant decrease in milk yields in dairy cows and buffalo and some metabolically disorders. The objective of this review is to known the heat stress metabolism, its causing factors and its preventative methods for increase the production performance through manage mental and nutritional procedures.

Keywords: Tropical, Heat, Temperature, Conduction, Convection, Radiation, Evaporation, Panting, Sweating, Moisture

Introduction
Climatic conditions of India are such that the hot and humid season is relatively long, there is intense radiant energy for an extended period, and there is generally the presence of high relative humidity. Thus, heat stress is chronic in nature especially for animal, there is often little relief from the heat during the evening hours, and intense bursts of combined heat and humidity further depress performance of animal. Lactating dairy cattle and buffaloes create a large quantity of metabolic heat and accumulate additional heat from radiant energy (West, 2003) [20]. Heat production and accumulation, coupled with compromised cooling capability because of environmental conditions, causes heat strain in the cattle and buffaloes to increase to the point that body temperature rises, intake declines and ultimately the cow's productivity declines.

Heat stress is caused by a combination of climatic factors like air temperature, humidity, solar radiation, wind velocity etc. A common time for experience adverse effects of high temperatures is during transport (Fiore *et al*, 2009) [6]. Transport is a multi affected stressor that can create or exacerbate existing heat loads. Handling of animal, increases body temperature. Animal are adversely affected any time the ambient temperature is more than their thermoneutral zone, which ranges about 25°C. Because that heat stress conduces to some disadvantageous affect on livestock, many researchers work about heat stress in animal.

Thermoneutral zone
The Thermoneutral Zone (TNZ) is defined as. "the range of ambient temperature within which metabolic rate is at a minimum, and within which temperature regulation is achieved by non evaporative physical processes alone" (Bligh & Johnson, 1973) [3]. The lower critical ambient temperature range point and the upper critical ambient temperature point indicate the limits of the TNZ. The ambient temperature below, which the rate of heat production of a resting homeotherm increases to maintain thermal balance, is the lower critical temperature (LCT). The upper critical temperature (UCT) may be defined as the ambient temperature when the: (a) metabolic rate increases; (b) evaporative heat loss increases; or (c) tissue thermal insulation is minimal (Silanikove, 2000) [14]. Below and above these temperature limits heat production is increased. The width of the thermoneutral zone will vary depending on age, species and breed, level of nutrition, previous state of temperature acclimation or acclimatization, level of productivity, housing conditions, insulation, and behavior etc (Yousef, 1985b) [22]. In order to more clearly define the TNZ (Silanikove, 2000) [14] suggested that the subdivision of the TNZ into a zone of thermal well-being is most suitable to describe the relation between an animal and its environment. Figure 1, illustrate this concept.

Management of traumatic proptosis in a pug: A case study

Sandeep Yadav, Vibha Yadav, RP Diwakar and Pramod Kumar

Abstract
A three years old male pug dog, weigh 10 kg was presented to Jai Pet Care Clinic Raebareli, Uttar Pradesh for treatment with unilateral traumatic proptosis. All clinical parameters were normal. Physical examination revealed partial prolapse of right eye globe with severe periorbital edema, haemorrhage, absence of menace and presence of miosis. Therapeutic management done by administration of triflupromazine @4mg/kg I/M for sedation, dexamethasone and gentamicine 0.2ml each in combination injected through intra palpebral route, which was repeated on 5th day. Animal was also given intramuscular injection of gentamicin @5mg/kg, dexamethasone @0.125mg/kg, vitamine B complex 2.0 ml and chlorpheniramine maleate @0.5mg/kg only once for 5 consecutive days. Eye drop of moxifloxacine and dexamethasone 4 times a day for instillation, chloramphenicol ointment 4 times a day for local application and enrofloxacin @5mg/kg orally once for 7 days were used. Animal recovered successfully after 7 days of regular treatment. Vision was assessed by simple vision testing using junction box, after 15 days of recovery and found normal.

Keywords: Pug, proptosis, therapeutic management

Introduction
Proptosis is forward displacement of globe which occur secondary to any blunt trauma to head [7]. Proptosis typically occurs in dogs following trauma to the face or head. Certain breeds of dog are more prone to eye proptosis than others because of their differences in facial conformation. The most common cause of proptosis in small breed dogs is a fight with a larger dog. During trauma, the globe is luxated from the orbit, and eyelid spasms prevent its retraction. Secondary orbital hemorrhage and swelling displace the globe further from the orbit following corneo-conjunctival drying and malacia [3]. Prognosis depends on pupil size and reflexes, duration of exposure, other globe or orbital damage, breed and other systemic trauma. Approximately 40–60% of dogs, but very few cats, recover vision. Traumatic proptosis can occur in any breed and in both dogs and cats. Only 20-40% of dogs that have the reattachment of the eyeball regain their vision.

Case history and observations
A three year old male pug of 10 kg weight was presented at Jai Pet Care Clinic Raebareli, Utter Pradesh with unilateral traumatic proptosis having recent history of blunt head trauma by hitting head against the wall. Clinical examination revealed partial prolapse of right eye globe (fig.-1) through the pulpebral fissure with severe periorbital edema (fig.-2), haemorrhage without fracture of skull. There was absence of menace and presence of miosis. Corneal examination revealed concurrent finding of pigmentary vascular keratitis. All clinical parameters of the pug were normal.

ABSTRACT

Forty two (42) apparently healthy, non-pregnant, non-lactating Chhotanagpuri ewe, having body weight ranging between 14.11±0.09 to 15.38±0.06 Kg were selected and selected ewes were isolated from rams 2 months prior to melatonin administration. The selected animals were allocated randomly into seven groups viz. Group-I [Normal control], Group-II [Long day (LD) control], Group-III [LD + Melatonin administration orally (3mg/day)], Group-IV [(LD + Melatonin administration subcutaneously (1mg/day)], Group-V [Short Day (SD) control], Group-VI [SD + Melatonin administration orally (3mg/day)] and Group-VII [SD + Melatonin administration subcutaneously (1mg/day)] comprising six animals in each group. Rams were then introduced into each group after completion of exogenous administration of melatonin. Blood sample without anticoagulant in vials was collected from each animal day before the start of experiment and there after every month up to fifth month. After administration of melatonin, serum glucose was decreased in group- III, IV, VI and VII in comparison to group-I, although this decrease was not statistically significant. An increasing trend of serum glucose was observed in all groups from third to fourth month. Total protein at first month was significantly ($P<0.05$) higher in group VI in comparison to 0 day. After administration of melatonin, total serum protein concentration was significantly ($P<0.05$) decreased in group VI in comparison to first month and continued up to third month. At fifth month, total serum protein was significantly ($P<0.05$) lower in group III, IV and VI in comparison to 0 day and first month.

Introduction

Sheep husbandry is backbone of rural economy in India. The Chhotanagpuri sheep is the only recognized breed of sheep found in Jharkhand with a few numbers in Bihar and West Bengal. This breed is maintained solely for mutton production. They produce coarse wool of poor quality. This is being utilized for carpet manufacturing. Sheep

EFFECT OF A-TOCOPHEROL ACETATE AND ZINC SUPPLEMENTATION ON LEPTIN HORMONE DURING DRY PERIOD AND EARLY LACTATION IN CROSS BRED COWS

Pankaj Kumar Maurya*, Anjali Aggarwal[1], Pramod Kumar and P.K. Choudhary
College of Veterinary Sci. & A.H., N.D. University of Agriculture & Technology, Kumarganj, Faizabad (UP)
[1]Dairy Cattle Physiology Division, National Dairy Research Institute, Karnal-132001 (Haryana)

Abstract

The study was conducted to investigate the effect of α-tocopherol acetate and zinc supplementation on Leptin Hormone during dry period and early lactation in cross bred cows. Twenty pregnant Karan Fries cows were selected on the basis of their body weight, BCS and parity: ten cows were kept in control group and other ten cows in treatment group which were supplemented with 1000 IU α-tocopherol acetate and 60 ppm zinc per day per cow. Blood samples were collected on the days -60, -45, -30, -15, -7, 0, +7, +15, +30, +45, +60 with respect to expected date of calving. Plasma was analyzed for Leptin hormone. Body condition score of all the experimental animals was recorded on the day of blood collection. At parturition, BCS decreased significantly ($P<0.01$) in control group than treatment group. The plasma concentration of leptin was decreased at parturition and the level was significantly ($P<0.001$) higher in treatment group as compared to control group (3.66 vs. 2.55 ng/ml). Plasma NEFA was significantly ($P<0.001$) lower in treatment group as compared to control group. The results of this study indicated that supplementation of α-tocopherol acetate and zinc have beneficial effects in changing Leptin hormone level in this way that improves body condition and metabolic status of the animals.

Keywords: *Leptin, Body Condition Score, Energy Metabolites, α-tocopherol acetate, Zinc*

Introduction

Leptin is a 16 kDa protein hormone and it is synthesized by white adipose tissue. Leptin is involved in regulation of feed intake, energy balance, immunity and reproduction (Houseknecht *et al.*, 2000; Ahima and Flier, 2003). After parturition, dairy cows suffer from an intense energy deficit caused by the onset of copious milk secretion and an inadequate increase in voluntary food intake which contributes to a decline in plasma leptin. This decline mirrors that of plasma insulin but is reciprocal to the profile of plasma growth hormone (GH), suggesting that both hormones may regulate plasma leptin in periparturient dairy cows (Block *et al.*, 2001). Energy deficit of early lactation reduces leptin synthesis in white adipose tissue (WAT), and suggest roles for insulin, GH and metabolic fuels in mediating this effect of energy balance (Block *et al.*, 2001). A concomitant suppression of immune functions and metabolic disorders during early lactation are related to decreased fertility (Butler and Smith, 1989). This may partly be due to decrease in blood concentrations of vitamins A & E and Zn (Meglia *et al.*, 2001, Chandra, 2009). To meet the nutritional demands of milk synthesis during early lactation, dairy cows need to mobilize body reserves causing negative energy balance until nutrient intake covers the demands.

Material and methods

Experimental design

The study was conducted at the Cattle Yard of National Dairy Research Institute, Karnal, Haryana (India). For the present study 20 Karan Fries (KF) peripartum cows were selected from the herd of National Dairy Research Institute, Karnal, 10 cows kept in Control group and other 10 cows in Treatment group. The cows in the control group were supplemented with no vitamins, and in the treatment group, they were given 1,000 IU of α-tocopherol acetate and 60 ppm zinc per cow per day from 60 days prepartum to 60 days postpartum over and above the normal feeding schedule at dairy farm of NDRI.

Blood sampling

Blood samples (10 ml/cow) were collected in the morning (6:00 AM) before feeding in sterile heparinised vacutainer tubes (BD VacutainerTM, UK) from jugular vein puncture, posing minimum disturbance to animal, on the days -60, -45, -30, -15, -7, 0, +7, +15, +30, +45 and +60 with respect to expected date of calving. Day '0' represented the day of calving. Blood samples were brought to the laboratory in the icebox soon after collection and centrifuged at 3000 rpm at 4°C for 20 min to separate the plasma. Plasma samples were stored at -20°C until analysis of Leptin hormone. Body condition score (BCS) of all the experimental animals was recorded on the day of blood collection using a scale of 1 to 5.

Sample analysis

Blood sample was analyzed for plasma leptin and NEFA. Plasma Leptin was determined by "Bovine Leptin ELISA Quantitation kit" from Cusabio Biotech Co., Ltd. The copper soap solvent extraction method modified by Shipe et al. (1980) was adopted for the estimation of plasma NEFA.

Statistical analysis

Statistical analysis of data was carried out to find the mean ± SE. Two way ANOVA was done to find significant difference between groups and days of experiment and their interaction by using SYSTAT 3.1 (2004) software. The correlations among the various parameters were also calculated (Snedecor and Cochran, 1994).

Results and Discussion

Leptin

The mean±SE of plasma leptin concentration of control cows was 6.06±0.10 ng/ml 60 days before calving and on the day of calving it decreased to 2.55±0.31ng/ml. Further, in treatment group the plasma leptin concentration was 6.19±0.11ng/ml 60 days before calving and on the day of calving it decreased to 3.66±0.11ng/ml. In present study decrease in the plasma leptin concentration of control and treatment group cows was 57.92% and 40.87% respectively from 60 days before calving to the day of calving. This decrease was more significant ($P<0.01$) from 30 days before calving to the day of calving in control group than treatment group. After parturition it's level remained low up to 30 days then started increasing up to 60 days of lactation.

In present study there was found a positive correlation between leptin with BCS and insulin and a negative correlation was found between leptin with NEFA in control and treatment group of cows around parturition. The plasma concentration of leptin was positively correlated with plasma concentrations of insulin and negatively correlated with plasma concentrations of growth hormone, cortisol and non-esterified fatty acids (Block *et al.*, 2001; Chelikani *et al.*, 2008). Sauerwein *et al.* (2004) investigated that in ruminants the decline in plasma leptin levels towards parturition is probably caused by the decline in adiposity and insulin concentrations. In ruminants and other animals, leptin is synthesized in proportion to the overall degree of adiposity and acts on the central nervous system to reduce voluntary feed intake (Ehrhardt *et al.*, 2000). Leptin, mainly produced in adipose tissue, inhibits feed intake and down-regulates adipose tissue deposition. Block *et al.* (2001) showed that leptin is negatively correlated with the amount of nonesterified fatty acids, which reflects the amount of fat mobilization. From early to mid pregnancy circulating leptin levels increased and remained elevated until late pregnancy in cattle (Liefers *et al.*, 2003; Villalobos *et al.*, 2007).

A B S T R A C T

Cattle and buffaloes experience different level of stress during summer and hot humid conditions. However, the assessment of the heat stress and the translation of the heat stress in terms of physiological and psychological strain is complex. For over a century attempts have been made to construct an index, which will describe heat stress satisfactorily. The many indices that have been suggested can be categorized into two groups: "*physiological indices*" and "*environmental*", or "*direct indices*". The first groups are sophisticated indices, which are based on physiological variables; they are difficult to calculate and are not feasible for daily use. The latter group comprises of simple indices, which are based on the measurement of basic environmental variables. In this group many indices are in use for over four decades: the "temperature humidity index" (THI) and the "*TGWB Index*". The following research on heat stress indices and their comparison and evaluation to animal production and their performance. With the present knowledge it is suggested to adopt the TGWB Index under tropical conditions is recommended because globe temperature takes into accounts Tdb and solar radiant heat exchange and can help in finding stress level.

Keywords

Heat stress, Environmental variables, Heat stress indices, TGWB Index, THI

Introduction

In India during summer cattle and buffaloes are exposed to severe environmental heat stress, which may deteriorate productivity and performance of animals may even threaten to their survival. Thus, it is expected that the physiological heat strain experienced by an animal will be related to the total heat stress to which they are exposed, serving the need to maintain body-ore temperature within a relatively narrow range of temperatures. Many attempts have been made to estimate the stress inflicted by a wide range of climate, or to estimate the corresponding physiological strain and to combine them into a single index—a heat stress index. The difficulties in creating a universal heat stress index are outlined in the present research and a simple way to

INTRODUCTION

A number of inorganic elements are essential for the growth, production and reproduction of animals [1]. In addition, mineral requirements are also influenced by age, parity, stage of pregnancy and stage of lactation. The inorganic elements are classified according to their requirements in animal body. Those required in greater quantities are referred as macrominerals (calcium, phosphorus, sodium, chloride, potassium, magnesium and sulfur). Macrominerals required in large amount each day and their concentration in diet is expressed as percentage of diet or in grams per kilogram of diet. Macrominerals has role in different physiological functions. Other elements required in much smaller amounts are referred as trace minerals (microminerals) i.e. copper, cobalt, iodine, iron, manganese, molybdenum, selenium, zinc, chromium and fluorine. Their concentration in diet is expressed as parts per million (ppm), which is equivalent to milligram per kilogram of diet or in some cases as parts per billion (ppb), which is equivalent to microgram per kilogram of diet. Adequate quantity of minerals are utmost important for proper functioning of various physiological functions in animals. Deficiency and excess both have detrimental effects on production and reproduction; thus significantly affecting the economics of animal husbandry.

Role of Various Macro Minerals in Animal Reproduction

Calcium (Ca): Calcium is an essential component of skeleton and plays a pivotal role in maintaining homeostasis of vertebrates [2]. The maximum portion of calcium present in the bone as hydroxyapatite (99%) and small fractions present in the cell membrane or endoplasmic reticulum (0.9%), extracellular fluid or serum (0.1%) and in cytosol (0.00002%) [3]. Extracellular calcium exist in three forms i.e. ionized (50%), complexes to anions (5%) such as citrate, bicarbonate, phosphate, or lactate and protein bound (45%). Ionized calcium involved in array of physiological processes such as muscular

Abstract

An assessment of any climate conditions requires extensive measurements to be health and production performance of animal in the climatic zone. This can be labour-intensive, time-consuming and consequently impractical for daily production and comfort assessments of the animals. Therefore, a simple indicator like a heat stress index is needed to enable a quick, valid and acceptable evaluation of animal climatic conditions on a regular basis. This can be explained by the unending quest to develop a "universal index," which has led to the proliferation of many proposed heat stress indices. In this research study is to discuss the selecting a suitable heat stress index for thermal planning and management purposes in hot and humid climatic zone for dairy industries. A method is proposed a defined strategy for selecting and recommending heat stress indices to be used in a particular climatic zone and worldwide based on a heat stress index. The performance of different heat stress indices used in dairy industries and other cattle farm varies based on the climatic conditions and the level of activities. Therefore, carefully selecting or establishing a suitable heat stress index is of paramount importance to ensure the comfort, health and increasing productivity of the cattle and buffaloes. These methods assess and select the most appropriate index for hot and humid climatic conditions to protect the cattle and buffaloes from thermal stress. Although complex, the method presents results that are easy to interpret and understand than any other methods.

Keywords: climatic zone, heat stress index, thermal stress, dairy industries.

Introduction

Heat stress is chronic in nature, there is often little relief from the heat during the evening hours, and intense bursts of combined heat and humidity further depress performance. Lactating dairy cattle and buffaloes create a large quantity of metabolic heat and accumulate additional heat from radiant energy [1]. The ability of many indices using these elements have been developed in past; but their utility remained limited. Majority of studies on thermal stress in livestock have used temperature-humidity index (THI). THI represent the combined effect of air temperature and humidity with level of heat stress. Milk yield and DMI exhibited significant declines when maximum THI reached 77. Later research determined that the critical values for minimum, mean, and maximum THI were 64, 72 and 76 respectively [2]. In addition, a climate change scenario was constructed by raising both the minimum and maximum temperatures by 2.76°C, which is a mid-range temperature change for approximate doubling of atmospheric greenhouse gas concentrations. The incidence of stress days as measured by THI greater than 80 has increased significantly over the 40-year period (60%) and the climate change scenarios suggested further, substantial increases (138%) in the frequency of such heat stress days. In addition, in the climate change scenario there was a very marked increase in days where animals could no longer thermo regulate by sweating alone [3]. Different animal species have different sensitivities to air temperature, humidity, solar radiation and wind velocity etc. Cattle and buffaloes have differences in their heat tolerant capacity. Cattle can tolerate high temperatures at low air humidity than buffaloes. This is due to the fact that, cattle can dissipate heat more efficiently by surface evaporation whereas buffaloes use surface evaporation for body cooling to a limited extent.

This research study posed the question of which index can be recommended for a hot and humid climate? In this paper, a method is used to compare a thermal comfort model with some of the most widely used heat indices in dairy industries and another cattle farm. The method is applied to predict the "comfort zone" and to recommend an index based on its production performance as close as possible to the "comfort zone." The comparative analysis uses comfort data including air temperature, airflow velocity, humidity and estimated physiological parameters such as respiration rate and rectal temperature.

Cattle and buffaloes have capacity to maintain their body temperature with in a precise limit even after exposure of environmental extremes [4]. Animals gain heat from three sources: chemical, mechanical and thermal. Chemical and mechanical heat transfer relates to metabolic processes and represents the body's main heat sources. The influence of the thermal environment on an animal is primarily exerted through energy exchanges involving convection, conduction, radiation and evaporation [5]. There are mechanisms by which the body can regulate its core temperature both at rest and during activity, and in both hot and cold or humid environments, along with health risks that are associated with physical activity in the aforesaid environments [6]. Assessment of "Thermoneutral Zone" must start with the maximum production with wellbeing of animal. It is extremely difficult to classify the many factors that affect thermal comfort. The interaction between the physical demands imposed upon an animal his physiological status, and his psychological attitudes. Because thermal comfort is rather subjective and restrictive, it is better to define a Thermoneutral Zone within which most animals will be comfortable. This necessitates the need to define a "zone" in which most of the animals will consider comfortable, the so-called comfort zone. This comfort zone will be ascribed using the climatic and physiological parameters of the environment and some existing thermal comfort models.

The Thermoneutral Zone (TNZ) is defined as "the range of ambient temperature within which metabolic rate is at a minimum, and within which temperature regulation is achieved by non-evaporative physical processes alone [7]. The lower critical ambient temperature range point and the upper critical ambient temperature point indicate the limits of the TNZ. The ambient temperature below, which the rate of heat production of a resting homeotherm increases to maintain thermal balance, is the lower critical temperature (LCT). The upper critical temperature (UCT) may be defined as the ambient temperature when the: (a) metabolic rate increases; (b) evaporative heat loss increases; or (c) tissue thermal insulation is minimal [8]. Below and above these temperature limits heat production is increased. The width of the thermoneutral zone will vary depending on age, species and breed, level of nutrition, previous state of temperature acclimation

The idea of the thermal index goes back to 18th century [9]. Without considering the dry-bulb temperature, perhaps the first published heat stress index was the wet-bulb temperature proposed by Haldane [10]. Since then a large number of heat stress indices have been proposed.

GROSS AND HISTOLOGICAL STUDIES OF THE URETER IN *MARWARI* SHEEP (*Ovis aries*)

Krishna Nand Singh[1], Sanjeev Joshi [2], Rakesh Mathur[2], Mukesh Kumar[1], Pramod Kumar[1], S.S. Sengar[1] K. K. Tripathi[1] and Rakesh Gupta[3]

Abstract

The present study was conducted on ureters of 15 *Marwari* sheep of either sex between the ages of 1.5 -2 years. It was a long and thin muscular tube begins from renal pelvis at the hilus and passes backward along medial border of kidney. In the Histological structure ureter was composed of tunica mucosa of transitional epithelium. The mucosa was thrown on to longitudinal folds giving the lumen a stellate appearance. Lamina propria is wide which was composed of fibroelastic connective tissue with many bundles of coarse collagen fibres. The tunica muscularis was consisted of inner longitudinal, middle circular, and outer longitudinal layers of smooth muscles. The outer layer tunica adventitia is continuous with fibroelastic connective tissue which contain blood vessels and nerve endings.

Key words: Ureter, Stellate Lumen, transitional epithelium, smooth muscle fiber.

Introduction

Marwari sheep constitutes a major portion of the sheep population in western part of Rajasthan which has 14.31 million sheep (about 40%) and plays an important role in the economy of arid and semi-arid tract. Low rainfall and scanty vegetation are common in the western part of Rajasthan and the conditions become oppressive when extreme environmental conditions bring about the adaptive changes in organs necessary for physiological adjustments in these extreme ambient conditions. The present investigation has been planned to study the gross and histological structure of the ureter to justify its importance and essentiality in the body. In mammals the ureters are the chief excretory ducts of the body.

Materials and Methods

The Gross study was conducted on 15 apparently healthy adult *Marwari* Sheep (*Ovis aries*) of either sex. The Ureters from the freshly slaughtered animals were procured from Municipal slaughterhouse, Bikaner.

For the histological examination the small pieces of tissues (2 mm size) were collected from 12 ureters (6 right and 6 left). From each, the tissues were collected from different anatomical regions to explore regional differences if any. The tissues were preserved in 10% formal saline for 48 hrs, Bouin's fluid for 12 hrs, and Zenker's fluid for 18 hrs (Singh, U.B. and Sulochana, S. 1996). Fixed tissue was latter washed in running tap water for 6-10 hours followed by dehydration in ascending grade of alcohol, clearing, embedding in paraffin wax of melting point of 58-60℃, preparation of blocks, section cutting (5-6 µm thick), and mounting of section on albuminized slides, drying of sections and finally stained with the histological stains (Luna, L.G. 1968). to demonstrate different histological structures of ureters.

Results and Discussion

Each kidney was connected to the urinary bladder by a ureter. It was a long and thin muscular tube begins from the renal pelvis at the hilus and passes backward along medial border ofthe kidney. It passes ferther caudally and enters in tothe pelvic cavity. It inclines inward and downward and open in to the bladder at the caudodorsal aspect. Similar findings were also reported by Konig and Liebich (2006) and Dyce *et al* (2010) in domestic animals.

In the histological structure the ureter of Marwari sheep was composed of tunica mucosa of transitional epithelium. The mucosa was thrown on to longitudinal folds giving the lumen a stellate appearance (Dellmann HD, 1993). Lamina propria is wide which was composed of fibroelastic connective tissue with many bundles of coarse collagen fibres which was dense towards the epithelium and loose towards the muscularis mucosa. The tunica muscularis was consisted of inner longitudinal, middle circular, and outer longitudinal layers of smooth muscles (Fig1. and Fig 2.). The outer layer, the tunica adventitia is continuous with fibroelastic connective tissue which contain blood vessels and nerve endings. Similar findings were also reported by Doaa Zaghloul *et al* in Camel, Woldemeskel *et al.* (1998) in sows and Konig and Liebich (2006) and Dyce *et al* (2010) in domestic animals. Whereas A.R. Sreeranjini *et al* (2010) found that the sub mucosa of intra renal ureteric branches and ureter in Japanese quail contained collagen, elastic and reticular fibers. Tunica muscularis of ureter contained few elastic fibers among smooth muscle fibers. Tunica adventitia was comprised of loose connective tissue containing collagen and elastic fibers.

Effect of *Withania somnifera* on Monocrotophos toxicity in commercial Poultry

Rishi Kant, RP Diwakar and Pramod Kumar

Abstract
The present study was conducted to investigate the protective efficacy of aqueous extracts of root and leaves of *W.somnifera* (Ashwagandha) against monocrtophos toxicity in broilers. Seventy two day old broiler chicks, were divided randomly and equally into six groups viz. Group I (Untreated Control), group II(MCP Control), *W. somnifera* root extract was given daily@ 100 and 300(mg/kg b.wt., orally) to group III and IV respectively in drinking water, *W. somnifera* leaf extract was given daily@ 100 and 300(mg/kg b.wt., orally)to group V and VI respectively in drinking water. On 21 day group II,III, IV, V andVI were administered single oral dose of MCP @ 1.34mg/Kg b.wt.($1/5^{th}$ of LD_{50}). There was no significant difference in haematological parameters in any of the experimental groups of birds after 1 day of single monocrotophos treatment except TEC which was significantly reduced in group II in comparison to group I birds. After 7 days there was a significant ($P<0.05$) decrease in the values of Hb, TEC and % lymphocytes in group II birds in comparison to group I birds. After 7 days *W. somnifera* root and leaf extract could not change the altered value of Hb to normal in groups III to VI, however leaf extract increased the depleted values of TEC and of % lymphocytes in group V and VI.
Monocrotophos significantly increased the activities of ALT, AST and ALP after 1 day of monocrotophos exposure in group II in comparison to group I birds. *W. somnifera* root and leaf extract significantly decreased ($P<0.05$) the values of these enzymes in the birds of group III to VI. In addition to that, root extract also reduced the value of serum creatinine, total protein and albumin in group IV in comparison to group II. Other parameters like globulin level, A:G ratio and activity of LDH remain unchanged. After 7 days of monocrotophos treatment activities of ALT, LDH and creatinine level were increased significantly in group II as compared to group I birds. The AST and ALP activities were unaltered in group II as compared to group I birds. Root and leaf extract showed their potential by decreasing the activity of ALT significantly in group III to VI birds in comparison to group II. However, the extract could not ameliorate the toxic effect of monocrotophos on LDH activity and creatinine level. The other biochemical parameters were unaltered.

Keywords: Monocrotophos, Ashwagandha (*Withania somnifera*) root and leaf extract

1. Introduction
Monocrotophos is an organic ester of phosphorus, which has the ability to inhibit the AChE. It is widely used to control insects and pests of rice and other crops and ectoparasiticide in animal husbandry practices (WHO 1993) [16]. Exposure of poultry to monocrotophos causes health consequences to poultry culminating in great economic loss, while also posing a potential threat to public health due to presence of pesticide residue in poultry meat (Pal and Kushwah, 1998, 2000) [8, 9]. Chronic exposure of chicks to small amount of organophosphates leads to deleterious effects on metabolism and immune system of birds (Garg *et al.* 2004) [2, 3]. Pharmacological screening of *W. somnifera* reveals that it is used as a tonic, stimulant, alterative, aphrodisiac, diuretic and abortifacient. Prolonged medication with *W. somnifera* caused a positive effect on weight, feed consumption, general resistance, liver weight and antistress effects in men and animals (Rao *et al.*, 1999, Archana and Namasivyam, 1999) [10, 1]. The present study was conducted to investigate the protective efficacy of aqueous extracts of root and leaves extract of *W. somnifera* in poultry exposed to monocrotophos.

Materials and Methods
Preparation of root and leaves extracts
After collection the plant materials were shade dried and powdered. The powders were further processed for aqueous extraction. The powder was soaked in distilled water for 24h with intermittent stirring at 40 °Cwith the help of magnetic stirrer. The infusions were filtered through muslin cloth and centrifuged at 400g for 15 minutes to get the supernatant. The filtrates were dried with the help of incubator with fan and lypholizer (37 °C) to get the final extracts.

INTEGRATION BETWEEN THE THERMAL STRESS INDEX (TGWB) AND THE LIVESTOCK STRAIN INDEX (LSI) AS A GUIDELINE FOR DAIRY FARMING IN TROPICAL CLIMATE

Abstract

A new thermal stress index (TGWB Index), based on Air temperature (Tdb), globe temperature (Tg) and wet bulb (Twb) temperature suggests as a potential substitute for the temperature humidity index (THI) for cattle in tropical climate. This new stress index, found to have a high correlation to THI, is constructed from fast reading meteorological response sensors (Tdb, Twb, and Tg) that take only a few seconds to reach equilibrium. Furthermore, the TGWB Index is the first stress index using direct measurements of solar radiation and is calculated as follows:
TGWB Index = 0.78 (Tg + Twb) + 35.8
The recently suggested Livestock Strain Index (LSI) is capable of indicating physiological strain and analyzing milk production of cattle. The LSI is constructed from rectal temperature (Tre) and respiratory frequency rate (Rf) as follows:
$LSI = 5\ (Tre_{obs.} - Tre_{min.}).\ (Tre_{max.} - Tre_{min})^{-1} + 5\ (Rf_{obs.} - Rf_{min.}).\ (Rf_{max.} - Rf_{min.})^{-1}$
Where Tre_{obs} and Rf_{obs} are the observed measurements Tre_{max} and Tre_{min}, and Rf_{max} and Rf_{min} are maximum and minimum simultaneous measurements taken at any time. The LSI is scaled from 0-10, whereby each variable LSI_{Tre} or LSI_{Rf} which represent the cardiovascular and the thermoregulation systems respectively. The purpose of this study was to develop guidelines based on TGWB Index and LSI for dairy cattle for combat to heat stress. In order to integrate LSI and TGWB Index, we decided to use both the LSI_{Rf} and LSI_{Tre} component, which represents the respiratory frequency rate and the strain reflected by the cardiovascular system. Furthermore, LSI_{Rf} and LSI_{Tre} are easier to measure, are easier to implement and simplifies the integration with TGWB Index. Concomitantly, it also categorizes the strain between 0-5, the higher the value, the higher the strain.

Key words: Tropical climate, Thermal stress, Indices, Solar Radiation, LSI, TGWB Index

Introduction

The incidence of heat stress as measured by the frequency of days with THI greater than 80 has increased significantly over the 40-year period on record. This is due to both changes in the temperature variables used and also the incidence of drought as drought years appear to be also associated with high stress frequency.

In hot climates, high ambient temperatures, humidity, wind speed, and high direct and indirect solar radiation are the main environmental stress factors that impose strain on animals (Finch, 1985, Silanikove, 2000). Heat stress indices range from simple measurements of ambient air temperature to indices that try to provide a weighted estimation of all environmental factors involved. Keeping the fact that heat stress is caused by multiple environmental or thermal factors, it is often misleading to use ambient temperature alone as the indicator of heat stress. Different heat stress indices have been proposed that indicate level of thermal stress. Thom suggested a Temperature-Humidity Index (THI) based on dry bulb and wet bulb thermometers. The Temperature Humidity Index (THI) has been widely used as a heat stress index in beef and dairy (cattle & buffaloes) industries (Stokka *et al.*, 1996: West, 1999; Mader *et al.*, 2002). Following a list of temperature humidity indices:

$THI\ 1 = (0.15 \times T_{db} + 0.85 \times Twb) \times 1.8 + 32$
(Bianca, 1962),

$THI\ 2 = (0.35 \times T_{db} + 0.65 \times Twb) \times 1.8 + 32$
(Bianca, 1962),

$THI\ 3 = [0.4 \times (T_{db} + Twb) \times 1.8 + 32 + 15$
(Thom, 1959),

$THI\ 4 = (0.55 \times T_{db} + 0.2 \times Tpo) \times 1.8 + 32 + 17.5$
(National Research Council, 1971),

$THI\ 5 = (1.8 \times T_{db} + 32) - (0.55 - 0.0055 \times RH) \times (1.8 \times T_{db} - 26) = 0.81 \times T_{db} + 0.143 \times RH) + 0.0099 \times RH \times T_{db} + 46.3$
(National Research Council, 1971),

$THI\ 6 = (T_{db} + Twb) \times 0.72 + 40.6$
(National Research Council, 1971),

$THI\ 7 = (T_{db} + 0.36 \times Tpo) + 41.2$
(Yousef, 1985a),

The above indices have been used to calculate stress for each combination of environmental variables corresponding to the measurements made in the animals, in order to assure that each animal response was associated to a given environmental condition. The index THI1 is used to monitor discomfort of temperature and humidity in humans. The THI2 and THI7 have been empirically determined for cattle exposed to heat stress conditions in climatic chambers. How these indices from controlled environments relate to field conditions? With diurnal fluctuation of environmental variables remain unanswered (Bohmanova *et al.*, 2007). The index THI3 is used to monitor the degree of discomfort in humans. The THI5 represents cattle heat stress index, designed to indicate level of heat stress of outdoors cattle (West, 2003); and THI6 has been developed by the United State Weather Bureau to describe discomfort in humans.

THI values of 70 or less are considered comfortable, 75 to 78 stressful, and values greater than 78 because extreme distress and animals are unable to maintain normal body temperature (Silanikove, 2000). The THI fails to reflect the contributions of other environmental factors, such as airflow and thermal radiation.

As noted before, the index has gained immense popularity over the years. The temperature humidity index (THI) is in use in temperate climatic condition for cattle. The Temperature Humidity Index (THI) has been widely used as a heat stress index in beef and dairy industries (Stokka *et al.*, 1996: West, 1999; Mader *et al.*, 2002). It is important to note the correlation of temperature humidity index (THI) to physiological responses was only partially tested and was based mainly on the correlation between the number of heat stress cases of dairy animal and the heat load as calculated by the THI. I have inroduced my new thermal stress index (TGWB) based on Air temperature (Tdb), globe temperature (Tg) and wet bulb (Twb) temperature as follows:

TGWB Index = 0.78 (Tg + Twb) + 35.8

This newly developed index was validated by using large databases and was found to be highly correlated to the temperature humidity index (THI). TGWB Index differs from other indices that have been suggested in the past for two main reasons. First, new thermal stress index (TGWB) based on Air temperature (Tdb), globe temperature (Tg) and wet bulb (Twb) temperature, aside from using temperature

Abstract

An IPCC special report on the impacts of global warming of 1.5 °C above pre-industrial levels would be a world first and, accordingly, no previous experience in the determination of acceptable heat stress limits, criteria or indices is wholly applicable. However, some tropical countries are already at beyond high temperature and much of the knowledge gained in managing and raring of animal at such heat stress will be helpful in making adequate planning for acceptable environmental control at the greater thermal tress being contemplated. Accordingly, it is necessary to take cognisance of the dairy industry's experience in most tropical countries and of standards and regulations already established in South America and elsewhere in order to ensure acceptable conditions and control standards that compare favourably and defensibly with those in other dairy industries. Different countries uses of heat stress limits, criteria and indices were investigated as it was necessary to determine to what extent any other indices, limits or criteria would be applicable to tropical conditions. In addition, it was necessary to establish whether there was a single heat stress index that could be used in thermal stress for tropical climatic conditions. It was found that an appropriate combination of heat stress indices would be required in planning for and ultimately controlling thermal conditions in tropical climatic conditions. The solar radiations and humidity being contemplated and the concomitant potential heat hazard present too great a risk for reliance on environmental component of heat stress, such as wet-bulb temperature at present in common use locally. The study recommends that a heat stress index, preferably WBGT be used to design an modern dairy farm's ventilation system and that wet-bulb temperature be used to monitor and control the system once it is implemented.

Introduction

Environmental conditions that is conducive to safe and productive for cattle and buffaloes. Although many aspects of a dairy farming environmental conditions would be much the same as those already prevailing in poultry, sheep, goat and other animal farming sector the variations in high metabolic energy requirement to which animal are exposed would increase by virtue of increased depth. The paper therefore offers some guidelines for the use of heat stress indices and limits as would be applicable for dairy farming.

Thermal conditions and the heat stress imposed on animal will be the most significant environmental consequences of dairy farming, indicating a need to quantify the effects of heat on animal health and their production performance. This represents a difference in purpose from the traditional concern with heat stress. The principal motivation in efforts to evaluate and control heat stress in the dairy farm has been to minimize its detrimental effects on animal. This has resulted in the development heat stress indices based same on physiological tolerance and production performance criteria. Given the critical impact that productivity will have on the success or failure of dairy farming criteria should form part of the fundamental basis for determining the thermal standards. In the past, a number of heat stress indices have been devised in attempts to combine various environment variables into a single number indicative of the heat stress imposed on cattle and buffaloes. Although such a number can provide some measure of environmental heat stress, there are many and varied criteria for evaluating the acceptability of thermal conditions for dairy farming.

Heat stress indices

The incidence of heat stress as measured by the frequency of days with THI greater than 80 has increased significantly over the 40-year period on record. This is due to both changes in the temperature variables used and also the incidence of drought as drought years appear to be also associated with high stress frequency.

In hot climates, high ambient temperatures, humidity, wind speed, and high direct and indirect solar radiation are the main environmental stress factors that impose strain on animals (Finch, 1985, Silanikove, 2000). Heat stress indices range from simple measurements of ambient air temperature to indices that try to provide a weighted estimation of all environmental factors involved. Keeping the fact that heat stress is caused by multiple environmental or thermal factors, it is often misleading to use ambient temperature alone as the indicator of heat stress. Different heat stress indices have been proposed that indicate level of thermal stress. Thom suggested a Temperature-Humidity Index (THI) based on dry bulb and wet bulb thermometers.

The Temperature Humidity Index (THI) has been widely used as a heat stress index in beef and dairy (cattle & buffaloes) industries (Stokka *et al.*, 1996: West, 1999; Mader *et al.*, 2002). Following a list of temperature humidity indices:

$$THI\ 1 = (0.15 \times T_{db} + 0.85 \times Twb) \times 1.8 + 32$$

(Bianca, 1962),

$$THI\ 2 = (0.35 \times T_{db} + 0.65 \times Twb) \times 1.8 + 32$$

(Bianca, 1962),

$$THI\ 3 = [0.4 \times (T_{db} + Twb) \times 1.8 + 32 + 15$$

(Thom, 1959),

$$THI\ 4 = (0.55 \times T_{db} + 0.2 \times Tpo) \times 1.8 + 32 + 17.5$$

(National Research Council, 1971),

$$THI\ 5 = (1.8 \times T_{db} + 32) - (0.55 - 0.0055 \times RH) \times (1.8 \times T_{db} - 26) = 0.81 \times T_{db} + 0.143 \times RH) + 0.0099 \times RH \times T_{db} + 46.3$$

(National Research Council, 1971),

$$THI\ 6 = (T_{db} + Twb) \times 0.72 + 40.6$$

(National Research Council, 1971),

$$THI\ 7 = (T_{db} + 0.36 \times Tpo) + 41.2$$

(Yousef, 1985a),

Black Globe Humidity Index:

EFFECT OF EXOGENOUS MELATONIN AND DIFFERENT PHOTOPERIODS ON LYMPHOCYTE PERCENT COUNT IN CHHOTANAGPURI EWE

P. K. Choudhary[1*], A. K. Ishwar[2], P. K. Maurya[1], Pramod Kumar[1]
D. Niyogi[3] and M. Kumar[4]

[1]Department of Veterinary Physiology and Biochemistry, [3]Department of Veterinary Pathology, [4]Department of Veterinary Anatomy and Histology, C.V.Sc. and A.H., N.D.University of Agriculture and Technology, Kumarganj, Ayodhya, U.P., [2]Department of Veterinary Physiology, B.V.C., B.A.U., Ranchi

Abstract

Forty two (42) apparently healthy, non-pregnant, non-lactating Chhotanagpuri ewe, having body weight ranging between 14.11±0.09 to 15.38±0.06 Kg were selected and selected ewes were isolated from rams 2 months prior to melatonin administration. The selected animals were allocated randomly into seven groups viz. Group-I [Normal control], Group-II [Long day (LD) control], Group-III [LD + Melatonin administration orally (3mg/day)], Group-IV [(LD + Melatonin administration subcutaneously (1mg/day)], Group-V [Short Day (SD) control], Group-VI [SD + Melatonin administration orally (3mg/day)] and Group-VII [SD + Melatonin administration subcutaneously (1mg/day)] comprising six animals in each group. Rams were then introduced into each group after completion of exogenous administration of melatonin. Blood sample without anticoagulant in vials was collected from each animal day before the start of experiment and there after every month up to fifth month. Lymphocyte % in third and fourth month of experiment was significantly ($P<0.05$) lower in all groups (group-I to VII) in comparison to 0 day, first and second month. At fifth month, lymphocyte % was significantly ($P<0.05$) higher in group III, IV, VI and VII in composition to third and fourth month of experiment.

Keywords: Ewe, Photoperiod, Melatonin, Lymphocyte percent count

Introduction

Short days enhance immune function in individuals with robust reproductive responses to photoperiod. Total splenic lymphocyte number, and macrophage counts were significantly higher in hamsters exposed to short days, as compared to animals exposed to long photoperiods (Brainard *et al.*, 1988). Photoperiodic influences on lymphocyte number and total white blood cell count have been reported for deer mice (Blom *et al.*, 1994); short day (LD 8:16) mice possessed more white blood cells than animals maintained in long day lengths (LD 16:8). Importantly, all laboratory studies of photoperiodic effects on immune function have reported enhanced immune function in short day lengths (Nelson and Demas, 1996). Although many field studies support this hypothesis, with data suggesting enhanced immune function and decreased disease prevalence during the winter as compared to the summer, a substantial number of studies have reported the opposite pattern of results (Nelson and Demas, 1996); i.e., reduced immune function is coincident with the short days of winter. These conflicting results can be resolved by considering additional environmental factors, not usually manipulated in laboratory studies. For example, winter-associated stressors (e.g., restricted food and low ambient temperatures) appear to counteract short day enhancement of immune function in the lab.

Exogenous administration of melatonin increased the lymphocyte percentage in Broiler chicks (Abozahra *et al.*, 1998), Rats (Anwar *et al.*, 1998), and Squirrels (Rai *et al.*, 2009). Rai and Haldar (2003) reported daily subcutaneous injection of melatonin at 17:30 to 18:00 hr significantly increased the lymphocyte count of blood in adult male squirrels, while pinealectomy decrease percent lymphocyte count in peripheral blood and bone marrow. The precise mechanism responsible for this melatonin induced increase in lymphocyte percentage is not clear. However, several mechanisms may be involved in this respect. Haldar *et al.* (2006) accessed the effect of melatonin on immune parameters in a seasonally breeding animal, the Indian palm squirrel F. pennant and bird P. asiatica during reproductive phases in vivo as well as in vitro. Melatonin treated squirrels and birds showed an increase in percent lymphocyte count (% LC) and percent stimulation pinealectomy in squirrels. Melatonin administration recovered all the decreased immune parameters to the control level (Rai and Haldar, 2003). MEL supplementation also enhanced all immune parameters in both in vivo and in vitro, suggesting that the immune system was sensitive during the reproductively active phase to MEL when peripheral melatonin level was low and the role of melatonin could be important for the maintenance of the immune status of seasonal breeders.

As reported by Etim *et al.* (2014[a]) immune status is a function of leucocytes, lymphocytes and Neutrophils. Lymphocytes are known to play key roles in immune defense system of both man and animals (Etim et al., 2014[b]). The objective of this experiment was to determine Lymphocyte percent count in Chhotanagpuri sheep after exogenous administration of melatonin following different photoperiods.

Materials and Methods

The present study was conducted in Department of veterinary physiology, College of veterinary science and A.H., Birsa Agricultural University, Kanke, Ranchi-6, Jharkhand located at 23.36°N latitude and 85.33°E longitude with an altitude of 651 m above mean sea level. Design of experiment was approved by the Institutional Animal Ethics Committee vide letter no.-139/528/RVC/IAEC. Forty two (42) apparently healthy, non-pregnant, non-lactating Chhotanagpuri ewes, having body weight ranging between 14.11±0.09 to 15.38±0.06 Kg reared under uniform managemental husbandry practices were selected. Selected ewes were isolated from rams prior to melatonin administration. The selected animals were allocated randomly into seven groups (viz. group-I to group-VII) comprising six animals in each group. Group-I [Normal control]:- The animals in this group were exposed to normal variation in day length. Group-II [Long day (LD) control]:- In this group in addition to natural sun light, artificial light was provided to animal for maintaining 16-18 hours of light every day for the period of one month and considered as long day control. Group-III [LD + Melatonin administration orally (3mg/day)]:- In this group in addition to natural sun light, artificial light was provided for maintaining 16-18 hours of light every day for the period of one month and after that 3 mg melatonin was administered orally for one month to each animal. Group-IV [(LD + Melatonin administration subcutaneously (1mg/day)]:- In this group in addition to natural sun light, artificial light was provided for maintaining 16-18 hours of light every day for the period of one month and after that 1 mg melatonin was administered subcutaneously for one month to each animal. Group-V [Short Day (SD) control]:- Animals in this group were provided only 8 hours natural day light and were then kept in a light-proof shed for 16 hours exposure in dark every day for the period of one month. This group served as short day control. Group-VI [SD + Melatonin administration orally (3mg/day)]:- Animals in this group were provided only 8 hours natural day light and were then kept in a light-proof shed for 16 hours exposure in dark every day for the period of one month and after that 3 mg melatonin was administered orally for one month to each animal. Group-VII [SD + Melatonin administration subcutaneously (1mg/day)]:- Animals in this group were provided only 8 hours natural day light and then were kept in a light-proof shed for 16 hours exposure in dark every day for the period

Abstract

Arsenic in drinking water is the major cause of arsenic toxicity. Most of the reports highlighted chronic Arsenic toxicity in animals is increasing. In contrast inorganic arsenic compounds are well known as animal and human carcinogens, based on sufficient evidence in carcinogenicity in animals. From health point of view gastrointestinal effects, anaemia, peripheral neuropathy, skin lesions, hyper pigmentation, liver and kidney damage in animals and humans are common findings in arsenicosis. Inorganic exposure in animals by the inhalation has been shown to be strongly associated with lung cancer, while ingestion of inorganic arsenic in animals has been linked to a form of skin cancer and also to bladder, liver and lung cancer. A socio-toxicological survey was conducted in order to find out arsenic prone area in Faizabad district. Survey report showing Arsenic contamination in water, soil and poultry meat of Faizabad district (73% Veterinary/human hospitals/farmers informed about the contamination) as depicted in table no.1. This helps in the selection of centers. After survey and collection, samples were analyzed in laboratory. 80 samples each of water, soil and poultry meat collected from different locations of Faizabad districts were analyzed for detection of arsenic level. Arsenic contents of samples were detected by Hydride Generation Atomic Absorption Spectrophotometer (HG-AAS). The average arsenic contents of water, soil and poultry meat of different areas are 0.00550±0.00304 µg/g, 5.5500±2.9810 µg/g and 0.17924±0.05247µg/g respectively.Correlation analysis showed a significant positive correlation between drinking water, soil and poultry meat (Correlation coefficient $r=0.623$, $p<0.01$) and correlation was also found positive at (Correlation coefficient $r=0.497$, $p<0.05$). On the basis of above observation and results this can be concluded that periodical survey, study and monitoring of level of arsenic in water, soil & poultry meat is essential.

Keywords: Arsenic,Hydride Generation Atomic Absorption Spectrophotometer (HG-AAS).

Introduction

Arsenic is a widespread pollutant in various regions of the world (Flora *et al.*, 2005). Weathering of rocks converts arsenic sulfides to arsenic trioxide, which enters the arsenic cycle as dust or by dissolution in rain, rivers, or groundwater (Mandal and Suzuki, 2002). The occurrence of high concentrations of arsenic in groundwater used for drinking purpose has been recognized as a major public health concern in several parts of the world. Arsenic has been found to accumulate in the plant tissues and results in reduction in their biomass (Drlickova *et al.*, 2013).

The World Health Organization (WHO, 2007) permissible limit for arsenic is 0.01mg/l for drinking water and FAO permissible limit is 0.10mg/l for irrigation water (Bhattacharya *et al.*, 2009; Ahsan and Del Valls, 2011), whereas the concentrations of arsenic in non-contaminated soils range from 0.1to10mg/kg (Kabata-Pendias and Pendias, 1992). The immediate and long-term impact of using arsenic contaminated water for irrigating paddy soils is a burning concern as arsenic can transfer from water to soil and several studies have proven this phenomenon. It is seen that the total exposure of arsenic to humans and animals is the sum total of exposures from the diet, drinking water, direct ingestion of soil and dust, inhalation and percutaneous absorption (WHO, 2000; Hopenhayn, 2006). The areas across the Gangetic plains in India and Nepal also recently reported as the area affected from Arsenic (Maharjan *et al.*, 2005). Drinking water is the primary and main route of exposure to arsenic. Maximum Permissible Limit(MPL) is the standard concentration of arsenic in drinking water which is not hazardous, is set by the US EPA at 10µg/l (EPA, 2001) and the value for concentration of arsenic in drinking water is recommended by the WHO is also 10µg/l (WHO, 1992). In West Bengal (India), the arsenic concentration in drinking water is about 60 to 3700µg/l and about 40 million people are affected from it (Acharyya, 2002). In middle Ganga plain, Bihar, 206 tube wells (95% of total) were analyzed for arsenic content and showed that 56.8% tube wells have exceeded arsenic concentration of 50µg/l and 19.9% have more than 300µg/l (Chakraborti *et al.*, 2003; Acharyya *et al.*, 1999). Arsenic may be present in the organic or inorganic form (Ahmed, 2003). Of the inorganic forms, arsenite (trivalent) and arsenate (pentavalent) are the two most prevalent and potential dangerous forms, while organic form of organoarsenicals is also important (Dopp *et al.*, 2004; Sharaf *et al.*, 2013).

Himalayan Mountain and Tibet plateau are considered as the biggest source of arsenic contamination in the Gangetic region and this contamination is evidently becoming life threatening in almost every year (Chakraborti *et al.*, 2009). Geographically Uttar Pradesh is situated in the northern region of India and border of Nepal and comes under upper and middle gangetic plain. The river Ganga and Ghaghara are two major river flows from northeast to southeast. Arsenic was introduced as a contaminant in Ballia district of U.P. for the first time in 2003 (Yasunori *et al.*, 2012). Status of Arsenic Contamination in Eastern U.P.: In U.P. Jal Nigam and UNICEF combinedly reported and identified in 18 districts. Arsenic above the 10 ppb limit for drinking and Arsenic according to WHO limit was found in 31 districts (Chaurasia *et al.*, 2015; WSSO U.P. 2011). Times of India also reported "Ground water arsenic contamination of Uttar Pradesh exceeds to the value of BIS (Bureau of Indian Standards) permissible limit of 0.01 mg/liter across 31 districts of the state.

Pandey *et al.* (2015) reported alarming situation and highly contaminated districts are Bahraich, Ballia and Lakhimpur Kheri among than Ambedkar Nagar, Bareli, Basti, Bijnaor, Chaudauli, Faizabad, Ghazipur, Gorakhpur, Meerut, Sant Ravidar Nagar, Shahjahanpur, Siddarth Nagar, Sitapur, Unnao and Kanpur (Yasunori *et al.*, 2012).

Materials and Methods

This study was designed to **identify the** different **arsenic prone** locations in Faizabad district **of eastern Uttar Pradesh.** The major objectives were: –

Abstract

The present study was carried out to evaluate the influence of Moringa oleifera leaf extracts on carcass traits and mortality of broiler chickens. A total of 250-day-old broiler chicks (Vencobb-430) were randomly distributed into five groups with 5 replicates of 10 birds in each. Different dietary treatments were: basal diet with no supplement (NC- negative control) and basal diet supplemented with antibiotics (PC-positive control), aqueous extract of 1.5% Moringa powder (MOAQE), ether extract of 1.5% Moringa powder (MOEE) and alcoholic extract of 1.5% Moringa powder (MOALE). Percent weight of various cut parts, eviscerated weight and drawn yield were evaluated after 35 days of experiment. The results showed significantly higher eviscerated weight and drawn yield percentage in Moringa extracts supplemented groups compared to PC group. PC and MOAQE group recorded significantly (P<0.05) higher drumstick % compared to NC, MOEE and MOALE group. Moringa extracts group recorded significantly (P<0.05) lower mortality than PCand NC group birds. From these results it was concluded that supplementation of Moringa extract of 1.5% Moringa oleifera leaf powder improved the carcass traits and reduced the mortality of birds.

Key words: Broiler, Extract, Carcass, Mortality and Moringa (words in alphabetical order)

Introduction

Major cost involved for poultry enterprise is in the form of feed. Various approaches such as feed supplements and additives are being used to obtain more net return and to minimize expenditure in feed (Agasheet *al*., 2017). *Moringa oleifera* leaf (MOL) has fascinated great attention as a non-traditional feed component because of its unique qualities. Moringa oleiferagrows fast, drought-tolerant tree native belonging to sub-Himalayan tracts of northern India, Pakistan, Bangladesh and Afghanistan. Moringa is currently cultivatedglobally in the tropics and subtropics (Fahey*et al*., 2001). Crude protein content in Moringa varies from 25% to more than 30% on a dry matter basis (Melesse et al., 2013), with a high proportion of essential amino acids (Liu *et al*., 2016). Moringa leaves, flowers and Pods are used as good sources of vitamins A, B and C, riboflavin, nicotinic acid, folic acid, pyridoxine, ascorbic acid, beta-carotene, calcium, iron and alpha-tocopherol (Dahot 11, 1988). Moringa leaves are the preferred part of tree for use in animal diets as leaf meal due to high nutritional and medicinal properties (Abbas, 2013). The meat obtained from broiler chickens is an excellent source of protein, vitamins, mineralsand lower in fat content, so having a great demand among non-vegetarians(Naji *et al*., 2013).Addition of*Moringa oleifera* leaf meal in broilers diet resulted significant increase in dressed weight, eviscerated weight and dressing percentage (Ayo-Ajasa *et al*. 2016). Dietary supplementation of Moringa leaves would be a potential strategy to improve the meat quality in broilers due to its antioxidant potential. It was further reported that phytosterols could lower malondialdehyde content and increase glutathione concentration in the breast muscle of broiler chickens (Na *et al*., 2013).

This study was carried out to evaluate the effect of different extracts (5%) of *Moringa oleifera* leaves powder as feed supplement in broiler diets on carcass characteristicsand mortality of broiler birds. (Please correct red marks)

Materials and Methods

The present experiment was conducted after an approval from institutional animal ethical committee (IAEC)' was obtained vide reference number IAEC/CVSc/P-36/2019. A total of 250 one-day old Vencobb-430 strain chicks were randomly allocated into five dietary treatment groups with 5 replicates of 10 chicks in each. The chicks were kept on five dietary treatments which includes a basal diet without any additive in negative control (NC) or that supplemented with antibiotics (Positive control-PC), aqueous extract of 1.5% Moringa powder (MOAQE), ether extract of 1.5% Moringa powder (MOEE) and alcoholic extract of 1.5% Moringa powder (MOALE) in basal diet. Birds were fed *ad libitum* in different phases of experimental trial. The composition of formulated experimental diets as per BIS (2007) has been given in Table 1.

The chicks were kept on deep litter system under uniform standard management conditions with availability of clean, fresh and wholesome drinking water. Mortality was recorded during the entire research period. At the end of trial one bird per replicate (5 birds/treatment) were selected randomly for the carcass evaluation and sacrificed after 12 hours pre-slaughter fast though drinking of water was allowed. After complete bleeding carcass were dipped in hot water (58°C) for 1-2 minutes and feather were removed. Evisceration was done by making a slit from tip of breast bone up to the area around the cloaca. Thorough washing and cleaning were done after evisceration. After that the carcass were kept hanging on the special racks for 5-10 minutes. The visceral organs were removed by supporting the bird with one hand via the incised abdomen. Eviscerated carcasses were weighed and cut parts like thigh, drumstick, breast, wings, back, head, neck and shank were also weighed.The relative weight of dressed, drawn yield and different edible cuts were calculated as percentage of live weight.

The data were analysed under completely randomized (CRD) by employing one way analysis of variance (Snedecor and Cocran, 1994) and means of different dietary treatments were compared with Duncan multiple range test. The P value lower than 0.05 was thought-out significant.

(Please correct red marks)

Results and Discussion

Carcass characteristics:

The data pertaining to the carcass traits of broilers presented in Table 2. The results showed that the dressed weight and thigh weight of different groups was similar and showed no significant (P>0.05) effect of various Moringa extracts. The eviscerated weightof aqueous extract (72.24), ether extract (73.10) and alcoholic extract (73.09) supplemented group broilers were similar to NC (72.05) group, however significantly (P<0.05) higher than PC (70.39). The drawn yield of MOAQE, MOEE, MOALE and NC also significantly (P<0.05) higher than PC group. Leg and drumstick weight % of PC group was significantly (P<0.05) higher than MOEE and MOALE group. However, leg weight was

ABSTRACT

An experiment was conducted on "Effect of land configuration and moisture regimes on productivity of hybrid maize (*Zea mays* L.) in summer season," during 2018-19 at Agronomy Research Farm, ANDUA and T, Kumarganj, Ayodhya (U.P.). The experiment accomplished of 12 treatment combinations and laid out in split plot design, replicated three times. The Experiment consisted of three land configuration *viz.* flat bed planting (P_1), ridge planting (P_2) and paired row planting on raised bed (P_3) were kept in main plots and four moisture regimes *viz.*0.5 IW/CPE ratio, 0.7 IW/CPE ratios, 0.9 IW/CPE ratios and 1.1 IW/CPE ratios were allotted in sub plots. The experimental results revealed that growth parameters, such as plant height, leaf area index, dry matter accumulation, days to 50 percent ear emergence and days to50 percent maturity and yield were obtained maximum with the paired row planting methods followed by ridge planting and flat bed planting and yield attributes such as number of cobs plant^{-1}, number grains row^{-1}, number of grains cob^{-1}, cob length (cm), cob girth (cm), grains weight cob^{-1}(g), cob weight (g), shelling percentage (%), grain yield (q ha^{-1}), stover yield (q ha^{-1}), and biological yield (q ha^{-1}) were also increased similarity in same treatment. In case of moisture regimes, the same trends were observed maximum when applied irrigation at 1.1 IW/CPE ratios as compared to other moisture regimes.

GENETIC STUDIES ON REPRODUCTIVE TRAITS OF HARIANA COWS

***Ashish Kumar Srivastava, Jaswant Singh and V.K. Singh**
*Assistant Professor, Department of LFC
College of Veterinary Sciences and Animal Husbandry
N.D.U.A.T., Kumarganj- Faizabad (U.P.)

Abstract

The performance records of 211 Hariana cows, progeny of 27 sires, born during the year 1966 to 1985 having at least records up to second calving were utilized in this study. These cows were maintained at D.D.D. farm, Mathura and livestock farm, Madhurikund (Mathura). The average post partum oestrus interval was estimated to be 185.43± 11.18, the heritability estimate of post partum oestrus interval was estimated to be 0.021±0.175. The magnitude of the effect of sires was non significant and the variation in post partum oestrus accounted due to sires was very small (8.7%) in total variation. The least squares means and their standard errors of number of service per conception were estimated to be 2.19±0.26. The heritability estimate of the number of service per conception was estimated to be 0.294±0.210. The contribution of sires was 21.8% in the total variation of the trait.

Introduction

The cow is an efficient machine for converting farm crops into useful human food like milk and milk products, which are the main source of animal protein in the diet of a large vegetarian population of the country. Hariana breed of zebu cattle has been well established dual-purpose breed known for its milk yield as well as for draught ability. The breed has reduced significantly and is continuing to decline at an alarming rate. Apart from the declining population, Hariana cattle have also deteriorated in their productivity (Joshi et al., 1995).

Materials and Methods

The present study was undertaken on Hariana cows. All the animals taken into consideration were farm bred. The data used in this investigation were collected from the pedigree sheets, milking register and breeding record of Hariana cows maintained at DDD Farm, Mathura. The performance record of 211 cows, having at least record up to second calving were collected for genetic studies. The statistical analysis of the data was carried out by using the LSMLMW (Least Squares and Maximum Likelihood Method)- Harvey (1990) PC-2 version computer programme and Henderson (1953) model were used.

Results and Discussion

The least squares mean of the post-partum oestrus interval along with their standard errors have been presented in table 1. The average post-partum interval was estimated to be 185.43±11.18 days. The frequency of animal in various PPO groups (class interval of 40 days) is about 23.69% animals had post-partum oestrus interval below 90 days. The maximum frequency of animals was in 90 to 130 days group (26.54%). Present observation is comparatively higher than the average of post-partum interval reported by Luktuke and Subramanium (1961), Singh et al., (1964), Arora et al., (1971), Acharya et al. (1971) and Khanna (1998) for Hariana cows. Whereas, Kohli and Suri, 1957, Kohli and Suri, 1960 and Tomar and Arneja, 1972 have reported comparatively higher post-partum oestrus in Hariana cattle.

Least squares analysis of variance was performed to study the effect of farm, period and session of calving are present in table 2. The perusal of the table revealed that the effect of farm was found to be non-significant on post-partum oestrus interval in Hariana cows, although the contribution of farm was highest (83.5%) in total variation. However, Ashraf et al., (2000) observed highly significant farm effect on post-partum oestrus interval. The effect of period and season of calving were found non-significant. However, Mahmoud et al., (1991) observed a significant effect of month of calving.

Heritability estimate of post-partum oestrus interval was estimated to be 0.021±0.175. The magnitude of the effect of sires was non-significant and the variation in PPO accounted for due to sires was very small (8.7%) in total variation. The findings were indicative of zero heritability for this trait in these animals. Similar observations were reported by Prasad (1958) for Tharparkar cattle and Singh et al., (1964) for Hariana cattle.

Conclusion

Any selection programme based on post-partum oestrus interval will not prove beneficial in these cattle because the genetic variability for this character in these animals does not seem to exist. In view of the above observations, improvement in managemental practices may lead improvement in this trait.

Abstract
An experiment was conducted during winter season of 2016-17 on Berseem (cv. Mescavi). The experiment comprised of twelve treatments viz. T_1 (control), T_2 (100% RDF, 20 kg N + 80 kg P_2O_5 ha^{-1}), T_3 (100% N through Farm Yard Manure (FYM), T_4 (100% N through Poultry Manure), T_5 (50% RDF +50% N through FYM), T_6 (50% RDF +50% N through Poultry Manure), T_7 (50% N through FYM+50% N through Poultry Manure), T_8 (50% RDF +25%N through FYM +25% N through Poultry Manure), T_9 (75% RDF +25% N through FYM), T_{10} (75% RDF +25% N through Poultry Manure), T_{11} (25% RDF +75% N through FYM) and T_{12} (25% RDF +75% N through Poultry Manure) were tested in Randomized Block Design with three replications. the results revealed that the maximum plant height, fresh weight of leaf and stem, dry weight of leaf and stem, shoot : root ratio $plant^{-1}$ and number of nodules $plant^{-1}$ were observed with the application of 100% RDF (20 kg N + 80 kg P_2O_5 ha^{-1}) followed by 75% RDF +25% N through poultry manure and 75% RDF +25% N through FYM.

Keywords: FYM, Poultry manure, INM, growth, RDF, plant height, and leaf

Introduction
Berseem (*Trifoliumalexandrinum* L.) is one of the most important winter forage crop of India, due to high forage yield, palatability and nutritive value. It has become a very popular as *rabi* forage in irrigated areas or all most all over the country. Berseem belongs to one of the largest and most useful plant family leguminaceae and sub family faboideae. Berseem is known as king of fodder crops and it is popular among the world. It is one of the oldest cultivated crops, domesticated in Egypt and later introduced into many other parts of the world. Berseem was introduced in India in 1903 (Roy *et al*., 2009) [3]. It is now widespread in the irrigated regions of west and south Asia. Most of the farmers conserved the berseem as hay to get cheap, palatable and nutritive forage during scarcity periods or early winter and summer. Berseem is a cheapest source of increasing milk production as well as improving soil fertility. Berseem can be sown in early autumn and can thus provide feed before and during the colder months but the optimum conditions are 18-25 °C. If the winter temperature falls to 6-8° C the crop growth is severely affected. This is nutritious, succulent and palatable fodder available for fairly long period during winter, spring and early summer (Chaterjee and Das, 1989) [2]. Grazing is possible though less common than cutting. The most important cultural practices that need to be carefully adjusted to achieve maximum benefit from the forage grass-legume mixtures. The ability to fix atmospheric nitrogen and convert it to a useable form for plant growth is the main trait to these legumes (Allen and Allen, 1981) [1].

Poultry manure is an excellent soil amendment that provides nutrients for growing crops and also improves soil quality when applied widely, because it has high organic matter content combined with available nutrients for plant growth (Ryssen *et al*., 1993) [7]. The application of FYM with chemical fertilizers and composted with rock phosphate to improve crops yield is very well established (Shafi *et al*., 2012) [8]. Fertilizers play an important role in enhancing forage productivity. Chemical fertilizers are soluble and immediately available to the plants; therefore, the effect is usually direct and fast, the price is lower and they are quite high in

ASSOCIATIONS AMONG BODY CONDITION SCORE, PRODUCTION PERFORMANCE AND UDDER HEALTH STATUS IN DAIRY COWS

Abstract

To assess the associations among body condition score at calving (BCSC), BCS during lactation (BCSL), production performance and udder health status of dairy cows, 50 cows (HF cross) at 2nd parity were selected randomly. The animals after random distribution into 3 groups i.e. group I (BCS<3.0, thin), group II (3.0<BCS>3.5, moderate), group III (BCS>3.5, fat) kept in observation for 120 days. The BCS of group-III cows were significantly ($P<0.05$) higher than group I. The FCM, fat and SNF was positively correlated with BCSC and negative with BCSL. The somatic cell score (SCS) was correlated negatively with BCSC and positively with BCSL.

Key words- BCS, Milk, Milk composition, Udder health, SCS

Introduction

Milk quality is as significant as the milk quantity in dairy animals. High yielding dairy cows had higher incidence of mastitis that can be assessed by somatic cell count (SCC) of milk (Kadarmideen and Bryce, 2001). Optimal body condition of dairy cow is important for obtaining elite herd and quality milk. Low or higher body reserves may pose a risk of lower milk yield and higher SCC in milk respectively (Berry et al., 2007). High yielding dairy cows exhibit negative energy balance after calving which may influence both immune and metabolic system of the individual that predispose the animals to mastitis. Body condition score had a favourable correlation with SCC, but it was not strong (Berry *et al* Loc. cit.). Dang et al., (2010) reported non-significant relationship between BCS and SCC. Hence, it is postulated that there are no consistent results regarding the relationship between body condition score and somatic cell counts of the dairy animals. Therefore, the present study was carried out to investigate the association among body condition score, production performance and udder health status of dairy cows.

Materials and Methods

This study was carried out in the area under subtropical zone of Indo-Gangetic plane. Fifty lactating dairy cows (HF cross) of second parity available at the Teaching Livestock Farm in the College of Veterinary Science and Animal Husbandry, N.D.U.A.T., Kumarganj, Faizabad (U. P.) and in the small dairy farms of the surrounding villages were selected. Observations were recorded for 4 months. The animals in farm and field conditions were maintained under loose housing system and the stanchion system, respectively. The data collected at fortnightly intervals were, the Body Condition Score (BCS), production performances and Somatic cell count (SCC). Milk yield of selected animals in the farm and the field were recorded on the observation days both morning and evening. Milk samples were collected directly from the animal during milking to assess the milk composition such as fat, SNF (solid not fat), CLR (corrected lactometer reading) by EKO milk ultra, milk analyser (Milkana KAM98-2A). The milk yield was further corrected on 4% fat basis (Fat corrected milk, FCM) according to the formula given by Gaines (1928) as under-

FCM = 0.4 × milk yield (l) + 15 × milk fat (kg).

Body condition score of animals after calving were assessed in the morning milking by the chart formulated by Prasad (1994) having 1-6 scale with 1 indicating under body condition and 6 representing over body condition of the dairy cows. 1 to 6 scales were further splitted in to half or quarter point increment (e.g., 2.5 or 3.25). For the better interpretation of BCS effect on the milk yield, milk composition and udder health status, the animals were divided in to three groups on the basis of BCS at calving i.e. group-I (BCS <3.0, thin), group-II (3.0≤BCS≥3.5, moderate) and group-III (BCS > 3.5, fat). The udder health status was determined by somatic cell count (SCC) of milk immediately after collection as per methodology of IDF (1984). The SCC was log-transformed into the fortnightly test day observation SCS (Somatic cell score) as $SCS=\log_{10}SCC$ (Mrode and Swonson, 1996).

The collected data were analyzed by SPSS (version 11.5). The means of various measurements were compared by Duncan's Multiple Range test (Duncan, 1955). The Pearson's correlation coefficient was estimated to find relationships among observations.

Results and Discussion

Out of 50 animals, 13 cows were classified as thin (group–I), 20 as moderate (group–II) and 17 as fat (group–III) at parturition. BCS of cows at calving was 2.83±0.06, 3.38±0.03 and 4.22±0.11, in group I, II and III, respectively (Table-1). BCSC differ significantly ($P<0.05$) among the three groups of cows. The BCS during calving to 15 days were significantly ($P<0.05$) higher than rest period of lactation. The declining BCS might be due to mobilization of body fat reserves to cover milk production during early lactation (Buckley *et al.*, 2000, Friggens *et al.*,

Influence of Different Therapy on Hematological Markers and Fertility Response in Anestrus Sahiwal Cows

Safayat Husain[1], Rajesh Kumar[1]*, Bhoopendra Singh[1], Sushant Srivastava[1], Rabindra Kumar[1], Pramod Kumar[2], Ashish Srivastava[3]

Abstract

The study was designed to evaluate influence of different therapy on hematological markers, resumption of ovarian cyclicity and conception rate in 24 anestrus Sahiwal cows, which were randomly and equally allocated to four groups as G1, G2, G3 and G4. Lugols iodine (2%, cervical painting with per rectal massage of genitalia thrice on alternate day) XXX herbal bolus (1 bid for 2 days, repeated on day 11 & 12 later in non-respondents) and modified ovsynch protocol (progesterone 100 mg s/c once a day for 6 days followed by GPG) was administered in G1, G2 and G3, respectively, while G4 kept as untreated control. All these animals were dewormed with bolus fenbendazole 3 g plus ivermectin 100 mg, once and supplemented with mineral mixture 30 g/day for 21 days before above therapies. Blood samples were collected thrice, i.e., on day 0, day of induced estrus/AI and day 21 post-AI (day 0, 21 and 63 in non-respondents) for hematological analysis. In general, hemogram and leucogram did not vary significantly within and among different groups, except neutrophil and lymphocyte. Cent per cent estrus induction response was observed in treatment group G1, G2 and G3, however, none of the cows resumed cyclicity in untreated control group G4. The treatment to estrus induction interval was 9.17±2.34, 8.33±2.36 and 16±0.00 days; treatment to fertile estrus interval was 33.6±8.40, 42.0±8.57 and 29.4±5.14 days and overall conception rate was 83.33, 66.66 and 83.33 % in group G1, G2 and G3, respectively, while nil in untreated anestrus cows.

Keywords: Anestrus, Conception, Estrus induction, Sahiwal cows, Therapy.

Introduction

Bovine anestrus syndrome is a most common single cause of infertility in dairy cattle that leads to huge economic losses in terms of prolonged calving interval, reduced calf crop and shorter productive life. Malnutrition is the most common cause of true anestrus featured by absence of estrus cyclicity with small smooth inactive ovaries. Bovine anestrus syndrome is a multifactorial disorder of the reproductive cycle which is characterized by absence of estrus signs manifested either due to lack of expression of estrus or failure of its detection. It can be normal physiological (pregnancy, lactation and in early postpartum period) or pathological (metritis, fetal resorption/PCL, pyometra, maceration and mummification). Many non-hormonal and hormonal drugs have been used to treat anestrus (Kumar *et al*., 2011; Dhami *et al*., 2015; Dhami *et al*., 2019; Kumar *et al*., 2020[a]). Among herbal therapeutics, various type of tropical plants are used traditionally to augment the reproductive performance. Some plants contain secondary metabolites which are effective in inducing estrus in postpartum anestrus cows (Pugashetti *et al*., 2009). Deficiency of minerals is also an important cause of anestrus in animals (Kumar *et al*., 2020[b]). This study was therefore designed to assess influence of different treatment protocols on hematological markers as well as on fertility response in true anestrus Sahiwal cows.

Abstract

The genetic worth of a sire can be measured directly but it has to be estimated either on the basis of phenotypic performance or observed value of a trait in the sire itself, or information from relatives in sex-limited traits such as milk yield.

The present investigation was undertaken on 1367 first lactation records of Sahiwal cattle maintained at GLF, Chak Ganjaria, Lucknow (U.P.) over a period of 71 years (1944-2014). The study was conducted on breeding value estimation of sires, relationship between Estimated Breeding Values (EBV's) for first lactation and life time traits using daughter's average, least-squares and best linear unbiased prediction methods of sire evaluation and effectiveness of these methods. The rank correlations among the breeding value of sires estimated from first lactation milk yield and life time milk were medium to high and highly significant (P<0.01). Therefore, the daughters of the sires selected on the basis of high first lactation milk yield would tend to produce higher life time milk yield. The product moment correlations among the estimated breeding value of the sires for first lactation traits by all the three methods ranged from medium to very high and highly significant (P<0.01) in all the three methods of sire evaluation.

Introduction

Cattle rearing has been an important source of livelihood in India and is closely associated with agricultural economy. The agriculture and allied sectors contribute nearly 14 per cent of the Gross Domestic Production. The agriculture and livestock are the main source of employment in rural areas and about 52 per cent of the population is engaged in agriculture and rearing of livestock in our country.

The effectiveness of sire evaluation is the backbone of any breed improvement programme. This investigation was planned to evaluate Sahiwal sires as its performance is remarkable in hot climate and has been recognized worldwide as one of the best milch breed (Hatsia et al., 2011). Various sire evaluation methods viz. daughter's average, least-squares analysis and best linear unbiased prediction (B.L.U.P.) were used to evaluate the sires and their effectiveness were compared for Sahiwal cattle. The information on the production of first lactation is mainly required for getting genetic improvement through selection, since it serves as an index of life time production in dairy cows. Therefore, it is very much essential for the sire evaluation to correlate the first lactation milk yield with life time milk production.

Materials and Methods

The data for the present investigation were collected over a period of 71 years (1944-2014) from pedigree sheet of 1367 Sahiwal cows born to 112 sires maintained at Government Livestock Farm, Chakganjaria, Lucknow (U.P.). Only the sires having the records on at least three or more daughters were included in the present study. The total duration of the present study was divided into 8 periods.

Out of 8 periods 7 are of 9 years each and 8th period of 8 years only. Each year was divided into three seasons namely winter (November-February), Summer (March- June) and Rainy (July- October). In order to classify the data for different periods and seasons year and season of calving was considered for all the traits.

Statistical Analysis

Rank correlation

After estimation of breeding value of sires, the sires were given rank as per their genetic merit. The Spearman's rank correlation between breeding values of sires derived by various methods was used to judge the effectiveness of different methods. The rank correlation was estimated as per methods developed by Steel and Torrie (1960).

$$r_s = 1 - \frac{6\sum d_i^2}{n(n^2-1)}$$

Where,

r = Rank correlation coefficient

n = Number of sires under evaluation

d_i = Difference of rank between paired items under two methods

The significance of rank correlation was tested by t-test as given below

$$t = r\frac{\sum(n-2)}{(1-r^2)}$$

It was compared with t-table value with (n-2) degree of freedom.

Simple product moment correlations

The simple correlations (r) between the estimated breeding values of bulls by different sire evaluation methods were also calculated by the following formula:

$$r_{(XY)} = \frac{Cov(XY)}{\sqrt{[Var\ (x)\ \ Var\ (Y)]}}$$

Where,

$$Cov\ (XY) = \sum XY - \frac{(\sum X)\ (\sum Y)}{n}$$

$$Var\ (X) = \sum X^2 - \frac{(\sum X)^2}{n}$$

$$Cov\ (Y) = \sum Y^2 - \frac{(\sum Y)^2}{n}$$

Where,

X, Y= The breeding value of sires estimated by two different methods

n= Number of pairs of breeding value

Rank correlation

The rank correlations of most efficient method (LSM) of sire evaluation for LTMY was statistically highly significant (P<0.01) with their values 1.00 ($\overline{D}$ and LSM), 0.71 ($\overline{D}$ and BLUP) and 0.71 (LSM and BLUP). For LTLL, the rank correlation between the different methods were 1.00 ($\overline{D}$ and LSM), 0.79 ($\overline{D}$ and BLUP) and 0.79 (LSM and BLUP). The rank correlation of estimated breeding values of LTMY between daughter's average and least squares method was very high (100%) (Table-1).

It revealed that ranking of sires for the estimated breeding value by daughter's average and least-squares method was similar while ranking of sires from BLUP was different. Similarly, for the LTLL, the rank correlation of estimated breeding values between ($\overline{D}$) and LSM was very high (100%). It revealed that ranking of sires for the estimated breeding value by $\overline{D}$ and LSM was similar while ranking of sires by BLUP was different.

Product moment correlation

The product moment correlations of most efficient method (LSM) of sire evaluation for LTMY with other two methods of sire evaluation (

Abstracts

The present study was conducted to investigate the effect of different litter materials on growth performance of Kadaknath chicks 300 Kadaknath chicks were raised on three litter treatments viz. Sand, rice hulls and rice hulls plus chopped paddy straw (1:1) co of two replicates in each treatment. The result showed that chicks reared on paddy straw + rice hulls litter had significantly hig weight, lower feed intake and better FCR($P<0.05$). The body weight of chicks raised under sand and rice hull litter did significantly, however the average daily feed intake of chicks under rice hulls was significantly higher than that of under sand performance index of the earlier study period was significantly higher in paddy straw + rice hulls followed by sand and r respectively.

Key words: Kadaknath, feed, body weight, sand, rice hulls, litter materials

Introduction

Desi fowls are cheaply reared as scavenging flocks by feeding household left over and their meat and egg taste are preferred over those of exotic chickens (Dessie and Ogle, 2001).Wood shaving has been standard choice for poultry litter for many years. Rice hulls appear to be a favourable alternative to wood shavings (Grimes *et al.*, 2007).Various types of litter materials like sand (shields *et al.*, 2005), gypsum (Grimes *et al.*, 2007), rice and wheat straw (Sreehari Sharma 2010), ground corn cob and soyabean straw(De Avila *et al.*, 2008) have been utilized as bedding materials for rearing of poultry birds. Sand has shown good potential as an alternate litter for more reuse quality and very less caking.

Pine shavings and saw dust are the most desirable and most widely used litter materials for broiler production in the United States. About 60% of farmers used saw dust as litter materials, 16.7% used wood shaving, 20% used both wood shaving and saw dust while 3.3% of farmers do not use bedding materials. The types of litter used by farmer depend on locality and availability (Kalu E. 2015) . Paddy husk is most commonly used litter material in northern India.Sigroha et al., (2017) used saw dust, wheat straw, rice husk, river bed sand and sandy soil as litter materials and found higher weight of birds at 42 days of age in wheat straw followed by sandy soil, saw dust, river bed sand and rice husk. As far as seen in literature there is no concert conclusion for litter type and thickness for various regions and climates. In view of above a study was undertaken with following objectives-

To investigate the effect of litter material on the growth perf of kadaknath fowls

To study the feed conversion efficiency of kadaknath fow various bedding materials

Materials and Methods:

The present investigation was carried out to study the different litter materials on growth performance, feed gain Kadaknath fowl. The study was carried out at the poultry Teaching Livestock and Poultry farm of the College of V science and Animal Husbandry, N.D.U.A.T. Kumarganj, U.P., situated at a distance of 42 km away from Faizabad cit km away from Jagdishpur Industrial area at an altitude o above sea level and latitude of 26° 47' North and longitude East and it falls in Eastern plain Zone of Middle Gange region of India.

Experimental period and climatic conditions

The experiment was conducted in the months of Nove February which comprised winter season of this region. Du period, the climatic parameters have been shown in table average minimum temperature recorded during study pe 12.54°C, while the average maximum temperature was There were a few showers of rain, ranging from 62 to 123 average was 92.5 cm during this period. The topography o almost even and most of the farm area remains dry round Parasitic infestation was moderate.

Climatological parameters recorded during experiment period

S.No	Climatological Parameters	Average Value	Average Max	Average Min
1.	Environmental temperature(°C)	18.7	24.86	12.54
2.	Relative humidity (%)	70.35	77.68	57.86

Experimental animals

To carry out present investigation, 300 straight run day old Kadaknath Chicks, from college hatchery were got issued. These 300 kadaknath chicks were divided into two batches; each batch consisted of 150 Kadaknath Chicks. Each batch was subdivided in three equal groups of 50 chicks viz. Group1 (sand), Group2(rice hulls), Group3(paddy straw + rice hulls) randomly distributed among three pens. Each pen was equipped with fresh litter, feeder and waterer. All the birds were raised on pukka floor with sand, rice hulls and paddy straw + rice hulls (50:50) as litter materials. Chicks were reared under standard uniform managemental practices up to the age of 42 days and observations for different parameters were recorded simultaneously. Thereafter, a replication was made with the next batch of chicks.

Brooding and rearing of chick

Brooder house

The cold room brooding method was applied for brooding an of Kadaknath Chicks in the brooder house. Brooding was pukka floor using deep litter system. Each group of Kadakna placed in separate pens which were visually isolated from e along with provision of adequate ventilation and artificial li brooder house.

Preparation of brooder house to receive Kadaknath chicl

Brooder house was properly scrubbed and cleaned at leas before the trail began. After the house, equipments were cleaned. The house was allowed to dry out thoroughly. The equipments were fumigated using 1% formalin. Three inches litter were made on the floor. Few days before the chicks equipments were arranged in brooder house and the elect were started to adjust temperature and light. The temperat the brooder house was slightly above 35°C. The corners of space were made rounded off with cardboard and metal chi to prevent chicks from piling up in the corner. All these pre

EFFECT OF DIFFERENT LITTER MATERIALS ON BEHAVIOR OF KADAKNATH FOWLS

Abstract

The present study was conducted to investigate the effect of different litter materials on behavior of Kadaknath chicks. A total 300 Kadaknath chicks were raised on three litter treatments viz. Sand, rice hulls and rice hulls plus chopped paddy straw (1:1) comprising of two replicates in each treatment. The results indicate that Kadaknath chicks reared on sand and rice hull litter had significantly higher proportion of time in activities like drinking, dust-bathing and perching than paddy straw+rice hulls. The behavioral activities like drinking, dust bathing, stretching, standing and perching in sand litter, dust-bathing, peaking, stretching, walking, lying and perching in rice hulls and peaking, stretching and standing in straw+rice hulls were seemed to be significantly differed in morning, noon and evening hour interval.

Keywords: Kadaknath, feed, behavior, sand, rice hulls, litter materials

Introduction

Desi fowls are cheaply reared as scavenging flocks by feeding household left over and their meat and egg taste are preferred over that of exotic chickens (Dessie and Ogle, 2001). Wood shaving has been standard choice for poultry litter for many years. Rice hulls appear to be a favourable alternative to wood shavings (Grimes *et al.*, 2007). Various types of litter materials like sand (shields *et al.*, 2005), saw dust (Grimes *et al.*, 2007), rice and wheat straw (Sreehari Sharma 2010), ground corn cob and soyabean straw (De Avila *et al.*, 2008) have been utilised as bedding materials for rearing of poultry birds. Sand has shown good potential as an alternate litter for more reuse capacity and very less caking.

Pine shavings and saw dust are the most desirable and most widely used litter materials for broiler production in the United States. About 60% of farmers used saw dust as litter materials, 16.7% used wood shaving, 20% used both wood shaving and saw dust while 3.3% of farmers do not use bedding materials. The types of litter used by farmer depend on locality and availability (Kalu E. 2015) . Paddy husk is most commonly used litter material in northern India.Sigroha et al., (2017) used saw dust, wheat straw, rice husk, river bed sand and sandy soil as litter materials and found higher weight of birds at 42 days of age in wheat straw followed by sandy soil, saw dust, river bed sand and rice husk. As far as seen in literature there is no concert conclusion for litter type and thickness for various regions and climates. In view of above a study was undertaken with following objectives-

- To investigate the effect of litter material on the behavior of Kadaknath fowls

Materials and Methods

The present investigation was carried out to study the effect of different litter materials on growth performance, feed gain ratio of Kadaknath fowl. The study was carried out at the poultry unit of Teaching Livestock and Poultry farm of the College of Veterinary science and Animal Husbandry, N.D.U.A.T. Kumarganj, Faizabad U.P., situated at a distance of 42 km away from Faizabad city and 38 km away from Jagdishpur Industrial area at an altitude of 113 m above sea level and latitude of 26° 47' North and longitude of 82° 12' East and it falls in Eastern plain Zone of Middle Gangetic Plain region of India.

Experimental period and climatic conditions

The experiment was conducted in the months of November to February which comprised winter season of this region. The average minimum temperature recorded during study period was 12.54°C, while the average maximum temperature was 24.86°C. There were a few showers of rain, ranging from 62 to 123 cm and average was 92.5 cm during this period. The topography of land is almost even and most of the farm area remains dry round the year. Parasitic infestation was moderate.

Experimental animals

To carry out present investigation, 300 straight run day old Kadaknath chicks, from college hatchery were got issued. These 300 kadaknath chicks were divided into two batches; each batch consisted of 150 Kadaknath Chicks. Each batch was subdivided in three equal groups of 50 chicks viz. Group1 (sand), Group 2(rice hulls), Group3 (paddy straw + rice hulls) randomly distributed among three pens. Each pen was equipped with fresh litter, feeder and waterer. All the birds were raised on pukka floor with sand, rice hulls and paddy straw + rice hulls (50:50) as litter materials. Chicks were reared under standard uniform managemental practices up to the age of 42 days and observations for different parameters were recorded simultaneously. Thereafter, a replication was made with the next batch of chicks.

Brooding and rearing of chick

Brooder house

The cold room brooding method was applied for brooding and rearing of Kadaknath Chicks in the brooder house. Brooding was done on pukka floor using deep litter system. Each group of Kadaknath chicks placed in separate pens which were visually isolated from each other along with provision of adequate ventilation and artificial light in the brooder house.

Preparation of brooder house to receive Kadaknath chicks

Brooder house was properly scrubbed and cleaned at least a week before the trail began. After the house, equipments were properly cleaned. The house was allowed to dry out thoroughly. The house and equipments were fumigated using 1% formalin. Three inches depth of litter were made on the floor. Few days before the chicks arrived, equipments were arranged in brooder house and the electric bulbs were started to adjust temperature and light. The temperature under the brooder house was slightly above 35°C. The corners of brooding space were made rounded off with cardboard and metal chick guards to prevent chicks from piling up in the corner. All these preparations were completed for Kadaknath chicks before they were procured to brooder house. A chick guard of about 15 cm height was used at a distance of 30 to 40 cm away from the brooder and was moved away for the every day. It was completely removed after two weeks.

Litter materials

For the present experiment three litter materials namely sand, rice hulls and paddy straw + rice hulls (50:50) were used for rearing the Kadaknath chicks. Rice hulls were procured from the nearby rice mill, paddy straw taken from village shivnathpur and sand was taken from kumarganj market. These litters were clean, dry and free from fungal growth. The thickness of litter was 3.0 cm. After spreading this litter on the floor with proper thickness was covered with newspaper up to 4 days of brooding.

Parameters recorded

Behaviour

The behaviours in the Kadaknath recorded in this study were chosen from preliminary observations and defined as a list of 12 states which have given here.

STUDY THE PHYSIO-HEMATOLOGICAL RESPONSE BEFORE AND AFTER DISBUDDING IN CALVES

Shiv Swaroop[1], P.S. Pramanik[1], K.D. Singh[2*], A.K. Verma[2], Vishuddha Nand[2] and A.K. Srivastav[1]

[1]Department of Livestock Production Management, College of Veterinary Science and Animal Husbandry NDUAT, Kumarganj, Faizabad- 224229, Uttar Pradesh, India [2]Department of Livestock Farm Complex, College of Veterinary Science and Animal Husbandry NDUAT, Kumarganj, Faizabad- 224229, Uttar Pradesh, India

Abstract

The aim of the present investigation was to examine the effect on Physio-haematological profile before and after disbudding in calves. The study was carried out at Livestock Farm Complex, College of Veterinary Science and Animal Husbandry, NDUAT, Kumarganj, Faizabad and nearby villages. Twenty four cattle calves were utilized to study Physio-haematological parameters that are Respiration Rate (RR), Pulse Rate (PR), Rectal Temperature (RT), Haemoglobin (Hb (gm/dl), Neutrophil (%), Basophil (%), PCV (%), Lymphocyte (%), Monocyte (%), TLC (10^3/ µl), Eosinophil (%) and N:L ratio) before and after disbudding in to four groups viz. control (T_0), lignocaine (T_L), tramadol (T_T) and lignocaine+tramadol (T_{L-T}). After medication calves were disbudded by hot iron method. The physiological parameters recorded just before (0h) and after disbudding on 1h, 6h and 24h. The blood samples were collected for haematological parameters just before (0h) and after disbudding on 6h, 24h and 72h. The results showed that, at 0h, 1h, 6h and 24h RR were significantly different among treatment groups. Only at 0h PR was significantly different among different treatment groups and during rest of the period up to 24h there is no significant different among groups. There was significant difference for RT only at 24h among different treatment groups. At 24h, T_0 group showed significantly lowest Hb (10.66±0.49%) which was statistically similar to T_T and T_{L-T} groups. At 0h, 6h and 72h means of PCV% were significantly different among treatment groups. There was no significant different in eosinophil, neutrophil and TLC among different treatment groups during the whole period of study. The lowest lymphocytes (64.00±1.00) was observed in T_T group at 6h. The T_0 group showed significantly lowest basophil (0.00±0.00) which was statistically similar to T_T and T_{L-T} groups but significantly different from T_L group at 6h. At the same interval, T_0 group showed significantly lowest monocytes (4.66±0.61) which was significantly different with T_L T_T and T_{L-T} groups. At 6h, T_0 group showed significantly lowest N/ L ratio (0.15±0.01) which was statistically similar to T_T and T_{L-T} groups but significantly different from T_L group. It may be concluded that generally physiological responses like RR, PR and RT were higher in control groups than treatment groups before and after disbudding. No significant difference was observed in eosinophil%, TLC, neutrophil% and monocyte% counts between control and treatment groups. However Hb%, basophil%, PCV% and lymphocyte% were significantly different between control and treatment groups. N/L ratio was significant only at 6h. Most of the cases T_{L-T} group showed comparatively better performance.

Introduction

Disbudding is painful yet common husbandry practice in the cattle industry, especially on dairy farms, because horniess cattle are safer (ALCASDE, 2009) and injuries to cattle and other animals are reduced (Prayaga, 2007). Dehorned cattle are safer to handle and cause fewer injuries to workers, other cattle, and farm animals (Stafford and Mellor, 2005). Cattle are also dehorned to reduce bruising and hide damage and to meet transport requirements (Gooneweardene and Hand, 1991; Faulkner and Weary, 2000; Prayaga, 2007). Several disbudding methods exist, including cautery, the use of caustic paste, and hot iron. All of these methods involve tissue damage and have been described as painful (Stafford and Mellor, 2005; 2011). The *Model Code of Practice for the Welfare of Animals: Cattle*, however, strongly advises against caustic disbudding (PISC, 2004).

Despite this knowledge, dehorning is commonly performed without pain relief because of the costs and impracticalities associated with researched methods (Petherick, 2005). The breeding of polled cattle eliminates the need for dehorning and because horns are inherited as an autosomal recessive with polledness being dominant (Long and Gregory, 1978), The legislation pertaining to dehorning and disbudding differ between countries like in Sweden, disbudding without local anaesthesia and sedation was banned in the 1992 Animal Rights Act (Bengtsson *et al.* 1996), but calves may be dehorned in Denmark without local anaesthesia until they are 4 weeks of age (Grondahl-Nielsen *et al.* 1999). The Council of Europe recommends the use of anesthesia for the dehorning of calves over 4 wk of age (Oliver, 2009). Pain control is also required for all calves under the *Canadian Code of Practice for the Care and Handling of Dairy* Cattle (NFACC, 2009). Furthermore, the Australian *Model Code of Practice for the Welfare of Animals: Cattle* recommends the use of local analgesics for dehorning calves over 6 month of age (PISC, 2004). Thus, the need to meet industry standards and the availability of suitable dehorning pain relief regimens for commercial production remain a challenge. Very little work has been done on the disbudding distress in Indian dairy animals particularly in indigenous animals.

Materials and Methods

The aim of the present investigation was to examine the Physio-hematological response before and after disbudding in calves. Study was carried out at the Instructional Livestock Farm Complex of the college of Veterinary Science and Animal Husbandry, NDUAT, Kumarganj, Faizabad and around the campus. Twenty four (24) farm born cattle calves of 2 to 3 weeks were randomly divided into four groups within each comprising of 3 males and 3 females, Control (T_0), Lignocaine hydrochloride (2%) @ 1 ml/ bud (T_L) (Tramadol @ 0.25 mg/ kg body weight I/M) (T_T) and Lignocaine + Tramadol at above dose rate (T_{L-T}). Medication was done 5-10 minutes before disbudding. Two doses of ligocaine per bud were injected for corneal nerve block in calves.

(a) Physiological responses

Physiological responses recorded before and after disbudding were as follows-

Respiration rate (no./ minutes)	Pulse rate (no./ minutes)	Body temperature (°F)

(b) Haematological parameters

Haematological responses recorded before and after disbudding were as follows

a) Hb (gm/dl)	d) Neutrophil (%)	g) Basophil (%)
b) PCV (%)	e) Lymphocyte (%)	h) Monocyte (%)

ABSTRACT: The present study was carried out by research scholar of department of veterinary & A.H. extension education, ANDUAT, Kumarganj, and Ayodhya in the eastern plain zone of Uttar Pradesh. The state was purposively selected because, broiler farming in Uttar Pradesh as already discussed is in developing stage as compared to southern, western and other north Indian states like Punjab, Haryana etc. There is a substantial gap in demand and supply of poultry meat and table eggs. Uttar Pradesh being the most populous state and having large population engaged in both contract and non contract broiler poultry production. The Eastern Plain Zone was selected purposively due to highest poultry population among all other zones. The Eastern Plain Zone comprises of 12 districts namely Ambedkar nagar, Azamgarh, Ballia, Barabanki, Chandauli, Faizabad, Ghazipur, Jaunpur, Mau, Sant Ravidas Nagar, Sultanpur and Varanasi. For the present study, three districts viz. Sultanpur, Amethi and Pratpagarh were selected purposively out of 12 districts, on the basis of poultry population. Two District Ambedkarnagar and Sultanpur were selected from eastern plain zone of Uttar Pradesh, purposively on the basis of poultry population and intensity of contract broiler farmers. From each block, two lists, one of contract broiler farmers and other of non-contract broiler fanners were prepared, from each list 20 contract and 20 non-contract poultry farmers having at least 2000 birds and two years of experience in poultry farming were selected randomly. Thus from each block 40 farmers (20 contract and 20 non-contract) were selected which make the total sample size of 160 broiler farmers (80 contract and 80 non-contract). Majority of the respondents (56.25%) were belonging to middle age category followed by young age (23.75) and old age (20.00) respectively. Maximum percentage (46.25%) of contract broiler farmers belonged to OBC caste followed by general (32.50%). Overall, 61.25 per cent of the broiler farmers in the study area were Hindu, followed by Muslim (38.75%). Majority (51.25%) of the contract broiler farmers belonged to nuclear family type, followed by joint family (48.75%). The result of socio-economic status like Age, education, family type, family size, experience, occupation of poultry farmer play important role in rate adoption and get more economy of poultry farmers in contract and non-contract pattern of broiler poultry farming.

Keywords: Socio-economic profile, Poultry farmers, Contract farming, Non-contract farming.

INTRODUCTION

Broiler poultry farming plays an effective role in improving the economic status of the rural poultry farmers by increasing their socioeconomic condition besides providing nutritious food through meat. There is regional variation in poultry production like contract and non-contract patter of poultry farming in India Poultry is one of the fastest growing segments of the agricultural sector in India today. During the 2013–14 fiscal years, the nation exported 4.3 million metric tons of poultry products to the rest of the world for a total of Rs. 565.87 crores (APEDA, 2013). Broiler farming plays an effective role in improving the economic status of the rural people by increasing their income besides providing nutritious food through meat. There is regional variation in poultry production in India. The northern region is lagging behind as compared to southern and with in northern region. In northern region UP has poor performance as compared to Haryana and Punjab. The total Poultry in the country is 851.81 Million in 2019, increased by 16.8% over previous Census. The total Backyard Poultry in the country is 317.07 Million in 2019, increased by 45.8% over previous Census. The total Commercial Poultry in the country is 534.74 Million in 2019, increased by 4.5% over previous Census. According to estimates, in India,

Abstract

A study was carried out at ANDUAT, Kumarganj, Ayodhya in the eastern plain zone of Uttar Pradesh. The Eastern Plain Zone was selected purposively due to highest poultry population among all other zones. The Eastern Plain Zone comprises of 12 districts namely Ambedkar nagar, Azamgarh, Ballia, Barabanki, Chandauli, Faizabad, Ghazipur, Jaunpur, Mau, Sant Ravidas Nagar, Sultanpur and Varanasi. The state was purposively selected because, broiler farming in Uttar Pradesh as already discussed is in developing stage as compared to southern, western and other north Indian states like Punjab, Haryana etc. There is a substantial gap in demand and supply of poultry meat and table eggs. Uttar Pradesh being the most populous state and having large Muslim population has huge potential for growth of poultry sector. So in this context two districts Ambedkarnagar and Sultanpur were selected from eastern plain zone of Uttar Pradesh, purposively on the basis of poultry population and intensity of contract and non-contract broiler farmers. Two block was selected from each district and from each block, two lists, one contract broiler farmers and other of non-contract broiler fanners were prepared. From each list 20 contract and 20 non-contract poultry farmers having at least 2000 birds and minimum two years of experience in poultry farming were selected randomly. Thus from each block 40 farmers (20 contract and 20 non-contract) were selected which make the total sample size of 160 broiler farmers (80 contract and 80 non-contract). Majority (58.75%) of the broiler farmers had medium level of adoption of housing management practices, followed by low (28.75%) and high (12.50%) level. Majority (55.00%) had medium level of adoption of brooding management practices. Majority (51.88%) of the broiler farmers had medium level of adoption of health care management practices, followed by low (29.37%) and high level (18.75%). While majority of contract and non-contract broiler farmers (50.00% & 53.75%) had medium level of adoption of health care management practices, followed by low (26.25 and 32.50%) and high (23.75 and 13.75%) level, respectively.

Key words: *Adoption level, Broiler farming, Contract farming and non-contract farming, Eastern plain Zone*

Introduction

Broiler farming plays an effective role in improving the economic status of the rural poultry farmers by increasing their income besides providing nutritious food through meat. There is regional variation in poultry production like contract and non-contract patter of poultry farming in India. The northern region is lagging behind as compared to southern and with in northern region. In northern region UP has poor performance as compared to Haryana and Punjab. The total poultry in the country is 851.81 Million in 2019, increased by 16.8% over previous Census. The total Backyard Poultry in the country is 317.07 Million in 2019, increased by 45.8% over previous Census. The total Commercial Poultry in the country is 534.74 Million in 2019, increased by 4.5% over previous Census. According to estimates, in India, a vertically integrated system produced 90% of the poultry in the Southern region, 80% in the Western region, 70% in the Eastern region, and 10% in the Northern region (Rajan 2006). Poultry is one of the fastest growing segments of the agricultural sector in India today. During the 2013–14 fiscal years, the nation exported 4.3 million metric tons of poultry products to the rest of the world for a total of Rs. 565.87 crores. (APEDA, 2013). The economic status also affect rate adoption of poultry farmers in contract and non-contract pattern of broiler farming. Good economic status have higher rate of adoption of scientific broiler farming like housing, brooding, feeding and health care management. **Materials And Methods**

The Eastern Plain Zone was selected purposively due to highest poultry population among all other zones. The Eastern Plain Zone comprises of 12 districts namely Ambedkar nagar, Azamgarh, Ballia, Barabanki, Chandauli, Faizabad, Ghazipur, Jaunpur, Mau, Sant Ravidas Nagar, Sultanpur and Varanasi. For the present study, three districts viz. Sultanpur, Amethi and Pratpagarh were selected purposively out of 12 districts, on the basis of poultry population. So in this context two districts Ambedkarnagar and Sultanpur were selected from eastern plain zone of Uttar Pradesh, purposively on the basis of poultry population and intensity of contract and non-contract broiler farmers. Two blocks was selected from each district and from each block, two lists, one contract broiler farmers and other of non-contract broiler framers was prepared. From each list 20 contract and 20 non-contract poultry farmers having at least 2000 birds and minimum two years of experience in poultry farming were selected randomly. Thus from each block 40 farmers (20 contract and 20 non-contract) were selected which make the total sample size of 160 broiler farmers (80 contract and 80 non-contract).

Results And Discusion

The adoption of scientific broiler farming practices was studied with respect to housing,brooding, and feeding and health care management practices. The results are presented in followingtable

Housing Management Practices:

Table 1.1 Distribution of poultry farmer Adoption level of contract and non-contract broiler farmers with respect to housing management practices:

ABSTRACT

India is a developing country. Agriculture and livestock husbandry plays crucial role in Indian rural economy. Dairy husbandry is an integral part of rural livelihood adopted as income generating activity by majority of the rural people. Women play a significant role in dairy development, even after many custom discriminations against them. Entrepreneurial attributes of one's personality indicate the success of an enterprise managed by individual. With this background an attempt have been made to study level of participation of women and men members in dairy husbandry practices, Milkipur block of Faizabad District in Uttar Pradesh, India. For the purpose multistage sample and single random sampling designs were applied and 100 dairy cooperative members (50 men and 50 women) were interviewed with the help of structured and pre-tested interview schedule. Ten entrepreneurial attributes were studied and its relationship with income generated through dairy husbandry was also confuted. The Overall Participation in dairy farming activities, the majority of male milk cooperative members in medium category (52%). Likewise, in case of female milk cooperative members majority in medium category (76%). Thus, it may be concluded that the female milk cooperative members were found better as compared to male milk cooperative members in Overall Participation in dairy farming activities. Focused that out of twenty-one selected independent variables, only five variables i.e. extension contact, entrepreneurial behavior, milk production, milk consumption and milk marketed were found highly significantly ($P \leq 0.01$) and positively correlated with the income through dairy cooperative. That is out of twenty-one selected independent variables, only four variables i.e. Social Participation, Participation in Health care, milk production and milk consumption were found significantly ($P \leq 0.05$) and positively correlated with the employment through dairy cooperative. The both dependent variables income generation and employment generation are positively and significantly ($P \leq 0.05$) correlated with each other.

Impact of stocking density on gait score and mortality in broiler chickens

KD Singh, PS Pramanik, Subodh Kumar, Rajesh Kumar, AK Srivastav and MK Verma

Abstract
The research was conducted to investigate the impact of stocking density (i.e., I.C.A.R., Venky·s and Amrit recommendations) on gait score & mortality in broiler chickens. A 500 day-old straight run commercial broiler strain "VENCOB" chicks were divided in two batches. Each batch was subdivided in 3 equal groups namely Gr 1 (I.C.A.R.), Gr 2 (Venky·s) and Gr 3 (Amrit). All the birds were raised on pucca floor with saw dust as litter material providing equal managemental practices. Walking ability was accessed at weekly interval up to 6 weeks of observation. The gait scoring system followed in the present study was Modified gait scoring system developed by Garner *et al.* (2002). Daily mortality of birds was recorded in morning hours &mortality rate was calculated weekly. The lowest and highest% of birds showing GS 0 under I.C.A.R. recommendation of stocking density have been found to be 83.93±0.64% (week 4) and 92.86±0.40% (week 6) respectively. Similarly the corresponding proportion of birds showing GS 1 were 6.07±0.78% (week 1) and 13.93±0.64% (week 4) respectively. Comparatively lesser % of birds show GS 2 and the lowest and highest L.S. means % of this were 0.00±0.40% (week 6) and 3.21±0.82% (week 3) respectively. Venky's & Amrit's observation were also similar as I.C.A.R. recommendation has been observed. Overall it has been observed that% of birds showing GS 0 was significantly more in I.C.A.R. followed by Amrit and Venky's during this study. However, highest% of birds showing GS 1 was recorded in Venky's recommendation followed by Amrit and I.C.A.R. Whereas, less than 5% birds exhibited GS 2 in this study in respective of stocking densities. There was no significant difference regarding% of birds with GS 2 in three stocking densities during all the weeks except at week 4. The overall mortality (%) was less than 5% over weeks under each placement densities. No significant difference was observed among mortality rates of broiler chickens under these three stocking densities during all the weeks studied. From present study, this can be concluded that leg health and walking ability was comparatively better under I.C.A.R. recommendation followed by Amrit and Venky's. However, effect of stocking density on mortality was non significant among three stocking

Keywords: gait score, foot pad lesions, stocking density, mortality and walking ability

Introduction
The total poultry population in India is 729.2 million, which is 12.39 percent higher than numbers in the previous census (Livestock Census, 2012) [21]. Poultry is one of the fastest growing sectors of Indian agriculture today, with annual growth rates of 5.57 percent and 11.44 percent in egg and broiler production, respectively. The value of output from the poultry sector was US$10 billion in 2014 (Rajendran *et al.*, 2014) [25]. Broiler production has been more vibrant than layer production within the poultry sector, with an annual growth rate of 11.44 percent, production of 3.725 million tons and employment of 4.29 million people (Index Mundi, 2015) [15]. India is the fourth largest producer of poultry meat in the world, valued at US$ 6.6 billion. Poultry production accounts for about 0.66 percent of India's GDP and 7.72 percent GDP from the livestock sector (Rajendran *et al.*, 2014) [25]. Poultry meat production increased from 0.069 million tons in 1961 to 3.725 million tons in 2014. The per capita availability of poultry meat is 2.8 kg; against recommended level of 11 kg (Rajendran *et al.* 2014 [25]; Index Mundi, 2015 [15]). The main reasons for improved broiler poultry production (Kalamkar, 2012; SAPPLPP, 2009) [17, 29] are: modernization of production practices; import o pure lines/grandparent stock; least-cost feed formulation; vaccines against major diseases provision of EAS and other input services; improved quality breeder management developments in poultry processing; and private sector partnerships through Contract Broil Farming. It is estimated that 37 percent of broiler production in India is under contracts, an about 78 percent of those contracts are concentrated in southern India (Rajiajwani, 2012) [26]. Gait scores (GS), a parameter used to evaluate walking ability (Kestin *et al.*, 1992; Garner *et*

Abstract

The present study was carried out in layer birds maintained at farmer field of Azamgarh under supervision of Krishi Vigyan Kendra, Kotwa, Azamgarh, (NDUAT, Kumarganj, Ayodhya) Uttar Pradesh spread over 3 years (2015-16 to 2016-17 and 2017-18). Causative agents were listed and per cent mortality was calculated during different seasons. There are four seasons, viz. winter, summer, southwest monsoon and northeast monsoon. Brooder and grower layer (0-20 weeks) and adult layer (21-68 weeks) were reared in deep litter/cage system of management. The overall mortality pattern during brooder and grower period (0-20 weeks) revealed that in southwest monsoon the mortality was the highest (53.32 %), followed by 26.22 % during summer, 14.33% in northeast monsoon and the lowest (6.11%) in winter. The overall mortality due to omphalitis was high (29.24%) and significantly (P<0.05) influenced by season. Colibacillosis, hepatitis and chicken pox incidences were also significantly (P<0.05) influenced by season and the overall per cent mortality incidences were 19.46, 17.04 and 6.09 respectively. Debility and non specific causes for mortality were 14.61 and 13.26 per cent respectively. The causes of mortality in layer chicken observed were hepatitis (40.56 %), Staphylococcal infection (18.56%), pneumonia (6.21%) and non specific (34.66%) in that order from high to low. The mortality during laying period due to hepatitis was higher during winter (66.66%) and southwest monsoon (45.00%). The incidences of pneumonia and Staphylococcal infections were observed only in monsoon.

Keywords: Layer chicken, Mortality Pattern, Season.

Introduction

The layer chicken (*Gallus domesticus*) a well known bird in western countries, is yet to be established on commercial point of view in the rest of the world especially in developing countries. Commercial layer farming is becoming popular in India and farmers started to show interest in rearing layer birds. The bird is quite suitable for socio-economical improvement of small and marginal farmers as it can be easily reared with little investment for housing, equipment and management. Since the economy of the poultry farm depends on livability of birds, the mortality records in a poultry farm are of immense importance to know the prevalence of diseases and for adopting preventive and control measures (Buragohain and Kalita, 2010). Information regarding mortality pattern of layers and the causes under local condition of Eastern Uttar Pradesh (Purwanchal) is inadequate. Considering the importance of proper documentation of layer diseases, which help in the analysis of occurrence of the diseases and finding out the etiological agent for taking appropriate disease control measures, the study was undertaken to assess the causes and pattern of mortality in layers under sub-tropical humid climate of Azamgarh.

Materials and Methods

The present study was carried out in layer chicken maintained at farmer fields of district Azamgarh under supervision of Krishi Vigyan Kendra, Kotwa, Azamgarh affiliated with NDUAT, Kumarganj, Ayodhya, Uttar Pradesh spread over 3 years (2015-16 to 2016-17 and 2017-18). Causative agents were listed and per cent mortality was calculated during different seasons. The four seasons of Azamgarh district are, winter (December, January and February), summer (March, April and May), southwest monsoon (June, July and August) and northeast monsoon (September, October and November). Layers were reared under deep litter/cage system and standard managemental conditions.

Brooder and grower poultry (0-20 weeks of age) and layer poultry (21-68 weeks of age) were reared in deep litter system. Mortality was recorded throughout the rearing period and post-mortem examination of all the 650 birds died was done. The data were analysed as per standard statistical procedure described by Snedecor and Cochran (1994).

Results and Discussion

Brooder and grower mortality (0-20 weeks of age)

The incidence of brooder and grower mortality is presented in Table.1. The overall mortality pattern during brooder and grower period (0-20 weeks) revealed that in southwest monsoon the mortality was the highest (53.32%), followed by 26.22 % during summer, 14.33 % in northeast monsoon and in winter the lowest (6.11 %). Apart from this, 22.39 per cent of mortality observed in summer may be due to stressors like high temperature with high humidity during which predispose bacterial, parasitic and other diseases. Behera *et al.* (2012) reported an overall brooding mortality in broiler chicken as 64, 24.5 and 11 per cent in summer, winter and rainy seasons respectively.

In the present study, mortality in brooder and grower was attributed to omphalitis, colibacillosis, hepatitis, debility, non-specific causes and chicken pox in that order from high to low. The highest mortality due to omphalitis was observed in summer (43.33 %) followed by winter (28.57%), southwest monsoon (26.55 %) and lowest in northeast monsoon (18.51 %) season. Highest mortality incidence due to omphalitis in summer followed by winter might be the reason of bacterial contamination such as E.Coli, staphylococcus, streptococcus and proteus contamination, which will be predominant in summer as well as winter. Terregino *et al.* (2000) found that the commonest causes of mortality in chicken at the first week were omphalitis, yolk sac infection and septicemia. Sharma *et al.* (2005) reported higher deaths due to omphalitis, weaklings, colibacillosis and pneumonia during first week in broilers. The incidence of colibacillosis in brooder and grower period in different season ranged from a low 6.09 % during northeast monsoon and a high 33.33 % during summer. The season had significant (P<0.01) influence on the incidence of colibacillosis. More incidences of colobacillosis in summer might be the reason of low water level leads to contamination. Hepatitis incidence was also influenced significantly (P<0.01) by season in this study up to 20 weeks of age with the value ranging from a low 2.29 % in southwest monsoon to a high 39.02% in northeast monsoon. Feed toxicity due to high humidity in monsoon season might be a possible reason. Incidence of chicken pox mortality (24.39%) was observed only in northeast monsoon. Debility and non-specific causes were found to be significantly (P<0.05) higher in southwest monsoon (23.60 % and 26.22 % respectively) and lower (4.87% and 6.09% respectively) in northeast monsoon.

Layer mortality (21-68 weeks of age)

The incidence of layer poultry mortality is presented in Table.2. The causes of mortality observed were hepatitis, nonspecific causes, Staphylococcal infection and pneumonia in that order from high to low in winter and southwest monsoon. The overall mortality pattern during laying period (21-68 weeks) revealed that in winter the mortality was the highest (38.46 %), followed by 25.64 % during southwest monsoon, 23.07 % in northeast monsoon and in summer the lowest (12.82 %). The overall mean mortality of 42.35% due to hepatitis was observed with a low incidence of 27.77 % in northeast monsoon and

Abstract: This study was conducted in Sultanpur district purposively selected because in this district there is highest milk production among all the entire district in Faizabad commissionery (U.P.). There are a total number of 69 milk cooperative societies under cooperative milk union Sultanpur district. These cooperative societies will be arranged in descending order according to the total milk collection at each cooperative society. From the list of cooperative societies, 10 milk cooperative societies having highest milk collection will be selected purposely. The list of member dairy farmers will be prepared from the selected milk cooperative society. From the list 10 members dairy farmers from each of the selected society would be selected randomly. So 100 members dairy farmers and non member dairy farmers would be identified thus a total of 200 dairy farmers will be the sample size for the study reveals that in case of Member dairy farmers in district Sultanpur dairy farmer, the maximum number of respondents58% were found in (32-82) of age group, like this 15 % literate, 73% other backward caste, 74% nuclear family, 62% medium family size (5-11 members), 93% marginal land holding size (less than 1 ha.), 36% agriculture occupation, 63% low categories annual income (up to 87165 Rs), 33% pucca houses, 72% in middle categories overall material possession (13 to 37 equipment), respectively. Likewise, in case of non member of dairy farmers, the majority of the respondents 59% were found in (32-61) of age group, like this 14 % literate, 65% other backward caste, 69% nuclear family, 79% medium family size (5-11 members), 98% marginal land holding size (less than 1 ha.), 37% agriculture occupation, 56% low categories annual income (up to 87165 Rs), 40% pucca houses, 62% in middle categories overall material possession (13 to 37 equipment), respectively.

Introduction

Livestock rearing are believed to be the first step of the primitive man toward civilization. Livestock has played a crucial role in the development and progress of mankind. They have provided human beings with food, energy, clothing and nutrition besides helping in transport and agricultural activities. They have also been mute companions to humans. Today, livestock rearing is not only a subsidiary source of income but. It provides livelihood insurance during extreme climatic conditions like drought flood etc. also. Being a predominantly agricultural economy, India has the one of the lives to cooperation largest population in the world. Presently, the livestock sector accounts for about 21 percent of the value of output of the combined crops and livestock sectors which constitute agriculture. This in turn is about 29 percent the total Gross Domestic Product (GDP) of the economy. In India more than 70 percent of the human population in villages depends on agriculture, animal husbandry and allied activities for their livelihood. Among many livestock enterprises, dairying is the most ancient occupation that established well in rural setting of the country. The dairying requires a lot of skilled and unskilled manual labor for its various kinds of activities like maintenance of animal, feeding, milking, cleaning of cattle sheds, taking care of calves, processing of milk and marketing etc. Thus, the employment potential is higher in dairy sector. Our country bears a rich tradition in dairying since the time of lord Krishna. Dairying has been inherent in Indian culture for centuries. Growing private investment in dairy processing facilities are also expected to provide further impetus to India's milk production over the coming years. The hub model was developed based upon farmer owned and managed milk collection and chilling centres in remote rural areas. Several measures have been initiated by the government to increase the productivity of livestock, which has results in increasing the milk production significantly from the level of 102.6 million tons at the tenth plan (2006-07) to 127.9 million tons at the end of the eleventh plan (2011-12). Milk production during 2013-14 and 2014-15 was 137.7 million tones and with an annual growth rate of 3.97% and 6.27% respectively. This means that the world's average farmer keeps 2.9 milk animals with an average annual milk yield of approximately 2.1 ton ECM/animal/year. Of course, building averages is an over simplification. There is a wide variation of dairy farms in the world ranging from less than 3 cows per farm in some countries to over 1,000 cows per farm in others. The simple example shows that milk production is performed distinctively in different countries and their dairy regions. The dairy farming systems differ significantly in terms of farm size, housing, mil king and feeding systems Hence, keeping in view the above facts into consideration, the present study was carried out with the following objectives: To study the social, economical, profile of the respondents [1,2].

Methodology

The study would be undertaken in Sultanpur district purposively because in this district there is highest milk production among all the entire District in Faizabad. There are a total number of 69 milk cooperative societies under cooperative milk union Sultanpur district. These cooperative societies will be arranged in descending order according to the total milk collection at each cooperative society. From the list of cooperative societies, 10 milk cooperative societies having highest milk collection will be selected purposely. The list of member dairy farmers will be prepared from the selected milk cooperative society. From the list 10 members dairy farmers from each of the selected society would be selected randomly. A similar number of non member dairy farmers having almost same socio economic characters would be selected from the same village [3-7].

[4]Scientist, KVK, NDUAT, Kotwa, Azamgarh-276207 (U.P.) India

Abstract

Backyard poultry has tremendous scope for quick and large term profit. In recent years, backyard poultry production has been extremely emphasized in sustaining and enhancing rural livelihoods for rural youth. A present study was undertaken in eight blocks of district Azamgarh of Uttar Pradesh to know the impact of trainings on scientific method of backyard poultry farming among small and marginal poultry farmers participated in KVK`s training programme. Collection of data regarding gain in knowledge and adopted level about improved poultry science technologies in backyard poultry farming were recorded before and after trainings. The findings revealed that 98.07 farmers gained knowledge in housing, 92.30% in breed awareness, 86.92%in balanced poultry feed, 80.76 % in vaccination, 69.23% in deworming, 59.61% in lime stone grit, 28.74 % in grazing and 10.00% in azolla feed, respectively. Study showed that very few farmers were known about scientific method of backyard poultry farming before training programmes whereas, after training programmes the level of adoption increased as 80.19% in concentrate feed, 79.80 % in breed awareness, 77.50% in vaccination, 67.31% in deworming, 51.92% in grazing, 50.96% in lime stone grit, 11.54% in housing, and in azolla feeding 10.0%. The overall adoption percentage by the farmers indicated that training had significant impact in uptake of new technologies.

Keywords: backyard poultry, training, vaccination, adoption level, farmers

Introduction

Poultry farming has now become a remunerative business and pre-eminence over all other livestock enterprises in the developing countries. Backyard poultry farming play an important role in the economic development of the country. In general, economic development refers to a process of upward changes of human resources which can be improved through increasing knowledge and attitude level of the rural take holders. Training is an integral and crucial input for the human resources development in all walks of life, be it agriculture, poultry husbandry, animal husbandry, fisheries or any other field for bringing out desirable changes in human behaviour (Biswas *et al.*, 2008). The concept of training programmes in scientific method of Backyard poultry farming through KVK grew substantially due to greater demand for improved poultry science technology by the farmers. Poultry population plays an important role in the national economy and socio-economic development of the landless, small and marginal farmers by supplementing family incomes and generating gainful employment.

The majority of the Kadaknath, Banraja are non-descriptive and native breeds also. Most of the farmers are rearing poultry under traditional pattern and lack of scientific knowledge. Therefore, the present study was undertaken with the specific objective to know the impact of trainingimparted by KVK, Azamgarh on scientific method of backyard poultry farming and feeding practices.

Materials and Methods

The study was carried outby NDUAT, KVK, Azamgarh in eight villages *viz.*, Gopalpur, Punarji, Auti pahalwanpur, Akma, Bharthahi, Mirza adampur, Panshabda and Surjanpur of eight blocks *viz.*, Palhani, Jahanganj, Bilariyaganj, Tahbarpur, Sathiyaon, Lalganj, Azmtgarh and Mohammadpur respectively, Azamgarh district were selected by NDUAT-Krishi Vigyan Kendra, Azamgarh, U.P., India (Table 1).

These blocks were selected because of large number of small and marginal farmers were participated in KVK`s training programme. Hands on on-campus training programmes were conducted on feeding, breeding and disease management under scientific dairy farming at KVK, Azamgarh. Participants took interest and eagerly participated in training programme. Pre-determined questionnaire supplied to trainees (rural youth farmers and farm women) participated in trainings organized at KVK to know and record their experiences.

Off-campus training programmes also organized for Self-help groups (SHGs) to visit their farm and confirm their adoption regarding scientific method of backyard poultry farming at farm level. During off campus trainings data were collected through personal contacts with the help of well-structured interview schedule. At end of training programme feedback form were collected from trainees. Inputs like dewormer, lime stone grit, balanced poultry feed and azolla seed culture and training materials were supplied. The selection of beneficiaries based on poultry farming trainees of KVK during preceding three years (2016-2018) was prepared. Out of 950 trainees list, only 520 farmers were randomly selected from that eight blocks. The gathered data were processed, tabulated, classified and analyzed in terms of percentage in the light of objectives of the study. Total practices were selected to find out the extent of knowledge and adoption of scientific method of backyard poultry farming.

Table-1: Selection of farmers from different blocks of adopted village

S. No.	Name of Block	Name of Villages
1.	Palhani	Gopalpur,
2.	Jahanaganj	Punarji
3.	Bilariaganj	AutiPahalwanpur
4.	Tahbarpur	Akma
5.	Sathiyaon	Bharthahi
6.	Lalganj	MirjaAdampur
7.	Azmatgarh	Panshabda
8.	Mohammadpur	Surjanpur

Results and Discussion

Gain in knowledge

The gain in knowledge by the respondents about scientific methods of backyard poultry farming and azolla feeding was measured in term of percentage. The data regarding gain in knowledge about scientific method of backyard poultry farming and feeding technologies were recorded under two heads *i.e.* knowledge before training and after training.

The data presented in the Table 2 revealed that, the beneficiary farmers of backyard poultry farming training programmes gained highest knowledge about housing system (semi intensive and intensive) (98.07%), followed by new breed (92.30%), balanced poultry feed (86.92 %), vaccination (F-1, Gumboro) (80.76%), deworming (69.23%), lime stone grit (59.61%), grazing (28.74 %), and andazolla feed (10.0%). The findings of the study revealed that farmers gained knowledge ranging from 10.0% to 98.07%. Verma *et. al.*, (2018) and Sivashankar and Khedgi (2011) revealed that training has a definite impact on the knowledge level of the respondents. This might be due to the fact that they were convinced through training programmes about scientific method of backyard poultry farming and azolla feeding by KVK, which were designed to import latest knowledge through work experience.

ABSTRACT

This study was conducted in Sultanpur district purposively selected because in this district there is highest milk production among all the entire district in Faizabad commissionery (U.P.). The study reveals that in case of Member dairy farmers in district Sultanpur dairy farmer, the maximum number of respondents constraints faced like, the women do not come out from the houses for taking care the animals because of social values, nonfunctional of animal insurance schemes, improved breed are not available in nearby market, lack of transport facilities, non availability of knowledge of insurance, lack of availability of green fodder, high cost of veterinary treatment, lack of remunerative milk prices and suggestions are growing green fodder and storage of straw, government must provide marketing facilities at village level for selling the milk and milk products, improved breeds should be made available in nearby markets, made appropriate infrastructure of shed, accumulate knowledge from veterinary officers, VLO, social campaigns regarding vaccination should be conducted in village, animal health clinic should be established nearest to the village, precision should be made by the govt. regarding fixation of prices with involvements of the dairy farmers. Likewise, in case of Non-Member dairy farmers in district Sultanpur dairy farmer, the maximum number of respondents constraints faced like, distantly located animal health clinic, nonfunctional of animal insurance schemes, lack of knowledge about cattle breed improvement for higher milk production, non availability of knowledge of insurance, lack of availability of green fodder, high cost of veterinary treatment, poor transportation also affects adversary in proper disposal of the products and suggestions are properly contact to veterinary doctor and means for reach to animal to AHC, proper prices for milk and milk products should be insured, lack of knowledge about cattle breed improvement for higher milk production, improved breeds should be made available in nearby markets, made appropriate infrastructure of shed, accumulate knowledge from veterinary officers, VLO and precision should be made by the govt. regarding fixation of prices with involvements of the dairy farmers.
Keyword – Dairy farmer, Dairy Society, Constraint, etc.

INTRODUCTION

The unique characteristic of Indian dairy industry is that bulk of milk production in our country is handled by small milk producers who are illiterate and ignorant of economic aspects of milk production dairying is a secure path and future of our neural development and became a commercial enterprise. It can contribute substantially to farmer's income. His way of looking to the daring has not been changed from subsidiary to commercial business. These problem seriously reduce the production potentials of animals, especially cross breeds as they are more susceptible to diseases, hardships and contingencies peculiar to the Indian climate. The reproductive capability the animal, a major concern in its economic losses to farmer's value in dairy farming is frequently related to paripartient events as undesirable health related to events during this period might result in tremendous economic losses to farmers. By the end of gestation in dairy make huge demands for energy, protein is such that it occurs at the most productive period of a lactating animal (Tholkappian and Satheeshkumar2014).

ABSTRACT

A study was undertaken in the Azamgarh district of Utter Pradesh to examine the effect of mineral mixture and deworming on regularization of estrus in dairy animals. Buffaloes (28; age group 4–8 years) of which 14 were in anestrus and 14 were repeat breeder and Cow (8; age group 4-6 years) of which 8 were repeat breeder were selected and dewormed on first day and from next day all the animals were allowed to lick a mineral mixture @ 40-50 grams daily for 90 days during October to December. Observations on all dairy animals revealed an average increase of milk production from 1.5- 2.0 litre per animal per day in 50% of the animals and in 50% animals comes in heat and conceives so, milk production decline and some animal stop milking. The fodder intake was also increased following mineral mixture supplementation and deworming in dairy animals. Moreover, some of the anestrus buffaloes came in heat during the study period however, after 20-30 days of completion of trial 75% (21/28) of the buffaloes and 62.55% (5/8) came in heat and conceived to first impregnation, which, normally show estrus from January to April. It was concluded that anthelmintic drugs decreases the parasitic load and mineral mixture being a good source of essential minerals improved milk yield, dry matter intake, general health status and reproductive performance of dairy animals.

Key words : *Mineral Mixture, Deworming, Anoestrus, Dairy Animals.*

In present time dairy sector faces major problems of infertility, repeat breeding and anoestrus in livestock which are hindering welfare of farming community. The farmers reared the animals are generally fed variable quantity of low quality feed resources like wheat straw and rice straw which are characteristically low in fermentable nitrogen, mineral, and readily available carbohydrate. These deficiencies result in low animal growth, poor reproduction, long calving interval, and infertility in animals. Inadequate nutrition is one of the factors that frequently limit the full utilization of the productive and reproductive potential of livestock in this region. Developing alternate feeding strategies for ruminant by enhancing the nutritive value roughage is of prime importance. A mineral mixture with locally available agricultural byproducts like wheat bran, rice bran, mustered cakes, common salt and molasses has been adoptable feed supplement which improves nutritional status of animals (Kang *et al.*, 2007).

Baseline survey to identify the commonly problem in dairy animal and an on farm trial (OFT) were formulated and conducted. However, the successful treatment and control of mineral deficiencies and practical methods of supplementation and reducing worm burden have been tried. Feeding of only the deficient minerals may not improve the general health status, production and reproduction of animals in these areas but also lower down the worm infestation. Hence, the present study was undertaken to evaluate the effect of mineral mixture as supplementary feeding and deworming on the general health condition, milk yield and reproductive performance of dairy animals.

MATERIALS AND METHODS

Adult Murrah and cross breed buffaloes (28) and cross breed cow (8) from different block and villages of Azamgarh district was selected by NDUAT-Krishi Vigyan Kendra, Azamgarh, U.P., India (Table 1). They generally fed their animal through grazing and variable quantity of local grasses and wheat straw. Trial was conducted during the period from October to December. The buffaloes were in 4-8 years and cross bred cow of 4-6 years age group. Anoestrus was observed in 28 buffaloes and 8 cows. All the animals were dewormed before supplementation of mineral mixture @ 40–50 gm/day daily for 90 days. Close observations were made on buffaloes on changes, if any, in feed intake, milk yield and oestrus activity. Statistical comparison of data was done as per Snedecor and Cochran (1994).

RESULTS AND DISCUSSION

Most of the selected buffaloes showed poor body condition with loss of musculature, dull and depressed with rough and dried skin coat. Anoestrus was the major problem as 100% of the selected buffaloes and cows had not shown estrus for the last over 6 months. The health condition of the selected buffaloes suggested that malnutrition and worm load might have been the cause of anoestrus.

However, after 90 days of supplementation with

ABSTRACT

The study was conducted in purposely selected Milkipur block of Faizabad district (U.P.) selected purposively. A total number of 120 respondent i.e. 60 beneficiaries women & 60 non-beneficiaries women were selected through random sampling. Finding that Contact of beneficiaries women was maximum with Gram pradhan (2.23). In case of informal sources, maximum contact of beneficiaries women was seen with family members (3.18). In case of mass media exposure, the maximum respondents among beneficiaries women were using mobile (5.9). Majority of respondents among beneficiaries women (78.33%) were in medium whereas majority (51.67%) of non beneficiaries women were having low level of economic motivation. Majority of respondents of beneficiaries women (65.00%) had medium and (61.67%) non beneficiaries women were having low level of risk orientation.. Majority of respondents of beneficiaries women (83.34%) had medium and half of the non beneficiaries women were having low level of scientific orientation.

INTRODUCTION

The Mahatma Gandhi National Rural Employment Guarantee Act (MNREGA) is the first tangible commitment to the poor. The scheme aims at providing employment as a source of income by ensuring their dignity. Thus, it was considered a unique scheme, which provides them Right to Work, trend in the Constitution under directive principles of state policy. In this sense the scheme was supposed to be the most unique scheme after independence as it provides them statutory right to employment. The government has a statutory obligation to provide employment to every rural household in a financial year [1-4]. Mahatma Gandhi National Rural Employment Guarantee Act (MNREGA) is a beneficial program for rural adult men and Women. MNREGA which was implemented by Ministry of Rural Development (MoRD), Government of India. MNREGA is the flagship program of the Government that directly touches lives of poor and promotes inclusive growth. It provides a right for guarantee employment of the rural population through an act of parliament. The National Rural Employment Guarantee Act (NREGA) was launched in 25 August, 2005. The Act received the assent of President on September 5, 2005 and was notified on September 7, 2005. It was implemented in India "s most backward districts on February 2, 2006. The law was initially called the National Rural Employment Guarantee Act (NREGA) but was renamed on 2 October 2009 as MNREGA. The MNREGA is an Indian job guarantee scheme,

Study on knowledge of rural women for food grain storage practices in Faizabad district

Archana Yadav, Dr. Deepa Verma and Dr. Subodh Kumar

Abstract
The study was conducted in Milkipur block of Faizabad district (U.P.) selected purposively. A total number of 100 beneficiaries were selected through random sampling. Five sample villages were selected on the basis of random sampling. The structure schedule was developed keeping in view the objectives and variables under study. The respondents were contacted personally for data collection. The percentage, mean and standard deviation were used for calculation and drawing the inferences. The majority of the respondent 62% were found in categories (31-50) of age group, 61% literate, 48% other backward caste, 62% joint family, 49% small size of landholding, 55% no participation in any organization, 70% economic motivation, 83% scientific orientation was found in medium categories respectively. In case of knowledge level regarding food grain storage practices of respondents the majority number of 79% respondents belongs to medium category.

Keywords: scientific orientation, economic motivation, beneficiaries

Introduction
The post-harvest losses in India amount to 12- 16 million metric tons of food grain each year, an amount that the World Bank stipulates could feed 1/3rd of India's poor. The monetary value of these losses amount to more than Rs. 50,000 crores per year (singh, 2010) [12]. Losses of food grains are reported due to attack of insects, pests and rats during storage. Therefore, control of rats becomes inevitable in the crop field, godowns, residential premises (Ramesh, 2001) [11]. During storage quantitative as well as qualitative losses occur due to insects, rodents and microorganisms. A large number of insect, pest have been reported to be associated with stored grains. As in India, women have a crucial role to play in post-harvest technology particularly that relating to winnowing and grain storage. Thus, Proper handling and management need to teach systematically to rural women in order to prevent or reduce losses to some extent.

Methodology
This study was conducted at N.D. University of Agriculture & Technology; Faizabad U.P. Faizabad district is selected purposively for the study undertaken. The Faizabad district is located in the eastern plain zone of U.P. A total of 100 women were identified as sample size for the study. Data will be collected through personal interview using with restructured schedule. The variables were selected according to the objectives of the study. For study the different constraints different scales were used. The scale developed by Supe (1969) was used to measure the economic motivation and scientific orientation. Tabulated data were analyzed by using statistical measurement like, standard deviation, mean etc.

Result and discussion
Socio-Economic Profile
Table -1 shows that majority of the respondents (15%) were observed in the category (above to 50) age group following category (up to 23) age group was found (23%) and the category (31-50) age group their percentage was found (62%) respondents. So, it focuses that the rural women of age group (up to 23) and (31-50) age group are mostly engaged in food grain storage practices under the study. In this table majority of the respondents (61%) were found belonging to the literate category and the rest (39%) were illiterate. It also indicates that maximum number of the respondents (48%) belong to backward caste, while the general caste and scheduled caste were 40 percent, respectively. It might to be because of majority of OBC population in Faizabad district was adopted agriculture as their main occupation so they were engaging storage of grains as their farm produce. Thus, it is concluded that majority of respondents (48%) of food grain storage practices were from backward caste.

Impact of MNREGA and level of awareness on Socio – economic profile of rural women in Faizabad district

Sadhana Gupta, Subodh Kumar and Manoj Kumar

Abstract
The study was conducted in purposely selected Milkipur block of Faizabad district (U.P.) selected purposively. A total number of 120 respondent *i.e.* 60 beneficiaries women & 60 non-beneficiaries women were selected through random sampling. Finding that majority of the beneficiaries women (43.33%) were observed in high category awareness awareness whereas the majority of non-beneficiaries women (38.33%) were observed in high category awareness Out of 18 variables studied, 11 namely *viz*- education, housing pattern, occupation, annual income, social participation, material possession, extension contact, economic motivation, risk orientation, scientific orientation and level of awareness were found to be highly significant difference between beneficiaries and non-beneficiaries women. Whereas 7 variables, i.e.- age, caste, family type, family size, type of worker, landholding area and marital status were shown non- significant difference between MNREGA beneficiaries and non-beneficiaries

Keywords: MNREGA beneficiaries, non-beneficiaries

1. Introduction

Social and economic development is the main aim of rural development for rural people, especially to bring about sustained improvement in their living condition through an increase in their income and access to social goods. The status of women is intimately connected with their economic status, which in turn, depends upon rights, roles and opportunity for the participation in economic activities. The economic status of women is now accepted as an indicator of a societal development. However, all development does not result in improving women economic activities. Pattern of women activities are affected by the prevailing social ideology and are also linked with the stage of economic development. Government implements different programmes to improve the social and economic development in rural India.

The Mahatma Gandhi National Rural Employment Guarantee Act (MNREGA) is the first tangible commitment to the poor. The scheme aims at providing employment as a source of income by ensuring their dignity. Thus, it was considered a unique scheme, which provides them Right to Work, trend in the Constitution under directive principles of state policy. In this sense the scheme was supposed to be the most unique scheme after independence as it provides them statutory right to employment. The government has a statutory obligation to provide employment to every rural household in a financial year.

Mahatma Gandhi National Rural Employment Guarantee Act (MNREGA) is a beneficial program for rural adult men and Women. MNREGA which was implemented by Ministry of Rural Development (MoRD), Government of India. MNREGA is the flagship program of the Government that directly touches lives of poor and promotes inclusive growth. It provides a right for guarantee employment of the rural population through an act of parliament.

The National Rural Employment Guarantee Act (NREGA) was launched in 25 August, 2005. The Act received the assent of President on September 5, 2005 and was notified on September 7, 2005. It was implemented in India "s most backward districts on February 2, 2006. The law was initially called the National Rural Employment Guarantee Act (NREGA) but was renamed on 2 October 2009 as MNREGA. The MNREGA is an Indian job guarantee scheme, enacted by legislation. MNREGA is a social security legislation with a right based framework. The purpose of the Act is to make resilient resources and enhance the income source platform of the rural inadequate. It aims to enhance livelihood security in rural areas by providing at least 100 days of guaranteed wage employment to every rural household whose adult members volunteer to do skilled and unskilled manual work.

This programme is effective targeting of marginalized groups (scheduled castes, scheduled tribes, BPL and women) and use of MNREGA as a supplementary income source during

A B S T R A C T

The indigenous technical knowledge (ITK) regarding animal husbandry is considered as old as domestication of various livestock species. Unfortunately, these practices which are in vogue throughout the rural India are little documented and there is danger of extinction of this knowledge. Thus it is become imperative to collect and document these practices. A semi structured interview schedule was used for the data collection from 10 traditional healers and 120 livestock owners. It was found that improved farm implements aid not only in saving labour but also increases working efficiency at farm. The majority of the respondents (56.67%) were found belonging to medium material possession category while 18.33 percent and 25.00 percent of respondents were of low and high material possession category, respectively.

Introduction

India's livestock sector is one of the largest in the world. According to 18th livestock census (2007) there are 199 million cattle, 105 million buffaloes, 72 million sheep, 141 million goats,11 million pigs and 649 million poultry birds in India, contributing 56.7 percent of world's buffaloes, 12.5 percent cattle, 20.4 percent small ruminants, 2.4 percent camel, 1.4 percent equine, 1.5 percent pigs and 3.1 percent poultry (Anonymous, 2011). In 2010-11, livestock generated output worth rupees 2075 billion (at 2004-05 prices) which constitutes 4 percent of the India's total GDP and 26 percent of the agricultural GDP. The word 'indigenous' means native born origination or produced naturally in a country or in specified area and the word knowledge means "assured belief practical skill, that is known, learning enlightenment" (Reijntjes *et al.*, 1993). The indigenous knowledge is also often taken to be synonymous with traditional knowledge (Richard, 1979). Also, the term indigenous is often interchangeably used with terms like traditional or local (Yadav, 1998). Traditional includes recent and future innovations provided and carried out by farmers but it does not mean "Absolute" i.e. neither absolute good nor bad (Pareira, 1993). However, Johnson (1993) feels that societies change through time constantly adopting new practices and technologies, making it difficult to define just how much and what kind of

The Histochemical Study of the Thyroid Gland of Chabro Chicken Reared in Summer and Winter Seasons

Amit Singh Vishen[1], Varsha Gupta, S.P. Singh, Abhinov Verma, Renu Yadav, Rakesh Kumar Gupta, K.N. Singh, Mukesh Kumar, Anand Singh

10.18805/ijar.B-3973

ABSTRACT

Background: Chabro is a strain of poultry birds especially designed for backyard farming and is more adoptive to climatic variations in the tropics. The thyroid gland plays an important role in controlling basal metabolic rate. Histochemical changes of the gland in association with seasonal changes have not been studied so far in Chabro chicken. The present study describes the season related variations in the histochemistry of thyroid gland.

Methods: The histochemical study was conducted on thyroid gland of eight to ten weeks old 24 apparently healthy Chabro chickens procured from Poultry Farm, DUVASU, Mathura. The birds were divided into two groups consisting of 12 chickens in each group reared in summer and winter seasons.

Result: The capsule showed mild reaction for PAS, protein and glycogen. Follicular cells showed intense reaction for bound lipids, protein and alkaline phosphatase. The colloid in summer season showed strong reaction for PAS at periphery and very strong reaction at center while in winter colloid showed strong PAS positive activity. The Chabro chicken thyroid was functionally more active in winter as compared to summer season because of increased diameter of all follicles and concentration of thyroid hormones level in winter season.

Key words: Chabro chicken, Histochemistry, Season, Thyroid gland.

INTRODUCTION

Thyroid is a bilobed structure situated on either side of trachea. It is the only gland in the body of both mammals and birds that stores hormone in its inactive form. The substance of the gland consists of roughly spherical thyroid follicles. The thyroid gland is a unique endocrine gland which plays an important role in controlling pre and post natal growth and differentiation of many organ systems. Chabro chicken was developed by Central Poultry Development Organization (CPDO) by crossing Barred Plymouth Rock with Red Cornish especially for the farmers of our country owing to more adoptive to climatic fluctuations and acclimatizes to the entire climatic zone. The study was conducted on thyroid gland because it plays an important role in basal metabolic rate, reproduction and development and growth of muscles and bones. On perusal of literature it is found that the histochemical studies in Chabro with special reference to season is very scanty. Hence, the present study is designed to record the seasonal behavior in thyroid gland.

MATERIALS AND METHODS

The present study was conducted in the year 2018 on thyroid gland of eight to ten weeks old 24 apparently healthy Chabro chickens procured from Poultry Farm, DUVASU, Mathura. The birds were divided into two groups consist of 12 chickens in each group (six male and six female) reared in summer and winter seasons. For histochemical observations, small pieces of the thyroid gland were collected and fixed in 10% neutral buffered formalin. Fixed tissues were processed by routine paraffin embedding technique (Luna, 1968) and 6µ paraffin sections were procured. For studying lipid and enzymes cryostat (15µ) sections were utilized. For histochemical and histoenzymic studies following staining procedures were carried out :

1.) Periodic Acid Schiff's (PAS) (Luna, 1968): For study of polysaccharides.
2.) Best's carmine method (Luna, 1968): For study of glycogen.
3.) Muller's Colloidal (hydrous) ferric oxide method (Luna, 1968): For study of Acid mucopolysacchandes.
4.) Acetone Sudan black method (Pearse, 1975): For study of bound lipids.
5.) The Calcium Cobalt method (Pearse, 1975): For study of Alkaline phosphatase.

Abstract
The microscopic studies of kidneys of 6 *Marwari* sheep showed that the thick fibrous capsule consisted of two layers. The outer layer of dense collagenous fibres with a few elastic fibres. Fibroblast and some smooth muscle cell were also present in outer layer. The inner layer consisted predominantly of reticular fibres with collagenous fibres and had a distinct thick smooth muscle layer. Interstitial tissue contained network reticular fibres which extended from the capsule to the apex of papilla. The juxtaglomerular structure and basement membranes were P.A.S. positive. The papillary duct lined with simple columnar epithelium which become transitional before opening into the papilla.

Keywords: *Marwari* sheep, Kidney, Histology, Capsule, Epithelium

Introduction
Marwari sheep constitutes a major portion of the sheep population in western part of Rajasthan which has 14.31 million sheep (about 40%) and plays an important role in the economy of arid and semi-arid tract. The present investigation has been planned to study the histological structure of the kidney to justify its importance and essentiality in the body. In mammals the kidneys are the chief excretory organs of the body. They have a major role in the maintenance of fluid and electrolyte balance and in control of the blood pressure.

Materials and Methods
For the histological examination the small pieces of tissues (2 mm size) were collected from 12 kidneys (6 right and 6 left). From each kidney, the tissues were collected from six fixed anatomical regions to explore regional differences if any. The tissues were preserved in 10% formal saline for 48 hrs, Bouin's fluid for 12 hrs, and Zenker's fluid for 18 hrs. Fixed tissue was latter washed in running tap water for 6-10 hours followed by dehydration in ascending grade of alcohol, clearing, embedding in paraffin wax of melting point of 58-60°C, preparation of blocks, section cutting (5-6 µm thick), and mounting of section on albuminized slides, drying of sections and finally stained with the H. & E. and special staining methods to demonstrate different components of kidney.

Results and discussion
The capsule and connective tissue septa
The kidneys were invested by a thick fibrous capsule which consisted of two layers Fig. (1), which simulate to the reports by [illegible] in bovine, Dellmann (1993) [1] in ruminants and Halder *et al* (2002b) [5] in spotted deer. Trautmann and Fiebiger (1957) [13] and Yadva and Calhoun (1958) [17] found that the fibrous capsule was composed of two distinct layers in horse, ox, Sheep and Goat. In the present study the outer layer was heavily laden with collagen fibres and fibroblasts were also seen between the collagen fibres. There oval nuclei were surrounded by a small amount of lightly acidophilic cytoplasm and cells had few short processes. Elastic fibres were very few between the collagenous fibres.
The inner thin layer consisted predominantly of reticular fibres with collagenous fibres. The reticular fibres were arranged parallel to the collagenous fibres and transversely dipped into the cortex of kidney. The inner layer had a distinct thick smooth muscle layer. Numerous smooth muscle cells were entangled between the loose collagenous and reticular fibres. Similar findings were reported by Gupta and Sharma (1991) [3] in yak and Zade *et al* (2007) [16] in panther. Whereas Malik *et al* (2001) [7] reported that thin renal capsule was composed of loose superficial and compact deep layers with inconspicuous smooth muscle fibres in Asian elephant.

Histological studies on the liver of Marwari Goat (*Capra hircus*)

Mahesh Kumar Bamniya, Rakesh Mathur, Sanjeev Joshi, KN Singh, Mukesh Kumar, Amit Vishen and S Gharu

Abstract
The histological studies were conducted on the liver of 15 Marwari goats. Histologically, the whole liver was invested by peritoneum, except where it was reflected as ligaments and where it adheres to the diaphragm. Underlying it, the liver covered by connective tissue covering called as glisson's capsule. It was composed of collagenous and reticular fibers and few smooth muscles. The reticular fibers formed the stroma. The hepatic lobules were made up of central vein, portal area and one cell thick cords, which were not delineated by connective tissue. The sinusoidals were narrow and somewhat cylindrical. These were lined by continuous endothelial cells resting on basal lamina. Kupffer cells were present attached to the endothelial cells. There were numerous mucous glands present in the mucosa of hepatic, cystic and common bile ducts. The centrilobular and the periportal hepatocyte were rich in the glycogen content.

Keywords: Histology, Marwari goat and Liver

Introduction
Marwari goat (*Capra hircus*) is a domestic animal distributed in the Marwar region of Rajasthan, comprising of Pali, Jodhpur, Jalore, Barmer, Bikaner, Nagaur, and Jaisalmer districts. The goat (*Capra hircus*), is one of the most important animal and the goat husbandry has been playing an important role in the economy of our country with special reference to milk, meat, manure and hide production. The Present study has been planned to justify the functional importance and essentially of the liver, the largest single organ. The resemblance of the structure of liver throughout the animal kingdom, from fishes up to higher vertebrates, encourages the interest to get factual structural details of that colossal gland. Important functions performed by the liver are secretion of bile, excretion of waste product, storage of glycogen and vitamins (Vit. A, D and B), synthesis of fibrinogen, prothrombin, albumin, globulin etc., phagocytosis of foreign particles, detoxification, intermediate metabolism of carbohydrates, proteins and fats and haemopoiesis in embryo. Liver plays an important role in digestion process of these nutrient matter and energy production. An understanding of the structure of liver is vital to the interpretation of these processes.

Materials and Methods
The present study was conducted on 15 apparently healthy adult Marwari Goat (*Capra hircus*) of either sex. The liver from the freshly slaughtered animals were procured from Municipal slaughter house, Bikaner. For the histological examination the small pieces of tissues (2mm size) were collected from 15 livers. From each liver, the tissues were collected from thirteen fixed anatomical regions to explore regional differences if any. The tissues were preserved in 10% formal saline for 48 hrs. Fixed tissue were later washed in running tap water for 6-10 hours followed by dehydration in ascending grade of alcohol, clearing, embedding in paraffin wax of melting point of 58-60 °C, preparation of blocks, section cutting (5-6 µm thick), and mounting of section on albuminized slides, drying of sections and finally stained with the following routine and special histological stains to demonstrate different components of liver.

Results and Discussion
The capsule and stroma
In present histological study the liver of Marwari goat was covered by outer peritoneal and the inner connective tissue covering. Similar findings were reported by (Leeson and Lesson, 1981) [4] in domestic animals, (Pareek, 2000) [10] in sheep and [6] and (Dellmann and Brown, 1981)

ABSTRACT

Tomato crop affected by different fungal diseases in which Fruit rot known as target spot disease incited by *Sclerotinia sclerotiorum* is one of the most destructive disease. Disease severity varied (30.50 to 18.60%) in different locations of Kanpur. Highest disease severity was (30.50%) and the lowest disease severity (18.60%) was noticed at the farmer's field of Billhore, Kanpur. *Sclerotinia sclerotiorum* is a soil borne pathogen which causes symptoms on ripe fruits. Pathogen isolated from infected fruits. Copper oxychloride, Kavach, Tebucanazol, Andrachite, Dithane M-45, Metalaxyl, Roko and Bavistin completely suspected the growth of pathogen*in vitro*. Among eight fungicides, Tebuconazol, Andrachite, Metalaxyl, Roko, and Bavistin were found effective against pathogen under *in vitro* and *in vivo* conditions. However, seven bio-agents (*Trichoderma* spp.), *T. koningii*, *T. virens*are found effective in bothconditions. *In vitro* eight fungicides were tested against pathogen in which Metalaxyl, Roko, Tebucanazol, Andrachite and Bavistin showed 100% growth inhibition. Seven bio-agents (*Trichoderma*spp.) were tested *in vitro* while, among them *T. koningii* showed maximum inhibition followed by *T. virens*, *T. longibrachiatum*, *T. atroviridae*, *T. asperallum*, *T. viridae* and *T. reesei*, respectively. Eight treatments were applied *in vivo* for disease management however, among them T_6 (*Bacillus subtilis* + bavistin) recorded the minimum disease incidence and maximum fruit yield.

Introduction

Sclerotinia sclerotiorum (Lib.) is a serious fungus affecting yield and product quality of many susceptible hosts. It is a widespread soil borne plant pathogen with an extremely wide host range of more than 400 plant species including many of economic importance (Gao *et al.*, 2014). *S. sclerotiorum* is responsible for more than 60 plant diseases (Purdy, 1979). The pathogen produces sclerotia, which survive for long periods and attackroots of growing and mature plants, resulting in root rot, basal stemcanker, and wilt (Duncan *et al.*,
