INTRODUCTION

A number of inorganic elements are essential for the growth, production and reproduction of animals [1]. In addition, mineral requirements are also influenced by age, parity, stage of pregnancy and stage of lactation. The inorganic elements are classified according to their requirements in animal body. Those required in greater quantities are referred as macrominerals (calcium. phosphorus, sodium, chloride, potassium, magnesium and sulfur). Macrominerals required in large amount each day and their concentration in diet is expressed as percentage of diet or in grams per kilogram of diet. Macrominerals has role in different physiological functions. Other elements required in much smaller amounts are referred as trace minerals (microminerals) i.e. copper, cobalt, iodine, iron, manganese, molybdenum, selenium, zinc, chromium and fluorine. Their concentration in diet is expressed as parts per million (ppm), which is equivalent to milligram per kilogram of diet or in some cases as parts per billion (ppb), which is equivalent to microgram per kilogram of diet. Adequate quantity of minerals are utmost important for proper functioning of various physiological functions in animals. Deficiency and excess both have detrimental effects on production and reproduction; thus significantly affecting the economics of animal husbandry.

Role of Various Macro Minerals in Animal Reproduction

Calcium (Ca): Calcium is an essential component of skeleton and plays a pivotal role in maintaining homeostasis of vertebrates [2]. The maximum portion of calcium present in the bone as hydroxyapatite (99%) and small fractions present in the cell membrane or endoplasmic reticulum (0.9%), extracellular fluid or serum (0.1%) and in cytosol (0.00002%) [3]. Extracellular calcium exist in three forms i.e. ionized (50%), complexes to anions (5%) such as citrate, bicarbonate, phosphate, or lactate and protein bound (45%). Ionized calcium involved in array of physiological processes such as muscular

Impacts of Stocking Density on Broiler Chicken Performance Stress Reaction and Mortality in Broiler Chicken

Pankaj Chauhan[1], Kunwar Dhananjay Singh[2*], Partha Sarathi Pramanik[3], Subodh Kumar[4], Ashish Kumar Srivastav[5], Krishna Kant Tripathi[6], Durgesh Nandan[7]

Abstract

The present study investigated the effect of stocking density on growth performance, stress reaction, and mortality in broiler chickens. Two hundred and forty (240) day-old straight run commercial broiler chicks (Vencob) were divided into two batches having 120 chicks each and further subdivided into three equal groups (G1, G2, G3) representing different stocking densities (20, 25, and 30-meter square/bird) having 40 chicks in each group. It was evident that, after the 2nd week, body weight gain of G3 group was significantly ($p<0.01$) higher than G2 and G1. In 4th week, body weight gain of G2 and G3 groups was significantly ($p<0.01$) higher than G1. After completion of 35 days of the trial, the last week's body weight gain of G2 (577.15 ± 28.78 g) was found significantly ($p <0.01$) higher than G1 (554.07 ± 28.78 g) and G3 (517.35 ± 28.78 g). During 1st week, the FCR of broiler chicken of G1 (1.96 ± 0.02) group was found to be significantly ($p <0.01$) higher than G2 (1.83 ± 0.02) and G3 (1.82 ± 0.02). During 3rd week, FCR of G1 (1.94 ± 0.02) group was significantly ($p<0.01$) higher, while at 4th week, the FCR of G3 (1.81 ± 0.03) was found significantly ($p<0.01$) higher than other groups. The least square means of H/L ratio were significantly higher in G1 and G3 groups as compared to the G2 group. During the experimental period, 2.5 % mortality was observed in G1 and G2 groups, whereas 5% in group G3.

Keywords: Body weight, Body weight gain, Broilers, Feed conversion ratio, and Heterophil-lymphocyte ratio.

Ind J Vet Sci and Biotech (2022): 10.48165/ijvsbt.18.4.08

Introduction

The poultry sector in India has valued at about Rs. 80,000 crores (2015-16), which is broadly divided into two sub-sectors – one with a highly organized commercial sector with about 80% of the total market share of Rs. 64,000 crore and the other being unorganized with about 20% of the total market share of Rs. 16,000 crore (National Action Plan for Egg and Poultry-2022). Broiler farming is a practicable business activity and has a huge scope for growth in India. The poultry industry is about Rs. 600 billion, about 0.77 % of the national GDP and 10 % of the livestock GDP of over five million people in the country (CARI vision 2050, 2013). Modern broiler houses are managed in extreme controlled environment. Birds should be provided with proper ventilation, temperature, and humidity at higher densities. Increasing stocking density without adversely affecting growth performance, feed conversion, meat quality, and welfare is a management technique used to reduce labor, housing, fuel, and equipment costs. With higher stocking densities, the profit per chicken decreases. The total production of meat per unit of floor surface increases, which results in higher profit. However, most farmers do not know adequate stocking density (Muniz *et al.*, 2006; Adebiyi *et al.*, 2011).

Stocking density is very important in broiler production (Tablante *et al.*, 2003). In an earlier study, feed conversion ratio, feed intake, and body weight gain were increased at high stocking density (Estevez, 2007). Environmental temperature, humidity, and ammonia concentration can all disturb broiler growth (Yi *et al.*, 2016; Zhou *et al.*, 2019). The effect of stocking density on feed conversion ratio and mortality has remained a debatable issue (Singh *et al.*, 2018). A decrease in growth performance and survivability of broiler chickens after an increase in ambient temperature has already been recognized (Gous and Morris 2005). Singh *et al.* (2017) recorded a higher frequency of foot pad lesions with higher stocking density in broiler chickens. When stocking density increases, it causes physiological stress in the birds. Stress causes the release of hormones and reorients the

Impact of stocking density on gait score and mortality in broiler chickens

KD Singh, PS Pramanik, Subodh Kumar, Rajesh Kumar, AK Srivastav and MK Verma

Abstract
The research was conducted to investigate the impact of stocking density (i.e., I.C.A.R., Venky's and Amrit recommendations) on gait score & mortality in broiler chickens. A 500 day-old straight run commercial broiler strain "VENCOB" chicks were divided in two batches. Each batch was subdivided in 3 equal groups namely Gr 1 (I.C.A.R.), Gr 2 (Venky's) and Gr 3 (Amrit). All the birds were raised on pucca floor with saw dust as litter material providing equal managemental practices. Walking ability was accessed at weekly interval up to 6 weeks of observation. The gait scoring system followed in the present study was Modified gait scoring system developed by Garner *et al*. (2002). Daily mortality of birds was recorded in morning hours &mortality rate was calculated weekly. The lowest and highest% of birds showing GS 0 under I.C.A.R. recommendation of stocking density have been found to be 83.93±0.64% (week 4) and 92.86±0.40% (week 6) respectively. Similarly the corresponding proportion of birds showing GS 1 were 6.07±0.78% (week 1) and 13.93±0.64% (week 4) respectively. Comparatively lesser % of birds show GS 2 and the lowest and highest L.S. means % of this were 0.00±0.40% (week 6) and 3.21±0.82% (week 3) respectively. Venky's & Amrit's observation were also similar as I.C.A.R. recommendation has been observed. Overall it has been observed that% of birds showing GS 0 was significantly more in I.C.A.R. followed by Amrit and Venky's during this study. However, highest% of birds showing GS 1 was recorded in Venky's recommendation followed by Amrit and I.C.A.R. Whereas, less than 5% birds exhibited GS 2 in this study in respective of stocking densities. There was no significant difference regarding% of birds with GS 2 in three stocking densities during all the weeks except at week 4. The overall mortality (%) was less than 5% over weeks under each placement densities. No significant difference was observed among mortality rates of broiler chickens under these three stocking densities during all the weeks studied. From present study, this can be concluded that leg health and walking ability was comparatively better under I.C.A.R. recommendation followed by Amrit and Venky's. However, effect of stocking density on mortality was non significant among three stocking.

Introduction
The total poultry population in India is 729.2 million, which is 12.39 percent higher than numbers in the previous census (Livestock Census, 2012) [21]. Poultry is one of the fastest growing sectors of Indian agriculture today, with annual growth rates of 5.57 percent and 11.44 percent in egg and broiler production, respectively. The value of output from the poultry sector was US$10 billion in 2014 (Rajendran *et al*., 2014) [25]. Broiler production has been more vibrant than layer production within the poultry sector, with an annual growth rate of 11.44 percent, production of 3.725 million tons and employment of 4.29 million people (Index Mundi, 2015) [15]. India is the fourth largest producer of poultry meat in the world, valued at US$ 6.6 billion. Poultry production accounts for about 0.66 percent of India's GDP and 7.72 percent GDP from the livestock sector (Rajendran *et al*., 2014) [25]. Poultry meat production increased from 0.069 million tons in 1961 to 3.725 million tons in 2014. The per capita availability of poultry meat is 2.8 kg; against recommended level of 11 kg (Rajendran *et al*. 2014 [25]; Index Mundi, 2015 [15]). The main reasons for improved broiler poultry production (Kalamkar, 2012; SAPPLPP, 2009) [17, 29] are: modernization of production practices; import of pure lines/grandparent stock; least-cost feed formulation; vaccines against major diseases; provision of EAS and other input services; improved quality breeder management; developments in poultry processing; and private sector partnerships through Contract Broiler Farming. It is estimated that 37 percent of broiler production in India is under contracts, and about 78 percent of those contracts are concentrated in southern India (Rajiajwani, 2012) [26].
Gait scores (GS), a parameter used to evaluate walking ability (Kestin *et al*., 1992; Garner *et*

Effect of different litter materials on growth performance of broiler chickens

VN Gupta, PS Pramanik, KD Singh, S Gautam, P Gautam, B Singh, G Pandey and D Nandan

Abstract
Two hundred forty day old Vencobb 400 straight run commercial broiler chicks were randomly divided into three groups with two replicates of 40 chicks in each to assess the effect of different litter materials on growth performance of broiler chickens. The broiler chicks were kept on rice husk, 50 % rice husk + 50 % paddy straw and wood saving in Tc, T_{MIX} and T_{WS} groups, respectively for a period of 42 days. The results of the experiment showed that broiler chicks kept under T_{mix} (3027.20^{b}±80.50g) i.e. combinations of paddy straw with rice hulls were heavier as compared to the other litter treatments. The overall body weight gain was numerically higher in T_{mix} as compared to the other litter treatments. It was also evident that feed intake was higher in T_c groups as compared to T_{MIX} and T_{WS} groups. The overall FCR was superior in T_{mix} group (1.84^{a}±0.21) as compare to other group T_{ws} (2.22^{ab}±0.15) and T_c (2.42±0.11). The results of the present experiment concluded that the growth performance indicated that final body weight, body weight gain, FCR were better in T_{mix} group than wood saving and the control group broiler birds however, feed intake was higher in T_c group.

Keywords: litter materials, paddy straw, rice hulls, broiler chicken

Introduction
The Poultry industry has emerged as the fastest growing segment of the livestock sector both globally as well as in India (Iisa Augustine and Ruchira Shukla, 2015) [7]. Now a days poultry meat is available for huge groups of consumers due to revolutionary mechanization of the poultry sector in recent years. The higher nutritional, sensory and economical characteristics of poultry meat have made it, far most famous animal food product globally. It has a high potential to generate foreign exchange earnings through export of poultry products to neighboring countries (Iisa Augustine and Ruchira Shukla, 2015) [7]. Broiler production is one of the most dynamic and fastest growing animal husbandry sub-sectors in India. The total poultry population has increased by 16.81% over in the recent census and the total poultry in the country is 851.81 million. However, in previous census 2012 it was 729.21 million in numbers (Livestock census, 2019) [12]. Due to increasing population growth, rising income and urbanization there is an increasing demand of animal protein source so that chicken meat has shown its fastest growth in last two decades.

The type of bedding can affect performance of broiler birds (Billgilli *et al.*, 1999b) [2]. The litter type affects litter bacteria and litter consumption which may influence the immunity and performance of broilers (Lien *et al.*, 1992) [10]. Common bedding materials include rice husk, paddy straw, wood shavings, sawdust, peanut hulls, shredded sugar cane, straw, and other dry, absorbent, low-cost organic materials. Sand is also occasionally used as bedding. The efficiency of litter type can be influence by various factors such as physical properties of the material used, particle size, build up moisture content and rate of caking. In many areas sawdust and wood shavings are most commonly used bedding materials for commercial poultry production. The higher cost, poor supplies and unavailability of these litter materials has encouraged the search for suitable substitute litter materials. Good bedding materials should absorb the moisture from body wastes, limiting the production of harmful pathogenic micro-organisms and ammonia, provide a dry, comfortable medium to broilers for dusting themselves in and rest upon. Therefore, it should be soft, compressible, absorbent and capable of drying quickly.

In this context the use of crop and wood residues as poultry litter seems to be promising. Hence, the present experiment was designed to assess the effect of different litter materials on

Impact of blue and green monochromatic light in comparison to white LED on the stress reaction and mortality rate of broiler chickens

P Gautam, PS Pramanik, KD Singh, MK Verma, S Gautam, AK Verma, VN Gupta and B Singh

Abstract
The present experiment was conducted to investigate the impact of blue and green monochromatic light in comparison to white LED on the stress reaction and mortality rate of broiler chickens. For a period of 42 days study two hundred forty day old Vencobb 400 straight run commercial broiler chicks were randomly divided into three groups with 2 replicates of 40 in each at the poultry unit of livestock farm complex, College of veterinary sciences and animal husbandry, A.N.D.U.A.T. Kumarganj, Ayodhya, (U.P). In first green-blue group (T_{GB}), the birds were kept on green LED light (GL) and blue LED light (BL) from 1-21days and 22-42 days, respectively. The broiler birds of Group T_W and T_C were kept in white and incandescent LED lights for 42 days, respectively. The findings revealed that the heterophil % differed significantly ($P<0.05$) at 6th week of age when broiler finished their light treatment duration (after shifting from green LED to blue LED at 4th week of age). The ratio of blood heterophil to lymphocyte was also significantly differed ($P<0.05$) at the 6th week of age. The H/L ratio was higher in T_C group (0.37±0.008) whereas, it was lowest in T_{GB} group (0.33±0.456) than T_W group (0.35±0.120) birds at 6th of age. This study indicated that birds were minimum stress level in T_{GB} group than other treatment groups. The mortality rate of broiler chicks was highest in T_W group (6.25%) and lowest in T_{GB} group (3.75%) than T_C group (5%) birds. The results of the present study concluded that, broiler birds under green-blue (1-21d in GL and 22-42d in BL) LED bulb treatment group had significantly ($p<0.05$) lower stress as drawn by a ratio of Heterophil: Lymphocyte, which was highest in incandescent bulb treatment groups followed by white LED groups.

Introduction
For the large section of poultry meat consumers, the comprehensive mechanization of the poultry segment has made the broiler meat available in the recent years. Now the broiler meat is far most globally famous animal food product due to its nutritional, sensory and economical properties. It has a high potential to generate foreign exchange earnings through export of poultry products to neighboring countries. The Poultry industry has emerged as the fastest growing segment of the livestock sector both globally as well as in India (Iisa Augustine and Ruchira Shukla, 2015) [6]. Broiler production is one of the most dynamic and fastest growing animal husbandry sub-sectors in India. The total poultry population has increased by 16.81% over in the recent census and the total poultry in the country is 851.81 million. However, in previous census 2012, it was 729.21 million in numbers (Livestock census, 2019) [14]. Due to increasing population growth, urbanization and rising income there is an increasing demand of animal protein source so that chicken meat has shown its fastest growth in last two decades.
Lighting is an important environmental cause in poultry production that is known to affect performance and behavior. Chickens are visually well equipped, and therefore light plays very important role in their wellbeing and productivity. Light is constituted of a wide spectrum of electromagnet (EM) waves. The visible part of the electromagnetic (EM) spectrum is relatively small and is formed of wavelengths from approximately 350 to 800 nm. The eyes of broilers seem to be more sensitive to the broader spectrum than humans and these can perceive ultraviolet and infrared as well.

Components of Light in Poultry Management
Artificial light can be described by distribution of light (photoperiod), colour (wave length)

Studies on relationship between milk yield and skin thickness of dairy animals

Durgesh Nandan, PS Pramanik, KD Singh, RP Diwakar, Gaurav Pandey and Vipin Yadav

Abstract
The aim of the present investigation was to examine the relationship between skin thickness and milk yield. The experiment was conducted at Livestock Farm Complex, C.V.Sc. & A.H., ANDUAT Ayodhya, Ram Newaj Singh Dairy Farm, Kumarganj, Ayodhya (UP) and Gorakhnath Singh Dairy, Baijnathpur Gorakhpur (UP) as per availability of lactating animals (Murrah buffalo, Gir and Sahiwal cows) which was 32 animals of each breed. A total of 96 dairy animals were studied in this experiment in which 32 Murrah buffaloes, 32 Sahiwal cows and 32 Gir cows ranging from first to fourth lactation periods. The dairy animals were selected on daily milk yield and total milk yield were recorded from the records over an average period of 120 days of lactation length. The skin thickness was measured from seven sites or regions namely neck, chest, abdomen, rump, hind quarter, udder and flank of each animal. The result shows that, in Murrah buffaloes the highest average DMY was 8.16 ± 0.52, 8.62 ± 0.55, 8.29 ± 0.78, 8.15 ± 0.55, 8.69 ± 0.77 and 7.86 ± 0.39 litres by animals under thin skin thickness of neck, chest, abdomen, hind quarter, udder and flank regions respectively. In Sahiwal cows, it was observed that the highest average DMY was 7.26 ± 0.31, 7.47 ± 0.65, 7.63 ± 0.48, and 7.69 ± 0.76 litres by animals under low skin thickness of neck, chest, abdomen and udder regions respectively. Where as in Gir cows it was observed that the highest average DMY was 6.23 ± 0.46, 6.06+0.41, 5.96 ± 0.51, 5.06 ± 0.36 and 6.03 ± 0.65 litres by animals under low skin thickness of neck, abdomen, hind quarter, udder and flank regions respectively. However, it was also observed that all the Murrah buffaloes, Sahiwal and Gir cows having thick skin of different regions were found to produce lowest milk yield per day. Least square analysis showed that the relation between DMY and skin thickness of thin, moderate and thick in different regions was found to be statistically non-significant except in flank regions where different types of skin thickness found significant (p<0.01). Further it was observed TMY and type of skin thickness in different regions were not found significant (p<0.01) except udder and abdomen regions where thick skin TMY were found to be statistically highly significant (p<0.01). It may be concluded that, the udder skin thickness was minimum followed by that in ascending order in the neck, chest, abdomen, hindquarter, flank and rump regions of the animals. Further it was evident that Murrah buffalo, Sahiwal and Gir cows under their skin thickness were found to produce more milk, while moderate skin thickness produced more milk and then thick skin thickness produced milk.

Keywords: Skin thickness, murrah, sahiwal, gir, parity, milk yield

Introduction
Dairying is an important enterprise for many countries of the world. As a result it has been an important source of income generation for rural families in the developing countries. With the increase in human population, the demand for milk has also been increased (Tollens *et al*., 2004) [17]. In India, milch cattle and buffalo breeds like Sahiwal, Gir, Red Sindhi, Deoni, Murrah, Surti, Mehasana etc. Are well adapted to the prevailing environmental conditions. Among all the milch breeds, Sahiwal is considered to be one of the important cattle milch breed and thrives well in many parts of India. Animals of this breed are known for their ability of heat tolerance, disease resistance and adaptability to low input system. The average milk yield of this breed has been reported between 2,725 and 3,175 kg in a lactation period of 300 days and certain individual cows have been reported to produce as high as 4,535 kg of milk (Sastry and Thomas, 2016) [15].
In India, majority of buffalo population belong to the riverine group and the milk production is the main function of these animals. It is reported that about 73.77 % of world buffalo population are found in South Asia. In India, the total buffalo population is recorded 108.70 million and about 51% of total milk production is shared by these animals (Livestock Census, Govt. of India, 2019).

Influence of herbal mixture, exogenous enzymes and butyric acid supplementation on nutrient digestibility, carcass characteristics and economics of broiler chickens

DK Chaudhari, Sachin Gautam, VK Singh, Ruma Devi, KD Singh, SP Singh, S Tewari and S Rao

Abstract
Three hundred commercial straight run, day old Ven Cobb 400Y chicks were divided into six groups with 5 replicates of 10 birds in each to assess the efficacy of herbal mixture, exogenous enzymes and butyric acid on their performance. The chicks were placed on basal diet with no supplement in negative control (NC) and basal diet supplemented with antibiotics, alcoholic extract of 0.5% herbal mixture, 0.5% herbal mixture (alcoholic extract) + 0.1% butyric acid, 0.5% herbal mixture (alcoholic extract) + 0.03% exogenous enzymes and combination of 0.5% herbal mixture (alcoholic extract) + 0.03% exogenous enzymes + 0.1% butyric acid in PC, HE, HEB, HEE and HEBE groups, respectively. The results of the analyzed data showed that DM and CP digestibility coefficient of herbal based non-antibiotic feed additive groups were similar to NC and PC group birds. Drawn weight yields were not affected by any additive supplements. The abdominal fat was significantly (P<0.005) lower in HEB and HE group birds as compare to NC and PC groups. Profit/bird live weight, benefit cost ratio and profitability of HEB group was significantly (P<0.05) better than NC, but (P<0.05) lower to PC group. It was concluded that, supplementation of alcoholic extract of 0.5% herbal mixture along with 0.1% butyric acid had no adverse effect on nutrient digestibility and carcass characteristics; however, profitability was higher than negative control birds.

Keywords: Herbal mixture, butyric acid, nutrient digestibility, carcass characteristics and economics

Introduction
Now a days poultry sector is one of the most popular and fastest growing livestock sector in India, contributing 10% of livestock and 0.7% of total GDP. The demand for low cost and processed quality chicken meat is growing by 15-20% annually. The aim of poultry production is to get proper growth rate, better feed conversion efficiency and maintaining optimal health to maximize production in terms of meat and egg. In poultry diet, antibiotic growth promoters (AGPs) are used for the protection against some diseases, toxins, improvement in nutrients absorption in intestines etc. However, the efficacy of antibiotics reduced due to development of resistance in pathogenic bacteria; besides this residues of antibiotics in meat have negative impact on public health. In most of the countries AGPs has been either regulated or banned (Lesson *et al*., 2015) [14]. So, there is need of finding alternatives to growth-promoting antimicrobials without affecting their production. Several substances like essential oil of herbs, organic acids, probiotics, prebiotics, exogenous enzymes etc. have been investigated in recent years, which are able to support productive performance and prevent the incidence of some diseases in poultry (Huyghebaert *et al*., 2011) [10].

Phytogenic feed additives are plant derivatives of plant extraxts, herbs and spices with extended activities viz., endogenous secretions in the gut, stimulation of feed intake and better growth. Herbs like aloe vera (*Aloe barbadensis*), ashwagandha (*Withaniasomnifera*), mangrail (*Nigella sativa*), turmeric (*Curcuma longa*), methi/fenugreek (*Trigonellafoenum-gracium*), neem (*Azadiractaindica*), punarnava (*Bhoeraviadiffusa*), tulsi (Ocimum sanctum), bhuiamla (*Phyllanthus emblica*) and garlic (*Allium sativa*) are commonly used as medicinal herbs in India and have antibacterial, antifungal, anti-inflammatory, antioxidant, growth promoting, hepatoprotective and immuno-stimulatory activities. Non starch polysaccharides (NSP) present in corn and soybeans are poorly digested by monogastric animals; represent a potential source

Screening of lentil genotypes against *Fusarium oxysporum* f. sp. *lentis* in field condition

Subhash Chandra, Mukesh Kumar, Neeraj Kumar Rajvanshi and Virendra Prasad Chaudhary

Abstract
Lentil (*Lens culinaris* Medik) is a member of Leguminosae family and it is commonly known as poor man's meat. Lentil wilt is a very destructive disease caused by fungus *Fusariumoxysporum* f. sp. *Lentis*. In India, lentil crop suffers a great loss due to this disease. The use of resistant variety is one of the best methods of disease management. Therefore, studies were planned to search out the genotypes against *Fusarium* wilt through sick plot technique. Keeping this point in view, one hundred forty three genotypes of lentil were tested for the resistance against *Fusariumoxysporum* f. sp. *lentis* in field condition, out of which 53 genotypes were found highly resistant, 35 genotypes were found resistant, 16 genotypes were found moderately resistant, 18 genotypes were found susceptible and 21 genotypes highly susceptible. None of these genotypes was found free from infection.

Keywords: Lentil, *Fusarium*, genotypes, resistant

Introduction
Lentil *(Lens culinaris* Medik) is a member of Leguminosae family and it is commonly known as poor man's meat. It has a high nutritional value and major source of dietary proteins (25%) after soybeans (Zia *et al.*, 2011) [8]. Lentil (*Lens culinaris* Medik L.) is the most important pulse crop in India and mostly grown in north east plain zone & central part of India. It is a diploid and self-pollinated crop which is grown in winter season and belonging to Order- Rosales, suborder- Rosneae, Family- Leguminaceae (fabaceae), subfamily- papilionaceae, genus- *Lens* and species- *culinaris* with chromosome number 2n=14. Among *rabi* pulses, lentil is next to chickpea. The total area under lentil in India was 1.49 m ha with a total production of 1.61 MT and 1006 Kg/ha productivity (Anonymous, 2018) [1]. In Uttar Pradesh, it is grown on 4.78 lakh hac. area with 4.47 lakh tones production and productivity 936 kg/ha (Anonymous, 2018) [1].

Lentil suffers from attack of a number of diseases such as vascular wilt; collar rots, root rot, stem rot, rust, powdery mildew downy mildew and fusarium wilt which are caused by *Fusarium oxysporum* f. sp. *lentis*. Average yield of lentil is low due to various diseases. Among the disease, foot and root rot of lentil caused by *Fusarium oxysporum* and *Sclerotium rolfisii* are common and the most serious disease in India. The fusarium wilt of lentil caused by *Fusarium oxysporum* f. sp. *lentis* is one of the most important and destructive disease in India wilt pathogen minimize crop yield and deteriorate the seed quality (Khare, 1991) [5]. The disease was first reported from Hungary but in India it was first observed in 1941 from Delhi and Karnal. If infection takes place in early stage the plant do not produced seeds, formed few in number when infection occurred in later stage. Wilt causes more damage at flowering and

To evaluate the efficacy of botanicals and chemical against *Cercospora* leaf spot of Sarpagandha (*Rauvolfia serpentina* L.) Benth Ex Kurz. *in vivo*

Veer Singh, Neeraj Kumar Rajvanshi, Subhash Chandra and Susheel Kumar

Abstract
Sarpagandha (*Rauvolfia serpentina*) belongs to family *Apocynaceae* is an evergreen, perennialshrub, erect of the height upto 60cm. It's root are tuberous with pale brown colour, leaves of the plant are in whorls of three lanceolate or obovate, bright green in colour, flowers are in irregular, corymbose infloresence with white and pink colour. Fruits are drupe, single or didymous shining black when fully riped. The minimum percent disease severity was recorded with Neem leaf extract (25.03) followed by botanicals spray, Tulsi leaf extract (27.15), Arjun bark extract (30.46) and Garlic bulb extract (34.66) while, maximum percent disease severity was recorded with Castor bean leaf extract (41.71) as compared to control (76.26). The minimum percent disease severity was recorded with Mancozeb @ 0.25% concentrations (21.77%).The maximum percent control was recorded with Neem leaf extarct (67.16%) followed by Tulsi leaf extract (64.81%), Arjun bark extract (59.94%) and Garlic bulb extract (53.20%) while, minimum percent disease control was recorded with botanical spray of Castor bean leaves extract (45.29%). Highest percent disease control was recorded in fungicide with Mancozeb @ 0.25 % (71.53%). The results showed that each plant extract were more or less inhibit disease growth of *Cercospora rauvolfiae*. The effectiveness of the extracts and the maximum disease management was recorded with Neem leaf extract.

Keywords: Mancozeb, Garlic, Sarpagandha

1. Introduction
Sarpagandha (*Rauvolfia serpentina* Benth.) genus name was given in honour of Dr. Leonhard Rauwolf, a 16th century German botanist, Physician & explorer. *Rauvolfia* is originated from South-East Asia. It is distributed in the Tropical region of Africa and America, Tropical Himalaya, Assam, Pegu, India, Java, Tennasserim, Deccan, Peninsula, Bihar, Sri Lanka, Malay Peninsula, Myanmar, Malaysia and Indonesia. In Nepal, it is found in tropical and subtropical regions from east to west along at 100-900m altitude. The roots of Sarpagandha (*Rauvolfia serpentina* Benth.) have been used in India from century they are prominent, tuberous, with pale brown colour usually branched, 0.5 to 2.5 cm in diameter up to 40 to 60 cm deep into soil. The uprooting of root of crop is recommended at winter (November-December). Roots of 16 exploitable sizes are collected 2-3 years after the plantation, but for commercial cultivation harvesting after 15-18 months is ideal, before digging of roots a light irrigation is suggested. 0.1-4.0 kg fresh roots are obtained from 1.5 years old plants. The average dry root yield of *Rauvolfia* was approximately 2-3 ton under average management

Evaluation of Pigeon pea genotypes for resistance to *Fusarium* Wilt

Subhash Chandra, Neeraj Kumar Rajvanshi, Ajay Kumar, Kumari Punam* and Ramesh Chand**

*Department of Plant Pathology, Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya – 224 229 (U.P.), *Department of Botany, J. P. University Chhapra (Bihar)*
***Department of Nematology, ND.U.A.&T., Kumarganj, Ayodhya – 224 229(U.P.), India*
<chandrasubhash75@yahoo.in>

Pigeon pea (*Cajanus cajan* L.) is widely adaptable to wide variety of climate and is one of the important legume crops of tropics and subtropics. It played a major role in nutritional security for the people taking cereal based diet. Beside their dietary value and nitrogen fixing ability, pulses also play an important role in sustaining intensive agriculture by improving physical, chemical and biological properties of soil and are considered excellent crop for diversification of cereal based cropping system.

Wilt disease caused by *Fusarium udum* Butler, is the most destructive soil and seed born disease of pigeon pea in India leading to heavy production losses. The *F. udum* is host specific to pigeon pea (Patel *et al*., 2011) and can survive in soil under wilted plant stubble for a long period. The best way of wilt management is by growing resistant varieties. For developing resistant varieties, resistant source are the basic requirement. Therefore, the present investigation was undertaken.

Seeds of 58 germplasm of Pigeon pea were obtained from the Department of Genetics and Plant Breeding, N.D.U.A.&T., Ayodhya and ICAR-IIPR, Kanpur. The germplasms were screened under sick plot technique. The plots (sick soil) showed over 90% wilt incidence in susceptible cultivar Bahar of Pigeon pea was used as test variety. After germination, observations were recorded regularly up to 60 days for the appearance of wilt symptoms and severity. The disease was recorded using 1-9 scale for the wilt disease.

Fifty eight germplasms of Pigeon pea were screened for their reaction to *Fusarium udum* in sick plot. It is evident (Table 1) that out of 58, 6 germplasms *viz*.; AKT 201030, IPA 96, IPAF, IPA 204, JSA 59 and WRGE 18 were found resistant, attributing to the higher concentration of phenol as observed by Haldar and Srinivasan (2007), 5 moderately resistant, 10 tolerant, 16 moderately susceptible and 21 germplasm were highly

Table 1. Performance of Pigeon pea genotypes against *Fusarium udum* under field condition (Sick plot technique)

Reaction (Rating scale)	Name of the genotypes
Resistant (1)	AKT201030, IPA96, IPAF, IPA204, JSA59, WRGE18.

Field evaluation of pigeonpea (*Cajanus cajan*) genotypes against fusarium wilt to disease resistance

Subhash Chandra, Neeraj Kumar Rajvanshi, Popin Kumar and Mukesh Kumar

Abstract
The pigeonpea germplasms/genotypes were evaluated to identify the sources of resistance to Fusarium wilt disease. The *F. udum* is host specific to pigeonpea and can survive in soil under wilted plant stubble for a long period. The best way of wilt management is by growing resistant varieties. Out of 54 screened genotypes, twenty one genotypes *viz.* BDN2001-6, BRG2-7, CORG2004-01, CORG990013, H2000-37, H2000-47, IPC7119, IPC8863, IPA14F, JKM186, JKM197, JKM204, JKM205, JKM209, KAWR11, KAWR91, NTL30, PT02-25, PT02-5, PT11-39, and PUSA2005-1 were found resistant, 15 moderately resistant, 13 tolerant, 4 moderately susceptible and 1 genotype were highly susceptible against fusarium wilt. The most susceptible variety Bahar showed 80 per cent wilting.

Keywords: Pigeonpea, *Fusarium,* germplasm, resistant

Introduction
Pigeonpea [*Cajanus cajan* (L.) Millsp.], also referred to as red gram or *arhar,* is a perennial shrub, with its centre of origin located in India. It is an important grain legume crop predominantly grown in the Indian subcontinent as an important source of dietary protein. In India, production of Pigeonpea was 42.54 Lac tones on area of 44.31 Lac ha with yield of 960 kg/ha (Anonymous, 2018) [1]. It is also cultivated in other parts of the world, including sub-Saharan Africa, Latin America, the Caribbean and South-East Asia. Its cultivation is increasing in semi-arid areas because of the crop's ability to thrive under prolonged drought and in degraded lands (Upadhyaya *et al*., 2012) [11]. The crop is mainly grown as annual using cultivars with different durations to maturity: 90 days (Short), 120 days (Medium) and 180 days (Long). It is cultivated as a perennial crop in several regions of India. The shift of pigeonpea cultivation from the traditional *kharif* season to pre *rabi* September sowing in north Bihar has not only shown an increased production potential of this important pulse crop but have also opened altogether a new possibilities in land use pattern of the rain fed areas of Bihar and adjoining states. Fresh pods are consumed as a vegetable; dried mature grains are used for cooking or in processing. Among the several factors responsible for reduction yield and quality deterioration of pigeonpea in India, diseases occupy a vital place. Among the diseases, wilt disease caused by *Fusarium udum* Butler, is the most destructive soil and seed born disease of pigeonpea in India leading to heavy production losses. The disease since been reported from Bangladesh, Ghana, Grenanda, Indonesia, Kenya, Malawi, Mauritius, Tanzania, Thialand, Trinida, Uganda and Zambia. In India it is the most serious problem all over the Pigeonpea growing states especially in U.P., M.P., Bihar and Maharashtra. In the epiphytotic conditions, disease incidence was recorded 15-25 per cent in general and up to 50 per cent (Butler, 1910) [2]. In Bihar and Uttar Pradesh, 5-10 per cent losses in standing crop are common feature every year (Singh, 2006) [10].

Materials and Methods
Seeds of fifty four genotypes of Pigeonpea were obtained from the Department of Genetics and Plant Breeding, N.D. University of Agriculture and Technology, Kumarganj, Ayodhya (U.P.) and IIPR, Kanpur. The genotypes were screened under artificial conditions (Sick plot technique) using the methods described by Nene *et al*., (1982) [5].

Screening of mungbean [*Vigna radiate* (L.) Wilczek] genotypes for resistance against mungbean yellow mosaic virus (MYMV) under field condition

Subhash Chandra, Neeraj Kumar Rajvanshi, Popin Kumar, Mukesh Kumar and MP Chauhan

Abstract
Mungbean (*Vigna radiata* L.) is also known as mung, moong, mungo. In India it is third most important pulse crop after chickpea and pigeonpea. Mungbean is an important short duration grain legume which is grown in different parts of the country, for grain and green manuring. It is an outstanding source of easily digestible proteins with low flatulence, which balances the staple rice diet in Asia. Mungbean yellow mosaic disease (MYMD) caused by whitefly (*Bemisia tabaci*) transmitted mungbean yellow mosaic virus (MYMV) is an important constraint of mungbean in India. Use of resistant genotypes is the best method of avoiding the occurrence of the disease. Keeping this point in view, out of fifty two genotypes of mungbean were tested for the resistance against MYMV during *Kharif* 2015 in field condition. The per cent disease incidence (PDI) of MYMV among 52 mungbean genotypes was worked out up to ninth week after sowing and it varied from 0 to 79.68 %. Out of fifty two mungbean genotypes, five were found resistance, eight were moderately resistant, seventeen genotypes were recorded moderately susceptible and twenty two genotypes were noticed susceptible. Five genotypes namely, PM 10-18, PUSA 1371, BM 2012-09, DGGV-2 and MH 810 found resistant during present investigation which can be used for the development of mapping population for the development of MYMV resistant varieties.

Keywords: mungbean, genotypes, resistance and yellow mosaic virus

Introduction
Mungbean (*Vigna radiata* L.) is also known as green gram, green bean, moong, mash bean, golden gram and green soy (Saminathan 2013) [10]. In India, the name green gram is more commonly used than mungbean (Chatterjee and Randhawa, 1952) [2]. It is third most important pulse crop of India after chickpea and pigeonpea. Mungbean can grow in all three seasons in India, *viz*., *Kharif* (July- Oct), *Rabi* (Sept- Dec) and summer (March- June). It is grown under rainfed condition during *Kharif* and on residual moisture during *Rabi* in eastern and southern part of the country. However, *Kharif* season crop occupies maximum area of its cultivation. Intercropping with sorghum, pearl-millet, maize, cotton, castor, pigeonpea etc., are popular. India alone contributes 54% of world production and covers 65% of the world acreage (Singh, 2011) [11]. It is grown in intercropping, catch cropping and relay cropping systems because of its short duration (less than 60 days). In India, mungbean is grown in an area of 4.32 m ha with production of 2.17 m tones and productivity of 502 kg/ha. Important mungbean growing states are Rajasthan, Maharashtra, Karnataka, Andhra Pradesh, Odisha, Bihar, Tamil Nadu, Madhya Pradesh and Uttar Pradesh (Anon, 2018) [1]. The standard worldwide yield of mungbean is very low (389 kg/ha) and its production has not increased over the year. The main reason for low yield is the susceptibility of the crop to insects, weeds and diseases caused by fungus, virus, nematodes and bacteria. Among these, the viruses are the most important group of plant pathogens affecting the production of the crop. They cause severe diseases and economic losses in mungbean and reducing seed yield and quality (Kang *et al*., 2005) [3]. Twelve viral diseases are reported on mungbean crop *viz*., Mungbean yellow mosaic virus (MYMV) disease, Bean yellow mosaic virus (BYMV) disease, Southern bean mosaic virus (SBMV) disease, Leaf crinkle virus (LCV) disease, Mungbean mosaic virus (MMV) disease, Cowpea aphid-borne virus (CABV) disease, Cucumber yellow mosaic virus (CMV) disease, Alfalfa

Evaluation of mungbean [*Vigna radiate* (L.) Wilczek] genotypes for resistance against web blight

Subhash Chandra, Neeraj Kumar Rajvanshi, MP Chauhan and Mukesh Kumar

Abstract
Web blight (*Rhizoctonia solani*) of mungbean is a very destructive disease caused by fungus *Rhizoctonia solani*. In India, mungbean crop suffers a great loss due to this disease.Use of resistant genotypes is the best method of avoiding the occurrence of the disease. Keeping this point in view, fifty two genotypes of mungbean were tested for the resistance against web blight in field condition. Out of fifty two genotypes of mungbean were carried out under field condition of natural infection, where twenty nine genotypes *viz*.; BM 2012-09, Palampur 93/kulu-4, LGC 574, NUL 516, T-44, SGC 20, SML 1082 (SC), IPM 312-19, IGKM 06-42, VG 10-008, MH 921, ML 2412, PUSA 571, RMG 1082, PUSA 1472, ML 2410, ML 2333, COGG-912, KM 2348, AKM 12-17, IPM 312-20, GM 11-02, KM 2241, ML 818, HUM-1, CO6, LGG 460, IPM 02-3 and GM 04-02 were found resistant, five genotypes were recorded moderately resistant, thirteen genotypes were noticed moderately susceptible, four genotypes *viz*.; NVL 825, DUG 5, VBN 4, RMG 1028 were recorded susceptible. Only one genotype K-851was found highly susceptible.

Keywords: Evaluation, mungbean, web blight, *Vigna radiate*

Introduction
Mungbean (*Vigna radiata*) belongs to fabaceae family along with good sources of protein, carbohydrates and vitamins for mankind all over the world. Mungbean (*Vigna radiata* L.) is also known as mung, moong, mungo. In India, the name greengram is more commonly used than mungbean (Chatterjee and Randhawa, 1952) [3]. It is third most important pulse crop of India after chickpea and pigeonpea. Mungbean can grow in all three seasons in India, *viz*., *Kharif* (July- Oct), *Rabi* (Sept- Dec) and summer (March- June). It is grown under rainfed condition during *Kharif* and on residual moisture during *Rabi* in eastern and southern part of the country. However, *Kharif* season crop occupies maximum area of its cultivation. Intercropping with sorghum, pearl-millet, maize, cotton, castor, pigeonpea etc., are popular. India alone contributes 54% of world production and covers 65% of the world acreage (Singh, 2011) [10]. It is grown in intercropping, catch cropping and relay cropping systems because of its short duration (less than 60 days). It is grown in intercropping, catch cropping and relay cropping systems because of its short duration (less than 60 days). In India, mungbean is grown in an area of 4.32 m ha with production of 2.17 m tones and productivity of 502 kg/ha. Important mungbean growing states are Rajasthan, Maharashtra, Karnataka, Andhra Pradesh, Odisha, Bihar, Tamil Nadu, Madhya Pradesh and Uttar Pradesh (Anon, 2018) [1].

Mungbean has been considered as "poor men's protein". It contains 26% protein, 51% carbohydrate, 4% minerals, 3% vitamins and 10% moisture (Khan, 1981) [7]. The standard worldwide yield of mungbean is very low (389kg/ha) and its production has not increased over the year. The main reason for low yield is the susceptibility of the crop to insects, weeds and diseases caused by fungus, virus and bacteria. Among these, the viruses are the most important group of plant pathogens affecting the production of the crop. They cause severe diseases and economic losses in mungbean and reducing seed yield and quality (Kang *et al.*, 2005) [6]. The crop is infected by a large number of pathogens consisting of (virus, bacteria, fungi and nematodes) which significantly contribute to poor yields. Among the diseases, Yellow mosaic, Web blight, Bacterial blight, Leaf crinkle, Powdery mildew, Cercospora leaf spot, Anthracnose and Macrophomina bight are important in different parts of the country which reducing the yield of mungbean heavily. Previously web blight was considered as minor disease.

Reaction of urdbean (*Vigna mungo*) genotypes against *Cercospora* leaf spot (CLS)

Subhash Chandra, Neeraj Kumar Rajvanshi, Popin Kumar, RM Tripathi and MP Chauhan

Abstract
The present investigation aimed to identify resistance in urdbean (Vigna mungo) against *Cercospora* leaf spot (CLS) in a field condition. The trial was conducted at Genetics and Plant Breeding Farm of Narendra Dev University of Agriculture and Technology, Kumarganj, Ayodhya. Forty six urdbean genotypes were screened in the summer season of the year of 2015- 2016. The severity of was recorded following 0-9 scale. The urdbean genotypes evaluated were grouped into different categories based on disease reaction. The present results indicated that genotype IPU 11-2, PU 10-23, KU 96-7, Pant U 19, TU 94-2, VBG 09-005, KPU 524-65, NIRB-004, DKU 11, Vamban 7, NDUK 13-6, CO 5, KUG 725, PU 10-16, NUL 7, Pant U 30, WBU 108, NIRB-003, Shekhar 3, NDUK 15-9, TU 67, VBG 12-062, RMG 353, IU 05-1, VBG 11-053, IPM 94-1, RUG 55 and TU 22 were resistant to CLS, 6 genotypes *viz.*; AKU 11-15, K 851, KU 96-3, LBG 645, NIRB-002, COBG 11-03 were exhibited moderately resistant, 05 genotypes *viz.*; LBG 623, MU 46, MU 44, KU 14-1, DBG 11 were showed moderately susceptible, 06 genotypes *viz.*; RUG 59, IPU 2-43, Pant U 31, KUG 479, IPU 13-1, KPU 129-104 were susceptible and only one genotype was highly susceptible. None of these genotypes was found free from infection. The urdbean genotypes which were found resistant the could be the choice for resistance against CLS.

Keywords: urdbean, *Cercospora*, *Vigna mungo*, CLS

Introduction
Pulses represent one of the most important foods that have been extensively used to cover basic protein and energy needs in day today life. Pulses have unique property of maintaining and restoring soil fertility through biological nitrogen fixation as well as covering and improving physical properties of soil by virtue of their deep root system. Urdbean or Blackgram (*Vigna mungo* L.) Hepper is the most important pulse crop of the *'vigna'* group. It is considered to have been domesticated in India from its wild ancestral form (*V. mungo* var. *Silvestris* Lukoki, Marechal & Otoul). Center of genetic diversity is found in India (Zeven and de Wet. 1982) [7]. It is an important crop of India and extensively grown over a wide range of agroclimatic zones of the country.

In India, urdbean occupies 4.50 m ha area, production 2.83 mt and productivity 628 kg/ha (Anonymous, 2018) [1]. Highest productivity of urdbean is reported from West Bengal followed by Andhra Pradesh and Uttar Pradesh. Urdbean is prone to several fungal diseases, among which *Cercospora* leaf spot (CLS) caused by *Cercospora* canescens. Eills and Mortin is one of the most important fungal disease of urdbean causing heavy yield losses particularly in Uttar Pradesh and Uttarakhand states. Disease is also reported from other states *viz.*, Punjab, Haryana, Bihar, Rajasthan, West Bengal, Himachal Pradesh and Jammu & Kashmir (Saksena and Dwivedi, 1973) [6]. Previously *Cercospora* leaf spot was considered as minor disease. Due to change in cropping system and introduction of yellow mosaic resistant varieties it is becoming an important fungal disease and constraint in production of this crop. Resistance is fundamental attributes of all living systems. Host plant resistance (HPR) is the most efficient and ecofriendly means of management. For exploitation of HPR, reliable field and controlled environment screening techniques are essential. Therefore, the present investigation was undertaken with an objective to identify the sources of resistance in different genotypes of urdbean against *Cercospora* leaf spot.

ABSTRACT

Tomato crop affected by different fungal diseases in which Fruit rot known as target spot disease incited by *Sclerotinia sclerotiorum* is one of the most destructive disease. Disease severity varied (30.50 to 18.60%) in different locations of Kanpur. Highest disease severity was (30.50%) and the lowest disease severity (18.60%) was noticed at the farmer's field of Billhore, Kanpur. *Sclerotinia sclerotiorum* is a soil borne pathogen which causes symptoms on ripe fruits. Pathogen isolated from infected fruits. Copper oxychloride, Kavach, Tebucanazol, Andrachite, Dithane M-45, Metalaxyl, Roko and Bavistin completely suspected the growth of pathogen*in vitro*. Among eight fungicides, Tebuconazol, Andrachite, Metalaxyl, Roko, and Bavistin were found effective against pathogen under *in vitro* and *in vivo* conditions. However, seven bio-agents (*Trichoderma* spp.), *T. koningii*, *T. virens*are found effective in bothconditions. *In vitro* eight fungicides were tested against pathogen in which Metalaxyl, Roko, Tebucanazol, Andrachite and Bavistin showed 100% growth inhibition. Seven bio-agents (*Trichoderma*spp.) were tested *in vitro* while, among them *T. koningii* showed maximum inhibition followed by *T. virens*, *T. longibrachiatum*, *T. atroviridae*, *T. asperallum*, *T. viridae* and *T. reesei*, respectively. Eight treatments were applied *in vivo* for disease management however, among them T_6 (*Bacillus subtilis* + bavistin) recorded the minimum disease incidence and maximum fruit yield.

Introduction

Sclerotinia sclerotiorum (Lib.) is a serious fungus affecting yield and product quality of many susceptible hosts. It is a widespread soil borne plant pathogen with an extremely wide host range of more than 400 plant species including many of economic importance (Gao *et al.*, 2014). *S. sclerotiorum* is responsible for more than 60 plant diseases (Purdy, 1979). The pathogen produces sclerotia, which survive for long periods and attackroots of growing and mature plants, resulting in root rot, basal stemcanker, and wilt (Duncan *et al.*,

Screening of lentil genotypes against *Fusarium oxysporum* f. sp. *lentis* in field condition

Subhash Chandra, Mukesh Kumar, Neeraj Kumar Rajvanshi and Virendra Prasad Chaudhary

Abstract
Lentil (*Lens culinaris* Medik) is a member of Leguminosae family and it is commonly known as poor man's meat. Lentil wilt is a very destructive disease caused by fungus *Fusariumoxysporum* f. sp. *Lentis*. In India, lentil crop suffers a great loss due to this disease. The use of resistant variety is one of the best methods of disease management. Therefore, studies were planned to search out the genotypes against *Fusarium* wilt through sick plot technique. Keeping this point in view, one hundred forty three genotypes of lentil were tested for the resistance against *Fusariumoxysporum* f. sp. *lentis* in field condition, out of which 53 genotypes were found highly resistant, 35 genotypes were found resistant, 16 genotypes were found moderately resistant, 18 genotypes were found susceptible and 21 genotypes highly susceptible. None of these genotypes was found free from infection.

Keywords: Lentil, *Fusarium*, genotypes, resistant

Introduction
Lentil *(Lens culinaris* Medik) is a member of Leguminosae family and it is commonly known as poor man's meat. It has a high nutritional value and major source of dietary proteins (25%) after soybeans (Zia *et al.*, 2011) [8]. Lentil (*Lens culinaris* Medik L.) is the most important pulse crop in India and mostly grown in north east plain zone & central part of India. It is a diploid and self-pollinated crop which is grown in winter season and belonging to Order- Rosales, suborder- Rosneae, Family- Leguminaceae (fabaceae), subfamily- papilionaceae, genus- *Lens* and species- *culinaris* with chromosome number 2n=14. Among *rabi* pulses, lentil is next to chickpea. The total area under lentil in India was 1.49 m ha with a total production of 1.61 MT and 1006 Kg/ha productivity (Anonymous, 2018) [1]. In Uttar Pradesh, it is grown on 4.78 lakh hac. area with 4.47 lakh tones production and productivity 936 kg/ha (Anonymous, 2018) [1].

Lentil suffers from attack of a number of diseases such as vascular wilt; collar rots, root rot, stem rot, rust, powdery mildew downy mildew and fusarium wilt which are caused by *Fusarium oxysporum* f. sp. *lentis*. Average yield of lentil is low due to various diseases. Among the disease, foot and root rot of lentil caused by *Fusarium oxysporum* and *Sclerotium rolfisii* are common and the most serious disease in India. The fusarium wilt of lentil caused by *Fusarium oxysporum* f. sp. *lentis* is one of the most important and destructive disease in India wilt pathogen minimize crop yield and deteriorate the seed quality (Khare, 1991) [5]. The disease was first reported from Hungary but in India it was first observed in 1941 from Delhi and Karnal. If infection takes place in early stage the plant do not produced seeds, formed few in number when infection occurred in later stage. Wilt causes more damage at flowering and

To evaluate the efficacy of botanicals and chemical against *Cercospora* leaf spot of Sarpagandha (*Rauvolfia serpentina* L.) Benth Ex Kurz. *in vivo*

Veer Singh, Neeraj Kumar Rajvanshi, Subhash Chandra and Susheel Kumar

Abstract
Sarpagandha (*Rauvolfia serpentina*) belongs to family *Apocynaceae* is an evergreen, perennialshrub, erect of the height upto 60cm. It's root are tuberous with pale brown colour, leaves of the plant are in whorls of three lanceolate or obovate, bright green in colour, flowers are in irregular, corymbose infloresence with white and pink colour. Fruits are drupe, single or didymous shining black when fully riped. The minimum percent disease severity was recorded with Neem leaf extract (25.03) followed by botanicals spray, Tulsi leaf extract (27.15), Arjun bark extract (30.46) and Garlic bulb extract (34.66) while, maximum percent disease severity was recorded with Castor bean leaf extract (41.71) as compared to control (76.26). The minimum percent disease severity was recorded with Mancozeb @ 0.25% concentrations (21.77%).The maximum percent control was recorded with Neem leaf extarct (67.16%) followed by Tulsi leaf extract (64.81%), Arjun bark extract (59.94%) and Garlic bulb extract (53.20%) while, minimum percent disease control was recorded with botanical spray of Castor bean leaves extract (45.29%). Highest percent disease control was recorded in fungicide with Mancozeb @ 0.25 % (71.53%). The results showed that each plant extract were more or less inhibit disease growth of *Cercospora rauvolfiae*. The effectiveness of the extracts and the maximum disease management was recorded with Neem leaf extract.

Keywords: Mancozeb, Garlic, Sarpagandha

1. Introduction
Sarpagandha (*Rauvolfia serpentina* Benth.) genus name was given in honour of Dr. Leonhard Rauwolf, a 16th century German botanist, Physician & explorer. *Rauvolfia* is originated from South-East Asia. It is distributed in the Tropical region of Africa and America, Tropical Himalaya, Assam, Pegu, India, Java, Tennasserim, Deccan, Peninsula, Bihar, Sri Lanka, Malay Peninsula, Myanmar, Malaysia and Indonesia. In Nepal, it is found in tropical and subtropical regions from east to west along at 100-900m altitude. The roots of Sarpagandha (*Rauvolfia serpentina* Benth.) have been used in India from century they are prominent, tuberous, with pale brown colour usually branched, 0.5 to 2.5 cm in diameter up to 40 to 60 cm deep into soil. The uprooting of root of crop is recommended at winter (November-December). Roots of 16 exploitable sizes are collected 2-3 years after the plantation, but for commercial cultivation harvesting after 15-18 months is ideal, before digging of roots a light irrigation is suggested. 0.1-4.0 kg fresh roots are obtained from 1.5 years old plants. The average dry root yield of *Rauvolfia* was approximately 2-3 ton under average management

ABSTRACT

The present study encompasses propaedeutics of traumatic pericarditis in 18 buffaloes presented as a guide to early diagnosis. The clinical findings recorded were chronic anorexia, prolonged standing with reluctance to sit or move, brisket oedema and abnormal faeces. The blood picture revealed the presence of band cell, leukocytosis and neutrophilia. Elevated AST was also noted in serology. After postmortem examination, traumatic pericarditis was categorized as fibrinous pericarditis, suppurative pericarditis and vegetative endocarditis.

Keywords: Buffaloes, propaedeutics, traumatic pericarditis

Traumatic pericarditis most commonly results from perforation of the reticulum by metal objects such as nails or wire that have been accidentally incorporated into feed and ingested. This may lead to localized peritonitis, sometimes involving neighbouring organs, and in severe cases, it results in generalized peritonitis (Purohit *et al*, 2015; Constable *et al*, 2017; Sodhi *et al*, 2019). Acute disease usually results in distinct signs that include anorexia, decreased milk production, fever, ruminal atony and tympany, abdominal pain, arched back, abdominal guarding and tense abdomen (Dabas *et al*, 2012; Parmar *et al*, 2017). The clinical signs in cattle with chronic disease on the other hand are often less apparent (Constable *et al*, 2017; Braun *et al*, 2018). Pinching of the withers, gradual application of pressure followed by the sudden release of pressure on the area between the xiphoid and the umbilicus using a pole and percussion of the abdominal wall with a rubber hammer over the region of the reticulum are the most useful foreign body tests for TRP (Dirksen *et al*, 1990; Braun *et al*, 2018). However, the picture may vary and it is assumed clinical propaedeutics may aid in early diagnosis that may help to stop the progression of the disease and thus save the valuable animal. Ferroscopy and blood trypsin inhibitor spot test (Suthar *et al*, 2012), Cardiac troponin-I and electrocardiographic findings (Devi *et al*, 2014), radiography (Tiwari *et al*, 2018), ultrasonography (Joseph *et al*, 2018) and glutaraldehyde coagulation test (Bishnoi *et al*, 2012) as an ancillary diagnostic aid for detection of severity of traumatic pericarditis in animals were well documented. The present study describes the clinico-pathological changes observed in 18 buffaloes affected with traumatic pericarditis.

Material and Methods

Animals and study design

The study was conducted on 18 buffaloes presented to Veterinary Clinical Complex of the Institute for a period of 4 years from September, 2016 to September, 2020 with a history of chronic anorexia, prolonged standing with reluctance to sit or move and abnormal faeces. A tentative diagnosis of cardiac insufficiency probably due to pericarditis was made based on the history and physical examination. All the animals underwent clinical examination according to the method of Rosenberger (1979). A tentative diagnosis was made based on clinical findings and blood examination. Traumatic pericarditis was also confirmed through postmortem examination and the animals were categorized as per heart lesions i.e. animals with fibrinous pericarditis, suppurative pericarditis and vegetative endocarditis (Sastry and Rao, 2001). The foreign material damaging the heart and peritoneum were collected during postmortem examination. The pattern of clinical findings recorded earlier were then studied.

Blood sampling

Two blood samples (about 10 ml) were collected from each animal from the jugular vein in a vacutainer

Study of Prolactin Receptor Gene (PRLR5) polymorphisms and its association with egg production in Kadaknath hens

Shiv Kumar Yadav*, S. K. Maurya, Alok Kumar Yadav[1], Anand Kumar and Kamalesh Yadav

College of Veterinary Science & Animal Husbandry,
Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad- 224 229 (UP) India
Received: 18-11-2011 Accepted: 04-02-2017 DOI:10.18805/ijar.v0iOF.8001

ABSTRACT

The present study was conducted to investigate the polymorphisms of prolactin receptor (PRLR5) gene and its association with egg production in Kadaknath hens. Egg production is a polygenic inheritance trait. Study was conducted on twenty female birds of Kadaknath kept for laying. Egg production performances were recorded as age at first laying (AFE), Body Weight at First Egg (WFE), Mean Egg Weight (MEW) and Total No. of Eggs at 90 days of laying (TEN). Genomic DNA isolated from 2- 3 of blood collected from wing vein of each bird was amplified for prolactin receptor (PRLR5) gene with specific primer by standardizing and optimising the PCR protocols. PCR was performed in a final volume of 20 µl. The amplified PCR products were resolved on the gels to generate polymorphisms. PRLR5 was digested with *BamHI*. Retriction digested products were run on 2% agarose gel electrophoresis. PRLR5 showed two alleles & two genotypes. The frequency of AA genotype at this locus was 0.75 & BB genotype was 0.25. The AFE (d), WFE (Kg), MEW (g) and TEN of Kadaknath hens in the present study were found to be 188.00±0.71, 1.26±0.03, 42.83±0.21 & 37.75±0.59 respectively. Birds with AA genotype of PRLR5 had a significantly ($P<0.05$) better WFE & AFE than BB genotype. Prolactin receptor (PRLR5) genes produced polymorphism in Kadaknath and were associated with egg production traits.

Key words: Egg production performance, Kadaknath, Prolactin receptor gene, PCR-RFLP.

INTRODUTION

Kadaknath is a native Indian breed of poultry. Meat of kadaknath is dark coloured & delicious, also attributed with medicinal qualities. Characteristics of Kadaknath poultry breed include Black coloured meat, Black blue plumage, Black hued internal organs. Most of the internal organs show intense black colouration due to deposition of melanin pigment in the organs. Locally it is known as Kalamasi and their black flesh is very delicious and popular among tribal people. Sometimes this flesh is being used for the treatment of many diseases by tribal, and is also considered an aphrodisiac (Thakur *et al.*, 2006).

Kadaknath do not lay eggs at particular time & start egg laying 6 months onwards. Eggs are in 2-3 clutches in a year with 25-30 eggs/clutch. Kadaknath tolerates extreme climatic conditions of summer heat and cold winter stress and thrives very well under minimal management inputs like poor housing, no health care or supplementary feeding while exhibiting appreciable degree of resistance to diseases compared to other exotic breeds of fowl (Thakur *et al.*, 2006).

The prolactin receptor (PRLR) is a specific receptor for prolactin, which is an anterior pituitary peptide hormone involved in various physiological activities and is essential for reproductive success. The prolactin receptor (PRLR) has an important role in the PRL signal transduction cascade, which is triggered at the onset of broodiness, and PRL exerts its biological functions by acting through the PRLR. Because the PRLR gene is on the Z chromosome, the hypothesis of sex-linked inheritance of broodiness may relate to PRLR gene via its role in PRL signal transduction. Chicken PRL and PRLR have been cloned and mapped (Ohkubo *et al.*, 2000). In avian species, a single form of PRLR containing a cytoplasmic domain comparable to that of the longest isoform of mammalian PRLR has been identified by cDNA cloning (Yamamoto *et al.*, 2003). The membrane-bound PRLR is closely related to the growth hormone receptor and is a member of the cytokine receptor family. Consistent with its diverse effects, the PRLR is expressed ubiquitously in chickens and turkeys (Leclerc *et al.*, 2007 a, b) and levels of receptor in target tissues are up and down-regulated in response to changes in the concentration of circulating PRL.

MATERIALS AND METHODS

Birds and production data: The birds from the poultry farm of College of Veterinary Science & Animal Husbandry, Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad were used for the present study. Twenty female birds of Kadaknath breed nearing their age of laying were taken for the present study. Birds were kept in separate

Prolactin Gene and Laying Performance in Aseel Birds

Abstract

Prolactin gene polymorphism at exon 5 of prolactin receptor gene (PRLR5) was studied in Aseel birds along with its interaction with laying performance. Laying performances were recorded as age at first laying (AFE), Body Weight at First Egg (WFE), Mean Egg Weight (MEW) and Total No. of Eggs at 90 days of laying (TEN). DNA was isolated from 2- 3 ml not clear of Blood from 40 birds collected from wing vein. PRLR5 locus was amplified by PCR and the product was restriction digested with Bam HI and resolved on 2% Agarose gels for genotyping. The AFE (d), WFE (Kg), MEW (g) and TEN of Aseel birds in the present study were found to be 188.40±0.22, 1.57±0.03, 43.61±0.36 & 35.48±0.40 respectively. The prolactin gene locus PRLR5 showed two alleles A & B. The frequencies of A and B alleles at this locus were 0.60 and 0.40 respectively. There was no interaction of various laying performances found with alleles of PRLR5.

Introduction

Egg productivity is the most important economic trait in egg-laying poultry. Endocrine and environmental factors such as length of photoperiod and feeding allowance can influence egg production [1]. However, a genetic factor would be a prerequisite. Egg production is a polygenic inheritance trait with low to moderate heritability depending on the period involved, a major opportunity for improvement in this trait lies in the period after 40 weeks of age [2,3]. In traditional breeding, genetic improvement based on estimated breeding values requires extensive data from a variety of sources. Prolactin (PRL) is a polypeptide hormone which plays a key role in egg production. Onset of incubation behavior is induced by an increase in PRL secretion, which results in regression of ovary & loss of egg production [4]. Polymorphism in the promotor region specially those that result in change of promoter binding sites, most likely influence mRNA expression and thus influence incubation behaviour and egg production [5]. The Asil or Aseel is a breed of chicken originating from South Punjab/Sindh area of Pakistan and India. The Aseel breed is known for its stamina, pugnacity, majestic gait, and dogged fighting qualities [6]. This breed is characterized by its hardiness and ability to thrive under adverse climatic conditions, and its meat is considered to have a desirable taste and flavor. The superiority of Aseel on other indigenous breeds is due to its hardiness, resemblance to Cornish and larger body size [7]. Almost all the varieties of Aseel are characterized with heavy body weight and poor egg production potential thus leading to low progeny size due to erratic ovulation, short or erratic clutches and broodiness. Due to different biological activities attributed to PRL and PRLR, they can be used as the major candidate genes in molecular animal breeding programs. There is scarce data in case of breeds like Aseel, thus present study was planned.

Materials and Methods

Birds and production data

The birds from the poultry farm of College of Veterinary Science & Animal Husbandry, Narendra Deva University of Agriculture & Technology, Kumarganj, and Faizabad were used for the present study. Forty female birds of Aseel breed nearing their age of laying were taken for the present study. Birds were kept in separate cages for the ease of sample & data collection and were fed ad libitum. The weights at first egg (WFE) were recorded in kg with a balance on the day when they gave their first egg. Age at first egg (AFE) was calculated from the records. Mean weight of eggs (MEW) was taken as average of daily egg weights over a period of 90 days of laying and recorded in g with the help of a monopan balance. Total no. of eggs (TEN) represented the number of eggs laid over the study period of 90 days.

Blood Collection and DNA isolation

Two to three ml of blood was collected from wing vein of each bird in a vacutainer tube containing EDTA. DNA was isolated from 2-3 ml of blood using High salt method of Montgomery and Sise [8] with slight modifications.

Polymerase chain reaction

Polymerase chain reaction was carried out in a Bio-Rad CFX96 Real Time system. Primer pair for PRLR5 was used as described by Rashidi et al. [9], to amplify a fragment of 250 bp from exon 5 of prolactin receptor gene. The sequence of primers is as follows:

Forward: 5'-TTGTCTGCTTTGATTCATTTCC-3'

Reverse: 5'-TGCATTTCATTCTTCCCTTTTT-3'

PCR was performed in a final volume of 50 µl containing:100 ng of genomic DNA, 0.5µM of each primer, 0.2 mm of each dNTPs, 1.5 mM MgCl2, 1.0 U Taq DNA polymerase and 1× reaction buffer. The cycle conditions for PCR included-Initial denaturation of

Analysis of Mitochondrial DNA Variation in Sahiwal Cattle

S. K. Maurya*

ABSTRACT

Four restriction enzymes were used to study the mitochondrial DNA restriction fragment length polymorphism (mtDNA RFLP) in Sahiwal cattle. D loop of mitochondrial DNA was amplified using a primer for D loop. Restriction endonuclease cleavage patterns of mitochondrial DNA of Sahiwal cattle were analyzed using restriction enzymes AvaII, Bam HI, EcoRI and HaeIII. Restriction enzymes AvaII and BamHI each showed two haplotypes; four haplotypes were shown by HaeIII, whereas EcoRI showed only one haplotype.

Introduction

Mitochondria are eukaryotic cell organelles involved in various cellular functions, including cell proliferation, apoptosis and, mostly important, energy production (Birch-Machin, 2006) by oxidative phosphorylation (Taanman, 1999). These organelles are responsible for approximately 90% of the energy produced by the mammal cell (Boettcher et al, 1996a, 1996b). Mitochondria have their own genome, which is maternally inherited in mammals and is an important source of cytoplasmic genetic variation (Gibson *et al.*, 1997; Birky, 2001).

Domestic cattle, one of the best-known livestock of human societies, are derived from the aurochs, *Bos primigenius*. Presently, there are large numbers of breeds in both *B. taurus* and *B. indicus* cattle in the world and they must be variants of these subspecies. In addition, some domesticated cattle breeds developed from a hybrid of *B. taurus* and *B. indicus* because the two subspecies can interbreed freely. It has been demonstrated that mitochondrial DNA (mtDNA) haplotypes specific for each subspecies exist in native populations of Asian cattle. Analysis of blood groups and protein polymorphisms supports this theory, because two distinct clades consistently appear in the phylogenetic tree of cattle. On the other hand, many taurine genes have been found in several zebu populations, suggesting that gene flow from taurines occurred in Asian zebu populations as an unusual pattern of introgression.

Before applying sequencing and other higher molecular biological tools in genetic studies, RFLP (restriction fragment length

Received 24 September 2016; Accepted 26 October 2016; Published online 15 November 2016

Abstract A study carried out to study egg production performance and polymorphism of prolacin gene at promoter region (PRL5). Primer pair PRL5 was used to amplify the 439 bp fragment of the chicken PRL gene containing AGCT sequence for AluI restriction enzyme. PRL5 locus for polymorphism was amplified by PCR and the product was resolved by eletrophoresis and performed in 2% agarose gel; Egg production performances were recorded as age at first laying (AFE), Body Weight at First Egg (WFE), Mean Egg Weight (MEW) and Total No. of Eggs at 90 days of laying (TEN). DNA was isolated from 2-3 of Blood of 20 birds collected from wing vein. The AFE (d), WFE (Kg), MEW (g) and TEN of Kadaknath hens in the present study were found to be 188.00 ±0.71, 1.26 ±0.03, 42.83 ± 0.21 and 37.75 and 37.75 ± 0.59 respectively. Theprolacin gene locus PRL5 showed two alleles C and T and three genotypes : CC, CT and TT. The frequencies of C and T aaeles at this locus were 0.50 and 0.50 respectively. The frequencies of CC, CT and TT genotypes were 0.30, 0.40 and 0.30 respectively. the birds of C allels had a significantly (P<0.05) better MEW and TEn than birds of T allele.

In-vivo anthelmintic efficacy of powder formulation of *Embelia ribes* fruits and *Vernonia anthelmintica* seeds on ovine gastrointestinal nematodes

Vinod Sinha, Amit Singh, VK Pal, SK Maurya, Jaswant Singh and Chandra Shekhar

Abstract
Powder formulation of *Embelia ribes* fruits and *Vernonia anthelmintica* seeds was evaluated *in-vivo* for anthelmintic efficacy against gastrointestinal nematodes in sheep. In this study, twelve naturally infected female sheep were selected based on egg per gram (EPG) and then randomly divided into two groups, group I (G I) and group II (G II) having six animals each. G I animals was treated with powder formulations of *Embelia ribes* fruits and *Vernonia anthelmintica* seeds (1:1) at the dose rate of 600 mg/kg.b.wt. orally whereas G II animals were left as untreated infected control. Faecal and blood samples were collected on days 0,3,7 and 10 PT to record reduction in faecal egg count and improvement in haematological and biochemical parameters post treatment. On day 10 PT, 62.07% reduction in faecal egg count was observed. Post treatment, there was improvement in haematological, total protein and albumin level indicating reduction in worm burden. AST, ALT and serum creatinine values post treatment suggested no side effects. Coproculture before and after treatment revealed *Haemonchus contortus* to be a predominant strongyle. The study revealed promising activity of the herbal formulations which can be further exploited to improve the efficacy against gastrointestinal nematodes of sheep.

Keywords: gastrointestinal nematodes, sheep, *Embelia ribes*, *Vernonia anthelmintica*, anthelmintic evaluation

Introduction
The problem of anthelmintic resistance poses a great challenge to the successful control programme for the effective management of gastrointestinal nematodes [1]. This eventually results in huge economic losses to the small and marginal farmers whose livelihood depends upon the rearing of sheep and goat. Emergence of resistance problem has been widely reported from various regions of India [2, 3, 4, 5, 6] which led to the search for alternative means of worm control which is not only effective but economical and eco-friendly. Now a day, efforts being made for the development, formulations and evaluation of anthelmintics of herbal origin as an alternative tool for the effective control of gastrointestinal nematodes.
Keeping the above facts in view, the present study was planned to evaluate the efficacy of powder formulations of *Embelia ribes* fruits and *Vernonia anthelmintica* seeds in sheep naturally infected with gastrointestinal nematodes.

Materials and Methods
Powder preparation- *Embelia ribes* fruits and *Vernonia anthelmintica* seeds after being procured from the local market were put in a hot air oven at 40 °C for 8hrs to remove moisture. They were then pulverized to a fine powder using an electric grinder, sieved and kept in air tight container at 4 °C. Both powders were then mixed in the equal ratio (1:1) to be used for *in-vivo* study.

***In -vivo* experiment**
For *in-vivo* study, twelve (12) adult female sheep, weighing 16-30 kg and naturally infected with gastrointestinal nematodes and having egg per gram of faeces (EPG) more than 500 were selected. They were randomly divided into two groups (Group I and Group II) having six animals each. Group I sheep was treated with *Embelia ribes* + *Vernonia anthelmintica* (1:1)

Abstract

Aqueous alcoholic (70% ethanol) extracts mixture of Embelia ribes fruits and Vernonia anthelmintica seeds was evaluated for anthelmintic efficacy in sheep having natural infection of gastrointestinal nematodes. Twelve infected sheep were randomly divided into two groups, Group I and Group II comprising six animals each. Group I sheep were treated with Embelia ribes fruits and Vernonia anthelmintica seeds extract (1:1) at dose rate of 100mg /kg. b.wt. orally whereas G II was kept as untreated infected control. Faecal and blood samples from each sheep were collected on 0,3,7 and 10-day post-treatment to record egg per gram of faeces (EPG) and haematological (Hb, PCV and TEC) and biochemical indices (Total plasma protein, serum albumin, ALP, ALT, AST & serum creatinine). On day 10 PT, decrease in egg per gram, improvement in haematological values and increase in serum protein level suggests promising anthelmintic values of aqueous alcoholic extract mixture of Embelia ribes fruits and Vernonia anthelmintica seeds.

International Journal of Livestock Research, 10(3),60-66. doi: 10.5455/ijlr.20200104064820

Introduction

Gastrointestinal nematodes pose a major challenge to the health and productivity of small ruminants causing unaccountable economic losses to small and marginal farmers. Control of gastrointestinal nematodes is largely based on the use of chemotherapeutic drugs but improper and injudicious use of anthelmintics has led to the emergence of resistant strain of the gastrointestinal parasites particularly, *Haemonchus contortus* (Coles,1997). The parasite has been documented to be resistant to all three broad spectrum families of

ABSTRACT

Present study was carried out to study egg production performance and polymorphism of Prolactin gene at promoter region (PRL24). Study was conducted on the Aseel hens kept for laying purpose at University poultry farm. Egg production performances were recorded as age at first laying (AFE), Body Weight at First Egg (WFE), Mean Egg Weight (MEW) and Total No. of Eggs at 90 days of laying (TEN). DNA was isolated from 2- 3 of Blood of 40 birds collected from wing vein. PRL24 locus of Prolactin was amplified by PCR and the product was resolved on 6% native PAGE for genotyping. The prolactin gene locus PRL24 showed three genotypes: II, ID & DD. The frequencies of these genotypes were 0.30, 0.45 and 0.25 respectively for II, ID and DD. The II genotype was associated with WFE; ID genotype with TEN and DD genotype was closely associated with MEW.

Introduction

The Asil or Aseel is a breed of chicken originating from South Punjab / Sindh area of Pakistan and India. The Aseel breed is known for its stamina, pugnacity, majestic gait, and dogged fighting qualities (Panda and Mahapatra, 1989). This breed is characterized by its hardiness and ability to thrive under adverse climatic conditions, and its meat is considered to have a desirable taste and flavor. The superiority of Aseel on other indigenous breeds is due to its hardiness, resemblance to Cornish and larger body size (Bhatti *et al.,* 1991). Almost all the varieties of Aseel are characterized with heavy body weight and poor egg production potential thus leading to low progeny size due to erratic ovulation, short or erratic clutches and broodiness. Prolactin (PRL) is a polypeptide hormone which plays a key role in egg production. Onset of incubation behavior is induced by an increase in PRL secretion, which results in regression of ovary & loss of egg production (Sharp, 1997). Polymorphism in the promotor region specially those that result in change of promoter binding sites, most likely influence mRNA expression and thus influence incubation behaviour and egg production (Cui *et al.,* 2006).

Due to different biological activities attributed to PRL, they can be used as the major candidate genes in molecular animal breeding programs. Thus, present study was

STUDIES ON THERAPEUTIC EFFICACY OF PHYTOGENIC MIXTURE IN MANAGEMENT OF SUB CLINICAL MASTITIS IN DAIRY CATTLE

Abstract

Sub clinical mastitis is a common problem of lactating cows. The higher the production potential, higher is the risk especially if the management is not proper. Antibiotic treatments of sub clinical mastitis is not recommended owing to public health concern. Herbs are safe and free from the menace of resistance. Polyherbal mix possess anti inflammatory, antibacterial, antioxidative, galactogogic and immunostimulatory properties, thereby open new vistas in mastitis therapy. The present study was therefore designed to study the therapeutic potential of polyherbal mix in management of mastitis. A phytogenic mixture was formulated using herbs having antimicrobial, anti inflammatory, immunostimulant and galactagogic properties and administered at two doses i.e. 100gm PO and 150 gm PO and compared with a standard antibiotic therapy. Poly herbal mix @ 150gm/animal daily had comparable therapeutic efficacy with standard antibiotic therapy but had better galactogogic properties. Both the groups had maximum efficacy of 83.33% as compare to 66.67% efficacy in group I. None of the animals in untreated control group showed recovery. Milk yield increased with 9.5% in comparison to an increase by 0.61% in antibiotic treated group.

Introduction

Mastitis is one of the most frequent infectious disease in dairy cattle and is a reason for heavy economic losses and antimicrobial drug uses in dairy cow (Minst *et al.*, 2012). Despite advancements, mastitis continues to rob the dairy industry in terms of decreased milk production, veterinary services, diagnostic, drugs, discarded milk, labour, decreased product quality, increase susceptibility to diseases, increased risk of culling and material for prevention (Hogeveen and osteras 2005). Of the two form of the mastitis, subclinical mastitis is subtle, causes huge economic losses and is difficult to detect as the cow appears healthy, the udder does not show any sign of inflammation and the milk appear normal, but milk production decreases by 10 to 20 % with undesirable effect on its constituents and nutritional value rendering it of low quality and unfit for processing (Holdway, 1992). Alternate medicine aims to boost animals' innate immunity to prevent the establishment of infection in udder. Nutrients supplements have been used with varying encouraging results. Herbs with immune stimulants properties or possessing galacto purifier, anti-inflammatory, antimicrobial properties can be exploited to keep this menace at bay. It will prove wonders if it possesses galactogenic effect too. Herbs been safe are definitely one of the best alternate to this problem as a polyherbal mixed can suffice the needs as desired without any ill effect or public health concerned. The concept of cure under single roof can be made possible if a polyherbal preparation is formulated with such ingredients that their amalgamation not only increases milk production but also cures the subclinical mastitis.

The present study was therefore designed to study the therapeutic efficacy of polyherbal formulation in treatment of subclinical mastitis.

Materials and Methods

The present study was conducted on twenty four cross bred lactating cows showing subclinical mastitis. The cross breds were the crosses of Holstein freisian and were housed, fed and managed under identical manage mental conditions. Screening test namely California mastitis test, white side test and somatic cell count were employed to screen cows for subclinical mastitis. Selected cows were given dietary supplementation with various doses of polyherbal mixture (PHM) containing *Withania Somnifera, Leptadenia reticulate, Bunium bulbocastanum, Tinospora cordifolia and Trigonella Foenum-Graecum*. The cows were randomly divided in to four different groups containing six animals in each group. Each animal of group I were given polyherbal mixture at the dose rate 100 gm (PHM-100) for 15 days. Cows of group II were supplemented with polyherbal mixture at the dose rate of 150 gm (PHM – 150) for 15 days. Cows in group III were supplemented with standard antibiotic treatment that is Ceftizoxime @ 2.5 gm single dose, 6 animals were kept as control and fed normal diet without any supplementation (Group IV).

Statistical analysis was done using t–test as described by Snedecor and Cochran (1994).

Results and Discussion

The efficacy of poly herbal mix was adjudged based on changes in blood and milk profile and comparing the pre and post therapy mastitis screening test indices.

Group I

Animal in group I (PHM, 100) supplemented with poly herbal mix @ 100gm PO for 15 days showed 66.67% recovery. The mean CMT score of 2.15 ± 0.28 on day 0 decreased significantly to 1.06 ± 0.15 after treatment. The mean WST and MST score point decreased insignificantly from 1.93 ± 0.316 and 1.74 ±0.51 to 1.09 ±0.246 and 0.83 ±0.17 respectively. A similar trend was noticed in SCC also as 0 days count decreased significantly from 6.42 ±0.89 ($x10^6$) to 3.24 ± 0.42($x10^6$) after the treatment.

Serum profiles

The levels of total proteins and albumin showed significant increase from 8.92 ±0.86 and 2.96 ±0.36 to 10.06 ±0.66 and 3.68 ± 0.36 respectively after therapy. The level of globulin increased from 5.85±0.154 to 6.26 ± 0.545 after therapy non-significantly. The ratio of albumin and globulin increased non-significantly from 0.50 ±0.118 to 0.58 ±0.116 after the treatment. A nonsignificant increase was observed in calcium level (gm/dl) from 7.09 ±1.71 to 8.69 ±1.40 after treatment. The level of phosphorous (gm/dl) increased from 6.26 ±0.35 to 6.64 ±0.35. (Table 3)

Hematology

The hemoglobin level increased from 8.11±0.27 gm/dl to 8.36 ±0.38 gm/dl. A significant increase in PCV was observed from 25.43 ± 2.06 to 28.63 ±1.54%. A significant decrease in leukocyte count was also recorded. It decreased from 10.82 ±0.65 to 8.36 ±0.80. Post therapy a decline was recorded in neutrophils (%) lymphocytes (%) and eosinophils Count (%) from 43.38±2.42 to 42.12±1.14; 55.63±1.45 to 53.51±1.43 and 1.28±0.26 to 1.04±0.24 respectively (Table 4).

Milk Profile

An increase in milk yield (lts) by 6.87% from 8.73±0.78 to 9.33±1.06 was recorded. A non-significantly increase in fat % from 4.23±0.48 to 4.33± 0.54 was noticed. Similar increase was observed in SNF% and total solid (%) also (Table 5 and 6).

Group II

In group II, 6 animals received supplementation of poly herbal mix @ 150 gm PO OD for 15 days out of which 83.33% (5 animals) recovered completely (Table 1) . A significant declining trend was recorded in the mean CMT score point (2.20±0.11 to 0.85±0.13), WST score point

Ethno-veterinary practices of goat farmers in different districts of Vindhyan Zone of Uttar Pradesh

Dinesh Kumar Yadav, Satya Vrat Singh, Ramakant, Jitendra Pratap Singh, Rakesh Kumar Gupta, SK Maurya and Debasish Niyogi

DOI: https://doi.org/10.22271/phyto.2021.v10.i1an.13794

Abstract
Ethno-Veterinary Medicine (EVM) is the use of medicinal plants, surgical techniques and traditional management practices to prevent and treat spectrum of livestock diseases. Ethnoveterinary practices used by goat farmers in different districts of Vindhyan zone were studied for rhinitis, bronchitis (coughing), pyrexia of unknown origin, enteritis, skin disorders, mouth ulcer and udder abnormality, and information collected from 120 respondents. In case of Rhinitis commonly used ingredients were neem oil, mustard oil, ajwain (*Trachyspermum ammi*), ginger (*Zingiber officinale*), jaggery, garlic (*Allium sativum*) and asafoetida. For treatment of Bronchitis, mostly respondents used neem oil and ajwain. Neem oil, mustard oil, ajwain. Salt, ginger and garlic were used to treat pyrexia. Heeng, Sesam leaves and neem oil were used for treatment of enteritis. Local application of neem oil and neem leaf paste was the most common practice for treatment of skin disorders. For treatment of mouth ulcer, maximum respondents used neem oil and 40% respondents used neem leaf. Alum, salt, neem oil and amla were used to treat udder abnormality in different districts of Vindhyan Zone.

Keywords: Ethnoveterinary practices, goats, Vindhyan Zone, Uttar Pradesh

Introduction
Traditional veterinary medicine is very important in developing countries where conventional remedies for animal health care are inaccessible or unaffordable to poor rural farmers (Nguyen *et al*., 2005; McGaw *et al*., 2007) [19, 16]. About 80% of people in the world today rely on folk (or traditional) medicine for treating both human and animal diseases (Iqbal *et al*., 2003; Muhammad *et al*., 2005) [11, 17]. According to the United Nations Food and Agricultural Organization (FAO), the lack of drugs to treat diseases and infections results in losses of 30–35% in the breeding sector of many developing countries, where poor animal health remains the major constraint to increased production (FAO, 2002) [8]. The use of animals for medicinal purposes is part of a body of traditional knowledge that is increasingly becoming more relevant to discussions on conservation biology, public health policies, sustainable management of natural resources, biological prospection and patents (Alves and Rosa, 2005; Alves *et al*. 2010a, b, c and Souto *et al*., 2009) [3, 6, 5, 4, 22].
Small scale farmers reported that use of commercial drugs is effective in reducing parasites that cause diseases (Iqbal *et al*., 2005; Mathias, 2007; Mwale and Masika, 2009) [12, 15]. However, their use causes harm if not used properly (McGaw *et al*., 2007) [16]. Since they are expensive (Maphosa and Masika, 2010) [14], rural farmers prefer ethno-veterinary medicine' on the other hand, other small scale farmers have been found to combine remedies (Githiori *et al*., 2003; Nalule *et al*., 2011; Tyasi and Nkohla, 2015) [9, 18, 25]. Farmers mostly use medicinal plants, which is a component of EVM, in controlling diseases (McGaw *et al*., 2000). Conventional medicine is a remedy or drug used for diagnosis, treatment of disease and for maintenance of health of an animal (Tyasi *et al*., 2015) [25]. Many diverse conventional products are available to control or treat livestock diseases (Papadopoulos *et al*., 2007) [20];

Materials and Methods
Ethnoveterinary practices used by goat farmers in different districts of Vindhyan zone were studied for rhinitis, bronchitis (coughing), pyrexia of unknown origin, enteritis, skin disorders, mouth ulcer and udder abnormality. Based on the nature of research problem, Ex-post facto research design was followed in the present study. The Vindhyan zone of Uttar Pradesh comprises the districts of Sant Ravidas Nagar, Mirzapur and Sonebhadra. From each selected district, two blocks were selected on the basis of highest goat population. From each block

Effect of a phytobiotic, supplemented in different form, on performance, hepatic marker enzymes and carcass characteristics of broiler chickens

VB Singh, VK Singh, S Gautam, SK Maurya, SP Singh, SS Sengar and Ankit Singh

Abstract
A study was conducted to evaluate the impact of a phytobiotic supplemented in different form in the diet on the performance, changes in hepatic marker enzymes and broiler's carcass characteristics. Two hundred fiftyVencobb-400Y strain broiler chicks were divided into five groups with 10 chicks in each five replicates. Each group was fed with different treatment i.e. a basal diet (NC), basal diet with antibiotic (PC), basal diet with herbal mixture powder (HP), basal diet with aqueous extract (AqE) and alcoholic extract of herbal mixture (AlE).The performance, liver function and carcass parameters of birds were ascertained. There was significantly (P<0.05) higher body weight gain (BWG) in AlE group compared to PC and NC group birds. Feed intake of AqE and AlE group birds were significantly (P<0.05) higher than NC, PC and HP group birds. Energy efficiency ratio (EER) and protein efficiency ratio (PER) of AlE groups was similar to PC, however significantly (P<0.05) higher than NC group broiler chickens. The serum ALT and AST level were significantly (P<0.05) lower in the birds that supplemented herbs in any form powder, aqueous or alcoholic. No significant effect of different treatments on broiler's dressed weight, giblet weight and drawn yield were observed. So, AlE supplementation had hepatoprotective impact and it improves performance of broiler chicken.

Keywords: Broiler, extract, performance and phytobiotic

Introduction
Feed additives are in dispensible element of poultry feed formulation and described as non-nutrient substances that accelerate growth, feed efficiency and are supposed to beneficial for health as well as nutrient metabolism of the animals and poultry (Church and Pond, 1988) [5]. In last few decades antibiotics were the most routinely used feed additives to improve growth and performance of broilers. However, due to the sever health concerns like alteration of natural gut microbiota and drug resistance, use of antibiotics in poultry industry have been banned in many countries (Karangiya *et al.*, 2016) [9]. Ban of antibiotics use in broilers feed ensuing to increased spread of bacterial diseases, poorer growth performance and worsened nutrient utilization in poultry flocks. So there are urgent need of alternative of feed antibiotics which can improve poultry performance without generating drug resistance and residual effect in poultry products. In this context various researchers dig out some possible alternatives of antibiotics like phytobiotics, probiotics, organic acids, prebiotics and synbiotics.
Phytobiotics can be defined as plant derived products like herbs, essential oils and oleorasins in feed supplementation improve broilers performance (Yang *et al.*, 2009) [19]. The bioactive compounds presents in plants and herbs showed greater potential as alternative of antibiotics due to their antimicrobial action, hepatoprotective properties and antioxidant activities (Toghyani *et al.*, 2011) [18]. Certain herbal formulations were tried successfully to improve growth performances, carcass yield (Singh *et al.*, 2016) [15] and gut health (Attia *et al.*, 2017) [2] in broilers. Therefore this study was aimed to evaluate the impact of an herbal preparation supplemented in different forms either powder, aqueous or alcoholic extract in broiler chickens the diets on their performance, hepatic marker enzymes and carcass characteristics.

INCIDENCE OF MAJOR REPRODUCTIVE HEALTH PROBLEMS OF DAIRY CATTLE IN SULTANPUR DISTRICT OF UTTAR PRADESH

S. K. Maurya, O. P. Singh, S. V. Singh and Vidya Sagar
College of Veterinary Sc. & A. H.
N. D. University of Ag. & Tech., Kumarganj, Faizabad

Abstract

Present investigation was carried out to assess the reproductive health problems in the cattle of farmers of different land holding capacity in Sultanpur district of UP. Out of the total animal assessed, 37.98% were found to be affected with one or more of the reproductive problems. The incidence was highest (45.06%) in the cattle of landless farmers, whereas, it was least (30.23%) in the cattle of large category. Anestrous, Repeat breeding and endometritis were found to be the major reproductive problems comprising more than two third of the cases. The minor problems included dystocia, abortions, retention of fetal membrane, still birth etc. Based on the findings, it is concluded that the cattle at the level of farmers are suffering from poor management and reproductive/ breeding systems that is needed to be improved.

Key words: Anestrus, dairy, Infertility, Reproductive disorders, Sultanpur

Introduction

India has diverse animal genetic resources and its relatively large livestock population is well adapted to and distributed among diverse ecological conditions and management systems. The major farm animal genetic resources of the country include cattle and buffaloes. Uttar Pradesh has the maximum number of total livestock population in India, with a number of 58.5 million.

In spite of the presence of largest animal genetic resources, the productivity (i.e., meat and milk) of livestock remains low in India, for various reasons, such as inadequate nutrition, poor genetic potential, inadequate animal health services, and other management-related problems.

However, animal performance depends not only on genetic merits, but also on other factors, such as nutrition, management, health, and environment. Thus, to ensure their success, crossbreeding programmes need to be monitored regularly, by evaluating the reproductive problems of the cattle under the prevailing management and environmental conditions. The farmers and livestock owners must be aware about proper management of their livestock. Thus, the present study was undertaken to evaluate the reproductive problems of dairy cattle in the Sultanpur district of UP under semi intensive farming system.

Materials and Methods

The livestock owners were selected from the 30 villages of 10 blocks in 5 tehsils of Sultanpur district. Farmers were selected on the basis of stratified random design for the present investigation. In each village, the livestock owners were categorized as per their land holding capacity, viz. landless, marginal (up to 1 ha), small (1.0 to 2.0 ha) and large (>2.0 ha) farmers. The pooled data comprised a minimum of 50 livestock owners from each socio-economic group. A total of 1514 cattle were included in the study. Cross-sectional study, employing questionnaire survey, and regular follow up using some laboratory evaluation were employed in this study. Each farmer was surveyed on the basis of a pre-tested questionnaire. The various reproductive problems identified were defined and recorded based on their standard descriptions/definitions. Data thus obtained were analyzed using standard statistical procedures.

Results and Discussion

The total number of cattle examined in different farmers group in Sultanpur district during the study and the number of animals found to be reproductively abnormal is represented in Table 1

Table 1 Incidence of cumulative reproductive disorders in cattle in different categories of farmers

	Total Animal Examined	Physiologically Reproductive normal animal		Animals with reproductive abnormalities	
	No.	No.	%	No.	%
Landless	395	217	54.94	178	45.06
Marginal	407	247	60.69	160	39.31
Small	418	270	64.59	148	35.41
Large	294	205	69.73	89	30.23
Total	1514	939	62.02	575	37.98

The incidence of one or more reproductive problem was 45.06%, 39.31%, 35.41% and 30.23% for the animals of landless, marginal, small and large categories respectively. For the pooled population, the incidence was 37.98 %. Incidence of different individual reproductive problems in cattle in different categories of farmers is represented in Table 2

Table 2 Incidence of various reproductive problems of cattle in different categories of farmers

	Landless		Marginal		Small		Large		Pooled	
	No.	%	No.	%	No.	%	No.	%	No.	%

ABSTRACT : The present study was conducted to study the epidemiological survey of gastrointestinal parasites in the goat in the Vindhyan zone of Uttar Pradesh. Total 72 faecal examinations was done from goat. The incidence of Strongylus was highest in Sant Ravidas Nagar and Mirzapur districts (each 25%) of this zone in comparison to 16.67% incidence in Sonebhadra district. Similarly, Trichuris (25%) was most commonly recorded in goats of Sant Ravidas Nagar and Mirzapur districts of this zone; its incidence was least in Sonebhadra district (8.33%). Amphistome (8.33%) was reported only from Sant Ravidas Nagar district. Only 31.67% of goat owners regularly dewormed their goats. Amongst GI parasites the incidence of Strongylus was highest. The present study provides basic data about the most prevalent GIT diseases among goats in different district of Vindhyan zone.

Key words : Gastrointestinal parasites, prevalence, goat.

INTRODUCTION

In India, parasitic infection is one of the most common problems of sheep and goats. In animals, parasitic diseases comprise of helminth, arthropods and protozoa but gastrointestinal nematodes are most common and widely distributed helminth parasite. A related study reported that among the gastrointestinal parasites (GIP), Strongyle nematodes are considered as one of the extremely pathogenic and economically significant parasites affecting small ruminants (Jurasek *et al*, 2010). Infections of gastrointestinal helminths and enteric protozoan parasites among goats are implicated in serious economic losses including morbidity and mortality, mostly for young animals (Majeed *et al*, 2015).

Helminthiasis, especially parasitic gastroenteritis, pose a serious health threat and a limitation to the productivity of small ruminants due to the associated morbidity, mortality, cost of treatment and control measures (Nwosu *et al*, 2007). In addition to these threats, infestation with helminthes lowers the animal's immunity and renders it more susceptible to other pathogenic infections; finally this may result in heavy economic losses (Garedaghi *et al*, 2011).

Gastrointestinal nematodiasis is caused by a variety of nematodes *viz*. *Haemonchus* spp., *Ostertagia* spp., *Trichostrongylus* spp., *Bunostomum* spp., *Strongyloides* spp., *Cooperia* spp., *Nematodirus* spp. results into parasitic gastroenteritis (PGE). Among them, *H. contortus* is a predominant and highly pathogenic gastrointestinal nematode responsible for impaired productivity in small ruminants throughout the world (Khalafalla *et al*, 2011).

Prevalence or occurrence of parasitic gastroenteritis caused by gastrointestinal nematodes is most commonly found in tropical and sub-tropical regions where the environmental factors like temperature, humidity and rainfall are conducive for propagation of pre-parasitic stages. The prevalence of gastrointestinal nematodosis greatly varies from region to region due to diversity in agro-climatic conditions. Several reports have been

Keywords

Buffalo, Proteins, Seminal plasma, Sperm characteristics

A B S T R A C T

Present study was carried out to assess the protein profile of Murrah buffalo seminal plasma by using SDS-PAGE and their relationship with the semen characteristics. Semen samples were collected by a bovine artificial vagina from Murrah buffalo bulls maintained at College of Veterinary Science, N. D. University of Agriculture & Technology, Kumarganj, Faizabad. Semen characteristics were measured using standard procedures. Seminal plasma was separated after centrifugation of semen at 5000 rpm for 10 min. The supernatants were collected and precipitated using nine volumes of cold ethanol, and the proteins recovered. These seminal plasma proteins were separated on a 12% SDS-PAGE using standard procedure. A total of 22 protein bands could be identified by the fractionation of seminal plasma protein on the SDS-PAGE; ranging from 14.1 kDa to 88 kDa. Some of these bands were more prominent in some samples. A protein fraction of 25.8 kDa was significantly correlated with progressive motility of sperm in frozen samples. The semen samples that had greater sperm viability showed a prominent fraction of 58 kDa protein in both fresh and frozen samples.

Introduction

Artificial insemination in cattle and buffalo is the common practice; and to keep the success at high, the quality of the semen must be good. Though efforts have been given by using different extenders to improve keeping qualities of frozen semen, still success is not satisfactory. Seminal plasma, which is a complex mixture of secretions from testis, epididymis and accessory glands, contains factors that modulate the fertilizing ability of sperm (Henalut et al, 1995). Bovine seminal plasma contains a family of major proteins, designated BSP-A1/-A2 and BSP-A3, with apparent molecular masses ranging from 15 to 17 kDa, and the BSP-30 kDa protein with molecular mass of 28–30 kDa, collectively called BSP proteins (Manjunath, 1984). The biological properties of BSP proteins have been extensively studied and it have been indicated that seminal plasma proteins reverts the cold-shock damage on ram sperm membrane (Jobim et al, 2004).

A correlation between seminal plasma proteins and fertility of the male has been reported in some species of domestic animals such as bull (Killian et al, 1993),

Effects of different meteorological variables on blood biochemical parametersin black Bengal goats

Asha Lata Murmu, RK Verma, Shiv Kumar Yadav, Sasmita Barik, SK Maurya and Sanjay Kumar

DOI: https://doi.org/10.22271/j.ento.2021.v9.i1aa.8407

Abstract
Despite having well-developed mechanisms of thermoregulation, animals do not maintain strict homeothermy under extreme climatic conditions. As a result, animals develop various adaptive mechanisms that enable them to survive under those conditions of extreme heat or extreme cold. The study was conducted on twelve healthy Black Bengal Goats to determine the effect of seasonal variations on biochemical profiles during autumn and winter. Blood samples collected from the jugular vein at fortnightly interval used for biochemical analysis. Among the biochemical constituents the mean concentration of glucose (mg/dl) was found to be significantly ($p<0.05$) higher during winter than the autumn season and observed to be inversely proportional to the THI. The estimated serum total protein non-significantly differed and was directly proportional to the THI. The serum mineral profile studied in Black Bengal Goat showed significant ($p<0.05$) variation in between the seasons. The serum calcium (mg/dl), inorganic phosphorous (mg/dl) and magnesium level were significantly ($p<0.05$) lowered during winter than autumn and were found to be directly proportional to the THI. The study revealed that some of the parameters studied were visibly drifted from normal values as a result of climate stress during the winter season.

Keywords: temperature humidity index, dry bulb temperature, wet bulb temperature, total serum protein

1. Introduction
In the present era, climate change is the most concerned and critical challenge that both human and animals were facing. Food, nutrition and environmental security in the new millennium are challenging job for the agricultural scientists. Alteration in temperature, rain, wind, radiation etc have a definite impact on the productivity of animals and hence implying the concerned food security also. Goats (*Capra hircus*) are the earliest animals to be domesticated for meat and milk purpose and are generally labeled as a "poor man's cow "and as a 'wet nurse' of infants in Europe (Mac Hugh and Bradley, 2001) [21]. Common breeds of goats found in India are Jamunapari, Marwari, Kutchi, Surti, Gohilwadi, Barbari, Gaddi, Chegu, Sirohi, Osmanabadi, Black Bengal, Beetal, Zalawadi, Mehsani. Among these, Black Bengal goats are found throughout West Bengal, Jharkhand, Bihar and Orissa regions of north eastern India. It has the specific feature of strong adaptability to various adverse socio-economic situation of the rural India and arid tropics because of its ability to conserve water, travel well, graze selectively and take willingly a wide variety of vegetation (Meferlane and Howard, 1972; Maloity and Taylor 1971; Merrill *et al.*, 1965) [23, 22, 24]. Goats adapt poorly to cold climates but make them relatively more adapted to areas of high temperatures (Shelton and spiller, 1977) [33]. Adaptation of animals for ecological stresscan affect serum biochemistry of livestock animals (Swanson *et al.*, 2004; Nazifi *et al.*, 2003) [36, 27]. Serum biochemical analysis constitute important panels in the diagnosis, prognosis and treatment of livestock diseases (Yokus *et al.*, 2006) [39]. The seasonal rythms reflect the endogenous adaptive mechanism to react in advance to the regular environmental changes associated with the seasons (Piccione *et al.*, 2009) [29]. Limited information is provided about the seasonal rythms of small ruminants like Goats in tropical climate (Piccione *et al.*, 2009; Alila-Johansson *et al.*, 2001, 2004) [29, 3]. Minerals also play an important role in increasing efficiency of livestock production and reproduction as they act as catalysts in the enzymes and hormonal systems of the body (Ceylan

EFFECT OF A-TOCOPHEROL ACETATE AND ZINC SUPPLEMENTATION ON LEPTIN HORMONE DURING DRY PERIOD AND EARLY LACTATION IN CROSS BRED COWS

Pankaj Kumar Maurya*, Anjali Aggarwal[1], Pramod Kumar and P.K. Choudhary
College of Veterinary Sci. & A.H., N.D. University of Agriculture & Technology, Kumarganj, Faizabad (UP)
[1]Dairy Cattle Physiology Division, National Dairy Research Institute, Karnal-132001 (Haryana)

Abstract

The study was conducted to investigate the effect of α-tocopherol acetate and zinc supplementation on Leptin Hormone during dry period and early lactation in cross bred cows. Twenty pregnant Karan Fries cows were selected on the basis of their body weight, BCS and parity. Ten cows were kept in control group and other ten cows in treatment group which were supplemented with 1000 IU α-tocopherol acetate and 60 ppm zinc per day per cow. Blood samples were collected on the days -60, -45, -30, -15, -7, 0, +7, +15, +30, +45, +60 with respect to expected date of calving. Plasma was analyzed for Leptin hormone. Body condition score of all the experimental animals was recorded on the day of blood collection. At parturition, BCS decreased significantly (P<0.01) in control group than treatment group. The plasma concentration of leptin was decreased at parturition and the level was significantly (P<0.001) higher in treatment group as compared to control group (3.66 vs. 2.55 ng/ml). Plasma NEFA was significantly (P<0.001) lower in treatment group as compared to control group. The results of this study indicated that supplementation of α-tocopherol acetate and zinc have beneficial effects in changing Leptin hormone level in such way that improves body condition and metabolic status of the animals.

Keywords: *Leptin, Body Condition Score, Energy Metabolites, α-tocopherol acetate, Zinc*

Introduction

Leptin is a 16 kDa protein hormone and it is synthesized by white adipose tissue. Leptin is involved in regulation of feed intake, energy balance, immunity and reproduction (Houseknecht *et al.*, 2000; Ahima and Flier, 2003). After parturition, dairy cows suffer from an inborne energy deficit caused by the onset of copious milk secretion and an inadequate increase in voluntary food intake which contributes to a decline in plasma leptin. This decline mirrors that of plasma insulin but is reciprocal to the profile of plasma growth hormone (GH), suggesting that both hormones may regulate plasma leptin in periparturient dairy cows (Block *et al.* 2001). Energy deficit of early lactation reduces leptin synthesis in white adipose tissue (WAT), and suggest roles for insulin, GH and metabolic fuels in mediating this effect of energy balance (Block *et al.* 2001). A concomitant suppression of immune functions and metabolic disorders during early lactation are related to decreased fertility (Butler and Smith, 1989). This may partly be due to decrease in blood concentrations of vitamins A & E and Zn (Meglia *et al.* 2001; Chandra, 2009). To meet the nutritional demands of milk synthesis during early lactation, dairy cows need to mobilize body reserves causing negative energy balance until nutrient intake covers the demands.

Material and methods

Experimental design

The study was conducted at the Cattle Yard of National Dairy Research Institute, Karnal, Haryana (India). For the present study 20 Karan Fries (KF) periparturn cows were selected from the herd of National Dairy Research Institute, Karnal. 10 cows kept in Control group and other 10 cows in Treatment group. The cows in the control group were supplemented with no vitamins, and in the treatment group, they were given 1,000 IU of α-tocopherol acetate and 60 ppm zinc per cow per day from 60 days prepartum to 60 days postpartum over and above the normal feeding schedule at dairy farm of NDRI.

Blood sampling

Blood samples (10 ml/cow) were collected in the morning (6:00 AM) before feeding in sterile heparinised vacutainer tubes (BD Vacutainer®M, UK) from jugular vein puncture, posing minimum disturbance to animal, on the days -60, -45, -30, -15, -7, 0, +7, +15, +30, +45 and +60 with respect to expected date of calving. Day '0' represented the date of calving. Blood samples were brought to the laboratory in the ice box soon after collection and centrifuged at 3000 rpm at 4°C for 20 min to separate the plasma. Plasma samples were stored at -20°C until analysis of Leptin hormone. Body condition score (BCS) of all the experimental animals was recorded on the day of blood collection using a scale of 1 to 5.

Sample analysis

Blood sample was analyzed for plasma leptin and NEFA. Plasma Leptin was determined by "Bovine Leptin ELISA Quantitation kit" from Cusabio Biotech Co., Ltd. The copper soap solvent extraction method modified by Shipe et al. (1980) was adopted for the estimation of plasma NEFA.

Statistical analysis

Statistical analysis of data was carried out to find the mean ± SE. Two way ANOVA was done to find significant difference between groups and days of experiment and their interaction by using SYSTAT 3.1 (2004) software. The correlations among the various parameters were also calculated (Snedecor and Cochran, 1994).

Results and Discussion

Leptin

The mean±SE of plasma leptin concentration of control cows was 6.06±0.10 ng/ml 60 days before calving and on the day of calving it decreased to 2.55±0.31ng/ml. Further, in treatment group the plasma leptin concentration was 6.19±0.11ng/ml 60 days before calving and on the day of calving it decreased to 3.66±0.11ng/ml. In present study decrease in the plasma leptin concentration of control and treatment group cows was 57.92% and 40.87% respectively from 60 days before calving to the day of calving. This decrease was more significant (P<0.01) from 30 days before calving to the day of calving in control group than treatment group. After parturition it's level remained low up to 30 days then started increasing up to 60 days of lactation.

In present study there was found a positive correlation between leptin with BCS and insulin and a negative correlation was found between leptin with NEFA in control and treatment group of cows around parturition. The plasma concentration of leptin was positively correlated with plasma concentrations of insulin and negatively correlated with plasma concentrations of growth hormone, cortisol and non-esterified fatty acids (Block *et al.*, 2001; Chelikani *et al.*, 2008). Sauerwein *et al.* (2004) investigated that in ruminants the decline in plasma leptin levels towards parturition is probably caused by the decline in adiposity and insulin concentrations. In ruminants and other animals, leptin is synthesized in proportion to the overall degree of adiposity and acts on the central nervous system to reduce voluntary feed intake (Ehrhardt *et al.*, 2000). Leptin, mainly produced in adipose tissue, inhibits food intake and down-regulates adipose tissue deposition. Block *et al.* (2001) showed that leptin is negatively correlated with the amount of nonesterified fatty acids, which reflects the amount of fat mobilization. From early to mid pregnancy circulating leptin levels increased and remained elevated until late pregnancy in cattle (Liefers *et al.*, 2003; Villalobos *et al.*, 2007).

Haematological and biochemical variables of blood are generally used to monitor and evaluate health, nutritional and physiological status of ruminants. The present research was conducted to study haemato-biochemical profile of goats in Vindhyan region of Uttar Pradesh, India. Total 120 blood samples were collected from 120 goats. All haematological parameters taken were within the normal range except haemoglobin, which was lower side of the normal range of the males and was the less than the normal range in females. The range of haemoglobin observed was 8.01 to 8.3 in male and 6.35 to 6.85 in female animals. In females, the packed cell volume was least and significantly lower in Mirzapur district (25.66). The range of total leucocyte count varied from 18.03 to 18.07 in male and 18.00 to 18.07 in females. The value of liver function test was within normal range. There were no significant changes in Liver function test enzymes (AST, ALT and Alkaline phosphatase) and bilirubin profile of goats in different districts of Vindhyan Zone.The value of kidney function test was within normal range. Only blood urea level is slightly higher in Sant Ravidas Nagar.

Introduction

Haematological tests are important tools for evaluation of physiological and health status of farm animals and almost indispensable in organic farming, where permitted veterinary interventions are strictly regulated and limited in scope. Haematological analyses in farm animals have been extensively discussed as an essential part of clinical examination often pointing to a specific differential diagnosis or suggesting a prognosis (Braun *et al.*, 2010; Polizopoulou, 2010; Antunovic *et al.*, 2019).

Biochemical and haematological variables of blood are generally used to monitor and evaluate health, nutritional and physiological status of ruminants (Al-Eissa *et al.*, 2012). The evaluation of blood constituents has been widely used as a marker to determine the efficacy of feed nutrient content and supplements (Belewu and Ogunsola, 2010)

ABSTRACT

Cattle and buffaloes experience different level of stress during summer and hot humid conditions. However, the assessment of the heat stress and the translation of the heat stress in terms of physiological and psychological strain is complex. For over a century attempts have been made to construct an index, which will describe heat stress satisfactorily. The many indices that have been suggested can be categorized into two groups: "*physiological indices*" and "*environmental*", or "*direct indices*". The first groups are sophisticated indices, which are based on physiological variables; they are difficult to calculate and are not feasible for daily use. The latter group comprises of simple indices, which are based on the measurement of basic environmental variables. In this group many indices are in use for over four decades: the "temperature humidity index" (THI) and the "*TGWB Index*". The following research on heat stress indices and their comparison and evaluation to animal production and their performance. With the present knowledge it is suggested to adopt the TGWB Index under tropical conditions is recommended because globe temperature takes into accounts Tdb and solar radiant heat exchange and can help in finding stress level.

Introduction

In India during summer cattle and buffaloes are exposed to severe environmental heat stress, which may deteriorate productivity and performance of animals may even threaten to their survival. Thus, it is expected that the physiological heat strain experienced by an animal will be related to the total heat stress to which they are exposed, serving the need to maintain body-ore temperature within a relatively narrow range of temperatures. Many attempts have been made to estimate the stress inflicted by a wide range of climate, or to estimate the corresponding physiological strain and to combine them into a single index—a heat stress index. The difficulties in creating a universal heat stress index are outlined in the present research and a simple way to

EFFECT OF EXOGENOUS MELATONIN AND DIFFERENT PHOTOPERIODS ON LYMPHOCYTE PERCENT COUNT IN CHHOTANAGPURI EWE

P. K. Choudhary[1*], A. K. Ishwar[2], P. K. Maurya[1], Pramod Kumar[1], D. Niyogi[3] and M. Kumar[4]

[1]Department of Veterinary Physiology and Biochemistry, [2]Department of Veterinary Pathology, [3]Department of Veterinary Anatomy and Histology, C.V.Sc. and A.H., N.D.University of Agriculture and Technology, Kumargunj, Ayodhya, U.P., [4]Department of Veterinary Physiology, R.V.C., B.A.U., Ranchi

Abstract

Forty two (42) apparently healthy, non-pregnant, non-lactating Chhotanagpuri ewe, having body weight ranging between 14.11±0.09 to 15.38±0.06 Kg were selected and selected ewes were isolated from rams 2 months prior to melatonin administration. The selected animals were allocated randomly into seven groups viz. Group-I [Normal control], Group-II [Long day (LD) control], Group-III [LD + Melatonin administration orally (3mg/day)], Group-IV [(LD + Melatonin administration subcutaneously (1mg/day)], Group-V [Short Day (SD) control], Group-VI [SD + Melatonin administration orally (3mg/day)] and Group-VII [SD + Melatonin administration subcutaneously (1mg/day)] comprising six animals in each group. Rams were then introduced into each group after completion of exogenous administration of melatonin. Blood sample without anticoagulant in vials was collected from each animal day before the start of experiment and there after every month up to fifth month. Lymphocyte % in third and fourth month of experiment was significantly ($P<0.05$) lower in all groups (group-I to VII) in comparison to 0 day, first and second month. At fifth month, lymphocyte % was significantly ($P<0.05$) higher in group III, IV, VI and VII in comparision to third and fourth month of experiments.

Keywords: Ewe, Photoperiod, Melatonin, Lymphocyte percent count

Introduction

Short days enhance immune function in individuals with robust reproductive responses to photoperiod. Total splenic lymphocyte number, and macrophage counts were significantly higher in hamsters exposed to short days, as compared to animals exposed to long photoperiods (Brainard *et al.*, 1988). Photoperiodic influences on lymphocyte number and total white blood cell count have been reported for deer mice (Blom *et al.*, 1994); short day (LD 8:16) mice possessed more white blood cells than animals maintained in long day lengths (LD 16:8). Importantly, all laboratory studies of photoperiodic effects on immune function have reported enhanced immune function in short day lengths (Nelson and Demas, 1996). Although many field studies support this hypothesis, with data suggesting enhanced immune function and decreased disease prevalence during the winter as compared to the summer, a substantial number of studies have reported the opposite pattern of results (Nelson and Demas, 1996); i.e., enhanced immune function is coincident with the short days of winter. These conflicting results can be resolved by considering additional environmental factors, not usually manipulated in laboratory studies. For example, winter-associated stressors [e.g., restricted food and low ambient temperatures] appear to counteract short day enhancement of immune function in the lab.

Exogenous administration of melatonin increased the lymphocyte percentage in Broiler chicks (Abozahra *et al.*, 1998), Rats (Anwar *et al.*, 1998), and Squirrels (Rai *et al.*, 2009). Rai and Haldar (2003) reported daily subcutaneous injection of melatonin at 17.30 to 18.00 hr significantly increased the lymphocyte count of blood in adult male squirrels, while pinealectomy decrease percent lymphocyte count in peripheral blood and bone marrow. The precise mechanism responsible for this melatonin induced increase in lymphocyte percentage is not clear. However, several mechanisms may be involved in this respect. Haldar *et al.* (2006) accessed the effect of melatonin on immune parameters in a seasonally breeding animal, the Indian palm squirrel F. pennanti and bird P. asiatica during reproductive phases in vivo as well as in vitro. Melatonin treated squirrels and birds showed an increase in percent lymphocyte count (% LC) and percent stimulation pinealectomy in squirrels. Melatonin administration recovered all the decreased immune parameters to the control level (Rai and Haldar, 2003). MEL supplementation also enhanced all immune parameters in both in vivo and in vitro, suggesting that the immune system was sensitive during the reproductively active phase to MEL when peripheral melatonin level was low and the role of melatonin could be important for the maintenance of the immune status of seasonal breeders.

As reported by Etim *et al.* (2014[a]) immune status is a function of leucocytes, lymphocytes and Neuteophils. Lymphocytes are known to play key roles in immune defense system of both man and animals (Etim et al., 2014[b]). The objective of this experiment was to determine Lymphocyte percent count in Chhotanagpuri sheep after exogenous administration of melatonin following different photoperiods.

Materials and Methods

The present study was conducted in Department of veterinary physiology, College of veterinary science and A.H., Birsa Agricultural University, Kanke, Ranchi-6, Jharkhand located at 23.36°N latitude and 85.33°E longitude with an altitude of 651 m above mean sea level. Design of experiment was approved by the Institutional Animal Ethics Committee vide letter no.-139/528/RVC/IAEC. Forty two (42) apparently healthy, non-pregnant, non-lactating Chhotanagpuri ewes having body weight ranging between 14.11±0.09 to 15.38±0.06 Kg reared under uniform managemental husbandry practices were selected. Selected ewes were isolated from rams prior to melatonin administration. The selected animals were allocated randomly into seven groups (viz. group-I to group-VII) comprising six animals in each group. Group-I [Normal control]:- The animals in this group were exposed to normal variation in day length. Group-II [Long day (LD) control]:- In this group in addition to natural sun light, artificial light was provided to animal for maintaining 16-18 hours of light every day for the period of one month and considered as long day control. Group-III [LD + Melatonin administration orally (3mg/day)]:- In this group in addition to natural sun light, artificial light was provided for maintaining 16-18 hours of light every day for the period of one month and after that 3 mg melatonin was administered orally for one month to each animal. Group-IV [(LD + Melatonin administration subcutaneously (1mg/day)]:- In this group in addition to natural sun light, artificial light was provided for maintaining 16-18 hours of light every day for the period of one month and after that 1 mg melatonin was administered subcutaneously for one month to each animal. Group-V [Short Day (SD) control]:- Animals in this group were provided only 8 hours natural day light and were then kept in a light-proof shed for 16 hours exposure in dark every day for the period of one month. This group served as short day control. Group-VI [SD + Melatonin administration orally (3mg/day)]:- Animals in this group were provided only 8 hours natural day light and were then kept in a light-proof shed for 16 hours exposure in dark every day for the period of one month and after that 3 mg melatonin was administered orally for one month to each animal. Group-VII [SD + Melatonin administration subcutaneously (1mg/day)]:- Animals in this group were provided only 8 hours natural day light and then were kept in a light-proof shed for 16 hours exposure in dark every day for the period

INTEGRATION BETWEEN THE THERMAL STRESS INDEX (TGWB) AND THE LIVESTOCK STRAIN INDEX (LSI) AS A GUIDELINE FOR DAIRY FARMING IN TROPICAL CLIMATE

Abstract

A new thermal stress index (TGWB Index), based on Air temperature (Tdb), globe temperature (Tg) and wet bulb (Twb) temperature suggests as a potential substitute for the temperature humidity index (THI) for cattle in tropical climate. This new stress index, found to have a high correlation to THI, is constructed from fast reading meteorological response sensors (Tdb, Twb, and Tg) that take only a few seconds to reach equilibrium. Furthermore, the TGWB Index is the first stress index using direct measurements of solar radiation and is calculated as follows:
TGWB Index = 0.78 (Tg + Twb) + 35.8
The recently suggested Livestock Strain Index (LSI) is capable of indicating physiological strain and analyzing milk production of cattle. The LSI is constructed from rectal temperature (Tre) and respiratory frequency rate (Rf) as follows:
$LSI = 5\ (Tre_{obs.} - Tre_{min.})\ (Tre_{max.} - Tre_{min})^{-1} + 5\ (Rf_{obs.} - Rf_{min.})\ (Rf_{max.} - Rf_{min})^{-1}$
Where Tre_{obs} and Rf_{obs} are the observed measurements Tre_{min} and Tre_{max} and Rf_{min} and Rf_{max} are maximum and minimum simultaneous measurements taken at any time. The LSI is scaled from 0-10, whereby each variable LSI_{Tre} or LSI_{Rf} which represent the cardiovascular and the thermoregulation systems respectively. The purpose of this study was to develop guidelines based on TGWB Index and LSI for dairy cattle for combat to heat stress. In order to integrate LSI and TGWB Index, we decided to use both the LSI_{Rf} and LSI_{Tre} component, which represents the respiratory frequency rate and the strain reflected by the cardiovascular system. Furthermore, LSI_{Rf} and LSI_{Tre} are easier to measure, are easier to implement and simplifies the integration with TGWB Index. Concomitantly, it also categorizes the strain between 0-5, the higher the value, the higher the strain.
Key words: Tropical climate, Thermal stress, Indices, Solar Radiation, LSI, TGWB Index

Introduction

The incidence of heat stress as measured by the frequency of days with THI greater than 80 has increased significantly over the 40-year period on record. This is due to both changes in the temperature variables used and also the incidence of drought as drought years appear to be also associated with high stress frequency.

In hot climates, high ambient temperatures, humidity, wind speed, and high direct and indirect solar radiation are the main environmental stress factors that impose strain on animals (Finch, 1985, Silanikove, 2000). Heat stress indices range from simple measurements of ambient air temperature to indices that try to provide a weighted estimation of all environmental factors involved. Keeping the fact that heat stress is caused by multiple environmental or thermal factors, it is often misleading to use ambient temperature alone as the indicator of heat stress. Different heat stress indices have been proposed that indicate level of thermal stress. Thom suggested a Temperature-Humidity Index (THI) based on dry bulb and wet bulb thermometers. The Temperature Humidity Index (THI) has been widely used as a heat stress index in beef and dairy (cattle & buffaloes) industries (Stokka *et al.*, 1996; West, 1999; Mader *et al.*, 2002). Following a list of temperature humidity indices:

$THI\ 1 = (0.15 \times T_{db} + 0.85 \times Twb) \times 1.8 + 32$
(Bianca, 1962),

$THI\ 2 = (0.35 \times T_{db} + 0.65 \times Twb) \times 1.8 + 32$
(Bianca, 1962),

$THI\ 3 = [0.4 \times (T_{db} + Twb) \times 1.8 + 32 + 15$
(Thom, 1959),

$THI\ 4 = (0.55 \times T_{db} + 0.2 \times Tpo) \times 1.8 + 32 + 17.5$
(National Research Council, 1971),

$THI\ 5 = (1.8 \times T_{db} + 32) - (0.55 - 0.0055 \times RH) \times (1.8 \times T_{db} - 26) = 0.81 \times T_{db} + 0.143 \times RH) + 0.0099 \times RH \times T_{db} + 46.3$
(National Research Council, 1971),

$THI\ 6 = (T_{db} + Twb) \times 0.72 + 40.6$
(National Research Council, 1971),

$THI\ 7 = (T_{db} + 0.36 \times Tpo) + 41.2$
(Yousef, 1985a),

The above indices have been used to calculate stress for each combination of environmental variables corresponding to the measurements made in the animals, in order to assure that each animal response was associated to a given environmental condition. The index THI1 is used to monitor discomfort of temperature and humidity in humans. The THI2 and THI7 have been empirically determined for cattle exposed to heat stress conditions in climatic chambers. How these indices from controlled environments relate to field conditions? With diurnal fluctuation of environmental variables remain unanswered (Bofumanova *et al.*, 2007). The index THI3 is used to monitor the degree of discomfort in humans. The THI5 represents cattle heat stress index, designed to indicate level of heat stress of outdoors cattle (West, 2003); and THI6 has been developed by the United State Weather Bureau to describe discomfort in humans.

THI values of 70 or less are considered comfortable, 75 to 78 stressful, and values greater than 78 because extreme distress and animals are unable to maintain normal body temperature (Silanikove, 2000). The THI fails to reflect the contributions of other environmental factors, such as airflow and thermal radiation.

As noted before, the index has gained immense popularity over the years. The temperature humidity index (THI) is in use in temperate climatic condition for cattle. The Temperature Humidity Index (THI) has been widely used as a heat stress index in beef and dairy industries (Stokka *et al.*, 1996; West, 1999; Mader *et al.*, 2002). It is important to note the correlation of temperature humidity index (THI) to physiological responses was only partially tested and was based mainly on the correlation between the number of heat stress cases of dairy animal and the heat load as calculated by the THI. I have inroduced my new thermal stress index (TGWB) based on Air temperature (Tdb), globe temperature (Tg) and wet bulb (Twb) temperature as follows:

TGWB Index = 0.78 (Tg + Twb) + 35.8

This newly developed index was validated by using large databases and was found to be highly correlated to the temperature humidity index (THI). TGWB Index differs from other indices that have been suggested in the past for two main reasons. First, new thermal stress index (TGWB) based on Air temperature (Tdb), globe temperature (Tg) and wet bulb (Twb) temperature, aside from using temperature

Management of traumatic proptosis in a pug: A case study

Sandeep Yadav, Vibha Yadav, RP Diwakar and Pramod Kumar

Abstract
A three years old male pug dog, weigh 10 kg was presented to Jai Pet Care Clinic Raebareli, Uttar Pradesh for treatment with unilateral traumatic proptosis. All clinical parameters were normal. Physical examination revealed partial prolapse of right eye globe with severe periorbital edema, haemorrhage, absence of menace and presence of miosis. Therapeutic management done by administration of trifluopromazine @4mg/kg I/M for sedation, dexamethasone and gentamicine 0.2ml each in combination injected through intra palpebral route, which was repeated on 5th day. Animal was also given intramuscular injection of gentamicin @5mg/kg, dexamethasone @0.125mg/kg, vitamine B complex 2.0 ml and chlorpheniramine maleate @0.5mg/kg only once for 5 consecutive days. Eye drop of moxifloxacine and dexamethasone 4 times a day for instillation, chloramphenicol ointment 4 times a day for local application and enrofloxacin @5mg/kg orally once for 7 days were used. Animal recovered successfully after 7 days of regular treatment. Vision was assessed by simple vision testing using junction box, after 15 days of recovery and found normal.

Keywords: Pug, proptosis, therapeutic management

Introduction
Proptosis is forward displacement of globe which occur secondary to any blunt trauma to head [7]. Proptosis typically occurs in dogs following trauma to the face or head. Certain breeds of dog are more prone to eye proptosis than others because of their differences in facial conformation. The most common cause of proptosis in small breed dogs is a fight with a larger dog. During trauma, the globe is luxated from the orbit, and eyelid spasms prevent its retraction. Secondary orbital hemorrhage and swelling displace the globe further from the orbit following corneo-conjunctival drying and malacia [7]. Prognosis depends on pupil size and reflexes, duration of exposure, other globe or orbital damage, breed and other systemic trauma. Approximately 40–60% of dogs, but very few cats, recover vision. Traumatic proptosis can occur in any breed and in both dogs and cats. Only 20-40% of dogs that have the reattachment of the eyeball regain their vision.

Case history and observations
A three year old male pug of 10 kg weight was presented at Jai Pet Care Clinic Raebareli, Utter Pradesh with unilateral traumatic proptosis having recent history of blunt head trauma by hitting head against the wall. Clinical examination revealed partial prolapse of right eye globe (fig.-1) through the pulpebral fissure with severe periorbital edema (fig.-2), haemorrhage without fracture of skull. There was absence of menace and presence of miosis. Corneal examination revealed concurrent finding of pigmentary vascular keratitis. All clinical parameters of the pug were normal.

ABSTRACT

In the Changing global scenario, exploding world population, limited natural recourses and environmental degradation are posing a greatest challenge to the sustainable production and reproduction of livestock for human population. Climate change has profound effect on livestock. The anticipated rise in temperature due to climate change is likely to aggravate the heat stress in livestock, adversely affecting their productive and reproductive performance. Heat is the major constraint in tropical and sub tropical climatic conditions which negatively affects production and reproduction of livestock species. Cattle and buffaloes experience different level of stress during summer and hot humid conditions. Climatic conditions in the India are such that the warm (or hot) season is relatively long, there is intense radiant energy for an extended period, and there is generally the presence of high relative humidity. Thus, heat stress is chronic in nature, there is often little relief from the heat during the evening hours, and intense bursts of combined heat and humidity further depresses the performance. Heat production and accumulation, coupled with compromised cooling capability because of environmental conditions, causes heat strain in the cattle and buffaloes to increase to the point that body temperature rises, intake declines and ultimately the cow's productivity declines. Temperature-Humidity Index (THI) available with different temperature and humidity weightage are suitable for different specific areas.

Key words : *Global Scenario, Climate change, Livestock, challenges, Heat stress index, THI.*

One of the greatest challenges to production from lactating dairy cattle and buffaloes facing dairy farmers in the India is heat stress. Climatic conditions in the India are such that the warm (or hot) season is relatively long, there is intense radiant energy for an extended period, and there is generally the presence of high relative humidity. Thus, heat stress is chronic in nature, there is often little relief from the heat during the evening hours, and intense bursts of combined heat and humidity further depress performance. Lactating dairy cattle and buffaloes create a large quantity of metabolic heat and accumulate additional heat from radiant energy (West, 2003). Heat production and accumulation, coupled with compromised cooling capability because of environmental conditions, causes heat strain in the cattle and buffaloes to increase to the point that body temperature rises, intake declines and ultimately the cow's productivity declines.

Rectal Temperature : A change in rectal temperature has been considered an index of heat stored in large animals and other mammals. For well-hydrated beef cattle living in temperate climates, the range of normal rectal temperature is 36.7 to 39.1°C (Cunningham, 2002).

Normal rectal temperature in Indian cattle has been reported to be 38.3 ± 0.3°C by Mullick (1961) and Bhattacharya et al., (1965). For zebu cattle and crossbred bullocks, normal rectal temperature was reported to be 38.3 and 38.4°C, respectively (Upadhyay, 1982). Heat inputs cannot be equal to heat outputs at all times; therefore, the maintenance of body temperature within this range is achieved through a system of temperature regulation. To regulate body temperature the animal have a variety of temperature sensors located within the body. There are specific temperatures sensitive neuronal structures located in the skin and in the mucous surfaces of the buccal cavity, in regions of the spinal cord, and in the hypothalamus of the midbrain (Bligh, 1985). These sensors relay information to the pre-optic area of the hypothalamus, which is thought to be the main centre for temperature regulation. The pre-optic area of the hypothalamus then initiates mechanisms to either increase or decrease heat loss or production (Cunningham, 2002). In the regulation of body temperature, the hypothalamus behaves as if it has a normal "set-point". When rectal temperature rises above or falls below the set point, heat losing, or heat gaining mechanisms are initiated (Cunningham. 2002).

Respiration Rate : The other method of evaporative heat loss available in cattle is via respiration. Respiration rate (RR) has long served as a gross indicator of heat during hot weather, increasing when animals need to maintain homoeothermy by dissipating excess heat stress as other avenues become inadequate (Hahn. 1999). The normal

HEAT STRESS INDICES, STANDARDS AND LIMITS WITH REFERENCE FOR CATTLE AND BUFFALOES

Abstract

An IPCC special report on the impacts of global warming of 1.5 °C above pre-industrial levels would be a world first and, accordingly, no previous experience in the determination of acceptable heat stress limits, criteria or indices is wholly applicable. However, some tropical countries are already at beyond high temperature and much of the knowledge gained in managing and rearing of animal at such heat stress will be helpful in making adequate planning for acceptable environmental control at the greater thermal stress being contemplated. Accordingly, it is necessary to take cognisance of the dairy industry's experience in most tropical countries and of standards and regulations already established in South America and elsewhere in order to ensure acceptable conditions and control standards that compare favourably and defensibly with those in other dairy industries. Different countries uses of heat stress limits, criteria and indices were investigated as it was necessary to determine to what extent any other indices, limits or criteria would be applicable to tropical conditions. In addition, it was necessary to establish whether there was a single heat stress index that could be used in thermal stress for tropical climatic conditions. It was found that an appropriate combination of heat stress indices would be required in planning for and ultimately controlling thermal conditions in tropical climatic conditions. The solar radiations and humidity being contemplated and the concomitant potential heat hazard present too great a risk for reliance on environmental component of heat stress, such as wet-bulb temperature at present in common use locally. The study recommends that a heat stress index, preferably WBGT be used to design an modern dairy farm's ventilation system and that wet-bulb temperature be used to monitor and control the system once it is implemented.

Introduction

Environmental conditions that is conducive to safe and productive for cattle and buffaloes. Although many aspects of a dairy farming environmental conditions would be much the same as those already prevailing in poultry, sheep, goat and other animal farming sector the variations in high metabolic energy requirement to which animal are exposed would increase by virtue of increased depth. The paper therefore offers some guidelines for the use of heat stress indices and limits as would be applicable for dairy farming.

Thermal conditions and the heat stress imposed on animal will be the most significant environmental consequences of dairy farming, indicating a need to quantify the effects of heat on animal health and their production performance. This represents a difference in purpose from the traditional concern with heat stress. The principal motivation in efforts to evaluate and control heat stress in the dairy farm has been to minimize its detrimental effects on animal. This has resulted in the development heat stress indices based same on physiological tolerance and production performance criteria. Given the critical impact that productivity will have on the success or failure of dairy farming criteria should form part of the fundamental basis for determining the thermal standards. In the past, a number of heat stress indices have been devised in attempts to combine various environment variables into a single number indicative of the heat stress imposed on cattle and buffaloes. Although such a number can provide some measure of environmental heat stress, there are many and varied criteria for evaluating the acceptability of thermal conditions for dairy farming.

Heat stress indices

The incidence of heat stress as measured by the frequency of days with THI greater than 80 has increased significantly over the 40-year period on record. This is due to both changes in the temperature variables used and also the incidence of drought years appear to be also associated with high stress frequency.

In hot climates, high ambient temperatures, humidity, wind speed, and high direct and indirect solar radiation are the main environmental stress factors that impose strain on animals (Finch, 1985, Silanikove, 2000). Heat stress indices range from simple measurements of ambient air temperature to indices that try to provide a weighted estimation of all environmental factors involved. Keeping the fact that heat stress is caused by multiple environmental or thermal factors, it is often misleading to use ambient temperature alone as the indicator of heat stress. Different heat stress indices have been proposed that indicate level of thermal stress. Thom suggested a Temperature-Humidity Index (THI) based on dry bulb and wet bulb thermometers.

The Temperature Humidity Index (THI) has been widely used as a heat stress index in beef and dairy (cattle & buffaloes) industries (Stokka *et al.*, 1996; West, 1999; Mader *et al.*, 2002). Following a list of temperature humidity indices:

$THI\ 1 = (0.15 \times T_{db} + 0.85 \times Twb) \times 1.8 + 32$

(Bianca, 1962).

$THI\ 2 = (0.35 \times T_{db} + 0.65 \times Twb) \times 1.8 + 32$

(Bianca, 1962).

$THI\ 3 = [0.4 \times (T_{db} + Twb) \times 1.8 + 32 + 15$

(Thom, 1959).

$THI\ 4 = (0.55 \times T_{db} + 0.2 \times Tpo) \times 1.8 + 32 + 17.5$

(National Research Council, 1971).

$THI\ 5 = (1.8 \times T_{db} + 32) - (0.55 - 0.0055 \times RH) \times (1.8 \times T_{db} - 26) = 0.81 \times T_{db} + 0.143 \times RH) + 0.0099 \times RH \times T_{db} + 46.3$

(National Research Council, 1971).

$THI\ 6 = (T_{db} + Twb) \times 0.72 + 40.6$

(National Research Council, 1971).

$THI\ 7 = (T_{db} + 0.36 \times Tpo) + 41.2$

(Yousef, 1985a).

A review: heat stress in cow and buffaloes in India

Pramod Kumar, Rishikant, Rabindra Kumar, KN Singh and Mukesh Kumar

Abstract
India is a tropical climatic country in which heat stress is an important disadvantageous factor that reduces the production performance of cattle and buffalo and conduces to significant decrease in milk yields in dairy cows and buffalo and some metabolically disorders. The objective of this review is to known the heat stress metabolism, its causing factors and its preventative methods for increase the production performance through manage mental and nutritional procedures.

Keywords: Tropical, Heat, Temperature, Conduction, Convection, Radiation, Evaporation, Panting, Sweating, Moisture

Introduction
Climatic conditions of India are such that the hot and humid season is relatively long, there is intense radiant energy for an extended period, and there is generally the presence of high relative humidity. Thus, heat stress is chronic in nature especially for animal, there is often little relief from the heat during the evening hours, and intense bursts of combined heat and humidity further depress performance of animal. Lactating dairy cattle and buffaloes create a large quantity of metabolic heat and accumulate additional heat from radiant energy (West, 2003) [20]. Heat production and accumulation, coupled with compromised cooling capability because of environmental conditions, causes heat strain in the cattle and buffaloes to increase to the point that body temperature rises, intake declines and ultimately the cow's productivity declines.

Heat stress is caused by a combination of climatic factors like air temperature, humidity, solar radiation, wind velocity etc. A common time for experience adverse effects of high temperatures is during transport (Fiore *et al*, 2009) [6]. Transport is a multi affected stressor that can create or exacerbate existing heat loads. Handling of animal, increases body temperature. Animal are adversely affected any time the ambient temperature is more than their thermoneutral zone, which ranges about 25°C. Because that heat stress conduces to some disadvantageous affect on livestock, many researchers work about heat stress in animal.

Thermoneutral zone
The Thermoneutral Zone (TNZ) is defined as. "the range of ambient temperature within which metabolic rate is at a minimum, and within which temperature regulation is achieved by non evaporative physical processes alone" (Bligh & Johnson, 1973) [3]. The lower critical ambient temperature range point and the upper critical ambient temperature point indicate the limits of the TNZ. The ambient temperature below, which the rate of heat production of a resting homeotherm increases to maintain thermal balance, is the lower critical temperature (LCT). The upper critical temperature (UCT) may be defined as the ambient temperature when the: (a) metabolic rate increases; (b) evaporative heat loss increases; or (c) tissue thermal insulation is minimal (Silanikove, 2000) [14]. Below and above these temperature limits heat production is increased. The width of the thermoneutral zone will vary depending on age, species and breed, level of nutrition, previous state of temperature acclimation or acclimatization, level of productivity, housing conditions, insulation, and behavior etc (Yousef, 1985b) [22]. In order to more clearly define the TNZ (Silanikove, 2000) [14] suggested that the subdivision of the TNZ into a zone of thermal well-being is most suitable to describe the relation between an animal and its environment. Figure 1, illustrate this concept.

ABSTRACT

Forty two (42) apparently healthy, non-pregnant, non-lactating Chhotanagpuri ewe, having body weight ranging between 14.11±0.09 to 15.38±0.06 Kg were selected and selected ewes were isolated from rams 2 months prior to melatonin administration. The selected animals were allocated randomly into seven groups viz. Group-I [Normal control], Group-II [Long day (LD) control], Group-III [LD + Melatonin administration orally (3mg/day)], Group-IV [(LD + Melatonin administration subcutaneously (1mg/day)], Group-V [Short Day (SD) control], Group-VI [SD + Melatonin administration orally (3mg/day)] and Group-VII [SD + Melatonin administration subcutaneously (1mg/day)] comprising six animals in each group. Rams were then introduced into each group after completion of exogenous administration of melatonin. Blood sample without anticoagulant in vials was collected from each animal day before the start of experiment and there after every month up to fifth month. After administration of melatonin, serum glucose was decreased in group- III, IV, VI and VII in comparison to group-I, although this decrease was not statistically significant. An increasing trend of serum glucose was observed in all groups from third to fourth month. Total protein at first month was significantly ($P<0.05$) higher in group VI in comparison to 0 day. After administration of melatonin, total serum protein concentration was significantly ($P<0.05$) decreased in group VI in comparison to first month and continued up to third month. At fifth month, total serum protein was significantly ($P<0.05$) lower in group III, IV and VI in comparison to 0 day and first month.

Introduction

Sheep husbandry is backbone of rural economy in India. The Chhotanagpuri sheep is the only recognized breed of sheep found in Jharkhand with a few numbers in Bihar and West Bengal. This breed is maintained solely for mutton production. They produce coarse wool of poor quality. This is being utilized for carpet manufacturing. Sheep

Abstract

The study was conducted to investigate effect of vitamin E and zinc on cortisol hormone during peripartum period in Karan Fries cows. Sixteen pregnant Karan Fries (KF) cows were selected from the herd of National Dairy Research Institute (NDRI) Karnal, on the basis of their body weight, BCS and parity. Eight cows were kept in control group and other eight cows in treatment group which were supplemented with 1000 IU vitamin E and 60 ppm zinc per day per cow. Blood samples were collected on the days -60, -45, -30, -15, -7, 0, +7, +15, +30, +45, +60 with respect to expected date of calving. Plasma was analyzed for Cortisol hormone. Body weight and Body condition score (BCS) of all the experimental animals were recorded on the day of blood collection. Plasma cortisol was significantly ($P<0.001$) lower in treatment group as compared to control group (2.98 vs. 3.10 ng/ml). There was a steady increase in the body weight of control and treatment cows towards parturition and was found a significant ($P<0.001$) difference between the control and treatment groups. The body condition score of control and treatment groups decreased by 33.05% and 17.76% respectively after calving. This showed that the control group cows lost significantly ($P<0.001$) more body condition as compared to treatment group cows. The results of this study indicated that supplementation of vitamin E and zinc have beneficial effects in changing cortisol level in this way that improves body condition and decreases the effect of parturition stress in the animals.

Keywords: Cortisol, Body Condition Score, Energy Metabolites, Peripartum period, Vitamin E, Zinc

Introduction

Cortisol is a steroid hormone that helps the body respond to stress. It is also called the stress hormone. It is released in response to stress and low blood glucose concentration. It is the principal glucocorticoid during the reproduction and lactation of cows [1]. Adrenal secretion of cortisol is modulated by a complex negative feedback mechanism involving the central nervous system, hypothalamus, pituitary and adrenals [2]. The synergistic action of endogenous cortisol along with other hormones has been found to be critical for parturition and initiation of lactation in domestic animals [3]. At term the corticosteroid concentration rises in the plasma of peripartum cows [4, 5]. Plasma total cortisol level increased from 2.13 ng/ml to 2.62 ng/ml till one day prepartum and increased to 6.08 ng/ml at parturition in crossbred cows. The level decline from 3.42 ng/ml on 1 day postpartum to 2.49 ng/ml at 3 day postpartum [6]. In Murrah buffaloes level of cortisol was found 1.46 ng/ml at 30 day prepartum which increased to 3.78 ng/ml at parturition and decline to 1.89 ng/ml at 3 day postpartum[7].

Cortisol concentrations have been used as a physiological marker of stress. During heat acclimation there is reduction of plasma cortisol that helps in reduction of heat production of animals[8]. An initial increase in cortisol occurs due to acute heat stress followed by a decline after prolonged exposure in cows. The animals adjust physiologically to elevated heat loads by decreasing adrenal corticoid output [9]. Cortisol concentrations have been found lower in high producing cows at day 30 than at day 90 or in nonlactating cows due to reduced pulse amplitude. Low cortisol concentrations likely participate in the enhanced production observed in high producing cows [10]. Heat exposure at temperature above 40°C has been found to raise the cortisol level to almost double the pre-exposure levels [11]. Similar results were also found by others in hot-dry, hot-humid and winter seasons in crossbred cows (4.17, 4.35 and 2.09 ng/ml respectively) [12].

Materials and Methods

Experimental design

The study was conducted at the Cattle Yard of National Dairy Research Institute, Karnal, Haryana (India). Karnal is situated on an altitude of 250 meter above mean sea level, latitude and longitude position being 29°42" N and 79°54" E respectively. The maximum ambient temperature in summer goes up to 45°C and minimum temperature in winter comes down to 0°C with a diurnal variation in the order of 15-20°C. For the present study 16 Karan Fries (KF) peripartum cows were selected from the herd of National Dairy Research Institute, Karnal. 8 cows kept in Control group and other 8 cows in Treatment group. The cows in the control group were supplemented with no vitamins, and in the treatment group, they were given 1,000 IU of vitamin E and 60 ppm zinc per cow per day from 60 days prepartum to 60 days postpartum. Animals were maintained in open area with asbestos roof in the sides of the open area, where the animals were offered feed. The open area had brick floor. The animals were free to move inside the controlled open area. All the animals were fed as per the standard feeding practices followed at the NDRI farm.

Blood sampling

Blood samples (10 ml/cow) were collected in the morning (6.00 AM) before feeding in sterile heparinised vacutainer tubes (BD VacutainerTM, UK) from jugular vein puncture, posing minimum disturbance to animal, on the days -60, -45, -30, -15, -7, 0, +7, +15, +30, +45 and +60 with respect to expected date of calving. Day '0' represented the day of calving. Blood samples were brought to the laboratory in the icebox soon after collection and centrifuged at 1,200×g at 4°C for 20 min to separate the plasma. Plasma samples were stored at -20°C until analysis of Cortisol.

Sample analysis

Blood sample was analyzed for cortisol. Plasma Cortisol was determined by "Cortisol EIA kit" from Cayman Chemical Company, Ann Arbour, USA. Body weight and Body condition score (BCS) of all the experimental animals was recorded on the day of blood collection using a scale of 1 to 5.

Statistical analysis

Statistical analysis of data was carried out to find the mean ± SE. Two-way ANOVA was done to find significant difference between groups and days of experiment and their interaction by using SYSTAT 3.1 (2004) software.

Results and Discussion

Cortisol

The mean±SE of plasma cortisol concentration of control cows was 2.87±0.09 ng/ml 60 days before calving and on the day of calving it increased to 3.24±0.07 ng/ml. Further, in treatment group the plasma cortisol concentration was 2.78±0.03 ng/ml 60 days before calving and on the day of calving it increased to 3.10±0.03 ng/ml. In present study, the overall mean±SEM of plasma cortisol concentration was found significantly ($P<0.001$, Table 2) lower in treatment group as compared to control group. Plasma levels of cortisol varied between 2.3-3.5 ng/ml during pre and postpartum in Holstein cows [13]. After 7 days of calving it's level started decreasing up to 60 day of lactation.

EFFECT OF EXOGENOUS MELATONIN AND DIFFERENT PHOTOPERIODS ON TOTAL LEUCOCYTE COUNT IN CHHOTANAGPURI EWE

P. K. Choudhary[1*], A. K. Ishwar[2], P. K. Maurya[1], P. Kumar[2] D. Niyogi[3] and M. Kumar[4]

Abstract

Forty two (42) apparently healthy, non-pregnant, non-lactating Chhotanagpuri ewe, having body weight ranging between 14.11±0.09 to 15.38±0.06 Kg were selected and selected ewes were isolated from rams 2 months prior to melatonin administration. The selected animals were allocated randomly into seven groups viz. Group-I [Normal control], Group-II [Long day (LD) control], Group-III [LD + Melatonin administration orally (3mg/day)], Group-IV [(LD + Melatonin administration subcutaneously (1mg/day)], Group-V [Short Day (SD) control], Group-VI [SD + Melatonin administration orally (3mg/day)] and Group-VII [SD + Melatonin administration subcutaneously (1mg/day)] comprising six animals in each group. Rams were then introduced into each group after completion of exogenous administration of melatonin. Blood sample without anticoagulant in vials was collected from each animal day before the start of experiment and there after every month up to fifth month. TLC at first month was significantly ($P<0.05$) higher in all short day groups (V, VI and VII) and significantly ($p<0.05$) lower in long day groups (II, III and IV) in comparison to 0 day. After administration of melatonin, TLC was significantly ($p<0.05$) higher in group III, IV, VI and VII in comparison to first month. At third and fourth month TLC was significantly ($P<0.05$) low in group VI and VII in comparison to second month.

Keywords: Chhotanagpuri ewe, Exogenous melatonin, Photoperiod, Total leucocyte count

Introduction

Melatonin signaling is necessary for photoperiodic adjustment in immune responses; it is difficult to parse the differential direct effects of melatonin on immune cells from indirect modulatory actions on other neuro-endocrine axes including the systems that control gonadal and adrenal steroids. However, the hypothesis that melatonin acts on immune function via down- stream hormonal effects has not been born out, as gonadectomy and steroid replacement has minimal effect on photoperiodic plasticity in immune system (Prendergast *et al.*, 2005). Further, although androgens tend to be immunosuppressive estrogens often have the opposite effect (Klein, 2008). Therefore, the short-day induced gonadal regression would likely induce opposite effects in males and females if sex steroids were directly responsible for photoperiodic adjustments in immune responses. In general, both males and females respond similarly to changes in day length (Bilbo and Nelson, 2005). Gonadal steroids probably serve to modulate the larger melatonin-mediated effects of day length rather than directly driving photoperiodic changes (Prendergast *et al.*, 2008).

Exogenous administration of melatonin increased the total leucocytic count and lymphocyte percentage in Broiler chicks (Abozahra *et al.*, 1998), Rats (Anwar *et al.*, 1998), and Squirrels (Rai *et al.*, 2006). Rai and Haldar (2003) reported daily subcutaneous injection of melatonin at 17:30 to 18:00 hr significantly increased the lymphocyte count of blood in adult male squirrels, while pinealectomy decrease total leucocyte count and percent lymphocyte count in peripheral blood and bone marrow. The precise mechanism responsible for this melatonin induced increase in total leucocytic count and lymphocyte percentage is not clear, However, several mechanisms may be involved in this respect.

The major functions of the white blood cells and its differentials are to fight infections, defend the body by phagocytosis against invasion by foreign organisms and to produce or at least transport and distribute antibodies in immune response (Etim, 2015). Thus, animals with low white blood cells are exposed to high risk of disease infection. While those with high counts are capable of generating antibodies in the process of phagocytosis and have high degree of resistance to disease and enhancing adaptability to local environment and disease prevalent conditions (Isaac *et al.*, 2013). As reported by Etim *et al.* (2014[a]) immune status is a function of leucocytes, lymphocytes and Neutrophils. Lymphocytes are known to play key roles in immune defense system of both man and animals (Etim et al., 2014[b]). The objective of this experiment was to determine total leucocyte count in Chhotanagpuri sheep after exogenous administration of melatonin following different photoperiods.

Materials and Methods

The present study was conducted in Department of veterinary physiology, College of veterinary science and A.H., Birsa Agricultural University, Kanke, Ranchi-6, Jharkhand located at 23.36[0]N latitude and 85.33[0]E longitude with an altitude of 651 m above mean sea level. Design of experiment was approved by the Institutional Animal Ethics Committee vide letter no.-139/528/RVC/IAEC. Forty-two (42) apparently healthy, non-pregnant, non-lactating Chhotanagpuri ewes, having body weight ranging between 14.11±0.09 to 15.38±0.06 Kg reared under uniform managemental husbandry practices were selected. Selected ewes were isolated from rams prior to melatonin administration. The selected animals were allocated randomly into seven groups (viz. group-I to group-VII) comprising six animals in each group. Group-I [Normal control]: - The animals in this group were exposed to normal variation in day length. Group-II [Long day (LD) control]: - In this group in addition to natural sun light, artificial light was provided to animal for maintaining 16-18 hours of light every day for the period of one month and considered as long day control. Group-III [LD + Melatonin administration orally (3mg/day)] - In this group in addition to natural sun light, artificial light was provided for maintaining 16-18 hours of light every day for the period of one month and after that 3 mg melatonin was administered orally for one month to each animal. Group-IV [(LD + Melatonin administration subcutaneously (1mg/day)]:- In this group in addition to natural sun light, artificial light was provided for maintaining 16-18 hours of light every day for the period of one month and after that 1 mg melatonin was administered subcutaneously for one month to each animal. Group-V [Short Day (SD) control]: - Animals in this group were provided only 8 hours natural day light and were then kept in a light-proof shed for 16 hours exposure in dark every day for the period of one month. This group served as short day control. Group-VI [SD + Melatonin administration orally (3mg/day)]: - Animals in this group were provided only 8 hours natural day light and were then kept in a light-proof shed for 16 hours exposure in dark every day for the period of one month and after that 3 mg melatonin was administered orally for one month to each animal. Group-VII [SD + Melatonin administration subcutaneously (1mg/day)]: - Animals in this group were provided only 8 hours natural day light and then were kept in a light-proof shed for 16 hours exposure in dark every day for the period of one month and after that 1 mg melatonin was administered subcutaneously for one month to each animal. Rams were introduced into each group after completion of exogenous administration of melatonin. Blood samples were collected from each animal day before the start of experiment and there after every month up to fifth month. Blood (0.5ml) was collected from each animal in clean EDTA coated tubes and Total Leucocytes Count ($x\ 10^3/\mu l$ blood) was counted as per

SELECTING A SUITABLE HEAT STRESS INDEX TO PROTECT CATTLE AND BUFFALOES IN HOT AND HUMID CLIMATE

Abstract

An assessment of any climate conditions requires extensive measurements to be health and production performance of animal in the climatic zone. This can be labour-intensive, time-consuming and consequently impractical for daily production and comfort assessments of the animals. Therefore, a simple indicator like a heat stress index is needed to enable a quick, valid and acceptable evaluation of animal climatic conditions on a regular basis. This can be explained by the unending quest to develop a "universal index," which has led to the proliferation of many proposed heat stress indices. In this research study is to discuss the selecting a suitable heat stress index for thermal planning and management purposes in hot and humid climatic zone for dairy industries. A method is proposed a defined strategy for selecting and recommending heat stress indices to be used in a particular climatic zone and worldwide based on a heat stress index. The performance of different heat stress indices used in dairy industries and other cattle farm varies based on the climatic conditions and the level of activities. Therefore, carefully selecting or establishing a suitable heat stress index is of paramount importance to ensure the comfort, health and increasing productivity of the cattle and buffaloes. These methods assess and select the most appropriate index for hot and humid climatic conditions to protect the cattle and buffaloes from thermal stress. Although complex, the method presents results that are easy to interpret and understand than any other methods.

Keywords: climatic zone, heat stress index, thermal stress, dairy industries.

Introduction

Heat stress is chronic in nature, there is often little relief from the heat during the evening hours, and intense bursts of combined heat and humidity further depress performance. Lactating dairy cattle and buffaloes create a large quantity of metabolic heat and accumulate additional heat from radiant energy [1]. The ability of many indices using these elements have been developed in past; but their utility remained limited. Majority of studies on thermal stress in livestock have used temperature-humidity index (THI). THI represent the combined effect of air temperature and humidity with level of heat stress. Milk yield and DMI exhibited significant declines when maximum THI reached 77. Later research determined that the critical values for minimum, mean, and maximum THI were 64, 72 and 76 respectively [2]. In addition, a climate change scenario was constructed by raising both the minimum and maximum temperatures by 2.76°C, which is a mid-range temperature change for approximate doubling of atmospheric greenhouse gas concentrations. The incidence of stress days as measured by THI greater than 80 has increased significantly over the 40-year period (60%) and the climate change scenarios suggested further, substantial increases (138%) in the frequency of such heat stress days. In addition, in the climate change scenario there was a very marked increase in days where animals could no longer thermo regulate by sweating alone [3]. Different animal species have different sensitivities to air temperature, humidity, solar radiation and wind velocity etc. Cattle and buffaloes have differences in their heat tolerant capacity. Cattle can tolerate high temperatures at low air humidity than buffaloes. This is due to the fact that, cattle can dissipate heat more efficiently by surface evaporation whereas buffaloes use surface evaporation for body cooling to a limited extent.

This research study posed the question of which index can be recommended for a hot and humid climate? In this paper, a method is used to compare a thermal comfort model with some of the most widely used heat indices in dairy industries and another cattle farm. The method is applied to predict the "comfort zone" and to recommend an index based on its production performance as close as possible to the "comfort zone." The comparative analysis uses comfort data including air temperature, airflow velocity, humidity and estimated physiological parameters such as respiration rate and rectal temperature.

Cattle and buffaloes have capacity to maintain their body temperature with in a precise limit even after exposure of environmental extremes [4]. Animals gain heat from three sources: chemical, mechanical and thermal. Chemical and mechanical heat transfer relates to metabolic processes and represents the body's main heat sources. The influence of the thermal environment on an animal is primarily exerted through energy exchanges involving convection, conduction, radiation and evaporation [5]. There are mechanisms by which the body can regulate its core temperature both at rest and during activity, and in both hot and cold or humid environments, along with health risks that are associated with physical activity in the aforesaid environments [6]. Assessment of "Thermoneutral Zone" must start with the maximum production with wellbeing of animal. It is extremely difficult to classify the many factors that affect thermal comfort. The interaction between the physical demands imposed upon an animal his physiological status, and his psychological attitudes. Because thermal comfort is rather subjective and restrictive, it is better to define a Thermoneutral Zone within which most animals will be comfortable. This necessitates the need to define a "zone" in which most of the animals will consider comfortable, the so-called comfort zone. This comfort zone will be ascribed using the climatic and physiological parameteers of the environment and some existing thermal comfort models.

The Thermoneutral Zone (TNZ) is defined as "the range of ambient temperature within which metabolic rate is at a minimum, and within which temperature regulation is achieved by non-evaporative physical processes alone [7]. The lower critical ambient temperature range point and the upper critical ambient temperature point indicate the limits of the TNZ. The ambient temperature below, which the rate of heat production of a resting homeotherm increases to maintain thermal balance, is the lower critical temperature (LCT). The upper critical temperature (UCT) may be defined as the ambient temperature when the: (a) metabolic rate increases; (b) evaporative heat loss increases; or (c) tissue thermal insulation is minimal [8]. Below and above these temperature limits heat production is increased. The width of the thermoneutral zone will vary depending on age, species and breed, level of nutrition, previous state of temperature acclimation

The idea of the thermal index goes back to 18th century [9]. Without considering the dry-bulb temperature, perhaps the first published heat stress index was the wet-bulb temperature proposed by Haldane [10]. Since then a large number of heat stress indices have been proposed.

ABSTRACT

The study was conducted to investigate the effect of α-tocopherol acetate and zinc on milk composition in Karan Fries cows. Twenty pregnant Karan Fries cows were selected two months before expected date of calving. The experimental animals were randomly divided in to two groups namely control group (ten cows) and treatment group (ten cows). Treatment group cows were supplemented with α-tocopherol acetate @ 1000 IU/day/cow and zinc @ 60 ppm/day/cow. Milk fat % was lower in treatment group than control group but the overall fat in treatment group was found significantly higher than control group (4.47±0.20 vs. 3.95±0.27, P<0.01). The overall mean milk protein % was found 3.08±0.04 vs. 3.05±0.11, milk lactose % 4.47±0.08 vs. 4.48±0.10 and SNF % 8.17±0.15 vs. 8.15±0.17 in control group and treatment group, respectively which showed that there was no significant difference between the groups. The overall mean (±SEM) of somatic cell count of milk was found significantly lower (P<0.001) in treatment group than control group. The results of this study indicated that supplementations of antioxidants like α-tocopherol acetate and zinc have beneficial effects in improving quality of milk.

Introduction

For good quality dairy products there is need to know the quality aspects of milk produced. Since the diet is the fastest way to modify the milk production and quality in animals, even if the relations between the feeding and milk composition are quite complex. Trace elements, along with vitamins and minerals, are essential nutrients for cellular metabolism. They are critical components of almost every aspect of how a body grows, develops, functions and reproduces. Vitamin E is crucially involved in immune system function, such that supplementation with supranutritional levels of the vitamin E, results in improved immune responses and milk production (Chawla and Kaur, 2005; Baldi, 2005; Baldi *et al.*, 2008; Chandra and Aggarwal, 2009). There was significant decrease of somatic cell count (SCC) in milk at 15 days of lactation (0.29×10^6 vs. 0.86×10^6) in cows supplemented with 1000 IU vitamin E / day during dry period (Kaur *et al.*, 2002). The somatic cell count is internationally recognized as a parameter for assessing the milk quality and udder health. The present

Abstract

The present study was conducted in Ambedkar Nagar district of Uttar Pradesh to establish scientific rational of high yielding buffaloes under field condition, effect of these most common field feeding practices on reproductive performance of Murrah buffaloes under farm condition. The On –Farm Trails were carried out in three different phases designated as Phase I, II and III. In phase-I, collection of data and feed samples from the field, in phase II calculation of chemical composition of feed and fodder samples collected from farmers, and phase III post-partum buffaloes were selected and divided into two groups of each farmers animals in each group, one as a control group (T0) and other one as a treatment group (T1). Control group was fed as per the ICAR (2013) feeding standard and in treatment group feed was offered two times a day 1 hr. before the milking time i.e. 5.00 AM and 4.00 PM and each buffalo were fed 3 kg gram chuni, 1.5 kg oil seed cake, 1.5 kg wheat dalia, 10 kg Berseem green fodder and 2 kg wheat straw in each time for 3 month. Significant results were found in the treatment group i.e. the lesser service period ($p < 0.05$) and lower services per conception ($p<0.01$) compared to control group. There was higher conception rate in treatment group (83.33%). It's clearly indicated that the feeding of higher energy and protein in the ration, results in buffaloes of treatment group was bred earlier, lower service per conception and higher conception rate.

Key words: Murrah buffaloes, Reproductive performance, Service period, Services per conception.

Introduction

India possesses great potential in animal husbandry sector being the largest milk producing country in the world with a production of about 97.1 million tons (14.9% of world, CSO, 2006). Our country also has the largest buffalo population, while we stand second in cattle population after Brazil. The per capita availability of milk has increased from 112 gm in 1970 to 241gm in 2005-06 (CSO, 2006). High milk yield during early lactation of the buffaloes create a challenge in meeting the animals' energy requirements. This period is characterized by a substantial decline in feed intake lipid mobilization leading to elevated plasma NEFA and hepatic triglycerides (TRG) content and protein mobilization. The resulting negative energy balance impairs reproduction. Post-partum fertility has a profound impact on the economic viability of dairy industry. Among various factors, peri-parturient disorders have been recognized as the most important factors influencing fertility. Lowered reproductive performance concomitant to steadily increasing milk production is a main concern for dairy industry world over. Numerous studies have reported that reproductive performance is compromised, primarily through delayed ovarian activity and reduced conception rates, by the demands of high milk yield (Nebel and MsGilliard, 1993; Beam and Bulter, 1999). Improved reproductive performance and reduced incidence of reproductive disorders, in order to resume normal fertility after parturition, adequate balance of protein, energy, trace minerals and antioxidant vitamins must be maintained after parturition. High level of concentrate feeding to buffaloes decreased the incidence of reduced days to first observed estrus and decreased services/conception (Jukola *et al.*, 1996; Kim *et al.*, 1997).

Materials and Methods

On–Farm Experiments were conducted by KVK Ambedkar Nagar in six villages, two each from blocks -Katehari and Jalalpur and Tanda on twelve farmers of district Ambedkar Nagar of Uttar Pradesh. Twenty-four buffaloes (≥18 liters milk) were identified and their owners interviewed to get the required information, Samples of feed and fodder offered to animals were collected and calculated for proximate principles as per (AOAC (1995). The chemical composition of feed and fodders is presented in Table-1. The DM content was lowest in green berseem (16.24%) among all green fodders, it might be due to succulent nature. The CP content in roughages was highest in berseem (16.47%) fallowed by multicut chari (11.52%) and sorghum (11.52%), while it was least in paddy straw (2.10%). The value is close agreement with those reported by Mudgal et al. (2003). The contrite mixture was mainly prepared incorporating locally available ingredients like rice bran, mustard cake, pigenpea and gram chunni, wheat bran, wheat grain etc., but most of farmers used these concentrate ingredients in adequate amount, some more or less. Some farmers were also aware to feed commercial concentrate like complete feed pullet to animals. Mustard cake contained high CP (37.12%) as compared to other concentrate ingredients, whereas EE content was highest in rice bran (12.78%). The ash content was found to be highest in rice bran (22.16%) fallowed by berseem green (20.22%).

Table -1 Chemical composition of feeds and fodders (% on DM basis)

S.N.	Feeds/ fodders	DM	CP	CF	NFE	EE	Total Ash
1.	Rice bran	92.42	12.30	14.58	38.90	12.78	22.16
2.	Mustard cake	91.87	37.12	9.35	37.16	9.81	08.59
3..	Pigeon pea chunni	92.64	18.70	17.20	53.55	2.30	08.02
4.	Gram chunni	92.25	12.47	38.62	42.10	1.62	04.86
5.	Wheat bran	93.31	16.29	7.76	67.81	3.35	04.78
6.	Wheat grain	92.28	10.34	4.69	80.52	2.45	02.46
7.	Paddy straw	92.20	2.10	37.59	42.97	0.85	16.39
8.	Wheat straw	93.67	3.04	38.18	48.19	1.02	16..81
9.	Sorghum green	18.27	9.42	26.88	48.82	2.34	11.86
10.	Berseem green	16.24	16.47	25.96	35.78	2.64	20.22
11.	Multicut chari	17.86	11.52	27.20	47.49	4.37	10.15

After collection of data, the amount of daily DM (Dry matter), DCP (Digestible crude protein) and TDN (Total digestible nutrients) intakes were calculated from the feed intake on the basis of average nutritive values(Table -2) of the feed and fodders (Rajhan, 2001).Length and Heart girth of each animal was measured to calculate the body weight. The collected data were made into tabular form through the various calculating process. To study the nutritional requirement of the buffaloes and body weight of the animals were calculated by using Shaeffer's formula (Sastry *et al.*, 1982): Body weight (kg) = {[(Heart girth in inches)2 × (length of body in inches)]

Assessment of occupational health hazards among farm workers involved in agricultural activities

Pragya Ojha and Abha Singh

Abstract
Indian Farm workers are highly involved in various agricultural operations. They perform a sequential work through manual efforts. In the present investigation efforts have been made to assess the occupational risk related to various agriculture activities and to compare the physical strength of male and female farm workers, during manual method to perform agricultural operations. For the study, twenty female and twenty male subjects were selected. From this study, it has been recommended that there is dire need to create awareness among the farm workers about the low cost improved technologies related to flower cultivation which can significantly improve the livelihood security and working conditions of farm workers. It will also reduce the level of occupational risk and enhance the physical strength of the workers.

Keywords: Occupational risk, Physical strength, Agricultural Workers, Agricultural Activity

Introduction
In the context of occupational safety and health, the term 'agriculture' is generally used in a broad sense including all activities directly related to cultivating, growing, harvesting and primary processing of agricultural products, animal and livestock breeding including aquaculture, and agroforestry. Agricultural work is dangerous; workers in this industry have among the highest rates of fatalities (BLS, 2014 and Liebman *et al.* 2013). Furthermore, Wang *et al.* (2013) also mentioned that work in agriculture involves exposures to a variety of hazards, including dust, noise, thermal stress, pesticides and other chemicals, and ergonomic risk factors. As a result, agricultural workers have elevated rates of injuries and illnesses. Das *et al.* (2011) also supported that agricultural works are associated with several occupational disorders among the farmers and agriculture farming involves several types of hazardous activities including prolonged and awkward postures. Agriculture workers perform many strenuous activities. These are: spading, carrying seeds, uprooting, transplanting saplings, harvesting or cutting crops, shelling, carrying crops, threshing, sweeping and winnowing. Therefore, the main aim of this investigation was to know the level of occupational health hazards among agriculture workers and an attempt was made to compare the physical strength of male and female farm workers during the performance of work.

Materials and Method
Selection of subject and field
From Faizabad district of Uttar Pradesh state, India, twenty male and twenty female subjects with normal health, without any major illness or cardio-vascular problems were purposively selected because only without illness or cardio- vascular problems, agricultural workers can perform the activities more efficiently. This study was conducted in the month of February-August in the year of 2016. The age range of the selected subjects was 20-55 years. Care was taken to select the female farm workers who were non pregnant and who can perform the agricultural activities regularly. The agricultural operations were performed for 7:00 A.M to12:30 P.M. and 2:00 P.M. to 5:30 P.M. Agriculture workers performed the continuous agriculture operations for 50 minutes and taking 10 minutes break.

Calibration of subjects: The subjects were calibrated with the Body Mass Index to determine their physical fitness index. The body mass index of subjects was calculated by dividing square of height (m2) to weight (kg).

Quantification of safety and Health Hazards
Semi quantitative observational tool to characterize safety and health hazards developed by Neitzel *et al.* (2014) has been used to quantify the level of safety and health hazards among

ASSESSMENT OF MUSCULO-SKELETAL DISORDER IN FLOWER PLUCKING WOMEN IN FAIZABAD DISTRICT OF UTTAR PRADESH

MANEESHA MISHRA *
Dr. ABHA SINGH **

ABSTRACT

Women play a significant and crucial role in Agriculture development, livestock production and Floriculture as a manager decision maker and skilled farm worker. In this study attempt has been made to study the role performed by farm women engaged in floriculture and to find out the MSD (Musculoskeletal disorder) and OH (Occupational Hazard) among women. The study was conducted in Faizabad District in U.P. 100 samples were taken of women involved in flower management. It was found from the study that majority of respondents (40%) suffered from the Back pain while (20%) women suffered Knee pain. The analysis of the study shows that Poor postures and finger nodes. Stress full work, unawareness of new techniques in the use of equipment and unwariness for safety measures were the reason for musculoskeletal discomforts. 70% women used foot wears due to the awareness of the advantages of it. The preferred activities by women were grading of flower (42%) as first followed by Deeping of flowers (34%), plucking of flower (12%) and storage flower (11%) respectively. The study will be use full in policy making designing women friendly implements for flower plucking and right posture training.

Key word: MSD (Muscule-Skeletal Disorder), Occupational Hazard, Knee pain, Back pain, Musculoskeletal Disorder.

Income generation for sustainable development of rural women

Abha Singh, Pragya Ojha, Sumant Pratap Singh and Namita Joshi

Abstract
Women constitute about 50% of total population, yet their status in the society pitiable. They put in 15 hours of work daily but their wages are less than men. The income generation activities undertaken by women are yet to prove its impact on them or it is more a self employment activity rather than a substantial source of income. Therefore there is a need to study if these micro income generating activities provide empowerment to rural women. The objective of this study is to find out if income generating activities under taken by rural women have increased their participation in decision making process. In this study income generating activity has been treated as independent variable and women empowerment as dependent variable. The study was conducted in Sultanpur district of Uttar Pradesh (U.P.) and both income generating and non income generating 150 women from each group were selected as sample. The pace of empowerment may be due to small amount of income generated. As a result of this, U.P. (Uttar Pradesh) government initiated several projects. Under this scheme women are encouraged to undertake some income generating programmes to raise their income which will their self confidence, bargaining power, promote stronger household food security and investment in children's schooling. From review paste researchers and personal experiences the following model is designed to show how women empowerment takes place. A similar model was tested by Estudillo and Esatka 1988, but model differs in measuring empowerment in terms of women participation in decision making. The study revealed that income earned by women has improved their status and empowerment is taken place but the speed of empowerment is slow..

Keywords: decision making, society, economic, farming, labor, village

Introduction
It is paradoxical that women constitute nearly 50 percent of world population and yet their social economic and welfare status is pathetic. Even today only a fraction of rural women are educated and majority is living under poverty, ignorance, and oppression. They still lack the access to information, science and technology, economic resources, political power and employment avenues. Their employment opportunities are dismal. What ever improvement in women employment is being claimed, it is mostly among urban women while rural women are still far behind and living in poor condition. The activity profile of women reveals that they put in 15 hours of work daily and yet their wages are lower than men. Besides this, they contribute nearly 50 to 70 percent of agricultural labour in farming and when working on own farm they are not paid. Although when they work as a labour on the farm of other farmers, they are paid less wages compared to men. The world community is aware of rural women's plight and four world conferences have been organized and truck load of resolutions have been passed. As a result of this, U.P. (Uttar Pradesh) government initiated several projects, notably DWACRA (Development of Women and Children of Rural Areas). Under this scheme women are organized in self help groups and are encouraged to undertake some income generating programmes to raise their income which will raise their self confidence, bargaining power, promote stronger household food security and investment in children's schooling. According to Cornelia Butler Flora Rural women help in income generation either by earning or by saving.

Critical analysis of the studies reflects that income generation activity should be encouraged for empowering the women. However none of these studies clearly state that the impact of income generation is positive and it has empowered the women. The major issue is how empowerment has been measured in these studies. Therefore, in this study women participation in various decisions making has been measured as an empowerment.

The second aspect which is yet to be tackled is the feeling of improvement of income and

Effect of integrated nutrient management on vegetative growth and flowering of African marigold (*Tagetes erecta* L.) Cv. Bidhan Marigold-2

Laxmi Kant, Ashok Kumar and Abhinav Kumar

Abstract
A field experiment was carried out to study the effect of integrated nutrient management on vegetative growth and flowering of African marigold (*Tagetes erecta* L.) Cv. Bidhan Marigold-2 at Main Experimental Station, Department of Floriculture and Landscape, Acharya Narendra Deva University of Agriculture & Technology, Narendra Nagar, Kumarganj, Ayodhya (U.P.) during the summer season of 2018-19 and 2019-20. The experiment was laid out in Randomized Block Design with16 treatment combinations replicated thrice to assess the effect of *Azospirillum*, PSB, FYM, Vermi-compost, Poultry manure and NPK (Recommend Dose of Fertilizers).
Results reveal that the application of *Azospirillum* @ 250 ml/ha + PSB @ 250/ha ml + Vermi compost @ 50 q/ha + 50% NPK (Recommend Dose of Fertilizers) left the significant response on vegetative growth and flowering of African marigold Cv. Bidhan Marigold-2. The treatment has resulted in maximum plant height, number of primary branches plant^{-1}, spread of plants, stem diameter at 30 days, earlier days to first bud initiation, days taken to flower bud opening, days taken to 50% flowering and maximum duration of flower in the field. Based on above results, it is concluded that the use of treatment combinations of *Azospirillum* @ 250 ml/ha + PSB @ 250/ha ml + Vermicompost@ 50 q/ha + 50% NPK (Recommend Dose of Fertilizers) on African Marigold Cv. Bidhan Marigold-2 are beneficial for the growers of Eastern Uttar Pradesh.

Keywords: Marigold, *Tagetes erecta* L., nutrient management, Azospiriillum, PSB, vermi-compost etc.

Introduction
African Marigold is an important commercial flower of India that belongs to the family Asteraceae (Composite). Marigold is a native of Central and South America especially Mexico. It also called 'Gainda' in the Hindi language. The genus *Tagetes* contain around 33 species, African marigold (*Tagetes erecta* L., 2n = 24) and French marigold (*Tagetes patula* L., 2n = 48) announced by (Rydberg, P. A., 1915) [8].
African marigold is one of the most important hardy flower crops which are grown commercially in different parts of the worlds. Marigold gained popularity among garden and flower dealers on account of its easy cultivation, wide adaptability of diverse soil and climatic conditions, the habit of profuse flowering, short duration to produce marketable flowers, and good keeping quality. In India, it is one of the most commonly grown loose flowers and extensively used on religious and social functions, in one form or another.
Agriculture, which largely depends on continuous use of chemical fertilizer is not only a burden for the farmer's or growers but is also responsible for the depletion of soil fertility which often affects productivity. Hence, efficient and judicious use of chemical fertilizers along with organic manure is imperative not only for obtaining more yields per unit area on a sustainable basis but also to conserve the energy and to avoid the problem of environmental quality.
Bio-fertilizers are the products containing living cells of different types of microorganisms, which are capable of mobilizing nutritive elements from non-usable form to usable form through a biological process. Azotobacter and PSB are free-living bacteria that help in N_2 fixation and solubilizing phosphorus in the soil. Nitrogen is an important metabolic element for the growth and development of the plant. It is essentially considered as metabolic activities, the transformation of energy, essential for the metabolism of protein and other biochemical product such as nucleic acid, chlorophyll and protoplasm. Phosphorus is the essential component of protoplasm and chlorophyll which caused conversion of photosynthesis into phospholipids resulting in adequate vegetative growth of the plant.

Studies on the effect of bio-inoculants and gibberellic acid on vegetative growth of African marigold (*Tagetes erecta* L.) Cv. Pusa Narangi Gainda

Anshuman Singh, Ashok Kumar and Abhinav Kumar

Abstract
A field experiment was carried out to study the effect of bio-inoculants and Gibberellic acid on vegetative growth and flowering of African marigold (*Tagetes erecta* L.) cv. Pusa Narangi Gainda" at the Main Experiment Station, Department of Floriculture & Landscape, Acharya Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj), Ayodhya (U.P.) during the years 2019-20 and 2020-21. The experiment was conducted in Randomized Block Design (Factorial) with 12 treatments replicated thrice to assess the effect Bio-Inoculants and Gibberellic Acid on Vegetative Growth of African Marigold. Results reveal that the application of Azotobacter by soil treatment 4L/ha and Gibberellic acid 200 ppm had left significant response on the growth of marigold. The maximum plant height, primary branches per plant, secondary branches per plant, plant spread, Plant basal diameter was obtained with the combination application of A_3 (Azotobacter by soil treatment 4L/ha) and G_4 (Gibberellic acid 200 ppm) whereas the minimum values were recorded in control. Interaction effect of both the treatment was found non-significant.

Keywords: Azotobacter, gibberellic acid, growth, flowering, marigold

Introduction
African marigold (*Tagetes erecta* L.) is one of important annual flower known for its aesthetic value and long blooming period. It belongs to family Asteraceae, a native of Central and South America especially Mexico. In India marigold was introduced by the Portugeses (Kalpan, 1960) [4]. In India, the present area under marigold cultivation is 55890 ha with a production of 5.1 lakh MT. Karnataka is the largest state in area of marigold in India with production of 74,900 MT from an area of 9100 ha. Madhya Pradesh ranks first in production (85,070 MT) from an area of 7780 ha.

Marigold can be grown in all seasons of which rainy and winter season crops are the main crops under eastern U.P. condition. The name genus *Tagetes* was derived from Etruscan *Tagetes* which refers to the ease with which plants of the genus come out each year either by seeds produced in the previous year, or by the stems which regrow from the stump already in place. The most commonly cultivated species of *Tagetes* are known variously as African marigold (*Tagetes erecta*), French marigold (*Tagetes patula*), Signet marigold (*Tagetes tenuifolia*) and mini marigold (*Tagetes minuta*).

The plants of Mexican marigold reach heights of between 50 and 100 cm. The root is cylindrical with fibrous and shallow branching system. The stem is striated, sometimes ridge, smooth or slightly with villi, cylindrical, oval and herbaceous to slightly woody, with resin channels in the bark, which are aromatic when squeezed. Opposite leaves at the bottom alternate at the top, up to 20 cm long, pinnate, composed of 11 to 17 leaflets, lanceolate to linear-lanceolate, up to 5 cm long and 1.5 cm wide, acute to acuminate, serrated to sub-holders, the lower ones of each leaf frequently setiform (in the form of threads), the superiors are sometimes completely setiform; with abundant round glands.

Microbial inoculants of selective micro-organisms like azotobacter which is free-living nitrogen fixing bacteria, help in improving soil fertility by the way of accelerating biological nitrogen fixation from atmosphere nearly 25 to 30 l nitrogen per hectare, solubilization of the insoluble nutrient in soil, generate little quantity of PGRs decomposing plant residues and stimulating plant growth and production by producing Phyto hormones, enhancing the uptake of plant nutrients by plant roots and thus help in sustainable crop production through maintenance of soil productivity.

Effect of foliar feeding on chemical attributes of Ber (*Ziziphus mauritiana* L.) under Sodic soil

Rahul Pal, Ashok Kumar and Abhinav Kumar

DOI: https://doi.org/10.22271/chemi.2021.v9.i1y.11446

Abstract
An experiment was carried out to study the "Effect of foliar feeding on chemical attributes of ber (*Ziziphus mauritiana* L.) Under sodic soil" in the year 2019-20. The experiment was conducted in Randomized Block Design with three replications. The foliar feeding of urea (2.0%), zinc sulphate (0.50%), borax 0.50% and K_2SO_4 0.50% a at peak flowering, peanut size of fruit and second growth phase significantly increased the fruit quality characteristics T.S.S. (20.86° Brix), Total sugars (9.58%), Reducing sugar (6.68%), Non- reducing sugar (2.90%), Acidity (0.25%), Ascorbic acid (95.66 mg/ 100 g pulp), Fruit yield per plant (33.63 kg/plant) and Fruit yield (9.37 t/ha.) over control. The maximum effect on all parameters, treatment T_{10} was observed best with the feeding of Urea 2.0% + $ZnSO_4$ 0.50% + Borax 0.50% + K_2SO_4 0.50%.
However, the combination of Urea 2.0% + $ZnSO_4$ 0.50% + Borax 0.50% + K_2SO_4 0.50% was found most effective in fruit quality of ber (*Ziziphus mauritiana* L.) under sodic soil.

Keywords: Foliar, chemical, attributes, Sodic, *Ziziphus mauritiana* L.

Introduction
The Indian Ber (*Ziziphus mauritiana* L.), which is also called Chinese date or Chinese fig, belongs to family Rhamnaceae and genus *Ziziphus*. It is tetraploid in nature with a chromosome number 2n=4x=48. Origin of ber is said to be India to south –western Asia. It is a drought hardy and can grow under the most hazardous condition of soil, water and climate and thus it has highly recommended for the arid and desert area of India. The cultivated area of ber increased due to better adoptability and higher return in arid, semiarid and irrigated areas. It is also known as "King of Arid Fruits".
Commercial cultivation usually extends up to 1000 m above sea level. It is known for its ability to withstand adverse conditions, such as salinity, drought and water logging. It has also been mentioned in holy books like Ramayana and Mahabharata. In India, area under ber is 49 million hectare and production consists of 481 million tonne 2017-18. In view of the recent development in production technology of this crop, the cultivation of ber crop is becoming increasing popular in many parts of India such as Rajasthan, Haryana, Uttar Pradesh, Gujarat, Madhya Pradesh, Bihar, Maharashtra, Andhra Pradesh and Tamil Nadu. It is reported to grow in other countries like Iran, Syria, Australia, USA, France and some parts of Italy, Spain, and Africa etc.
Gola is an early variety and popular in Delhi, Haryana, Uttar Pradesh and other adjoining areas. Among the different cultivars of ber, Gola is an extremely drought hardy, early and extensively grown variety. The fruit is ovate to round in shape and the size of fruit is medium. It develops greenish to golden yellow colour at ripening stage. The quality of fruit is excellent but cannot stand long transport. The average weight of fruit varies from 15-20g.
Foliar feeding of nutrients has certain advantages over soil feeding. Foliar feedings are highly effective with rapid pant response and also useful to maintain their optimum concentration in the plant during growth and fruit development. But very scanty information is available on foliage nutritional aspects, which can be valuable in making judicious fertilizer recommendation for profitable production of ber. The foliar feeding of fruit trees has gained much importance in recent years, as fertilizers applied through soil are needed in higher quantities because some amounts leach down and some amounts become unavailable to the plants due to complex soil reaction.

Studies on the effect of bio-inoculants and gibberellic acid on flowering of African marigold (*Tagetes erecta* L.) cv. Pusa Narangi Gainda

Anshuman Singh and Ashok Kumar

Abstract
The present investigation was carried out to "Studies on the effect of bio-inoculants and Gibberellic acid on flowering of African marigold (*Tagetes erecta* L.)" at the Main Experiment Station, Department of Floriculture & Landscape, Acharya Narendra Deva University of Agriculture & Technology, Kumarganj, Ayodhya (U.P.) during winter season in the year 2019-2020 and 2020-21. The experiment was conducted in Randomized Block Design (Factorial) with 12 treatments replicated thrice to assess the effect Bio-Inoculants and Gibberellic Acid on flowering attributes of African Marigold.
During the investigation, the treatment A_3G_4 (Azotobacter by soil treatment 4L/ha and Gibberellic acid 200 ppm) has given the maximum beneficial effect on the flowering parameters (days to first bud initiation (40.67, 38.67 days), days to first flowering(50.67, 49.00 days), days taken 50% flowering (63.00, 61.33 days), duration of flowering (54.00 and 55.00 days), length of flower stalk (8.67,9.33cm), number of flowers per plant (55.33, 56.33) fresh weight of flower (10.89, 11.33 g), dry weight of flower (0.98, 0.98) and flower diameter (7.89, 8.00 cm) during winter season in the year 2019-2020 and 2020-21 as compared to individual application of GA_3 and Azotobacter treatments but their interaction effect was found non-significant.

Keywords: Bio fertilizer, plant growth regulators, growth, marigold

Introduction
The African marigold (*Tagetes erecta* L.) is a popular annual flower that is prized for its beauty and extended blooming period. It is a member of the Asteraceae family and is endemic to Central and South America, particularly Mexico. The Portuguese introduced marigold to India (Kalpan, 1960) [7]. The current marigold growing area in India is 55890 ha, with a production of 5.1 lakh MT. Karnataka has the highest marigold production in India, with 74,900 MT produced from a 9100 ha area. From a total area of 7780 hectares, Madhya Pradesh produces the most (85,070 MT).
Marigold grown in all seasons, rainy and winter crops being the most common in eastern Uttar Pradesh. The name *Tagetes* comes from Etruscan Tagetes, which refers to the ease with which the genus' plants emerge each year, either from seeds generated the previous year or from stems that renew from the stump already in place. African marigold (*Tagetes erecta*), French marigold (*Tagetes patula*), Signet marigold (*Tagetes tenuifolia*), and tiny marigold (*Tagetes tenuifolia*) are the most commonly cultivated Tagetes species (*Tagetes minuta*).
Marigold has numerous applications. Marigold is a multipurpose crop that yields a brilliant harvest. It's widely grown as a loose bloom throughout India. The loose flowers are used to make garlands, baskets, and veni, among other things. The petals are frequently used to create unique greeting cards, stationary, envelopes, and corporate gifts by embedding them in handmade paper. It's also utilized as a flavouring agent in a variety of bread goods, dairy products, yoghurt, and ice cream, and its powder and extracts have been allowed for use as sole colourants in chicken feed. Marigolds have also been identified as a food plant for some Lepidoptera caterpillars, such as the dot moth, as well as a nectar source for other butterflies. Marigold is a highly successful nematode control crop when used as a trap crop for nematode (*Helicoverpa armigera*) management in tomato fields. Marigold is becoming a more important commercial source of carotenoid pigments. The primary pigment in the flowers is xanthophyll, of which lutein accounts for 80 to 90% in the form of palmitic and myristic acid esters. Tagetes oil is an aromatic oil derived from *Tagetes minuta* that is used as a fly repellant and has larvicidal qualities. Mexican marigold plants grow to be between 50 and 100 cm tall.

To determine Aloin A & B content in *Aloe vera* (*Aloe barbadensis* Miller) leaf gels

Abhishek Singh, Dr. Pratibha Singh, Dr. Ramesh Pratap Singh and Dr. NA Khan

Abstract
The present investigation was conducted at Acharya Narendra Dev University of Agriculture and Technology, Kumarganj, Ayodhya during the year 2018-19 and 2019-20. Aloin, an anthraquinones molecule found in the bitter yellow sap of the middle leaf layer, has a strong laxative effect. The experiment revealed that Aloin A maximum in IC-112532 (0.87 ppm) and minimum in IC-112512 (0.80 ppm) and Aloin B maximum in IC- 112512 (1.27 ppm) and minimum in IC-283610 (1.17 ppm).

Keywords: Aloin, *Barbadensis*, anthraquinones

Introduction
Aloe vera is a cactus-like plant that grows in hot, arid climates and is currently grown in large quantities due to strong demand. It is regarded as an all-purpose herbal plant with a high rating throughout recorded history. The thick, tapering, spiky leaves of aloe grow from a short stem near the ground. It's not a cactus, but rather a Liliaceae tree called *Aloe Barbadensis* (Ghazanfar, 1994) [1]. Among the 75 potentially active constituents in *Aloe vera* are vitamins, enzymes, minerals, carbohydrates, lignin, saponins, salicylic acids, and amino acids (Richard, 2005) [8]. The vascular layer of *Aloe vera* plants contains two major liquid materials: first, a bitter yellow latex located beneath the strongly cutinized epidermis of the leaves and containing a high concentration of anthraquinone compounds; and second, a bitter yellow latex located beneath the strongly cutinized epidermis of the leaves within the vascular layer and containing a high concentration of anthraquinone compounds, which has been used throughout the centuries as a cathartic and for medicinal purges; and, second, the inner central zone's thin-walled tubular cells form a translucent mucilaginous gel (parenchyma) that has been used since past to treat burns and other wounds, where it's thought to extend the speed of healing and reduce the risk of infection (Joseph & Raj, 2010) [6]. Aloin, an anthraquinones molecule found in the bitter yellow sap of the middle leaf layer, has a strong laxative effect (IARC, 2016) [4]. Except within the pharmaceutical industries, the aloe plant was first used commercially in the manufacturing of "aloin", a latex substance (a yellow sap). In the food industry, it's the potential to be used as a food preservative (substitute of sulphur dioxide in preserving fruit and vegetables). Because of its anti-oxidant characteristics, it's becoming more popular as a natural covering. The leaf powder is employed during a number of ayurvedic medicines because it contains antioxidants, dietary fibre, iron, etc. Many researchers have tried to figure out what active ingredients are present in *Aloe vera* gel (Habeeb *et al.*, 2007) [2]. Proteins, lipids, amino acids, vitamins, enzymes, inorganic substances, and various carbohydrates are contained in polysaccharides located within the inner leaf parenchymatous tissue or pulp, (Hamman *et al.*, 2008) [3]. When the leaves are removed from the basal portion of the mother plant, the sap starts draining out immediately products made from *Aloe vera* plants such as gel, aloin, etc. (Pandey *et al.*, 2016) [7].

Materials and Methods
Aloin A & B content was estimated by the method of thin layer chromatography (TLC) is given by Izmailov and Shraiber (1938) [5].

Crystallization/drying
To carry out thin layer chromatography pre coated silica gel plates spectrophotometer is used

Nutritional Evaluation of Milky Mushroom *calocybe indica*) grown on different substrates

Surya Bala Yadav, RP Singh, PK Shukla and RN Kewat

Abstract
Milky mushroom (*Calocybe indica*) is a potential new species to-the world mushroom growers. This species is suitable for hot humid Climate and can be cultivated indoor at high temperature and high humid areas. Milky mushroom is gaining popularity among the edible mushroom because of its white attractive robust sporocaps highest ptotein content long self life and taste. This variety of mushroom can be cultivated easily at home without much expenditure. The different substrates were tested along and in combination with spent wheat straw (SWS) to determine the effect of substrates nutritional level on the nutritive value of fruiting bodies produced. Mushroom have attracted to attention of human from very ancient times and the use of mushroom is an old as human civilization. Mature fruit bodies are C. Indica contains high protein content (19.72%) it has 12 amino acids. Out of all amino acids glycine is predomiment and the essential acids like tryptophan, methionine and Lysine conteut in dry weight baris are 0.92, 0.93 and 7.86 (mg/ 100g protein).

Keywords: Milky mushroom, Protein essential Amino acids

1. Introduction
Milky mushroom is a alternative source of a protein for a predominantly vegetarian population of this country has to concentrate on a vegetable protein. Mushroom has been recognized by FAO as food contributing to the protein nutrition the countries depending largely on cereals. The quality of mushroom protein is for superior to the vegetable and is a good as a just inferior to animal protein. It is because all the essential amino acids are present is mushroom most abundant amino acid is lysine. Mushroom are rich in lysine and tryptophan can effective by supplement the cereals in terms of protein quality gain in body weight of mice fed on mycelia of P sajor-caju and P. Ostreatus has been reported other indices of protein quality like chemical score. Essential amino acids, biological value protein score and nutritional value index also been employed in mushroom.

Mushrooms are good source of many vitamins specially those of B complex group but are relatively poor in fat soluble vitamin A, D, E and K. Amongst B Complex vitamin mushrooms are specially rich in thiamine (B) riboflavin (B2), niacin and biotin folic acid and vitamin B12, which are generally absent in plant feeds are present in mushroom though a small quantities. As little as 3 grams of fresh mushrooms may provide the recomended daily intabe of vitamin B12.

As a few calories high protein diet with almost no starch and sugars, mushrooms are the delight of diabeties due to high K: Na ratio. Few calories and low fat (rich in linoleic acid and lacking cholesterol). Mushroom are the choice of the dietician for those suffering with obesty hypertension and atherosclerosis (heart disease). Alkaline ash and high fibre content make them suitable for those suffering from hyperacidity.

Materials and method
The present experiment were carried out in mushroom cultivation rooms and research laboratory of the Department of plant Patnology and Biochemistry, N.D. University of Agriculture and Technology Kumarganj, Faizabad during 2006-2007 and 2007-2008. The treatment comparise 10 level of straw in which 1-5 levels are pure different Straw are 6-10 levels are Different pure straw with SWS (spent wheat straw).

Protein content-
The content of protein in dried fruiting bodies was determined by lowry's (1951) method depending on the quantitating colour obtained from the reaction of protein with folin's reagent.

Identification and evaluation of rice (*Oryza sativa* L.) genotypes for drought and salinity tolerance: Growth and yield approach

Narendra Pratap Verma, RK Yadav, AK Singh, Shambhoo Prasad, Pratibha Singh, Alok Kumar Singh and Pradip Kumar Saini

Abstract
The investigation entitled Identification and evaluation of rice (*Oryza sativa* L.) genotypes for drought and salinity tolerance: growth and yield approach" was conducted during *Kharif* season, 2020-21 and 2021-22 at the field of Student's Instruction Farm, Acharya Narendra Deva University of Agriculture & Technology, Kumarganj, Ayodhya-224 229 (Uttar Pradesh). In same manner 72 rice genotypes/varieties were grown for phenotype screening for Salinity in Augumented Block Design in saline soil with four checks (two resistant check Narendra Usar Dhan 3 and CSR -10, two susceptible check Barani Deep and Jaya) and growth and yield parameters data were recorded. *i.e.,* Plant height at 65, 80 DAT (cm), Plant height at maturity (cm), Tiller number plant^{-1} (count), Flag leaf area (cm^2), Fresh weight plant^{-1} (g), Dry weight plant^{-1} (g), Panicle length (cm), Numbers of grains panicle^{-1} (count), Test weight (g), Grain Yield plant^{-1} (g). Reduction in growth parameters like, plant height, tiller number shoot fresh weight and dry weight was noted in all 40 genotypes under low moisture stress as well as in salinity stress. Drought tolerant variety Nagina-22 show minimal reduction in above said character under low moisture stress. While drought susceptible variety IR-64 show maximum reduction in these character under low moisture stress. In salinity stress salt tolerant variety CSR-10 & Narendra Usar -3 show less reduction with respect to susceptible varieties Jaya which show maximum reduction under salinity condition and Yield component like, Panicle length, total number of grains, test weight, and yield per plant of all verities decreased under both low moisture stress and salinity stress. However under drought condition, maximum reduction was noticed in IR-64 followed by Jaya while lowest reduction was seen in Nagina-22 followed by DRR-44, DRR-42 Sukha Dhan-5 & Sushk Samrat. In case of salinity stress minimum reduction in yield attributing traits was seen in tolerant varieties CSR-10, Narendra Usar-3, CSR-36, CSR-43 & Narendra Usar-2 while maximum reduction was found in susceptible varieties, Barani Deep, Jaya & IR-64.

Keywords: Rice, drought, salinity, growth and yield

Introduction
Rice (*Oryza sativa* L.) is a plant of Asian origin, belonging to the family of Graminae (Poaceae). Rice is the most widely cultivated food crop in the world and plays a very important role in providing essential nutrients to a large segment (approximately 90% of the Asian population) of the world's population as it is the staple food of more than half of the world's population and is considered as the backbone of food security in India, China, and other Southeast Asian countries (USDA 2020-21). Rice is cultivated on an area of 164.19 mha in the world with an annual production of 650.19 million tons (509.87 million tons of mild rice) Statista, 2022) and more than 142 mha in Asia. Rice occupies 43% of total food grain production and 46% of total cereal production. India ranks second among the top rice producers in the world after China. Within the country, rice occupies 1/3 of the total cropped area, contributes about 40 to 43% of total food grain production, and continues to play a key role in the national food and livelihood security system (Annual report 2021-2022 Dept. of agriculture & farmer welfare MA&FW India). India ranked first in the area having 45.07 million hectares and second in production 122.27 million tonnes. The productivity of rice in India is 2713 kg per hectare. The area and production of rice in the U.P. are 5.68 mha & 15.66 million tonnes per hectare respectively. Which is 12.60% of the total area in India & 12.81% of total production in India. The productivity of rice in UP is 2759 kg per hectare. UP has ranked first in the area and second in production (Agriculture statistics at a glance, 2021).

Biochemical and physiological studies on Rhizobium inoculated chickpea (*Cicer arietinum* L.) cultivar grown in eastern Uttar Pradesh

Harendra Singh, Mritunjay Tripathi*, Pratibha Singh and Rajan Pratap Singh

Department of Biochemistry, N.D. University of Agriculture and Technology, Kumarganj, Faizabad-224 229, Uttar Pradesh, India.

Received: 29-04-2016 Accepted: 23-03-2017 DOI: 10.18805/lr.v0iOF.9103

ABSTRACT

Health promoting biochemical parameters of fifteen distinct chickpea cultivar (Desi and Kabuli) showed wide variability in their biochemical and physiological composition, malic acid content, days to 50% flowering, primary branches per plant, number of pods per plant. Malic acid content polled mean ranged from 0.40 to 0.49 % in control, *rhizobium* inoculated 0.46 to 0.54% and 0.42 to 0.50% in control, *rhizobium* inoculated 0.49 to 0.54 % at 45 DAS and 90 DAS respectively, pooled mean primary branches per plant in different genotypes ranged from 4.45 to 5.70 in control and 4.90 to 6.45 in *rhizobium* inoculated chickpea genotypes, days to 50% flowering in chickpea ranged from 75.00-87.00 days in control, *rhizobium* inoculated 75.00-86.00 days, number of pods per plant in chickpea ranged from 21.98-62.91 in control, *rhizobium* inoculated 26.85-73.02. The research result about the biochemical characteristics of control and rhizobium inoculated chickpea genotypes are expected to provide guidelines for the researches confronted with the need to use such typical food seed in India as well as in the rest of the world.

Key words: Cultivar, Days to 50% flowering, Malic acid content, Number of pods per plant, Primary branches per plant.

INTRODUCTION

Chickpea is ancient cultivated crop of South Asia, the middle East and the South Africa that has grown for many years in these regions (Shah *et al*., 2012). It is a rich source of proteins and provides best food of vegetarians (Yadav *et al* .,2007). It contain about 16-31.2 % proteins and 38.1-73.3 % carbohydrates (Schirali,1988). Like other grain legumes, chickpea is a good source of mineral and vitamins. Consumption of whole seed of chickpea is desirable science its seed coat contribute about 70 % of the total seed calcium (Williams and Singh,1987).

The leaves of chickpea secretes malic acid but the significance of this secretion is not known. The PEP carboxylase activity and the secretion of malic acid are associated with the presence of glands on the surface of leaves and fruit. PEP activity increase while malic acid secretion and malic dehydrogenase activity decrease in water stress plants. However, the significant malic acid secretion in chickpea should be consider in relation to the insect pest of the plant (Koundal and Sinha, 1983).

Different chickpea varieties showed genetic variability for plant height, number of primary branches, number of secondary branches, number of pods per plant and total biological yield (Qureshi *et al*, 2004).

Besides, this medicinal importance can not over looked as scurvy patients are advised by the doctor to take germinated gram seed to get rid-off. Malic and oxalic acid collected from green, leaves of gram are prescribed for intestinal disorders (Wealth of India 1950). Germinated seeds are recommended as a prophylactic agent against deficiency, diseases. Keeping in view of above utmost importance of chickpea pertaining to human health, diversified use and insufficient inferences of the present investigation was undertaken.

MATERIALS AND METHODS

The present investigation on "Biochemical and Physiological studies on Rhizobium inoculated chickpea (*Cicer arietinum* L.) cultivar grown in eastern U.P." was carried out at Student's Instructional Farm and in the laboratory of Department of Biochemistry during *rabi* season of 2010-11 and 2011-12. After harvesting the seeds were collected and stored in desiccators for the analysis of various biochemical parameters.

Malic acid content was determined by the method described in A.O.A.C. (1970). The total number of primary branches per plant on five plants randomly selected from each line was counted and averaged out at the line of maturity. Days to 50 % flowering was recorded as the number of days from sowing to the date on which 50 percent plants of each plot flowered. Total number of seeds bearing mature pods were counted separately from sampled five plants in each row and averaged out for single plant.

Effect of different substrates on the growth and yield of milky mushroom (*Calocybe indica* P & C)

Surya Bala Yadav, RP Singh, Pratibha Singh and PK Shukla

Abstract
Milky mushroom (*Calocybe indica*) is one of the most potential species of mushroom, being cultivated in tropical and subtropical parts of India. It's high productivity, beautiful shape and colour, pleasant flavour and good shelf life are the major characters responsible to establish it among the mushroom growers and consumer. At present it is mostly being cultivated on wheat straw, however, like other mushroom, it can also be grown on other substrates. Keeping in view the economic of production different substrates were tested along and in combination with spent straw (SWS). Observation on time of taken for spawn run indicated that there was not much difference among the substrates; it look 20-30 days. Extent of spawn run varied greatly among the substances and it was highest in wheat straw (WS, 98.38) followed by sugarcane bagasse (Scb, 97.75), Scb + SWS 96.75, paddy straw (Pds, 95.5), PdS + SWS 94.5, WS + SWS 92.5, mustard straw + SWS (MS + SWS 73.75, MS 15.5, pigeonpea straw + SWS (PgS + SWS 10.0), and PgS 4.8 respectively. No difference was observed in time taken for pinhead initiation after casing. Effect of different substrates on length, average weight and number of fruiting bodies was mostly observed significantly. Highest yield of fruiting bodies was recorded in wheat straw followed by Scb, Scb + SWS, PdS, PdS + SWS, WS + SWS, MS + SWS, MS, PgS, SWS and PgS respectively. All the substrates were found productive upto varying degree of extent except pigeonpea straw. Usefulness of SWS was also proving in combination with different substrates.

Keywords: Substrates, *Calocybe indica*, pigeonpea, Milky mushroom

1. Introduction
Milky mushroom is commonly known as dudhiya mushroom. It is recommended as most suitable diet for diabetic patients. It is a important and used as vegetable in Indian food. Mushroom having various shape, size and colours. All quite different in character, appearance, edibility. Commonly a consist is cap or piles and stalk or stipe but other may have additional structures like annules and valva performing various functions in the life cycle of the fungus. This mushroom naturally grown on the humas rich soil under trees and in agriculture field in local language it is called "Kundu" or more popularly Dhudhi "Chhata". During rainy wind form of *C. indica* were observed near Calcutta and their edibility was confirmed. Natural occurrence of plains of Tamil Nadu, Rajasthan and U.P. The nutritive value of milky mushroom in comparable with other mushroom. Due to its alkaline and higher fibre content, it is highly suitable for people with hyper acidity and constipation protein content in *C. indica* has been documented to range between 17.7-28.5 per cent, fat 4.1 per cent, crude fibre 2.3-3.4 per cent and carbohydrate 50.0-64.0 per cent.

According to an estimate (Chang, 2002), total world production of mushroom was 12 million tones and it is being increased annually more than 12 per cent during 1981 to 1997. Highest production is done in China while U.S. is the biggest consumer of mushrooms. World production of cultivated mushroom in 1981 was 1257.2 thousand mt, in 1986, 2176.0 thousand mt, in 1990, 3794 thousand mt, in 1994, 4909.3 thousand mt, in 1997, 6158.4 thousand mt (Singh and Mishra, 2006) [16].

First attempt on the induction of fruiting bodies of *Calocybe indica* P & C in culture by (Purkayastha, 1979) [11] was made almost three decades ago. However, only limited success was achieved on its cultivation and exploitation till 1990 (Chakraverty *et al.*, 1981; Doshi *et al.*, 1989; Purkayastha and Nayak, 1981) [2, 6, 12]. Later, owing to efforts made under all India Coordinated Mushroom Improvement Project (AICMIP), it is now being cultivated on commercial scale during summer throughout the country.

Cultivation of *C. indica* is mainly done on substrates like wheat, paddy straw, sugarcane wastes, etc. Spawning is done with spawn @ of 4% of wet weight of straw containing about

QUALITY PARAMETERS OF TOMATO (*LYCOPERSICON ESCULENTUM* MILL.) STRAINS / VARIETIES AT RIPENING STAGE GROWN IN EASTERN U. P.

Brijesh Kumar*, Pratibha Singh, R. N. Kewat, R. K. Yadav and S. K. Vishwakarma
Department of Agril. Biochemistry, Narendra Deva University of Agriculture and Technology Kumarganj, Ayodhya- 224 229 (U.P.) India

Abstract

Ten germplasms of tomato namely NDTH-90, NDTH-101, NDTH-108, Kalyanpur Selection-2, Kalyanpur Selection-3, Kalyanpur Selection-6, IIVR Selection-2, CO-3, Arka vikas and Pusa Early Dwarf were analysed at ripening stage.

The data obtained in the experiment showed the highest fruit size length and diameter (4.83, 7.17 cm) at ripening stage was found in variety Pusa Early Dwarf & Arka vikas. Maximum fruit weight (95.33g.) and specific gravity (1.28 ml/cc) at ripening stage in variety CO-3 & Pusa Early Dwarf .Whereas maximum ascorbic acid (27.67 mg/100) at ripening stage was found in variety NDTH-101 and total mineral (0.80 mg/100g) at ripening stage was found in variety Arka vikas. Total acidity (0.50 %) at ripening stage was found in variety Pusa Early Dwarf. Maximum lycopene (4.93 mg/100g) at ripening stage was found in germplasms Kalyanpur Selection-6 and β carotene (1.50 mg/100g) at ripening stage was found maximum in germplasms Kalyanpur Selection-3. Whereas, total chlorophyll (1.77 mg/100g)at ripening stage was found maximum in germplasms NDTH-90 chlorophyll a & b (1.27, 0.58 mg/100g) at ripening stage was found maximum in variety/germplasms NDTH-108 & Pusa Early Dwarf .Whereas Polyphenol oxidase (35.87 unit/mg) and Peroxidase enzyme (1.80 unit/mg) were found maximum in variety /germplasms Arka vikas & NDTH-108. have highest total sugar (6.40 %) and non-reducing sugar (1.80 %) at ripening stage was found maximum in variety CO-3, T.S.S. content (4.83 %) at ripening stage was found highest in germplasms NDTH-101 and reducing sugar (4.77 %) was found maximum in germplasms Kalyanpur Selection-6, Total free amino acid (12.73 mg/100g) as found maximum in germplasms Kalyanpur Selection-6. Maximum lycopene (4.93 mg/100g) at ripening stage was found in germplasms Kalyanpur Selection-6.

Key words:- Fruit size, weight, specific gravity, colour, lycopene, β carotene, chlorophyll a and b , ascorbic acid, total mineral, titrable acidity, Polyphenol oxidase, Peroxidase. T.S.S., total sugar, non-reducing sugar, reducing sugar, lycopene and total free amino acid.

Introduction

The tomato (Lycopersicon esculentum Mill.) is one of the most widely consumed and most popular fresh vegetable in the industrialized world. Tomato belongs to the family Solanaceae having diploid chromosome number (2n=24). It is the world's largest vegetable crop after potato and sweet potato but it tops the list of canned vegetables. It is an important condiment in most diets and a very cheap source of vitamins and antioxidents. It also contains a large quantity of water and calcium and Niacin which are of great importance in the metabolic activities. Tomato is a good source of vitamins A, C, E and minerals that are very good for body and protect the body against diseases (Taylor, 1987).

Tomato is the second most widely grown vegetable crop in the world other than potato **(Hanson et al., 2001)**. Canada is the second larger producer of tomato next to Mexico. Total area of world under tomato cultivation is 4.50 million ha and total production is 240.51 million tonnes with 31.8 tonnes /ha productivity whereas, in India total area is 0.767 million ha and production is 16.385 million tonnes with 21.353 million tonnes /ha productivity. In U.P., total area is 0.010 million ha, production is 0.413 million tonnes with 39.488 million tonnes /ha productivity. **(NHB, 2014-15)**. Tomato crop is adapted to a wide variety of climates ranging from the tropics to within a few degrees of the Arctic Circle. However, in spite of its broad adaptation, production is concentrated in few warm and rather dry areas. Though, it is a perennial plant in tropical climates, it is grown as an annual in North America. Tomatoes find numerous uses in both fresh and processed forms that include ketchup, sauces, pastes and juice. Tomato is considered as an important cash generating crop for small holders and medium scale commercial farmers providing employment opportunity in the production and processing industries **(Naikaet al., 2005)**.

Tomatoes commonly consumed in daily diets are a major source of antioxidants. Tomatoes being an important source of potassium, phosphorus, magnesium, iron, so necessary to the normal activity of nerves and muscles. Vitamins as A, B and C tomatoes is the third source of vitamin C in our diet and the fourth for vitamin A, through its content in beta-carotene or pro vitamin A. Phytosterols, compounds that help to keep cholesterol under control folic acid, which helps eliminate homocysteine, an amino acid whose metabolism is dependent on the metabolism of vitamins from B complex, especially that of folic acid. Compositionally, the tomato has a unique nutritional and phyto-chemical profile. The major phyto-chemicals in tomato are the carotenoids consisting of 60 to 64% lycopene, 10 to 12% phytene, 7 to 9% neurosporene, and 10 to 15% carotenes. Tomatoes based foods are the world rich sources of lycopene (Sgherri et al., 2008). Based on a fresh weight basis, tomato (on average) contains about 35 mg/kg of lycopene, with red cultivars containing in average 90 mg/kg of lycopene and yellow ones only 5 mg/kg Processed tomatoes (sauce, paste, juice, and ketchup) contain 2- to 40-fold higher lycopene than fresh tomatoes.

Materials and Methods

The experiment was conducted in the department of vegetable science at MES of vegetable farm, Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya (U.P) during the Rabi season 2016-2017. The climate of Ayodhya comes under the category of semi-arid.

The fruit size has been taken by varnier callipors and specific gravity by water displacement methods. Total chlorophyll, total free amino acid and chlorophyll a and d were analysed by Jayraman (1981). TSS and acidity have been done by Rangana (1986) Reducing sugar have been analysed by Miller (1959) and Total sugar by the Dubois,et.al method. Lycopene have been done by Adsule etal.1979 and β carotene by Collumn method, 1953.Total mineral content have done by hort and Fischer, 1971 method and ascorbic acid by AOAC,1970 method. Polyphenol oxidase have been determined by Farkas *etal.* 1962 and Peroxidase was analysed by MaCune and Galston 1959.

Results and Discussion

The fruit length varied from 3.90-4.83 cm at ripening stage was respectively. These results are nearly corresponding with **Chattopadhyay *el al.* (2013)**. The fruit size decreases at ripening stage is attributed to the loss of moisture and carbohydrates in accordance with **Karki (2005)**. The fruit diameter varied from 4.80-7.17 cm at ripening stage. These results are nearly corresponding with **Chattopadhyay *el al.* (2013)**. The fruit size decreases at ripening stage is attributed to the loss of moisture and carbohydrates in accordance with **Karki (2005)**.

In the present investigation, average fruit weight of tomato varieties / strains at ripening stage was ranged from 46.97-95.33 g, the similar data was found by Leonardi *et al.* **(2000)**. The fruit weight decreases within excepted of weight loss per cent, the mean weight loss at ripening stage was varied weight loss 11.16 per cent are in accordance with **Getinet *et al.* (2008)**.

Biochemical and physiological studies on Rhizobium inoculated chickpea (*Cicer arietinum* L.) cultivar grown in eastern Uttar Pradesh

Harendra Singh, Mritunjay Tripathi*, Pratibha Singh and Rajan Pratap Singh

Department of Biochemistry, N.D. University of Agriculture and Technology. Kumarganj, Faizabad-224 229, Uttar Pradesh, India.

Received: 29-04-2016 Accepted: 23-03-2017 DOI: 10.18805/lr.v0iOF.9103

ABSTRACT

Health promoting biochemical parameters of fifteen distinct chickpea cultivar (Desi and Kabuli) showed wide variability in their biochemical and physiological composition, malic acid content, days to 50% flowering, primary branches per plant, number of pods per plant. Mulic acid content polled mean ranged from 0.40 to 0.49 % in control, *rhizobium* inoculated 0.46 to 0.54% and 0.42 to 0.50% in control, *rhizobium* inoculated 0.49 to 0.54 % at 45 DAS and 90 DAS respectively, pooled mean primary branches per plant in different genotypes ranged from 4.45 to 5.70 in control and 4.90 to 6.45 in *rhizobium* inoculated chickpea genotypes, days to 50% flowering in chickpea ranged from 75.00-87.00 days in control, *rhizobium* inoculated 75.00-86.00 days, number of pods per plant in chickpea ranged from 21.98-62.91 in control, *rhizobium* inoculated 26.85-73.02. The research result about the biochemical characteristics of control and rhizobium inoculated chickpea genotypes are expected to provide guidelines for the researches confronted with the need to use such typical food seed in India as well as in the rest of the world.

Key words: Cultivar, Days to 50% flowering, Malic acid content, Number of pods per plant, Primary branches per plant.

INTRODUCTION

Chickpea is ancient cultivated crop of South Asia, the middle East and the South Africa that has grown for many years in these regions (Shah *et al*., 2012). It is a rich source of proteins and provides best food of vegetarians (Yadav *et al* .,2007). It contain about 16-31.2 % proteins and 38.1-73.3 % carbohydrates (Sehirali.1988). Like other grain legumes, chickpea is a good source of mineral and vitamins. Consumption of whole seed of chickpea is desirable science its seed coat contribute about 70 % of the total seed calcium (Williams and Singh,1987).

The leaves of chickpea secretes malic acid but the significance of this secretion is not known. The PEP carboxylase activity and the secretion of malic acid are associated with the presence of glands on the surface of leaves and fruit. PEP activity increase while malic acid secretion and malic dehydrogenase activity decrease in water stress plants. However, the significant malic acid secretion in chickpea should be consider in relation to the insect pest of the plant (Koundal and Sinha, 1983).

Different chickpea varieties showed genetic variability for plant height, number of primary branches, number of secondary branches, number of pods per plant and total biological yield (Qureshi *et al*, 2004).

Besides, this medicinal importance can not over looked as scurvy patients are advised by the doctor to take germinated gram seed to get rid-off. Malic and oxalic acid collected from green, leaves of gram are prescribed for intestinal disorders (Wealth of India 1950). Germinated seeds are recommended as a prophylactic agent against deficiency. diseases. Keeping in view of above utmost importance of chickpea pertaining to human health, diversified use and insufficient inferences of the present investigation was undertaken.

MATERIALS AND METHODS

The present investigation on "Biochemical and Physiological studies on Rhizobium inoculated chickpea (*Cicer arietinum* L.) cultivar grown in eastern U.P." was carried out at Student's Instructional Farm and in the laboratory of Department of Biochemistry during *rabi* season of 2010-11 and 2011-12. After harvesting the seeds were collected and stored in desiccators for the analysis of various biochemical parameters.

Malic acid content was determined by the method described in A.O.A.C. (1970). The total number of primary branches per plant on five plants randomly selected from each line was counted and averaged out at the line of maturity. Days to 50 % flowering was recorded as the number of days from sowing to the date on which 50 percent plants of each plot flowered. Total number of seeds bearing mature pods were counted separately from sampled five plants in each row and averaged out for single plant.

Biochemical and antioxidative characters of underutilized fruits (Aonla, Bael, Ber, Jackfruit and Kaitha)

Anil Kumar and Pratibha Singh

Abstract
Biochemical and antioxidative evaluation of five underutilized fruit germplasms/varieties i.e Aonla (NA_6 and NA_7), Bael (NB_5 and NB_9), Ber (Karaka and Umran), Jackfruit (NJ_2 and NJ_3) and Kaitha (K_1 and K_2) resulted a slight variation within two varieties of each fruit containing to total soluble solid (TSS), malic acid, total phenols and ascorbic acid. Antioxidative characters were found higher in fresh fruit as compared to storage. On whole germplasms/varieties i.e Aonla (NA_6 and NA_7), Bael (NB_5 and NB_9), Ber (Karaka and Umran), Jackfruit (NJ_2 and NJ_3) and Kaitha (K_1 and K_2) were found best in terms of qualitative as well as biochemical and antioxidative evaluation.

Keywords: Underutilized fruits, TSS, malic acid, total phenols, and ascorbic acid

Introduction
Southeast Asia is represented by more than 500 species of fruits, while the Indian region of diversity represents 344 species of fruits having vast potential for new crops (Arora, 1995). Despite the vast biochemical and genetic diversity of these fruits, only important fruits like mango, banana, citrus and guava have gained in the productivity and acceptability by the people. Many of the indigenous tropical and temperate fruits have still remained underexploited due to the lack of awareness of their potential, market demand and low and erratic bearing in many cases. In view of the great importance of these underutilized fruit species and urgent need to strengthen the biochemical, genetic resources and improvement work.

India is the second largest producer of fruits in the world nearly covers 6.36 million hectares of area with a total production of over 88.82 million metric tonnes with productivity of 13.97 tonnes/ha. In Uttar Pradesh it is grown on 0.46 million hectares with production of 8.54 million metric tonnes, under fruit crops ranks first in terms of area, but production-wise it ranks third (Horticultural Statistics at a Glance, 2015-16) [13].

There are several fruits taken by human as its nutritional importance but several fruits are present in nature which are also nutritionally important and superior in quality but are rarely used by human because people are not aware of its nutritional importance, these fruits are known as minor fruits *viz.*, Ber, Bael, Aonla, Kaitha, Jackfruit, Karonda, Imli etc.

Gorh is a ber variety was superior in terms of ascorbic acid (176.45 mg/100g), protein (3.13%) and TSS (24.01%) (Abbas *et al.* 2012) [2]. Fresh aonla fruits of cv. Chakaiya had moisture, TSS, total sugars, reducing sugars, acidity, ascorbic acid, pectin, tannin, crude fibre, pH and browning were recorded as 86.50 per cent, 10.10 per cent, 8.53 per cent, 5.14 per cent, 1.85 per cent, 662 mg/100 g, 1.93 per cent, 2.93 per cent, 3.07 per cent, 2.90 and 0.063, respectively (Daisy and Singh 2007). Biochemical analysis of wood apple (Kaitha) revealed that the total soluble solids ranged from 12.45 to 14.67^0 Brix, ascorbic acid from 4.87 to 6.26 mg (per 100 g), reducing from 2.70 to 3.11%, non-reducing sugar from 4.90 to 6.79% and total sugar from 7.60 to 9.74% (Pandey *et al.*2013) [18]. Biochemical constituents of bael fruits such as total soluble solids, total sugars, reducing sugars and acidity percentage were analyzed to be 28.20, 16.72, 4.53 and 0.39, whereas ascorbic acid, total carotenoids, pectin and total phenols were found to be 17.21 mg/100 g, 45.33 mg/100 g, 2.40, 23.66 mg/100 g, respectively (Punam *et al.* 2009) [21]. Jagadeesh *et al.* (2010) [14] reported the biochemical parameters starch content (67.30%), TSS: Acid ratio (34.69%) and titratable acidity (31.76%) exhibited a wide variation of jackfruit clones for crop improvement.

Abstract: The present study was conducted to develop low fat fibre enriched paneer suitable to meet the requirement of people suffering from obesity, heart diseases, hypertension and diabetes. Double toned milk was successfully utilized for preparation of lowfat paneer with acceptable sensory attributes like appearance, colour, flavor, texture and overall acceptability. Four coagulants namely allum, citric acid, curd and lemon at a minimum level of 0.6, 0.2, 22.0 and 3 percent, respectively were needed for coagulation of milk. Standardization of pressure for preparation of lowfat paneer from double toned milk resulted in a paneer with optimum moisture and highest paneer yield when pressure equal to the weight of whey was applied.

Introduction

Paneer is Heat-acid Coagulated and an important indigenous milk product, which is extensively used as base material or filler in preparation of large number of culinary dishes. According to PFA act "Paneer means the product obtained from cow or buffalo milk or combination thereof by precipitation with sour milk, lactic acid or citric acid". Marble white color, mildly acidic taste, nutty flavor, spongy closely knit body and smooth texture are characteristics of a good quality paneer. Paneer is a South Asian variety of non-fermentative, non-renneted, non-melting and unripened type of soft cheese obtained by acid and heat coagulation of milk. Paneer is highly nutritious and wholesome food as it contains high amount of milk fat, protein, minerals along with moderate number of vitamins and other minor nutrients. Paneer is considered to be a rich source of animal protein for the vegetarian people, having a high biological value ranging between 80.38 and 86.56 [1]. For the preparation of this type of paneer, generally buffalo milk having a fat to SNF ratio of 1:1.65 is preferred. Because of its high fat content health-conscious people generally do not like to consume conventional paneer.

With increasing demand for paneer, advancement in the development of paneer is very important. Various advanced techniques can be applied in this venture but main problem with application of such techniques is consumer awareness regarding changes in textural & sensory quality of paneer. Therefore, in the present study efforts were made to development of low-fat fibre-enriched paneer because paneer contains high amounts of fat and no fibre.

Material and Methods

The study was conducted in the Department of Food Science and Nutrition, College of Community Science, Acharya Narendra Dev University of Agriculture & Technology, Kumarganj Ayodhya. The raw milk sample was procured from the local market. Other material skimmed milk, toned milk and double toned milk required for the product preparation were procured from the local market and Ayodhya market.

Standardization of coagulants

To prepare paneer four coagulants namely allum, citric acid, curd and lemon juice were tried and it was found that citric acid @ 0.2 per cent, allum @ 0.6 per cent, lemon @ 3.0 percent and curd @ 22.0 per cent could curdle the milk.

Standardization of weight and time for paneer preparation: After coagulation of milk different pressures 500g, 450g, 365g (weigh of whey) for 20 minutes was applied on the paneer to obtain paneer with appropriate moisture content and good texture.

Result and Discussion

Standardization of coagulants

The minimum level of coagulants needed for preparation of low-fat paneer from double toned milk. Four coagulants namely allum, citric acid, curd and lemon were tried. Citric acid @ 0.2 per cent resulted in curdling of milk whereas allum, lemon and curd at the level of 0.6, 3.0, 22.0 per cent resulted in curdling of milk [Table-1].

Table-1 *Minimum level of coagulants needed for preparation of low-fat paneer (Cottage cheese) from double toned milk (Mean ±SE)*

SN	Coagulants	Minimum level of coagulants needed (%)
1	Allum	0.6
2	Citric acid	0.2
3	Curd	22.0
4	Lemon	3.0

Various coagulants at various strength have been tested for coagulation of milk. Raja, *et al.*, (2014) [2] prepared paneer using 7.0 per cent buffalo milk and 30 per cent soya milk and 1.0 per cent acetic acid as coagulants. Several coagulants namely lemon juice, citric acid, tartaric acid and lactic acid have been tested for coagulation of milk by Kumar, *et al.*, (1998) [3], Sachdeva and Singh, (1987) [4]. They also reported that citric acid was more acidic as compared to curd. The strength of coagulants affects the body and texture of paneer, according to Khan and Pal, (2011) [5].

Identification and evaluation of rice (*Oryza sativa* L.) genotypes for drought and salinity tolerance: Growth and yield approach

Narendra Pratap Verma, RK Yadav, AK Singh, Shambhoo Prasad, Pratibha Singh, Alok Kumar Singh and Pradip Kumar Saini

Abstract
The investigation entitled Identification and evaluation of rice (*Oryza sativa* L.) genotypes for drought and salinity tolerance: growth and yield approach" was conducted during *Kharif* season, 2020-21 and 2021-22 at the field of Student's Instruction Farm, Acharya Narendra Deva University of Agriculture & Technology, Kumarganj, Ayodhya-224 229 (Uttar Pradesh). In same manner 72 rice genotypes/varieties were grown for phenotype screening for Salinity in Augumented Block Design in saline soil with four checks (two resistant check Narendra Usar Dhan 3 and CSR -10, two susceptible check Barani Deep and Jaya) and growth and yield parameters data were recorded. *i.e.,* Plant height at 65, 80 DAT (cm), Plant height at maturity (cm), Tiller number plant^{-1} (count), Flag leaf area (cm^2), Fresh weight plant^{-1} (g), Dry weight plant^{-1} (g), Panicle length (cm), Numbers of grains panicle^{-1} (count), Test weight (g), Grain Yield plant^{-1} (g). Reduction in growth parameters like, plant height, tiller number shoot fresh weight and dry weight was noted in all 40 genotypes under low moisture stress as well as in salinity stress. Drought tolerant variety Nagina-22 show minimal reduction in above said character under low moisture stress. While drought susceptible variety IR-64 show maximum reduction in these character under low moisture stress. In salinity stress salt tolerant variety CSR-10 & Narendra Usar -3 show less reduction with respect to susceptible varieties Jaya which show maximum reduction under salinity condition and Yield component like, Panicle length, total number of grains, test weight, and yield per plant of all verities decreased under both low moisture stress and salinity stress. However under drought condition, maximum reduction was noticed in IR-64 followed by Jaya while lowest reduction was seen in Nagina-22 followed by DRR-44, DRR-42 Sukha Dhan-5 & Sushk Samrat. In case of salinity stress minimum reduction in yield attributing traits was seen in tolerant varieties CSR-10, Narendra Usar-3, CSR-36, CSR-43 & Narendra Usar-2 while maximum reduction was found in susceptible varieties, Barani Deep, Jaya & IR-64.

Keywords: Rice, drought, salinity, growth and yield

Introduction
Rice (*Oryza sativa* L.) is a plant of Asian origin, belonging to the family of Graminae (Poaceae). Rice is the most widely cultivated food crop in the world and plays a very important role in providing essential nutrients to a large segment (approximately 90% of the Asian population) of the world's population as it is the staple food of more than half of the world's population and is considered as the backbone of food security in India, China, and other Southeast Asian countries (USDA 2020-21). Rice is cultivated on an area of 164.19 mha in the world with an annual production of 650.19 million tons (509.87 million tons of mild rice) Statista, 2022) and more than 142 mha in Asia. Rice occupies 43% of total food grain production and 46% of total cereal production. India ranks second among the top rice producers in the world after China. Within the country, rice occupies 1/3 of the total cropped area, contributes about 40 to 43% of total food grain production, and continues to play a key role in the national food and livelihood security system (Annual report 2021-2022 Dept. of agriculture & farmer welfare MA&FW India). India ranked first in the area having 45.07 million hectares and second in production 122.27 million tonnes. The productivity of rice in India is 2713 kg per hectare. The area and production of rice in the U.P. are 5.68 mha & 15.66 million tonnes per hectare respectively. Which is 12.60% of the total area in India & 12.81% of total production in India. The productivity of rice in UP is 2759 kg per hectare. UP has ranked first in the area and second in production (Agriculture statistics at a glance, 2021).

Controling pod borer (*Heliocoverpa armigera*) by natural toxin(s) in pigeon pea

NA Khan, Raja Husain, Anamika Kaushal, Pratibha Singh, KN Singh

Received: 09 February 2017; Revised Accepted: 13 April 2017

ABSTRACT

Among various constraints pigeon pea production, the insect pest has one of the prime importance. *Helicoverpa armigera* is one of the most divesting pests of this crop. Excessive use of chemical pesticides has resulted in environmental degradation, adverse effects on human health and other organism. For eradication of this insect, the researchers have shifted from chemical to biological control. The naturally killed larvae of *Helicoverpa* were crushed and growth was tested on LB agar plate, which got the *Helicoverpa* larvae dead due to bacterial micro-organism and growth on PDA media indicated the presence of fungi. The protein profiling of bacterial protein on (SDS-PAGE) 12%, indicated very low molecular weight of protein which was responsible for death of *Helicoverpa armigera*. The ammonium sulphate fraction of bacterial protein was applied @ 30%, 60% and 70% on live larvae. The rate of mortality was maximum in case of 70% ammonium sulphate fractionated protein.

Keywords: Ammonium Sulphate, PDA media, SDS-PAGE, Sephadex G-75

Introduction

Pigeon pea is an important pulse/grain legume and commonly known as red gram or arhar. It is the rich source of protein, iron, iodine and essential amino acids likewise methionine, lysine, tyrosine (Alykroid and Doughty 1964) and also supply vitamins-B, minerals and fats. The presence of different type of proteins and their smaller molecules including alkaloids, is flavones, polyphenols and a variety of oligosaccharides make legume seed unique in providing nutraceuticals. Asia produces 3.00 million tones grains from 3.81 million hectare area with 789 kg/ha productivity. India accounts for 78% of global output with current production of 2.45 million tones from 3.80 million hectare recording average yield of 686 kg/ha. In UP it is grown on 0.33 million hectare area producing 0.30 million tones of grain with average yield of 910 kg/ha (FAO, 2006). Among various constrains of pigeonpea production, the insect pest are of prime important. Pigeon pea is crop of intermediate plant type with long duration hence serves as an ideal host for many insect pests. Disease and insect pest are estimated to cause yield losses from 470 to 988 kg ha^{-1} (FAO STAT, 2008). More than 200 insect species have been reported infesting this crop. Major pest of pigeon pea are pod fly and pod borer. In India 3 species of *Helicoverpa* are found viz. *H. armigera*, *Helicoverpa assulta* and *H. peltigera* .The larvae of *H. armigera* destroys the buds, flowers and pods. It bores inside the pod of pigeon pea during vegetative state and damages inside the pod. In the absence of pod larvae feeds on foliage. The world wide annual losses caused by *H.armigera* in pigeon pea are $ 317 million (Shanower *et al;* 1999). In India yield losses of pigeon pea due to insect and disease ranged from 470 to 988 kg ha^{-1} which accounts for 29-85% of grain yield in different cultivars. The non-judicious use of chemical insecticides has led to the development of resistance to one or more multiple insecticides in over 500 species of insects (Akhurst,

Changes in the cell wall degrading enzyme and peroxidase activities during development and ripening of guava cv. Allahabad Safeda (*Psidium guajava* L.)

Aparna Dube, Mritunjay Tripathi and Pratibha Singh

Department of Biochemistry, College of Agriculture, Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad - 224 229 (U.P.), India

Received April 7, 2017 and Accepted July 9, 2017

ABSTRACT : Changes in the activities of cell wall degrading enzymes pectinmethylesterase (PME) and cellulase along with activity of antioxidant enzyme peroxidase (POD) were investigated during development and ripening stages of guava fruit cv. Allahabad Safeda. PME activity increased up to the climacteric peak of respiration, whereas cellulase showed progressive increase in activity throughout ripening. Similarly, POD activity decreased during development of the fruits and increased in the pre-ripening and ripening stages.

Key Words : Guava, enzyme changes, cellulase, peroxidase, fruit ripening

Guava (*Psidium guajava* L.) is the most important commercially grown fruit crop that occupies a crucial place in the horticultural wealth of our nation and ranks fourth with respect to area and production. In recent years, this fruit crop has gained considerable prominence on account of its high nutritive value, pleasant aroma, good flavour and availability at moderate price (Negi *et al.*, 2014). Although, our country has great potential to produce high quality guavas and to export them to other countries, its marketability is still limited to local markets due to delicate nature of the fruit, poor handling practices, and inadequate transportation and storage facilities. Ripening is the process by which fruits attain their desirable flavour, quality, colour, palatable nature and other textural properties. The most obvious feature of guava fruit ripening is softening,which reflects chemical and physical changes in cell wall. Fruit softening is associated with cell wall disassembly and modifications to the pectin fraction are some of the most apparent changes that take place in the cell wall during ripening.

Materials and Methods

Guava (*Psidium guajava* L.) fruit *cv.* Allahabad Safeda was used as experimental material which was harvested from Main Experiment Station, Horticulture Farm, NDUAT, Kumarganj during winter season. The sample was free from blemishes, any visible sign of disease, infestation and physical injury. For enzymic studies, pulp without seeds from fresh fruits was dipped in liquid nitrogen and stored in an ultra-freezer maintained at 80 ± C.

Cell Wall Degrading Enzymes

Enzyme assays

Pectinmethylesterase : Pectinmethylesterase activity (PME, EC 3.1.1.11) was assayed by the procedure of Mazumdar (2003). Enzyme was extracted from fruit pulp (5g) by homogenizing with a mixture of 10 per cent sodium chloride solution, 1 per cent EDTA and 1 per cent PVP at 4°C for 15 minutes. PVP was added to bind the phenolic compounds which inhibit enzyme activity. The homogenate was adjusted at 7.0 pH with 0.1 N NaOH solution. Then it was centrifuged (30000g) at 4°C for 10 minutes. The supernatant was used as an enzyme extract for assay of enzyme activity. The reaction mixture containing 20 ml of 1 percent pectin solution and 5 ml of 1 M NaCl were taken in a beaker. Then 10 ml of distilled water was added to it and the beaker was placed over a hot water bath at 30°C. The reaction was started by addition of 10 ml of enzyme extract with continues stirring. The pH of the reaction is adjusted to 7.5. The reaction was carried out at 30°C

ABSTRACT

Aloe vera has a long history as a medicinal plant with diverse therapeutic applications. This study determined biochemical composition and enzymatic activity of *Aloe vera* leaves. Five genotypes of aloe vera leaves were analysed biochemically and enzymatically. Germplasm IC-112517 showed maximum gel percentage (97.00 %), maximum moisture percentage (97.03) and IC-112527 contain maximum per cent of carbohydrate (64.20%), total mineral (11.10%) and total sugar content (30.07%) and total chlorophyll content (0.20 mg/gm). The germplasm IC-285626 showed maximum per cent of crude fibre content (11.43%). Germplasm IC- 112527 showed maximum catalase enzyme activity (1.92unit/ml) and peroxidase enzyme activity (1.67 unit/ml). Overall this investigation has provided a succinct resume of information regarding the biochemical composition and enzymatic activity of *Aloe vera* leaves. It would be worthwhile embarking on an intensive scientific experimentation and investigation on this valuable medicinal plant and to promote its large scale utilization.

Introduction

Aloe vera (*Aloe barbadensis*) is a perennial, drought resisting succulent plant belonging to the Liliaceae family with its origin in the African continent. The *Aloe vera* plant has been known and used for centuries for its health, beauty, medicinal and skin care properties (Rai *et al.*, 2011). The parenchyma cells contain a transparent mucilaginous jelly which is referred to as *Aloe vera* gel (Ramachandra and Rao, 2008). In India it is used as tonic for anemia, poor digestive function and liver disorders. *Aloe vera* is being used as an ingredient for functional food, mainly in the development of health drinks and beverages like tea, *etc.* (Singh *et al.*, 2010). *Aloe vera* is the most commercialized aloe species and processing of the leaf pulp has become a large worldwide industry. In the food industry it has been used as a source of functional foods and as an ingredient in other food products for the production of gel containing health drinks and beverages. In the cosmetic and toiletry industry, it has been used as base material for the production of powders, capsule, creams, lotions, soaps, shampoos, facial cleansers, oils and other products for both external and internal uses for a wide variety of indications (Hamman, 2008; Haque *et al.*, 2012). *Aloe* has broad range of pharmacological

ABSTRACT

The present investigation was carried out to study the Nutritional component in finger millet. Biochemical characteristics such as protein, Total minera! content carbohydrate content,Total sugar content and reducing sugar content were studied in present investigation in finger millet varieties. Ten germplasm such as namely VL- 175, VL-149, VL-101, VL-201, VL-204, VL-315, VL-324, VL-347, VL-124 and VL-146 were selected for present investigation and were analyzed for biochemical parameters the variation in . Protein content ranged from 7.60 – 9.20%, total mineral from 2.50 to 3.50%, total carbohydrate content from 69.70 to 74.80 %. Total sugar from 1.40 to 2.90 % and reducing sugar 0.50-0.90 % these parameters were effective for selection of better germplasm in finger millet.
Key word- Finger millet, Protein, Total mineral, carbohydrate, Total sugar and reducing sugar.

INTRODUCTION

Finger millet (*Eleusine coracana*) belongs to family Poaceae. Which is also known as 'ragi' in India is an important staple food for people belong to the low socio-economic group. It is the third most important minor millet in India. It is also known as African millet. . As nutritional supplement, the food products are fed to pregnant and lactating mothers, babies and the sick persons. Finger millet is primarily consumed in developing countries and it is often referred to as a "crop for the poor" or a "famine food", because of and high nutritional and medicinal properties it has proved to be a "super cereal". Rich source of phytochemicals and dietary fibre which offer several health benefits. The hyperglycemic activity of ragi millet has evidence the hypoglycemic, hypochole-sterolaemic, nephroprotective and anticataractogenic properties of finger millet, suggesting its utility as a functional ingredient in diets for diabetics. The women with signs of cardiovascular disease like high blood pressure, increased cholesterol content. It also forms an essential part of nervous system and cell membranes. The body metabolism linoleic acid into arachidonic acid and docosahexaenoic acid, respectively, which are essential to the normal development of the central nervous system (Brich *et al.* 2007).

Brown varieties contained (1.2–2.3%) higher proportions of polyphenols than white (0.3–0.5%) varieties of this minor millet.'The main polyphenols in this minor millet are phenolic acid and tannin, while flavonoids are present in small quantities. Ragi had highest phytic acid (685 mg/100g) total polyphenols 298 mg/100g, and tannins (18.75mg/100g), flavonoids (23.68 mg/100g) and trypsin inhibitors (102.6mg/100g) (Kumar *et al* 2013). Most of the Indian diet is deficient in one or two nutritional component so this millet is helpful in providing protein, vitamin and minerals. Considering the importance ragi millet the present study was conducted to estimate various nutritional content.

METHODS AND MATERIALS

Experimental Materials:

Ten germplasm of Finger millet (Ragi) namely VL- 175, VL-149, VL-101, VL-201, VL-204, VL-315, VL-324, VL-347, VL-124, VL-146 were collected from different parts of country Kosi, Uttarakhand, Almora, Uttarakhand, Patna, Bihar, and Rachi Jharkhand were used as experimental materials in the field trail.

Bio-chemical evaluation of landraces/hybrid rice in Eastern Uttar Pradesh

NITIN VIKRAM[1*], RAJA HUSAIN[2], RAJ NARAYAN KEWAT[3], PRATIBHA SINGH[4] and N.A. KHAN[5]

Department of Biochemistry, N.D. University of Agril. & Technology, Kumarganj, Faizabad - 224 229 (Uttar Pradesh)

Received : 16 June 2016 ; Revised accepted : 24 December 2016

ABSTRACT

The physico-chemical characteristics such as physical (seed size, L/B ratio, grain classification), chemical (alkali spreading value, amylose content), cooking characteristics (cooking time, KLAC, elongation ratio), organoleptic quality and protein profiling were studied for landraces/hybrid rice varieties from Eastern Uttar Pradesh. Some of landraces/hybrid rice varieties are with excellent biochemical characteristics. The rice variety MEPH 113 which has good grain quality could be used in breeding programmes. Highest seed length (10.29 mm) and seed breadth (3.11 mm) and amylose content (24.53) was recorded in hybrid rice MEPH 113, whereas lowest value 7.89 mm, 2.00 mm and 14.58 for the same quality were observed in Narendra Lalmati and NDR 97 respectively. Maximum protein bands were recorded in NDR 97 and IR 64 (12) and minimum were recorded in XRA 27934. The paper has concentrated on the physical characteristics and organoleptic test and biochemical analysis with consumer preferences of rice varieties. Organoleptic analysis always helps the consumers to select better rice varieties for their consumption and use. It is also emphasized that the training and recruiting the sensory expert panel are important in the process of sensory analysis and organoleptic test. The co-efficient of correlation between L/B ratio and cooking time, alkali spreading value, amylose content was negative significant and seed length, seed breadth, KLAC were positive significant.

Key words : *Acrylamide, Alkali spreading value, Bio-chemical characters, Hybrid rice, Protein, Seed size.*

INTRODUCTION

Rice (*Oryza sativa* L.) is a member of family *Poaceae* is a cereal foodstuff which forms an important part of the diet of many people worldwide. It provides 21% of the human per capita energy and 15% of the protein globally (FAO, 2003). More than 90% of the world's rice is grown and consumed in Asia, where 60% of the calories are consumed by 3 billion Asians (Khush, 1997). India stands first in area, second in production, followed and preceded by China on these two aspects (Bajpai *et al.*, 2012). Grain quality has always been an important consideration in rice variety selection and development. Rice grain quality is a complex characteristic including many components such as appearance, cooking qualities and eating qualities (Rabiel *et al.*, 2004). Rice is consumed in the milled form, the physical attributes of the intact endosperm are of foremost importance in determining consumer preference. Therefore, the percentage of head grain, grain dimensions, weight, chalkiness, translucency of the grains, cooking and eating quality should be considered during the development of hybrid varieties (He *et al.*, 1998). The eating and cooking properties are affected by the starch, protein and protein interaction, only structural changes occur rather than the change in the starch and protein interactions.

The present investigation was carried out with the objective of studying several quantitative, qualitative and nutritional parameters among popular rice varieties of India.

MATERIALS AND METHODS

The investigations were carried out during *kharif* season 2013-14 and 2014-15 at the Student's Instructional Farm, Narendra Deva University of Agricultural & Technology, Kumarganj, Faizabad, Uttar Pradesh. Five varieties of hybrid rice Ankur 7042, XRA 27934, KPH 466, MEPH 113 and Pusa RH 42 were collected from the Crop Research Station, Masodha, Faizabad and landraces of rice Narendra Lalmati, Sarjoo 52, IR 64, Narendra 2064 and Narendra 97 collected from the Department of Genetics and Plant Breeding, N.D. University of Agriculture and Technology, Faizabad. These rice varieties were employed as the experimental material in trials. The row to row and plant to plant spacing were kept 20 cm and 15 cm, respectively. The seeds were sown at the rate of 22.5 kg

Biochemical composition of pearl millet germplasm collected from Eastern UP

JP Verma, RN Kewat, Pratibha Singh, RP Singh, Brijesh, Ajay Kumar and KK Mishra

Abstract
The present Investigation was carried out to study biochemical properties of pearl millet (*Pennisetum glausum* L.) genotypes. The various biochemical parameters such as corbohydrate NDBH-2(64.24g/100g), Protein Content pearl millet-3(11%), amino acids like tryptophan content NDHB-5(1.23mg/100g), lysine content NDBH-2(0.55mg/100g), Anti nutritional factors such as total phenolic content pearlmillet-5(49.69%) and tannin content pearl millet-6(1.84mg/100g) were recorded maximum in present investigation.

Keywords: pearl millet, corbohydrate, protein, tryptophan, lysine, total phenolic content, tannin content, total sugar & nonreducing sugar

Introduction
Pearl millet (*Pennisetum glaucum* L.) is also known as spiked millet, candle millet or dark millet in europe, cattail, pecillaria in USA, Bulrish millet or dukhn in Africa, Bajra, Combo or sajje in India. Pearl Millet is originated in central Africa. Pearl millet crop is grown in tropical semi-arid region of the world primarily in Africa and Asia. The hight of the pearl millet plant thay may range from 0.5-4.0 meter.

In India the major pearl millet growing states are Rajasthan, Maharasthra, Gujrat, UP and Haryana. These states together accounted for 92% of area and total pearl millet production of 9.20 million tonnes and productivity of 1161kg/ha (Anonymous, 2014) [2]. In Haryana, Pearl millet production was 8.31 lakh tonnes and productivity of 2057 kg/ha in an area of 4.04 lakh hectare, giving a yield of 1161kg/ha (Anonymous, 2014b) [3]. The starch content of pearl millet grain ranges from 62.8 to 70.5% reducing sugar from 0.1 to 0.26% pearl millet is also a good source of fat having about 4.36 to 7.11%. (Anonymous, 2015 Karamvir *et al.* 2015) It is free from major antinutrients but contain low amount of phenolics (Simwemba *et al.* 1984, kumar 2015). Total caltivated area in UP is around 0.84 million ha and production 0.95 metric tonnes. (Agriculture statistics Report 2014) People affected by gluten retated disorders such as celiac, non celiac gluten sensitivity and Wheat allergy suffers, needed gluten free diet can replaced gluten containing cereal in their diet. 100g pearl millet seed provides 11% protein, 73% corbohydrate, Mg 14mg and some other important nutrient like selenium 2.7µg (USDA).

Material and Methods
Ten germplasm of pearl millet were collected from different districts of utter pradesh namely Gonda Faizabad Balrampur Sultanpur Jaunpur Gazipur Bahraich and lakhimpur were used as experimental material. Samples of Pearl millet were brought to Biochemistry laboratary of NDUAT & Kumarganj Faizabad (UP) after collection. They were analyzed for various biochemical parameters. The collected pearl millet seed were cleaned dried and dried seeds were then crushed in pestle mortar in to powder form. The biochemical properties of the pearl millet powder were analyzed and the results were summarized. Total carbohydrate content analyzed by yamme and wills (1954) [10] Total Protein content in grain was determined by lowery's method (1951) [14] tryptophan content was estimated by the method given by spies and chamber (1949) [16], lysine content was estimated by felker *et al.* (1950), Total Phenolic content inpearl millet was analyzed by the method as described by swain and hillis (1984) [11], tannin content in pearl millet was determined by the method given by Rangana (1986).

Result and Discussion
The results on biochemical composition of pearl millet seed powder are shown in table. total corbohydrate in various germplasm was ranged between 54.42-64.24g /100g highest corbohydrate content was notieced in NDBH-2 (64.24g/100g).

Response of organic farming on quality evaluation of rice (*Oryza sativa* L.)

Harendra Singh, RP Singh, Divya Prakash Singh, Pratibha Singh and Rajan Pratap Singh

Abstract
The present investigation entitled "Response of organic farming on quality evaluation of rice (*Oryza sativa* L.)" was carried out during *kharif* season on randomized block design with four replications in sarjoo- 52 variety. Five treatments of organic farming were taken namely T_1 (In situ decomposition of rice straw and pressmud @ 5.0 t/ha with PSM and *Azotobacter*), T_2 (In situ decomposition of rice straw and FYM @ 5.0 t/ha with PSM and *Azospirillium*), T_3 (In situ decomposition of rice straw with pressmud @ 10.0 t/ha and PSM), T_4 (In situ decomposition of rice straw with FYM @ 10.0 t/ha and PSM), T_5 (In situ decomposition of rice straw with poultry manure @ 5.0 t/ha and PSM).
Maximum and minimum test weight of rice variety was noticed in treatment T_5 (29.00g) and treatment T_3 (25.00g). Highest L: B ratio was recorded in treatment T_5 (3.00) while minimum L: B ratio was noticed in treatment T_3. Maximum starch iodine blue value was recorded in treatment T_5 (70.73%) while minimum starch iodine blue value was recorded in treatment T_4 (70.60%). The protein content was observed maximum in T_5 (8.85%) and minimum protein content was noticed in T_3 treatment (7.73%). The amylose content was noticed highest in T_5 treatment (22.90%) and minimum content was reported in T_3 treatment (20.47%). The total mineral content of rice grain was observed maximum in T_5 treatment (1.40%) while minimum content was recorded in T_3 treatment. The protein profiling of rice grain quality indicates the prominent bands showed in the T_5, T_4 and T_3 treatment while light band showed in T_1 and T_2 treatments.

Keywords: organic farming, rice, protein, amylose, total mineral, protein profiling

Introduction
Rice is the staple food of more than 60 per cent of world's population. About 90 per cent of all rice grown in the world is produced and consumed in the Asian region. In India, rice is the most important and extensively grown food crop, occupying about 44.8 million hectare of land. Organic farming refers to a particular farming system that uses organic manure, limited range of naturally derived chemicals. Organic farming uses no growth regulators, artificial additives; biosides are synthetic chemical sprays (Beharrell and Macfie, 1991) [2]. Overall goal of organic farming is to use agricultural methods that have the smallest impact of the environment and provide the largest benefits to the people (David Suzuki Foundation, 2002) [3]. The National organic board of USA defines organic farming as an ecological production management system that promotes and enhances biodiversity, biological cycles and soil biological activities. The focus is on ecological compatible production system and process, not on the product itself or the specific inputs (GOI, 2001) [6]. Balance fertilization through organic soruces collectively improves the grain quality and soil health. Keeping in view the immense role of organic farming in rice crop, the present investigation entitled "Response of organic farming on quality evaluation of rice (*Oryza sativa* L.) were under taken.

Materials and Methods
The experiment was conducted at Agronomy experiment farm of Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Faizabad (U.P.) in randomized block design having four replications. The experiment comprised of five treatments *viz.*, T_1 (In situ decomposition of rice straw and Pressmud @ 5.0 t/ha with PSM and *Azotobator*), T_2 (In situ decomposition of rice straw and FYM @ 5.0 t/ha with PSM and *Azospirillium*), T_3 (In situ decomposition of rice straw with Pressmud @ 10.0 t/ha and PSM), T_4 (In situ decomposition of rice straw with FYM @ 10.0 t/ha and PSM)and T_5 (In situ decomposition of rice straw with Poultry manure @ 5.0 t/ha and PSM). Rice crop (sarjoo -52) was sown at proper moisture. The test, weight was measured by electronic balance and L:B ratio was determined on the basis of average length and width of rice seed. Starch iodine blue value was

Assessment of Some Biochemical Characters of Four Mango Verities (Mangifera *India L.*) at Different Stages of Fruit Maturity

Siya Ram[1]*, Mohammad Halim Khan[2], and R.P. Singh[3]

[1]Department of Agricultural Biochemistry, Atarra P.G. College, Atarra (B. U. Jhansi), Banda (U.P.) - 210201, India.
[2]Department of Soil Science & Agricultural Chemistry, Atarra P.G. College, Atarra (B. U. Jhansi), Banda (U.P.) - 210201, India.
[3]Department of Biochemistry, N.D. University of Agriculture & Technology, Kumarganj, Faizabad (U.P.) –224229, India.

Abstract

Two sets of experiment were conducted at Mango orchard of Devgaon, Faizabad (U.P.) and SHUATS, Allahabad (U.P.) during two consecutive years of 2008-09 and 2009-10 with 4 varities of mango fruits namely "Dashehari, Langra, Chaunsa and Safeda" to asses some physicochemical and biochemical characteristics of mango fruits at 30, 60 and 90 days after fruit settings. Premature, mature and ripened fruits were evaluated for total sugar, protein, β-carotene and crude fibre content. Result revealed that highest amount of total sugar (20.62 and 20.84%), protein (0.90 and 0.91%) and β-carotene content (3031.00 and 3052.00µg/100g) at 90 days after fruit setting were recorded with Dashehari while maximum crude fibre content was noticed in Safeda (1.24 and 1.26%) at 30 days after fruit setting in 2008-09 and 2009-10 respectively. The minimum total sugar (17.26 and 17.33%), protein (0.81 and 0.83%), β carotene content (2373.00 & 2398.67 µg/100g) at 90 day, were recorded with Safeda while minimum crude fibre (0.61 & 0.62%) were recorded with Dashehari in both the year's of experiment.

Introduction

Mango (Mangifera *india L.*) belongs to the Anacardiaceae family, is one of the most important tropical fruits commercialized and consumed worldwide fresh or processed, having an attractive colour and distinct taste and aroma. India is the largest producer of mango accounting for nearly 50% of the total world production, 34.9% of the area under fruit crops in India, and 20.7% of the total fruit production of the country [1]. In Indian context, it is an important fruit crops ruling both domestic & export market. It is an excellent source of fibre and bioactive compounds such as carbohydrate, carotenoids, provitamins, vitamin C, protein, phenolics and other health promoting qualities [2]. Based on these qualities it is recognized as one of the best fruit in the world market and known as king of fruits. The biochemical composition of mango fruits differs among the cultivars and the stage of maturity. Mango fruits are highly perishable due to enzymatic and non enzymatic reaction that takes place during maturation, affecting nutritional, sensorial, physicochemical & biochemical properties. Besides riching in carbohydrates (sucrose, glucose, fructose and maltose), in mango fruits there are about twelve amino acids have been identified including the essential ones like alanine, aspartic acid, lysine, leucine, cystine, valine, arginin, phenylalanine and methionine. The highest concentrations of these amino acids are observed in fruits just after fruit set and the concentrations decreased with fruit development [3]. The aroma and flavor content were also varying widely among the mango cultivars and there is no one typical formulation of flavor component of mango fruits. In ripened mango fruits aroma and good flavor is released due to monoterpene hydrocarbons [4]. Both ripened and unripened fruits are used extensively by food processing industry to prepare variety of products, such as syrup, jam, squash, juice, cereal flakes, pickles, chutneys, candy, jam, jelly, squash, mango chips and nectar etc. [5]. Generally, mango is consumed at all stages of fruit development from the tiny imperfectly set fruits, that shed abundantly on to develop beyond the initial stage to the fully mature ones and development stages of the fruits including mature and ripened stage. Little information about some varietal physicochemical characteristics has so for been recorded [6, 7].

EVALUTION OF NUTRITIONAL VALUE AND ANTI NUTRITIONAL FACTORS OF KODO MILLET *(PASPALUM SCROBICULATUM* L.). GERMPLASM GROWN IN EASTERN (U.P.)

Radhey Shyam[1] and R. P. Singh[2]

[1&2]Department of Biochemistry, N.D. University of Agriculture & Technology, Kumarganj, Faizabad-224 229 (U.P.) India

Abstract

The persent study was conducted to evalutate ten advanced germplasm of Kodo millet for nutritional and anti nutritional factors during *kharif* season 2014-15 at the students Student's Instructional Farm of Narendra Deva University Agriculture and Technology, Kumarganj Faizabad (U.P.) India. A significant variation was detected for all traits suggested that there was considerable variability among germplasm. The protein content was recorded in the range of 8.56 to 9.44 per cent Maximum protein content was recorded in the germplasm K-6 (9.44%) followed by K-10 (8.90%) The total free Amino Acid content was recorded in the range of 62.01 to 72.62 mg/100g. Maximum total free amino acid content was recorded in the germplasm K-6 (72.62 mg/100g) and total mineral was recorded in germplasm K-10 (3.31%). Curde fiber content was recorded in germplasm K-8(8.73%) and total carbohydrate content was found between ranged 63.25 to 65.28% and maximum carbohydrate found in germplasm K-5 (65.28%). Total sugar content was found in the range of 2.41 to 3.92%. Maximum total sugar was found in the germplasm K-4 (3.92%). The anti nutritional content such as tannin was found in the range of 106.38 to 124.75 (mg/100g). Phytic acid 126.38 to 136.58 (mg/100g) and total phenol 18.83 to 21.83 (mg/100g). On the basis of overall germplasm were found superior K-4, K-5, K-6, K-8, K-9 and K-10 and utilized in further research work.

Key words: Cooking attributes, kodo millet.

Introduction

Kodo millet, one of the ancient grain of the world, originated from Africa and domesticated in India few thousand years ago is a drought resistant plant. This millet crop is grown in arid and semi-arid regions of African and Asian countries. In India, kodo millet is grown mostly in the deccan region and the cultivation extends to the foothills of Himalayas.

Kodo millet (*Paspalum scrobiculatum* L.), is an indigenous cereal of India and widely distributed in damp habitats across the tropics and subtropics of the World. It occupies an area of 9.08 lakh ha with an annual production of 3.11 lakh tonnes and average productivity of 342 kg/ha (Ahmad and Yadav. 1996). Kodo millet is propagated from seed, ideally in row planting instead of broadcast sowing and its preferred soil type is a very fertile, clay based soil (Agricultural service in, 2013). The kodo millet is prone to lodging at maturity, causing loss of grain (Dewet *et al.* 1983).

The Kodo millet is mainly grown in Madhya Pradesh, Andhra Pradesh, Tamil Nadu, Bihar, Gujarat, Uttar Pradesh, Maharashtra and Orissa. It is cultivated in U.P. mostly in Gorakhpur, Basti, Gonda, Deoria, Mirzapur and Sitapur districts. These millets are grown during *Kharif* (rainy season) and sown with the onset of the southwest monsoon. The Kodo grains are recommended as a substituted for rice to the patients suffering from diabetes.

Kodo millet contains 66.6 g of carbohydrates and 353 kcal energy per 100 g of grain, comparable to other millets. It also contains 3.6 g of fat per 100 g. It provides minimal amounts of iron, at 0.5mg/100 mg, and calcium, 27mg/100 mg. Kodo millet also contain high amounts of polyphenols, an antioxidant compound. (Hedge and Chandra, 2005). Kodo and little millets can be used for preparation of malted and alcoholic beverage production. (Nikita Sethi 2016).

Kodo millet is very easy to digest, it contains a high amount of lecithin and is excellent for strengthening the

STUDIES ON PHYSICALAND BIOCHEMICAL CHARACTERISTICS OF KODO MILLET GERMPLASM [*PASPALUM SCROBICULATUM* L.]

Radhey Shyam[1] and R.P. Singh[2]

[1&2]Department of Biochemistry, N.D. University of Agriculture & Technology, Kumarganj, Faizabad-224 229 (U.P.) India

Abstract

Millets are one of the oldest foods known to humans and cultivated since time immemorial. Kodo millet [*Paspalum Scrobiculatum* L.] is nutritious, healthy and versatile and hence would be a worthy addition to one's diet. Significant differences in nutrient composition and physico-chemical characteristics were observed of kodo millet. Moisture content of kodo millet seed was observed on the range 7.25 to 10.03 percent. Diameter of seed (1.71-1.97mm). kodo millet exhibited excellent cooking attributes The cooking time ranged from 9.61 -12 .21 minutes. Amino acids namely methionine was recorded (72.79 to 94.34 mg/g), Trypto Phane found in range (25.55 to 33.27 mg/g) and lysine was recorded (135.17 to 179.17 mg/g). The reducing sugar was found in the range (1.27 to 1.72 %) and non reducing sugar was recorded between (1.02 to 2.65 %). Followed by germplasm K-7 (2.21 %). On the basis of overall germplasm were found superior K-2, K-6, K-8, K-9 and k-10 and utilized in further research work.

Key words: Cooking attributes, kodo millet

Introduction

Kodo millet (*Paspalum Scrobiculatum L.*) is a group of grassy plant with short slender culm and small grains possessing remarkable ability to survive under severe drought. Kodo millet is multipurpose crop which is cultivated for food and fodder it can be cultivated in all types of soil and sustains adverse climatic condition. It is fast growing millet, occasionally producing ripe grains in 40 days after seedling (Nagar and Sharma 2005). Nutritionally kodo millet is an important crop and a good source of protein, which is highly digestible and is an excellent source of dietary fibre with good amounts of soluble and insoluble fractions. The carbohydrate content is low and slowly digestible, which makes the kodo millet a nature's' gift for the modern mankind who is engaged in sedentary activities. Moisture content determines the shelf life and milling characteristics of the grains it is interesting to note that kodo millet exhibited lower moisture content than other minor millets such as Proso, Little, Foxtail and Kodo millet with values ranging from 10.60 to 15.00 percent (Kulkarni and Naik 1999)

The Kodo millet is mainly grown in india, Pakistan, philipinse, indonacia weaitname, Thailand west affrica. It is measurd food source in the decame flatau of india. Kodo millet is nutrouse grown and good substituted in rice or weight the nutricutical composition. mainely protein fiber and mineral content are much hair the maijor cerial in rice. The kodo millet grain composed on 8 per cent protein the maijor protein fraction in kodo millet in glutein it is an excellent source of fiber 9 per cent as compare to rice (0.2%) and wheight (1.2%).

The nutritive value of millet is comparable to other staple cereals like wheat and rice; some of them are even better with regard to average protein, fat and mineral contents (Gopalan *et al.* 2007). Minor millets have also excellent nutritional value in view of their good protein content and better amino acid profile. Their starch composition and low glycemic index (which make them ideal for diabetic patients) are also accompanied by gluten free status of the flour, thus making them very suitable for the preparation of weaning products.

Millet is the richest source of Ca among cereals (340 mg/100g) of which only 162 mg/100 g is bioavailable in the raw grain. Processing improved its bioavailability up to 227 mg/100 g. Iron availability improved from 0.34 to 1.4 mg/100g due to processing Total free amino acids

ABSTRACT

The present investigation was conducted in four varieties of mango fruits namely Dashehari, Langra, Chausa and Safeda during 2008-09 and 2009-10. All the varieties of mango were collected from orchard of Devgaon, Faizabad (U.P.) to study the mineral profile and ascorbic acid content of mango fruits at 30 days, 60 days and 90 days after fruit setting. Mineral makeup was evaluated for important mineral content i.e. Ca, Mg, K, P, Fe and S. The result showed high variation among the mineral makeup and ascorbic acid content of ripened mango fruits. Highest amount of Ca, Mg, K, P, Fe and S content were noticed in Safeda (0.142%), Dashehari (0.254%), Dashehari (146.01 ppm), Safeda (0.022%), Safeda (0.673%) and Safeda (0.052%) respectively while lowest content were found in Chausa (0.138%), Chausa (0.189%), Chausa (108.66 ppm), Chausa (0.019%), Langra (0.622%) and Chausa (0.032%) respectively during ripened state in 2008-09. In 2009-10, the highest such mineral content were recorded in Langra (0.136%), Chausa (0.344%), Safeda (117.89 ppm), Dashehari (0.022%), Safeda (0.682%) and Safeda (0.038%) respectively, whereas lowest amount were observed in Safeda (0.128%), Dashehari (0.165%), Dashehari (78.96 ppm), Langra (0.017%), Dashehari (0.058%) and Dashehari (0.35%) in ripened fruits. Ascorbic acid content in mango fruits at different stages was observed between 13.37-26.33 mg/100g in 2008-09 and 14.67-27.33 mg/100g in 2009-10.

Introduction

Mango (*Mangifera indica* L.) belongs to the family Anacardiaceae, is one of the most important tropical fruits commercialized and consumed worldwide fresh or processed, having an attractive colour and distinct taste and aroma. India is the largest producer of mango accounting for nearly 50% of the total world production, 34.9% of the area under fruit crops in India, and 20.7% of the total fruit production of the country (1). In Indian context, it is an important fruit crops ruling both domestic & export market. It is an excellent source of fibre and bioactive compounds such as carbohydrate, carotenoids, provitamins, vitamin C, protein, phenolics and other health promoting qualities (2). Mango is the main fruit of Asia and developed its own importance all over the world. Being an useful and delicious fruit, it was the part of culture and religion

ABSTRACT : Fisheries play a promising role in socio-economic development by providing nutritional security for the I population and contribute to the economic upliftment of fisher folks. A total of 15 major 45 medium and over 102 minor of the country provide one of the richest fish resources of the world. It is however 15 major rivers that covers 83% of dra basin accounts for 85% of surface fold. The Uttar Pradesh has vast potential of aquatic resources and that offer consid scope for development of inland fisheries and aquaculture.

The fresh water resources of Uttar Pradesh have total area of 1, 61,372 hectare. Out of 123 species recorded in Uttar Pra about 33% are Ornamental fishes, rest 77% are potential food fishes and 10% are potential sport fishes. In India total species of fishes have been recorded – Freshwater species recorded are 877,113 are brackish and 1563 are from the water environment.

On the basis of the results obtained from the present study, it may be concluded that application of small indigenous f collected from Kushinagar, Gorakhpur and Faizabad district of Eastern Uttar Pradesh resulted in:-The healthy fish selected for the present investigations for morphometric and proximate compositions. The biochemical observations i present investigation shows carbohydrate ranges between 0.17-7.70%, protein 14.26-20.57%, reducing sugar 10.31-25.4 100g, non-reducing sugar 13.23-29.73 mg/100g, total sugar 23.85-56.48 mg/100g, total moisture 71.00-78.67%, fat 4.29%, total mineral content 1.11-4.26%,calcium 166.67-1197.00 mg/100g, phosphorous 113.00-351.67 mg/100g, iron 33.57 mg/100g, tryptophan 0.96-1.67g/16gN, methionine 0.14-2.40g/16gN,and lysine3.25-6.95 g/16gN. The Statistical sup morphometric enriched biochemical composition in *Puntius chola* and *Puntius ticto* species while *Chela bacalla* species less Morphometric but enriched in biochemical composition. The *Colisa fasciata* and *Puntius sarana* species are ri mineral content.

Key words : Small fishes, biochemical parameters.

INTRODUCTION

Fisheries play a promising role in socio-economic development by providing nutritional security for the Indian population and contribute to the economic upliftment of fisher folks. A total of 15 major 45 medium and over 102 minor rivers of the country provide one of the richest fish resources of the world.

The Uttar Pradesh has vast potential of aquatic resources that offer considerable scope of inland fisheries development and aquaculture. The four major constituents in the edible portion of fish are water, protein, lipid (fat or oil) and ash (minerals). Proper knowledge on the biochemical composition of fish finds application in several areas. Today there is an ever-increasing awareness about health foods and fish is finding more acceptances because of its special nutritional qualities. In this context, a proper understanding about the biochemical constituents of fish less become a primary requirement for nutritionists and dieticians.

Fish and fishery products are used in animal fe Fish as a whole is considered to have a great pote for food and thus can be expected to provide relief f malnutrition. Also, it is a very good source of prot have a high content of water and lipid soluble vitam minerals and polyunsaturated fatty acids (PUFAs) c 3 family. It is believed that Omega-3 fatty acids f fish can lower body triglycerides thus reducing chances of heart diseases. Fish also reduces bl pressure by small but significant amounts and impr blood clotting regulation. Fish however, is very suscept to microbial and chemical deterioration like lipid oxidat hydrolysis and protein denaturation etc.

The nutritional and medicinal value of fish has b recognized from time immemorial (Srivastava, 19

ABSTRACT

Rice is rich in genetic diversity, with thousands of varieties grown throughout the world. Rice cultivation is the principal activity and source of income for about 100 million households in Asia and Africa. Rice has potential in a wide range of food categories. Besides having nutritional and medicinal benefits, the byproducts of rice are equally important and beneficial. By-products from growing rice create many valuable and worthwhile products. Rice grain quality characteristics such as physiological and chemical based on consumer preferences like appearance, cohesiveness, tenderness on touching, chewing, taste, aroma, elongation and overall acceptability were studied for hybrid and landraces/traditional rice varieties.

Keywords
Grain, milling, organoleptic, kernel length and variety

Introduction

Rice (*Oryza sativa* L.) is a plant belonging to the family of Poaceae. It is one of the three major food crops of the world and forms the staple diet of about half of the world's population. The global production of rice has been estimated to be at the level of 650 million tones and the area under rice cultivation is estimated at 156 million hectares (FAOSTAT, 2008). Physiological characters of the plant are inherent characters determining the crop yield which plays an important role in variety selection (Miah *et al.*, 1996). Keeping the quality of aroma and other grain quality in aromatic fine rice is a big challenge as yield is inversely related to protein and aroma content (Terman, 1969). Hybrid rice is reported to contribute 5.6% of India's total rice production, nearly 15 years after its introduction and promotion. Hybrid rice is used in several preparations and has commercial and industrial importance. Besides grain its straw is used as fodder, packing insulation materials and in the manufacturing of the card board etc. In the Asian diet rice contributes almost 28- 54% proteins. Rice provides 27% of the world nutritional energy and 20% of overall nutritional protein (Bashir *et al.*, 2007). Grain quality in rice is very difficult to define with precision as preferences for quality vary from country to country. The cooking quality preferences vary in different countries (Azeez and Shafi, 1966). The aim of this study was to determine the physicochemical characteristics of selected

Periodical evaluation of enzymes and pigments in mango varieties during storage in card board carton by post harvest application of salicylic acid

Shivendra Kumar Vishwakarma, RP Singh, Pratibha Singh and RN Kewat

Abstract
Four varieties of mango namely Dashahari, Langra, Chausa and Safeda had been taken for the experiment. At maturity condition, mango fruits were harvested and stored in cardboard carton by post harvest application of salicylic acid at 0.1, 0.5 and 1.0 g/l doses. The analysis of pectin methyl esterase, cellulase, polyphenol oxidase, peroxidase, total chlorophyll and beta carotene were done at five days intervals after storage. Highest pectin methyl esterase enzyme activity (0.91 units/g) was reported in variety Dashahari at five days ambient storage period by 1.0 g/l salicylic acid application. Maximum cellulase and polyphenol oxidase enzyme activity (12.84 and 56.38 units/g) was reported in the variety Dashahari at five days ambient storage period by 0.1 g/l salicylic acid application. Highest peroxidase enzyme activity (463.69 units/g) was reported in variety Dashahari at 20 days ambient storage period after the application of 0.5 g/l salicylic acid treatment. Maximum total chlorophyll content (39.86 mg/g) was reported in the variety Dashahari at five days storage by 1.0 g/l salicylic acid application. Highest beta carotene content (3495.93 µg/100g) was reported in the variety Dashahari at 20 days ambient storage period by 0.5 g/l salicylic acid treatment. The present study indicated that after salicylic acid application pectin methyl esterase, cellulase, polyphenol oxidase and chlorophyll content decreased but the peroxidase and beta carotene content increased during storage in cardboard carton

Introduction

The total production of fruits and vegetables in the world is around 370 million tonnes. India ranks first in the world with an annual output of 32 million tonnes fruits; accounts for about 8 per cent the world fruits production (N.H.B. database, 2011) [20]. The total production of mango fruit in India is 15188 million tonnes with an area of about 2297 hectare. The biochemical composition of mango fruit differs among the cultivars and the stage of maturity. Mango fruit is rich in carbohydrates, carotenoids, organic acids, polyphenols, vitamins and minerals etc. A comprehensive report has been made on the biochemical composition after analysis of more than 25 varieties of mango is moisture 73.0 - 86.7 per cent, carbohydrate 11.6 – 24.3 per cent, protein 0.5 – 1.0 per cent, minerals 0.3 – 0.7 per cent, beta carotene 6375 – 20750 µg/ 100 g, vitamin C 6.8 – 38.8 mg/ 100 g (Anonymous, 1994) [2]. According to the Ministry of Food Processing Industry statement " the lack of processing and storage of fruits and vegetables results in huge wastages estimated at about 35 per cent the value of which is approximately Rs. 33000 crores for perishable and Rs. 15000 crores for non-perishable annually."

A worldwide increase in the demand of fresh mango fruit is being observed, increasing the prospect for producing countries (Amin *et al*., 2007) [1]. However, like all other fresh commodities, its market potential is also linked with the fruit quality and market access (Anwar and Malik, 2007) [3], whereas certain postharvest factors, like insect-pest and disease management, are important from production point of view, proper post-harvest treatments and packaging are required for maintaining better quality, extended shelf life and having access to international markets (Anwar and Malik, 2007) [3].

Salicylic acid (SA) is a colourless, crystalline organic carboxylic acid which is found in plants, especially in fruits, in the form of methyl salicylate. It is also known as 2-hydroxybenzoic acid, with functions as a plant hormone. Most investigators have focused on the role of

Evalution of physiological characteristics, nutritional composition and anti-nutritional factors of kodo millet *(Paspalum scrobiculatum* L.*)*. Germplasm grown in eastern U.P.

Radhey Shyam and RP Singh

Abstract
The present study was conducted to evalutate ten advanced germplasm of kodo millet for physiological traits, nutritional composition and anti-nutritional factors during khrif season 2014-15 at the student's Instructional Farm of Narendra Deva University Agriculture and Technology, Kumarganj Faizabad (U.P.) India. A significant variation was detected for all traits suggested that there was considerable variability among germplasm. Moisture content of kodo millet seed was observed in the range 7.25 to 10.03 percent. The yield/ear of kodo millet germplasm was found in the range of 12.24 to 15.82 q/h. The test weight in various germplasm was found in the range of 3.39 to 5.19 g seed. The protein content was recorded in the range of 8.56 to 9.44 per cent Maximum protein content was recorded in the germplasm K-6 (9.44%) followed by K-10 (8.90%) The total free Amino Acid content was recorded in the range of 62.01 to 72.62 mg/100g. Maximum total free amino acid content was recorded in the germplasm k-6 (72.62 mg/100g). Amino acids namely methionine was recorded (72.79 to 94.34 mg/g), Trypto Phane found in range (25.55 to 33.27 mg/g) and lysine was recorded (135.17 to 179.17 mg/g). And total mineral was recorded in germplasm k-10 (3.31%). Highst curde fiber content was recorded in germplasm k-8(8.73%) and total carbohydrate content was found between ranged 63.25 to 65.28% and maximum carbohydrate found in germplasm K-5 (65.28%). The reducing sugar was found in the range (1.27 to 1.72%) and non-reducing sugar was recorded between (1.02 to 2.65%). followed by germplasm K-7 (2.21%). Total sugar content was found in the range of 2.41 to 3.92%. Maximum total sugar was observed in the germplasm K-4 (3.92%). The anti-nutritional content such as tannin was found in the range of 106.38 to 124.75 (mg/100g). Phytic acid 126.38 to 136.58 (mg/100g) and total phenol 18.83 to 21.83 (mg/100g). Minimum tannin content (109.85 mg/100g) was found in germplasm K-6.while lowest in germplasm KK-1. Minimum phytic acid (126.91 mg/100g) was found in germplasm K-6. While lowest in germplasm KK-1. Minimum total phenol content (19.50 mg/100g) was found in germplasm K-10. While lowest found in germplasm K-6. On the basis of overall germplasm were found superior K-4, K-5, and K-6, K-8, K-9 and k-10 and utilized in further research work

Keywords: Tannin, phytic acid, total phenol, reducing sugar, free amino acids

Introduction

Kodo millet, one of the ancient grains of the world, originated from Africa and domesticated in India few thousand years ago is a drought resistant plant. This millet crop is grown in arid and semi-arid regions of African and Asian countries. In India, kodo millet is grown mostly in The Deccan region and the cultivation extends to the foothills of himalayas.

Kodo millet, (*Paspalum scrobiculatum* L.), is an indigenous cereal of India and widely distributed in damp habitats across the tropics and subtropics of the World. It occupies an area of 9.08 lakh ha with an annual production of 3.11 lakh tonnes and average productivity of 342 kg/ha. (Ahmad and Yadav. 1996) [2]. Kodo millet is propagated from seed, ideally in row planting instead of broadcast sowing and its preferred soil type is a very fertile, clay based soil. (Agricultural service in, 2013) [1]. the kodo millet is prone to lodging at maturity, causing loss of grain. (Dewet *et al.* 1983).

The kodo millet is mainly grown in Madhya Pradesh, Andhra Pradesh, Tamil Nadu, Bihar, Gujarat, Uttar Pradesh, Maharashtra and Orissa. It is cultivated in U.P. mostly in Gorakhpur, Basti, Gonda, Deoria, Mirzapur and Sitapur districts. These millets are grown during Kharif (rainy season) and sown with the onset of the southwest monsoon. The kodo grains are recommended as a substituted for rice to the patients suffering from diabetes.

Kodo millet contains 66.6 g of carbohydrates and 353 kcal energy per 100 g of grain, comparable to other millets. It also contains 3.6 g of fat per 100 g: It provides minimal amounts of iron, at 0.5mg/100 mg, and calcium, 27mg/100 mg. Kodo millet also contain high

Impact of salicylic acid and card board carton on quality attributes of mango varieties

Shivendra Kumar Vishwakarma, RP Singh, Pratibha Singh and RN Kewat

Abstract
The present investigation had sixteen treatment combinations, which had been replicated three times and was laid out in Completely Randomized Design. At maturity condition mango fruits were harvested and stored in cardboard card board carton by post harvest application of salicylic acid at 0.1, 0.5 and 1.0 g/l doses. The data revealed that lowest physiological loss weight (2.12 %) was recorded in Langra variety at five days storage by 0.5 g/l salicylic acid application. Maximum pectin content (1.96 %) was recorded in Langra variety at 15 days ambient storage period by 0.5 g/l salicylic acid application. Highest pectin methyl esterase (0.91 units/g) reported in variety Dashahari at 5 days storage by 1.0 g/l salicylic acid application. The highest polyphenol oxidase enzyme activity (56.38 units/g) was noticed in variety Dashahari at 5 days storage by 0.1 g/l salicylic acid treatment. Highest peroxidase activity and beta carotene content (463.69 units/g and 3495.93 µg/100g) was reported in Dashahari variety at 20 days ambient storage period by 0.5 g/l salicylic acid application. Maximum TSS content (28.00 Brix°) was reported in variety Chausa at 20 days ambient storage period by 0.5 g/l salicylic acid treatment. Thus the presented study indicated that salicylic acid enhanced the TSS, beta carotene, peroxidase activity but decreased the polyphenol oxidase and pectin methyl esterase enzyme activity. Salicylic acid significantly decreased the physiological loss weight during storage in cardboard carton.

Keywords: mango, salicylic acid, card board carton, PME, polyphenol oxidase, peroxidase, TSS, beta carotene, physiological loss weight

Introduction
India is an agriculture based country where, different types of fruits and vegetables are grown. The total production of fruits and vegetables in the world is around 370 million tonnes. India ranks first in the world with an annual output of 32 million tonnes fruits; accounts for about 8 per cent the world fruits production [1]. The total production of mango fruit in India is 15188 million tonnes with an area of about 2297 hectare. The mango fruit has been cultivated in Indian sub-continent for over 4000 years and has been the favorite of the Kings and commoners because of its nutritive values, taste, attractive fragrance and health promoting qualities and now it is recognized as one of the best fruit in the world market and also designated as 'King of Fruits'. The biochemical composition of mango fruit differs among the cultivars and the stage of maturity. Mango fruit is rich in carbohydrates, carotenoids, organic acids, polyphenols, vitamins and minerals etc.
According to the Ministry of Food Processing Industry statement '' the lack of processing and storage of fruits and vegetables results in huge wastages estimated at about 35 per cent the value of which is approximately Rs. 33000 crores for perishable and Rs. 15000 crores for non-perishable annually.'' Due to mishandling, inadequate storage or lack of post harvest technical knowledge, producer and traders have to face about 30-40 per cent losses [2]. Spoilage of mango due to end rot and anthracnose limit its storage potential and the shelf life is decided on the basis of spoilage during storage. The loss of water from fruit is due to skin evaporation (transpiration) and to some extent respiration. When the fruit losses weight, shriveling will occur and the appearance will deteriorate, thus reducing its market value [3].
Salicylic acid (SA) is a colourless, crystalline organic carboxylic acid which is found in plants, especially in fruits, in the form of methyl salicylate. It is also known as 2-hydroxybenzoic acid with functions as a plant hormone. Most investigators have focused on the role of salicylic acid in induction of disease resistance. Exogenous supply of salicylic acid has been reported to delay the ripening of apples [4], peach [5], persimmon [6], mango and tomato fruits [7] probably

Studies on biochemical parameters of hybrid rice varieties in the Faizabad region of eastern Uttar Pradesh, India

Shilpa Singh and RP Singh

Abstract
The experiment was carried out at the Department of Biochemistry, Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Faizabad as a part of PhD work. The seven varieties of hybrid rice namely- Dhani, US-312, 6201, 6302, 6444, JK-401, PHB-71 and 3 check varieties namely- Swarna, Sambhamah and Pusa Basmati were purchased from local market at Kumarganj, Faizabad from year 2012 to 14. The results highlighted that, the variety Pusa Basmati found highly superior overall the varieties and noticed, highest reducing sugar (0.34%), protein (8.43%), tryptophan (0.21 /16g N) and methionine (2.16g/16g N) content.
The highest (1.80 %) total mineral content found in Sambhamah followed by (1.66 %) Pusa Basmati and found highly significant and superior over 6201 and lysine (2.13g/16g N) followed by (1.92g/16g N) 6444 over US-312. The highest (74.71%) carbohydrate content was recorded in Swarna followed by (72.92%) Dhaniand highly superior over 6302. Like vise the variety PHB-71 found highest (1.52%) total sugar content followed by (1.25 %) Pusa Basmati and highly superior over 6302.

Keywords: carbohydrate, protein and total mineral, tryptophan, methionine and lysine

1. Introduction
Rice (*Oryza sativa* L.) is a plant belonging to the family of grasses, Poaceae. It is one of the three major food crops of the world with respect to acreage and production and forms the staple diet of about two third of the world's population. More than 90 per cent of the rice produced and consumed in Asian countries. Asia is the leader in rice production accounting for about 90 per cent of the world's production. Over 75 per cent of the world supply is consumed by people in Asian countries and thus rice is of immense importance to food security of Asia. In India, the rice is cultivated on 43.81 million hectare with production of 96.43 million tones (Anonymous, 2010) [1]. The demand for rice is expected to increase further keeping in view the expected increase in the population.
The projected demand for rice can only be met by maintaining steady increase in production over the years. Several breeding strategies are being employed in increasing the yield potential of rice and those among the available strategies; hybrid rice offers an immediate opportunity to break the yield plateau set by the semi-dwarf rice varieties after the first green revolution. In the recent years, much emphasis is given for the cultivation of hybrid varieties. Hybrid rice technology has proved to be one of the most feasible and readily adoptable approaches to break the yield barrier, as they produced about 15-20 per cent more than the best of the improved or high yielding varieties. Being convinced of the potential of hybrid rice technology in enhancing the production, India adopted this technique and has released nearly more than forty-three hybrids for commercial cultivation. Hybrid technology has been widely acclaimed and accepted. Hybrid rice is the commercial rice crop from F1 seeds of cross between two genetically dissimilar parents. Good rice hybrids have potential of yielding 15-20 per cent more than the best inbred variety grown under similar conditions (Nguyen van Suan, 1998) [10]. Hybrid rice was introduced commercially in China in 1976.
Keeping in view of above facts, potentially inclination towards hybrid rice by developed country and having vital chemical constituents hidden in it, the present study have been conducted.

ABSTRACT

The present paper describes some of the important facts relating to nutritional and anti-nutrional properties of foxtail millets. The various biochemical parameters such as protein content Kakun-2 (13.00%), carbohydrate content Kakun-6 (75.00%), crude fibre content Kakun-6 (8.25%), Total mineral content Kakun-2 (3.72%), tryptophan content Kakun-6 (38.73 mg/g protein), lysine content Kakun-2 (26.64mg/100g) were also noticed in present investigation. Antinutritional factor such as Total phenol content Kakun-2 (2.10%) and Phytic Acid content Kakun-2 (115.51mg/100g) were found reported minimum in the present germplasm. So the germplasm were utilized in the further research work.

Key word : *Foxtail millet, Protein, Total mineral, carbohydrate, Total sugar and reducing sugar, Total phenol, Phytic acid.*

Foxtail millet (*Setaria italica*) is belongs to the family Poaceae, subfamily Panicoideae. It is known by different names in different languages stich as kaon (Bengali), kanghu (proya), korra (Telugu), tenai (Tamil), thana (Malayalam), navane (Kannada), kangni (Punjabi), kakun(Hindi) and kang (Marathi).A self-pollinating crop with chromosome number 2n=18. Foxtail millet is an annual grass with slim, vertical, leafy stems which can reach a height of 120-200 cm (Baker, 1998). Foxtail millet is tasty, with a mildly sweet, nut-like flavour and contains a myriad of beneficial nutrients. It is nearly 10-13% protein, contains moderate amounts of fibre, B-complex vitamins including niacin, thiamin, and riboflavin, the essential amino acid methionine, lecithin, and some vitamin E. It is particularly high in the minerals iron, magnesium, phosphorous, and potassium. The seeds are also rich in photochemicals, including phytic acid, which is believed to lower cholesterol, and phytate, that is associated with reduced cancer risk (FAO, 2008). It is also being used traditionally for feed supplement for pregnant mother and under 3 years old baby in Numfor Island (Rumbrawer, 2003). They are consumed traditionally as health and vitality foods by the labour class. Foxtail yellow seeded cultivars, medicinally used as astringent, digestive, emollient and stomachic. It is also used in the treatment of dyspepsia, poor digestion and food stagnancy in abdomen. In the northern area of China it has been widely used as a nourishing gruel or soup for pregnant and nursing women, and has been applied in food therapy. Foxtail millet is highly nutritious, non-glutinous, and like buckwheat and quinoa, is not an acid forming food so it is soothing and easy to digest. It is considered to be one of the least allergenic and most digestible grains available and it is a warming grain that helps to heat the body in cold or rainy seasons and climates (Kamara *et al.*, 2009).

MATERIALS AND METHODS

Experimental Materials : Ten varieties of foxtail millet genotypes were selected as the experimental material o the farmers field of different districts of U.P. Samples c Foxtail millets were brought to Biochemistry laboratory o Narendra Deva University of Agiculture & Technology Kumarganj Falzabad (U.P.) after collection.. Foxtail millet were collected and analyzed for various biochemica parameters. The collected foxtail millet were cleaned dried. The dried seeds was then crushed by a pestle and mortel. Finally, the product was the desired foxtail millet powder. The chemical properties of the foxtail millet powder were analysed and the results are summarized. Protein content analysed by Lowry's method (1951) by .Total carbohydrate content analysed by Yamme and Wills (1954). Total sugar content analysed by Dubois *et al.* (1950) using phenol reagent. Reducing sugar estimated by Miller (1959). Total mineral content was estimated by the method as described by Hart and Fisher (1971). The content of crude fibre in dried foxtail powder were analysed by the method as described by Hart and Fisher (1971). Total phenol analysed by the method of Swain and Hillis (1984) and phytic acid estimatrd by the method of Wheeler and Ferrel (1971).

RESULTS AND DISCUSSION

The results on identity, strength and assay of foxtail millet seed powder and proximate composition are shown in Table 1, 2 and 3. Protein content in various germplasm was obtained between 11.85 to 13.00 per cent. Maximum protein content was recorded in the germplasm Kakun-2 (13.00%) statistical analysis of the data showed that all the germplasm of Foxtail millets were found significant regarding protein content. Studied on protein contents found similar range of protein (Mohamed *et. al.* 2009). Analyzed nutritional composition and found that millet

ABSTRACT

The present investigation was carried out to study the physical and biochemical properties of Pearl millet (Pennisetum glaucum L.) genotypes. The kernel husk ratio in Pearl millet germplasm was found in the range of 64:36 to 80:20.The colours of Pearl millet were very attractive with Pale yellow and light gray. The colour plays an important role as far as consumer's acceptance is concerned. The average test weights of grain sample taken for the study were noticed between 5.35 to 12.98 of Pearl millet germplasm, respectively. The various biochemical parameters such as Carbohydrate content NDBH-2 (64.24g/100g), crude fibre content in Pearl millet-4 (2.30g/100g), Total mineral content in Pearl millet-3 (2.26 g/100g) were also noticed in present investigation.

Key word: Pearl millet, total mineral, carbohydrate, crude fibre and seed colour of seeds.

Received 21.09.2017 Revised 24.10.2017 Accepted 03.11.2017

INTRODUCTION

Pearl millet (*Pennisetum glaucumL*) is also known as spiked millet, candle millet or dark millet in Europe; cattail, pecillaria in USA; bulrish millet or dukhn in Africa; bajra, combo or sajje in India. Pearl millet is originated in central Africa. Pearl millet crop is grown in tropical semi-arid region of the world primarily in Africa and Asia. Pearl millet is well adapted to production system characterized by low rainfall (200-600 mm), low soil fertility and high temperature. Pearl millet belongs to the family gramineae (Poaceae, Grass family). The height of the pearl millet plant may range from 0.5 – 4.0 meter. The grains color may be nearly white, pale yellow, brown, grey, salt blue or purple. The grains of the pearl millet are about 3 to 4 mm long much longer than those of other millets. The weight of seeds usually ranges from 1.4 to 2.5g with a typical mean of 0.8gram [1]. India is the largest producer of pearl millet covering about 8.7 million ha of marginal and sub marginal lands. Rajasthan, Gujarat, Haryana, Uttar Pradesh and Maharashtra are the fifth important states cultivar of these crops. Total cultivated area of Pearl millet in Uttar Pradesh is around 0.84 million ha and production 0.95 metric tonns. [2]. People affected by gluten related disorders, such as celiac, non-celiac gluten sensitivity and wheat allergy suffers, who need gluten free diet can replaced gluten containing cereal in their diet. 100 gram pearl millet are provided 378 kcal energy, protein 11 percent, Carbohydrate 73 per cent, fat 4 percent, Several vitamin B, minerals such as calcium 8 mg, iron 3 mg, magnesium 114 mg and some other nutrients like selenium 2.7 micro gram (USDA).

MATERIALS AND METHODS

Ten germplasm of Pearl millet were collected from different districts of Uttar Pradesh namely Balrampur, Sultanpur, Faizabad, Jaunpur, Gazipur, Bahraich and Lakhimpur were used as experimental materials. Samples of Pearl millets were brought to Biochemistry laboratory of Narendra Deva University of Agriculture & Technology, Kumarganj Faizabad (U.P.) after collection. They were analyzed for various physical and biochemical parameters. The collected Pearl millet was cleaned, dried and dried seed was then crushed by a pestle and mortar. Finally, the product was the desired Pearl millet powder. The chemical properties of the Pearl millet powder were analyzed and the results are summarized. The milling per cent of Pearl millet grain include the dehusking and determining by traditional method using wooden pestle and mortar determining hand operated wooden pestle mortar steel persist. One hundred gram Pearl millet germplasm were weight on balance and their husk was remove with hand operated okhali finally the husk and kernel weight were recorded and there ratio was calculated.1000 grains of Pearl millet were randomly selected from threshed crop of each plot and their weight recorded on balance to obtain test weight of

ABSTRACT

The present study was conducted in the section of Germplasm Evaluation Division at the National Bureau of Plant Genetic Resources, New Delhi. Together with wheat and rice, maize is one of the three most important crops in the world. One of the reasons maize is a staple food across the world is its high nutritional value, with high levels of starch and also valuable proteins and oils. However, maize is naturally almost deficient in lysine and tryptophan, which are two of eight amino acids regarded as essential for humans, so it needs to be part of a balanced diet. Various maize genotypes were studied for amino acid profile like by using High Performance Liquid Chromatography. The results of this study indicated that the Glutamic acid was found in the range of 19.74 to 23.57(g/16 g.N) which is highest while Tryptophan found lowest 0.77 to 1.05 (g/16 g.N) almost negligible. The study also reveals the presence of other important amino acids. These findings will help to develop improved maize having an answer to better nutrition.

Key words : *Maize. Glutamic acid. Tryptophan. Leucine. HPLC*

Maize (*Zea mays*) is the only species usually included in the genus Zea, of the tribe Maydeae of the family Poaceae. Maize is a type of cereal grain and first adopted and cultivated by the Latin American countries. Maize is the third most important crop after wheat and rice in the world. It is used directly as food for human consumption and as feed for animals. Its importance arises both because of its great productivity and grown over an extremely wide environmental range. A robust, monoecious annual grass though generally tall, varies in height from 0.43m to sometimes over 6m in different varieties and regional types. The lower leaves being like broad flags, 50-100cm long and 5-10cm wide. The stems are erect, conventionally 2-3m in height, with many nodes. Maize kernel like the kernels of the other cereals consists of three main parts, namely hull or bran coat, embryo or germ and starchy endosperm. Maize constitutes an important source of carbohydrates, protein, vitamin B & B_{12} and minerals. It is an excellent source of carbohydrate and is complete in nutrients compared to other cereals. The average protein content of maize is about 10 percent; about half of the protein consists of zein, which is especially low in lysine and tryptophan amino acids (Douswell *et al.*, 1996). Maize protein is unbalanced with respect to its content of essential amino acid, rich in leucine and low in lysine, tryptophan and methionine. Furthermore maize oil contains a high level of polyunsaturated fatty acids and natural antioxidant (Okoruwa, 1996).

Maize is used in more ways than any other cereal for human consumption, as a food grain, a fodder crop and for hundreds of industrial purposes. Its grain, stalk, leaves, cobs, tassel and silks all have commercial value in some settings. In industrialized countries larger proportion of the grain is used as livestock feed and as industrial raw material for food and nonfood uses. Maize is the major source of starch and starch-based industrial products in many parts of the world. Grain alcohol from maize is traditionally the source of bourbon whiskey. Stigmas from female cornflowers, known popularly as corn silk, are sold as herbal supplements. Maize oil may be used with linseed oil as a paint material. With the advent of biotechnology, it has been suggested that maize hybrids will be developed for specific industrial uses by changing the chemical composition of the kernel. In view of this, the present study was undertaken to estimate total amino acids in maize especially deficient amino acids also.

MATERIALS AND METHODS

The present investigation was planned and conducted in the division of Germplasm Evaluation Division at the National Bureau of Plant Genetic Resources, New Delhi in 2008. The eight genotype of maize seeds were analyzed in the laboratory by HPLC and reported the Profile of amino acids. Weighed approx .004-.006 gm maize powder in a phial. Samples were placed in a lyophilizer to

ABSTRACT

The experiment was conducted in Randomized Block Design with three replications, wheat variety NW-1014. The experiment was laid out in field condition with seven treatments *viz.* T_1 (control), T_2 (60 kg SSP ha^{-1}), T_3 (60 kg DAP ha^{-1}), T_4 (80 kg SSP ha^{-1}), T_5 (80 kg DAP ha^{-1}), T_6 (100 kg SSP ha^{-1}), T_7 (100 DAP ha^{-1}). The different levels and sources of phosphorous were applied in field basal before sowing of seeds. Observations were recorded as germination percentage, (15 DAS after sowing) growth parameters, biochemical changes at 30, 60, 90 DAS and maturity after sowing. Yield and yield attributes traits were also recorded at harvest stage of crop. All the treatments increased the germination percentage, growth characters and biochemical changes superior over control. The maximum germination percentage was recorded with 80 kg DAP ha^{-1} over other treatments including control. Growth characters as plant height (cm) was found significantly superior, number of tillers plant^{-1}, dry matter plant^{-1}, total chlorophyll content (mg g^{-1} fresh weight), carbohydrate (mg g^{-1} dry weight) and protein content (%) in leaves were found significantly superior with basal application of 80 kg DAP ha^{-1} followed by 100 kg SSP ha^{-1} over control. Yield and yield contributing traits *viz.* length of spike (cm), number of spike plant^{-1}, grains spike^{-1}, number of grains plant^{-1}, yield (g plant^{-1}), 1000 grains weight (g), yield (q ha^{-1}) and harvest index (%) were also found statistically superior with basal application 80 kg DAP ha^{-1} followed by basal application of 100 SSP ha^{-1} over control.

Wheat (*Triticum aestivum* L.) is the important crop of India. It is consisting second position in both area and production after rice in India as well as world after china. The Northern and Western part of India has maximum area and production under wheat cultivation. Indian wheat can be classified into four type (1) Emmer wheat (*Triticum dicoccum Schub L.*), (2) Macroni wheat (*Triticum durum Desf.*) (3) Common bread wheat (*Triticum aestivum L.*) and (4) Indian dwarf wheat (*Triticum spherococcum Mihl.*). Uttar Pradesh, Madhya Pradesh, Punjab, Bihar, Rajasthan, Haryana, Maharashtra and Gujarat are major wheat growing state in our country; of these U.P occupies a first place in terms of both area and production. Wheat is one of the important cereals due to its relatively higher niacin and thiamine content. In addition, it is also rich in "gluten" which provides spongy cellular texture of bread and baked product with shrinking of arable land due to urbanization and industrialization, the wheat cultivation is also being pushed to marginal lands including salt affected soil.

Sodic soil is widespread in the world and in India. It occurs mainly in Indo-Gangetic alluvial plains, where it is estimated to cover about 2.8 mha. In India, salt affected soils are spread 7.0 mha. of which, 1.29 exists in U.P. alone (Abrol and Bhumbla 1971). However, information on salt affected area in India indicates for 13.0 mha (Yadav and Gupta, 1984). Salt affected soils contain excessive concentration of chloride and sulphate of sodium, calcium and magnesium (Saline soil) or excess of exchangeable sodium (alkaline or sodic soil) along with carbonate and bicarbonate. These affected soils are extensively distributed in arid and semi arid parts of Haryana, Punjab, Uttar Pradesh, Rajasthan, Gujrat, and Maharastra. The soil affected soil in U. P. are spread over several districts including Sultanpur, Raibarreilly, Azamgarh, Etawah, Pratapgarh, Ballia, Mau, Mainpuri, Hardol, Kanpur, Faizabad, Jaunpurand Fatehpur (Singh and Tyagi 1980).

The detrimental effect of sodicity on biomass production is attributed to osmotic as well as toxic effect of the ions on the physiological and biochemical function of the cells. The increasing level of soil sodicity resulted reduction in plant growth, tiller production, root and shoot (Dargan *et al.*, 1976). Soil sodicity has been found to deforess protein synthesis and accelerate its degradation in plants. In general, the level of reducing sugar and starch decreased in chloroplast, while those of non reducing sugar increased under saline condition. Salinity reduced growth and productivity in crop species due to excessive amount of salts, especially sodium cloride in the soil. Sodium cloride induces osmotic and ionic effects, leading to changes in plant metabolism (Qadir *et al.*, 2008) and reduced plant growth and development in many crop science (Sing *et al.*, 2007).

ABSTRACT

The present investigation was conducted at M.E.S., Vegetable Science and analysis was carried out in the Laboratory of Department of Agricultural Biochemistry, N.D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) during Rabi season 2016-17. Ten germplasms of tomato namely NDTH-90, NDTH-101, NDTH-108, Kalyanpur Selection-2, Kalyanpur Selection-3, Kalyanpur Selection-6, IIVR Selection-2, CO-3, Arka vikas and Pusa Early Dwarf were analysed at ripening stage. Tomato germplasms with successive ripening stages were grown in Completely Randomized Design with three replications. In respect of tomato fruit have been collected separately and analysed for physical and biochemical parameters. The physical parameters namely, fruit size, fruit weight, colour and specific gravity were determined whereas, biochemical parameter were explored for the determined of lycopene, β carotene, total chlorophyll, chlorophyll a, chlorophyll b, ascorbic acid, total mineral, total free amino acid, total acidity and activity of enzyme, polyphenol oxidase and peroxidase. The data obtained in the experiment showed the highest fruit size length and diameter (4.83, 7.17 cm),at ripening stage was found in variety Pusa Early Dwarf & Arka vikas. Maximum fruit weight (95.33g.) and specific gravity (1.28 ml/cc) at ripening stage in variety CO-3 & Pusa Early Dwarf. Whereas Maximum ascorbic acid (27.67 mg/100)at ripening stage was found in variety NDTH-101and total mineral (0.80 mg/100g)at ripening stage was found in variety Arka vikas. Total acidity (0.50 %) at ripening stage was found in variety Pusa Early Dwarf. Maximum lycopene (4.93 mg/100g) at ripening stage was found in germplasms Kalyanpur Selection-6 and β carotene (1.50 mg/100g) at ripening stage was found maximum in germplasms Kalyanpur Selection-3. Whereas, total chlorophyll (1.77 mg/100g) at ripening stage was found maximum in germplasms NDTH-90 chlorophyll a& b (1.27, 0.58 mg/100g) at ripening stage was found maximum in variety/germplasms NDTH-108 &Pusa Early Dwarf. Whereas, polyphenol oxidase (35.87 unit/mg) and peroxidase enzyme (1.80 unit/mg) were found maximum in variety /germplasms Arka vikas & NDTH-108 at ripening stage.

Introduction

The tomato (*Lycopersicon esculentum* Mill.) is one of the most widely consumed and most popular fresh vegetable in the industrialized world. Tomato belongs to the family Solanaceae having diploid chromosome number (2n=24). It is the world's largest vegetable crop after potato and sweet potato but it tops the list of canned vegetables. It is an important condiment in most diets and a very cheap source of vitamins and antioxidents. It also contains a large quantity of water and,

To determine Aloin A & B content in *Aloe vera* (*Aloe barbadensis* Miller) leaf gels

Abhishek Singh, Dr. Pratibha Singh, Dr. Ramesh Pratap Singh and Dr. NA Khan

Abstract
The present investigation was conducted at Acharya Narendra Dev University of Agriculture and Technology, Kumarganj, Ayodhya during the year 2018-19 and 2019-20. Aloin, an anthraquinones molecule found in the bitter yellow sap of the middle leaf layer, has a strong laxative effect. The experiment revealed that Aloin A maximum in IC-112532 (0.87 ppm) and minimum in IC-112512 (0.80 ppm) and Aloin B maximum in IC- 112512 (1.27 ppm) and minimum in IC-283610 (1.17 ppm).

Keywords: Aloin, *Barbadensis*, anthraquinones

Introduction
Aloe vera is a cactus-like plant that grows in hot, arid climates and is currently grown in large quantities due to strong demand. It is regarded as an all-purpose herbal plant with a high rating throughout recorded history. The thick, tapering, spiky leaves of aloe grow from a short stem near the ground. It's not a cactus, but rather a Liliaceae tree called *Aloe Barbadensis* (Ghazanfar, 1994) [1]. Among the 75 potentially active constituents in *Aloe vera* are vitamins, enzymes, minerals, carbohydrates, lignin, saponins, salicylic acids, and amino acids (Richard, 2005) [8]. The vascular layer of *Aloe vera* plants contains two major liquid materials: first, a bitter yellow latex located beneath the strongly cutinized epidermis of the leaves and containing a high concentration of anthraquinone compounds; and second, a bitter yellow latex located beneath the strongly cutinized epidermis of the leaves within the vascular layer and containing a high concentration of anthraquinone compounds, which has been used throughout the centuries as a cathartic and for medicinal purges; and, second, the inner central zone's thin-walled tubular cells form a translucent mucilaginous gel (parenchyma) that has been used since past to treat burns and other wounds, where it's thought to extend the speed of healing and reduce the risk of infection (Joseph & Raj, 2010) [6]. Aloin, an anthraquinones molecule found in the bitter yellow sap of the middle leaf layer, has a strong laxative effect (IARC, 2016) [4]. Except within the pharmaceutical industries, the aloe plant was first used commercially in the manufacturing of "aloin", a latex substance (a yellow sap). In the food industry, it's the potential to be used as a food preservative (substitute of sulphur dioxide in preserving fruit and vegetables). Because of its anti-oxidant characteristics, it's becoming more popular as a natural covering. The leaf powder is employed during a number of ayurvedic medicines because it contains antioxidants, dietary fibre, iron, etc. Many researchers have tried to figure out what active ingredients are present in *Aloe vera* gel (Habeeb *et al.*, 2007) [2]. Proteins, lipids, amino acids, vitamins, enzymes, inorganic substances, and various carbohydrates are contained in polysaccharides located within the inner leaf parenchymatous tissue or pulp, (Hamman *et al.*, 2008) [3]. When the leaves are removed from the basal portion of the mother plant, the sap starts draining out immediately products made from *Aloe vera* plants such as gel, aloin, etc. (Pandey *et al.*, 2016) [7].

Materials and Methods
Aloin A & B content was estimated by the method of thin layer chromatography (TLC) is given by Izmailov and Shraiber (1938) [3].

Crystallization/drying
To carry out thin layer chromatography pre coated silica gel plates spectrophotometer is used

Assessment of physicochemical properties of minor fruits (aonla, bael, ber, jackfruit and kaitha)

Anil Kumar, Pratibha Singh and Mahesh Singh

Abstract
Physicochemical and nutritive evaluation of five minor fruit germplasms/varieties i.e Aonla (NA_6 and NA_7), Bael (NB_5 and NB_9), Ber (Karaka and Umran), Jackfruit (NJ_2 and NJ_3) and Kaitha (K_1 and K_2) resulted a slight variation within two varieties of each fruit pertaining to size of fruit, peel/shell per cent and pulp per cent. Specific gravity was higher in Ber-U (Ber- Umran) (0.99%) followed by Ber- K (Ber-Karaka), K_1, K_2 and NA_7 (0.98%). Minimum specific gravity was recorded in NJ_2 (0.46%). Biochemical investigation of minor fruits, resulted a slight variation within two germplasms/varieties of each fruit pertaining to total mineral content, protein content and crude fibre. Total mineral content was higher in NB_5 (1.73 g/100g) followed by NB9 (1.71 g/100g) and minimum total mineral content were noticed in K_1.Protein and crude fibre was maximum in K_2 (6.92 g/100g) and NB_5 (6.38 g/100g). Lowest protein and crude fibre content were found in NA_6 (0.53 g/100g) and NA_7 (1.20 g/100g).On the whole germplasms/varieties Aonla (NA_6 and NA_7), Bael (NB_5 and NB_9), Ber (Karaka and Umran), Jackfruit (NJ_2 and NJ_3) and Kaitha (K_1 and K_2) were found best in terms of qualitative as well as physicochemical and nutritive evaluation.

Keywords: Minor fruits, size of fruit, peel/shell, pulp, specific gravity, total mineral, protein and crude fibre.

Introduction
India is the second largest producer of fruits in the world nearly covers 6.36 million hectares of area with a total production of over 88.82 million metric tonnes with productivity of 13.97 tonnes/ha. In Uttar Pradesh it is grown on 0.46 million hectares with production of 8.54 million metric tonnes, under fruit crops ranks first in terms of area, but production-wise it ranks third (Horticultural Statistics at a Glance, 2015-16) [9].
There are several fruits taken by human as its nutritional importance but several fruits are present in nature which are also nutritionally important and superior in quality but are rarely used by human because people are not aware of its nutritional importance, these fruits are known as minor fruits *viz*., Ber, Bael, Aonla, Kaitha, Jackfruit, Karonda, Imli etc. The around 72 to 73 per cent Baelpulp could be extracted, fruit weight ranged from 455 to 2010 g. The fruit colour varied from greenish to yellowish with yellow colour pulp. The average specific gravity and sphericity was 0.97 and 0.96 respectively (Kenghe and Potdar 2009) [12]. All ber varieties differed significantly on the basis of their physical analysis. Foladi was observed as one of the superior variety in terms of fruit size (13.29 cm2), fruit weight (36.99 g), stone size (2.09 cm2) and stone weight (2.31 g). However, maximum flesh ratio (10.59%) was in Gorh variety. Gorh was superior in terms of vitamin-C (176.45 mg/100g), protein (3.13%) and TSS (24.01%). The highest reducing sugars (5.64%) were observed in Khobani. Dehli White excelled in nonreducing sugars (6.12%) (Abbas *et al.* 2012) [1]. Fresh aonla fruits of cv. Chakaiya had fruit length (3.27 cm), fruit diameter (4.00 cm), fruit weight (37.27 g), pulp weight (33.11 g) and seed weight (4.16 g). Moisture, TSS, total sugars, reducing sugars, acidity, ascorbic acid, pectin, tannin, crude fibre, pH and browning were recorded as 86.50 per cent, 10.10 per cent, 8.53 per cent, 5.14 per cent, 1.85 per cent, 662 mg/100g, 1.93 per cent, 2.93 per cent, 3.07 per cent, 2.90 and 0.063, respectively (Daisy and Singh 2007) [4]. Physicochemical analysis of wood apple (Kaitha) revealed that the average fruit weight ranged from 140.08 to 256.65 g, fruit length and width from 6.50 to 8.40 cm and 6.16 to 7.43 cm respectively, specific gravity from 1.04 to 1.74, and pulp weight from 60.33 to 176.00 g, Total soluble solids ranged from 12.45 to 14.67^0 Brix, ascorbic acid from 4.87 to 6.26 mg (per

Abstract

This research investigation was undertaken in ANDUAT, Kumarganj, Ayodhya, Uttar Pradesh, India to study the numerical optimization of natural convection heat suppression in a solar flat plate collector with straight fins. Optimal characteristics of an array of thin fins attached on the absorber plat were obtained by Particle Swarm Optimization algorithm (PSOA). Free convection considered dominant in the cavity. Governing equations contained continuity; momentum and energy are discretized by finite volume method. The medium is considered incompressible, whose free convection is dominant and Boussinesq approximation is applied. A simplified model of real systems is applied with free convection. Free convection problem is solved by SIMPLER algorithm. Two confined cavities with aspect ratios 30 and 60 are considered as flat plate solar collectors. The results indicate that significant reduction on the free convection heat loss can be obtained from solar flat plate collector by using plate fins, and an optimal plate fins configuration exit for minimal natural convection heat loss for a given range of Rayleigh number. Reduction of up to a maximum of 25% at 0 inclination angle was observed in aspect ratio 30. Results showed PSOA is able to obtain characteristics of attached adiabatic fins on the absorber plate also it can obtain optimal inclination angle of cavity to decrease heat losses from solar collectors. The results obtained provide a novel approach for improving design of flat plate solar collectors for optimal performance.

Keywords: Particle swarm optimization algorithm, solar collectors, natural convection

1. Introduction

Flat plate solar collectors are technique to utilizing solar energy. The flat plate absorbs incoming solar radiation and converts it in to heat and also transfers this heat to a fluid flow. Glazing cover plate prevents from heat loss by force convection but when temperature difference between flat plate and glazing cover plate exceeds to a critical value, natural convection will exist between absorber and cover plate. In present work of heat loss from absorber plate is reduced by investigating optimal characteristics of an array of thin fins are considered. Grossman et al. (1977) expanded a model for heat transfer in a flat plate solar collector with a rectangular channel for water or air fluid flow. The analysis was performed for temperature and heat flow distributions in both dimensions of the collector to investigate the thermal boundary layer development. Overall efficiencies are calculated for uniform solar

Abstract: The experiment conducted at Mahamaya College of Agricultural Engineering & Technology, Ambedkar Nagar (U.P.). The pump tested for analysis performance is ELGIMACE model no. LLO3022 single acting reciprocating pump equipped with 2 HP three phase induction electric motor with 1440 rpm. A hose measuring of water source of 4.12x3.25x1.23. G.I.20 mm size, suction pipe was used. The delivery pipe was high density pliable reinforced rubber pipe to withstand abundant pressure (up to 25 kg/cm^2). Stop watch was measuring discharge of 1/100 sec. of leastcount. For three different speeds of 242 rpm, 285 rpm and 344 rpm with five dissimilar pressures are 1.5 kg/ cm^2, 5.7 kg/cm^2, 10.3 kg/cm^2, 15 kg/cm^2 and 24 kg/cm, pump was tested. Track record of all pipe pressure used for this testing was measured by a pressure gauge having adequacy 0-35 kg/cm. In motor shaft a V(twin) belt the electric connection was energized and a pulley with minimum diameter 6.25 cm was fitted. The outcomes based on the exploratory observation showed that the efficiency rises when pressure is rises. At speed of 344 rpm the efficiency is detected 90% and at dupe speed the volumetric efficiency is 77% for least pressure 1.5 kg/cm and volumetric efficiency is 95% for maximum pressure 24 kg/cm^2. The discharge increases as pressure goes up and it is showed by the average discharge and pressure, which is almost linear. The relationship sequence is mostly same for all above circumstances; this stated that discharge is mutual to the pressure for a reciprocating pump.

Index Terms: Discharge, Efficiency, Volumetric efficiency, Pressure, rpm, Static head, Reciprocal and Pressure head.

I. INTRODUCTION

Reciprocating pump is a pneumatic machine which gets converted in hydraulic energy from mechanical energy. A cylinder containing a reciprocating piston absorbs liquid which expend a thrust (impel) force on the liquid and hike its hydraulic energy (pressure energy of liquid). It's a kind of positive displacement pump which comprises of piston or plunger. It is used at a place where relatively small amount of water is to be delivered at high pressure. Water in cylinder is displaced by the movement of piston for the functioning of reciprocating pump. Valves control the flow. A piston or plunger is cylindrical piece which moves backward and forward inside hollow cylinder. Reciprocating pump's capacity depend on the sizes of cylinder chamber, piston length and piston stroke. Electric motor engine operate a pump which have to come into prominence in a large lift irrigation schemes, high output levels can be quickly attained and managed by this process. Reciprocating pump generates high head, but their capacity is smaller compared to other types of pump. Reciprocating pump works on single acting independent suction and discharge strokes works on double acting suction and they discharge in both the direction. Although, recommendation of specific purpose pumps is very tough due to the inaccurate figures about scientific information such as efficiency discharge, head relation and other characteristics. Understanding all this circumstances, under laboratory conditions a study was approached for evaluation of volumetric efficiency, pressure discharge relationship and speed-power-discharge.

Abstract: The study was made in order to establish correlation between rainfall and ground water fluctuation of Ambedkar Nagar District in Uttar Pradesh through regression analysis. To study the trend in ground water level in eastern U.P. Ambedkar Nagar a model was fitted known as regression model with data for every year from 2008-2017 .The developed model equation is $Y' = -3.59 \times 10^{-3}X + 13.767810$ .The coefficient of correlation between water table and rainfall was observed as − 0.5735. The result of study had been evaluated through r^2, RMSE and EC were found to be -0.574, 1.23 & 96.6% respectively. The above empirical equation may be useful in prediction of water table depth from rainfall for base line for boring of tube well for timely irrigation of crop.

Index Terms: Rainfall, Regression Analysis, Correlation, Groundwater, Fluctuation.

I. INTRODUCTION

In 1959-60 the area underground water irrigation which is less than six million hectare but went up to 18 million hectare in 1980-81 to 33 million hectares in 1999-2000. More than half of the total irrigation is based on ground water, the share of ground water in area increasing from 30% in 1960-61 to 58.77% in 1999-2000. The area underground water is increasing progressively because it the most reliable and cost effective source of irrigation (Joshi, 2002).

The rainfall contributes to the annual increment in the ground water reserve which in turn is reflected in the rise of water table during the post monsoon period. Estimation of water table is needed for planning and developing the resources. With increasing demand for water for both agricultural and industrial use, the need to develop ground water resources to maximum possible extent has gained importance. The main component of recharge of ground water is precipitation. The ground level is an indicator of ground water availability. Ground water is an important resource of irrigation of India. It contributes to enhance agricultural production was better realize during green revolution and miss management has result in several problem likes fluctuation in water table and increasing in depth of will. In last 10 year out of total monitoring wells 60% showed depletion in water table depth during per monsoon dry session. This leads to associated problem off lowering tube well depth and drying of open dug wells in the areas. Few areas with associated problem of lowering tube well depth and drying of open dug wells has becomes the major issues. This also indicates the decreasing trend of ground water table depth over a period of time. The fluctuation of water table is mainly depending upon the precipitation received in the area. Being insufficient annual rainfall and which is not sufficient to crop production, it is become essential to have the use of ground water. For irrigation purpose the ground water is utilized through tube well, pumping etc. For installation of the tube well is necessary to know the base the depth of table.

The present investigation entitled to "develop the model for the prediction and relationship between rainfall and ground water fluctuation of Ambedkar Nagar District" was carried out with objective to establish correlation between rainfall and ground water fluctuation.

Abstract

In India, cotton is mostly picked manually. Though, commercially available cotton harvesters were tried for Indian varieties, their high initial cost and their higher capacity made their use uneconomical for small or medium-size farms. Keeping in mind the conditions of Indian farms, a tractor operated cotton header has been developed. The developed machine was evaluated on RCH-773 and F-2383 cotton varieties. The forward speed significantly affected the picking capacity of both varieties i.e. RCH-773 and F-2383. Maximum picking capacity was 1865.01 and 559.50 kg/h, found at FL2, FS1, A1 and S2 combination for both varieties respectively. There was a significant effect of finger spacing observed on picking efficiency, ground loss and stalk loss for both varieties. The maximum picking efficiency was 95.56 and 94.89%, found at FL1, FS1, A2 and S1 combination for both varieties, respectively. The optimum combination of machine was found with 700 mm finger length (FL1), 16 mm finger spacing (FS1), 15 degree finger angle (A2) and 4.5 km/h forward speed (S2).

Keywords: Cotton header, cotton harvesting, picking efficiency, finger length, ground loss

Introduction

Cotton fabric alone accounts for half of the fiber worn in the world. The world demand for all fibers is expected to rise, in volume terms, from 74 million tons in 2010 to 95 million tons in 2020 (Barik, 2010). Cotton is an important commercial crop of India, having a cultivated area of 11.7 M ha, the largest in the world. Though, India is the largest producer of cotton in the world, but the yield is much less as compared to the average yield of the world. The average yield of cotton in the world is 766 kg ha^{-1}. Australia has the highest average yield of cotton as 2151 kg ha^{-1} while the average yield of cotton in India is only 540 kg ha^{-1} (Anon, 2014).

In the world, approximately 30% of seed cotton harvesting is done by mechanical harvesters. In some countries like USA, Australia and Israel, nearly 100% seed cotton is picked by mechanical harvesters. In terms of percentage, a significant amount of

Abstract
The development of simulation model is a powerful tool for prediction of performance and can help designers to optimize the dryer geometry at various operating conditions. Commercialization of any drying technology for agro processing or industrial use needs thorough performance prediction and evaluation of system in techno-economic perspectives.
Estimation of solar radiation at Hisar with the help of ASHRAE model has been in close agreement with the observed values taking 5% as level of significance. Thus the model can safely be used to predict isolation at Hisar. The calculated efficiency of the flat plate solar collector using the data at different point in the solar dryer during testing has been consistent.

Introduction

Drying is one of the essential unit operation performed to increase the shelf life of agricultural / horticultural produce and it is one of the most practical methods of preserving food and the quality of horticultural produce. Use of proper drying techniques can significantly reduce the post-harvest losses of fruits and vegetables (Atikan and Alam, 2018). There exist many technical problems associated with open sun drying namely cloudiness and rain, insect infestation, high level of dirt and atmospheric pollution and intrusions from animals and men. In addition to this there is no control on the drying process (VijayaVenkata Raman et al., 2012). Hence, developing countries, receiving significant amount of solar radiation must realise the importance of controlled drying using solar energy. Traditional method for fruits and vegetables drying in rural areas in India is to spread the products on the ground with exposure to the sun in the open air. Sun-drying method may be efficient and cheap process but has disadvantages such as contamination by dirt, insects and bacteria and loss due to wetting by rain squirrels (Esper and Muhlbauer, 1998). These are usually accepted as an inherent part of the method of processing. In order to protect the products from above mentioned disadvantages and also to accelerate the time for drying the products, control the final moisture and reduce wastage through bacterial action. Solar energy is fast becoming an alternative source of energy because of the high rate of depletion of the conventional energy sources. It has many advantages over other alternative source of energy such as wind because of its abundant, inexhaustible, renewable and non-polluting nature. Equally, it can be tapped at a relatively low cost. The associated danger of fire or other hazards are less (Ekechukwu and Norton, 1999).

Whereas, controlled solar drying system leads to faster rate of drying and exposure of products against rain, dust, storm, birds, rodents, insects and pests are avoided. This ensures better quality of dried products which would fetch higher prices (Hossain and Bala, 2007). In solar drying method, faster drying takes place which result a significant reduction in drying time. Product dried in solar dryer are superior in quality (colour and flavour). Though the same superior quality product can be obtained by using electricity or electric power, but the electric operations are expensive and are not within the reach of our rural and tribal population. There is also inadequate supply of electricity in rural areas. In such conditions solar-energy crop dryers appear increasingly to be attractive as commercial propositions (Das and Kumar, 1989).

The development of simulation model is a powerful tool for prediction of performance and can help designers to optimize the dryer geometry

Abstract

Cotton is an important commercial crop of India, having 12.81 M ha cultivated area that is the largest in the World. In India 100% of the cotton is harvested manually. Cotton can be harvested mechanically by commercially available cotton pickers (the most commonly used) or cotton strippers, which remove all the cotton bolls. A conceptual design of 3 row finger type cotton header was done by keeping in view the harvesting of local cotton varieties and agronomic practices. Based upon review, important design and operational parameters such as finger type cotton header such as finger length, finger spacing, finger angle and forward speed were selected for the study. All the sub-assemblies like header frame, finger, reel, auger and power transmission were created using NX-8 CAD software at Mahindra Applitrac, Mohali. Based upon 2D drawings and bill of material (BOM), a tractor operated three row cotton header was developed and fabricated. The location of center of gravity of the developed machine was 186 mm nearer from the rear axle (longitudinal) than the normal tractor, 123 mm offset from the left side of rear axle (lateral) instead of at the center as for normal tractor and 400 mm above than the normal tractor from the ground (height).

Keywords: Cotton header, CAD, Cotton stripper, 3D modeling, Center of gravity

Introduction

It is estimated that the world requirement for all fibres is expected to rise from 74 million tonnes in 2010 to 95 million tonnes in 2020. Current split of various fibers namely cotton, cellulosics, jute and other natural fibers, wool and synthetics is 40.0, 50.0, 5.0 and 2.0 and 3.0 %, respectively (Barik, 2010). Cotton is an important commercial crop of India, having approximate 12.81 million ha cultivated area that is the largest in the world. Although, India is the largest producer of cotton in the world yet its yield is much less as compared to the world average yield. The average yield of cotton is only 540 kg/ha as compared to 2151 kg/ha in Australia as against the

Efficacy of the prototype electrostatic nozzle for cotton crops

B. Patel[1], M. Singh[2], P.K. Mishra[3*], G.S. Manes[2] & M.K. Patel[4]

[1]*Department of Farm Machinery and Power Engineering, Chaudhary Charan Singh Haryana Agricultural University, Hisar, India*

A prototype of an electrostatic nozzle was developed for spraying cotton crops in a project titled 'Design and development of an electrostatic nozzle for agricultural applications'. The study was carried out to evaluate the locally-developed electrostatic nozzle and compare its performance with an imported electrostatic nozzle and solid cone nozzle (conventional knapsack sprayer) in the cotton crop at the departmental research farm of Punjab Agricultural University, Ludhiana, India. Different spray performance parameters, *i.e.* number median diameter (NMD), volume median diameter (VMD), uniformity coefficient, droplet density, the volume of spray deposition, and area covered with droplets were determined with the help of water-sensitive paper (WSP) method of deposition collection. There was comparatively less variation in uniformity coefficient with the imported and locally-developed electrostatic nozzles than the solid cone nozzle at a 5 % level of significance. The average droplet density obtained with both the imported and locally-developed electrostatic nozzles was significantly more compared to the solid cone nozzle. The area covered by the droplets of the locally-developed prototype of the electrostatic nozzle was more than the solid cone nozzle. The volume of spray deposition differed significantly for all three treatments at a 5 % level of significance. Overall, there was no significant difference in the performance of both electrostatic sprayers, but they were found to be more effective than the solid cone nozzle.

Key words: electrostatic nozzle, uniformity coefficient, droplet density, volume of spray deposition.

INTRODUCTION

Cotton is one of the most important textile fibres in the world, accounting for about 35 % of the total worldwide fibre usage. It is the single most cash crop that is cultivated extensively throughout the world. India, China and the United States of America are the major cotton-producing countries and together account for approximately two-thirds of total world cotton production (Anon 2015a). India is the largest cotton-producing country in terms of total production with an average of 6.10 Mt per year on a total sown area of 11.8 Mha. However, it has the 33rd ranking in the world in terms of yield per hectare because of a low average yield of about 517 kg/ha as compared to the world's average of about 566.27 kg/ha (Anon. 2015b).

Although cotton production and yield increased by introducing new crop varieties and production practices, still significant yield loss was observed as 4.1, 6.5, and 8.8 % in the cotton crop in three districts of India, namely Firozpur, Mansa, and Bathinda, respectively (Dhawan *et al.* 2008). Crop loss due to different insects has been reported to run to 18.0 to 50.0 % (Dhaliwal *et al.* 2010). In an another study the range of yield loss due to cotton leaf curl virus disease was reported to be from 81.4 to 88.4 % in all northern cotton-growing states of India (Monga 2014, as cited in Kumar Sain *et al.* 2019)

There are several spraying methods to protect crops from pests and diseases. Based on the volume application rate, there are three types of sprayers: high volume sprayer, low volume sprayer, and ultra-low volume sprayer. The high volume sprayer leads to loss of spray due to the larger size of droplets and more liquid application

Received 5 May, 2016; Accepted 25 January, 2017

Development and introduction of high capacity, precise, reliable and energy efficient machinery/equipment is the need for judicious use of inputs. Manufacturing of agricultural machinery in India is varied in nature and starts from village artisans, tiny units, cottage to small scale industries, organized tractor and agricultural machinery manufacturers including energy and processing machinery industry. Precision in application rates for higher input-use efficiency can be achieved only by improving the designs of the existing machinery/equipment. Precision index (PI) of machine/equipment is based on its capability to perform a given task in an accurate manner. It is a worthwhile attribute to compare the performance of different equipment and operations to enhance the productivity of a given farm. The purpose of study was to propose an index, that is, PI to select efficient and precise machine/equipment for the farmers. PI values were calculated for three types of machinery namely zero seed cum fertilizer drills, planters and spraying machines. It was concluded that drill Make 2, tested in the year 2004, was having the highest PI value, that is, 0.87 or 87% followed by drill Make 1 having PI value 0.86 or 86% tested in the same year. Drill Make 5 tested in the year 2013 was having minimum PI value, that is, 0.80 or 80%. PI value for happy seeder machine was 0.88 or 88%. During the testing of multi-crop planter in year 2014, the variability of doubling attribute was more, that is, 28% followed by missing having 20% value and produced influence on PI which was observed to be 0.83 or 83%. PI of semi-automatic and automatic potato planter was found to be 0.70 and 0.80, respectively. The value was not much satisfactory and could be ranked under average category. PI of electrostatic sprayer mounted with single as well as twin nozzle was observed to be the highest, that is, 0.89 followed by PI of air assisted sprayer with single and double nozzle, that is, 0.83 and 0.84, respectively.

Key words: Precision index, zero till seed cum fertilizer drill, happy seeder, spraying machines, planting machines.

INTRODUCTION

Mechanization imparts capacity to the farmers to carry out farm operations, with ease and lesser drudgery. It helps the farmers to achieve timeliness, precisely meter and apply costly input with better efficacy and efficiency. Efficient machinery helps in increasing productivity by about 30% (Kulkarni, 2012) besides enabling the farmers

A B S T R A C T

Sugarcane is multipurpose crop that serves as source of sugar, juices, jaggery and various products for man and raw materials for industry. But prior to the process of machining process, some processing is required to remove the solid particles, spots and sludge on the cane. The processing of sugarcane strip for industrial or human use involves different operations of which peeling is a major one and cannot be neglected. Of all the unit operations involved in cane processing, several processes have been mechanized successfully. This study presents the features, prospects, performance evaluations and limitations of some sugarcane peeling machines in world like the fixed outer drum peeler, automated cane peeler, knife-edge type self-fed peeler, etc. Their peculiar advantages and operational parameters such as machine speed, output capacity, peeling efficiency and cane losses were evaluated. Aside from the manual ones, the ranges of the peeling efficiency and cane loss were recoded in range of 59.9 – 91.4 % and 2–4% respectively. As machine speed increased, the output capacity and cane loss increased while peeling efficiency decreased. Mechanization of this peeling process has the potential of encouraging growth in cultivation, cane utilization and improving the product quality of value-added products. The product quality, processing efficiency, minimum loss of cane and increased processing rate will be affected by improved sugarcane peeling process.

Introduction

The sugar cane family is made up of over 30 sugar cane varieties. Sugar cane is a perennial grass that thrives in hot, humid locations like Brazil and India. The sugar derived from sugar cane is used in syrups, juices, and molasses, but the rest of the plant can also be used in the production of environmentally friendly paper products.

The juice from the sugar cane's stalk is highly prized and is the source of 70% of the world's sugar. It also has the highest number of calories per unit area of any plant. Fresh sugarcane juice is a popular beverage in many countries particularly in Asian region such as China, India, Malaysia and Thailand due to its taste and cheap price. Flavonoids that can be found in sugarcane juice have the abilities to protect cells from degenerative processes and to reduce the development of health problems

■ **ABSTRACT :** Mahua stamen remover was evaluated for its performance. It was tested at four moisture levels (11.9, 13.17, 15.64 and 17.66 % d.b.) and three feed rates (15, 21, 27 kg/h). The stamen removal efficiency and whole flower recovery were determined to optimize feed rate and moisture content of mahua flower for better performance of the machine. The present study revealed that the optimum flower moisture content and feed rate were found to be 13.17 per cent and 15 kg/h, respectively with stamen removal efficiency of 88.23 per cent and whole flower recovery of 81.2 per cent.

Mahua *(Madhuca indica)* of Sapotaceae family is a large tree found inthe deciduous forest of India. Every part of the mahua tree is used by the tribals for their livelihood. Its flower is used as foods and can be fermented to alcoholic drinks due to its high sugar content. It is a multipurpose tree providing food, fuel, timber, green manure, oil, oil cake, liquor and raw materials for several products and is one of the most important trees of Indian forest. It also has a religious and a high bio-esthetic value in the tribal culture. It is one of those multipurpose forest tree species that provide an answer for the three major Fs *i.e.,* food, fodder and fuel (Banerji and Mitra, 1996). It is very important from the point of view that it can help inpromoting nutritional and economic security in backward areas.

The estimated annual production of mahua flower is around 2 lakh tonnes (*www. jhamfcofed.com*) in Jharkhand. Mahua tree produces edible flowers and fruits. The ripe flowers, which fall from the tree, are collected. The yield per tree ranges from 100-200 kg. Mahua is also famous for its seed oil.

Mahua flower can be utilized in a variety of ways in home, as animal feed and also as raw material for industrial products. They can be used as a sweetener inpreparation of many local dishes like *Halwa, Kheer, Puri* and *Burfi* (Patel and Naik, 2008). It is also used for preparation of bakery and confectionary goods. Tribal people also use it for brewing alcohol. It contains tannin as tannins are excellent antioxidant that helps in giving the structure, texture and flavour to wine. Mahua flowers are also considered good for cooling and are used as a tonic and demulcent. However, an estimated 90 per cent of the production goes into brewing beverages. Mahua has various types of medicinal uses due to its tannin content. It is used as anti-diabetic, antiulcer, hepato protective, anti-pyretic, anti-fertility, analgesic, anti-oxidant, swelling, inflammation, piles, emetic, dermatological, laxative, tonic, anti-burn, anti-earth worm, wound healing headache and many more problems (Patel *et al.,* 2012). On account of various advantages of mahua

ENERGY INPUT FOR FODDER CROP PRODUCTIONS UNDER DIFFERENT TYPES OF FARMING SYSTEMS

Pramod Kumar Mishra*, Sunny Sharma, Himanshu Tripathi and Dharmendra Pandey

Lovely Professional University, Phagwara, Punjab, India

Abstract

The pattern of energy utilize in cultivation of fodder crop was studied under traditional and partially mechanized farming system. It was observed that the total operational energy was found to be 6883.83 MJ/ha and 7298.73 MJ/ha in traditional and partially mechanized farming system respectively. Out of which 48.52 and 56.21 percent was utilized by direct source of energy in different farming systems, whereas 51.48 and 43.79 percent was utilized by indirect sources of energy. The total energy cost in traditional farming system was Rs 86450 /ha. Similarly, the cost of energy in partially mechanized system was Rs 93201 /ha. This difference clearly indicates that traditional farming system can be replaced by partially mechanized farming system with more return.

Key word: Partially mechanized farming system Energy ratio, energy productivity etc.

Introduction

Energy is integral part to national development process and to provide major vital services that improve human requirements; fuel for cooking, light for living, motive power for transport, and electricity for modern communication. In agricultural sector, its use is in every form of inputs., seed, fertilizer, agro-chemical for plant protection, machinery use for various operation, housing, transport, and processing. Apart from solar energy, production agriculture uses basic additional energy inputs., soil, water, tractive power, chemicals for growth of plants. The amount of energy invested through these inputs and quantity actually used by the plant govern the crop growth and yield during their life cycle.

Singh *et al.* 202 has estimated that total energy input Indian agriculture increased by 3.6 times. In modern agriculture, commercial energy sources (fuel, machinery and chemicals) contribute bulk of the energy supplies to the production system. Commercial energy use in agriculture has been increasing since revolution with increasing use of diesel and electricity in farm operations. The share of agriculture in electricity consumption has increased from 3.9% of the total consumption in 1950-51 to 29.6% in 1993-94. Total commercial energy use in agriculture increased nearly fivefold with growth rate of 11.8% between 1980-81 to 1994-95. The share of agriculture in total consumption in the country increasing marginally from 3.2 to 5.2% during the same period. Increase in land productivity and efficient diversification of agriculture for better economic return to the producers will call for significantly higher level of input to agriculture (Mahapatra, 1991).

India is presently under heavy stress on account of a large-scale exploitation for fuel wood, timber and fodder, mismanagement of forest resources and frequent fires. There is acute shortage of fodder especially green nutritious fodder, which is major cause of low productivity of livestock, especially in hilly area (Deb Roy *et al.*, 1989). The main reasons for low productivity is insufficient and low quality fodder and feed including grazing facilities (Deb Roy, 1993). Therefore, India has been the home of major draught, milch and dual-purpose breeds of cattle. Indian dairy production system is complex and generally based on traditional and socioeconomic considerations. However, there has been a rapid change in way of agriculture (*i.e.* cropping system, water resources, diversification of crops, intensification of agriculture), increasing use of mechanical power, transformation from

In vitro efficacy test of fungicides against *Ustilaginoidea virens* causing false smut of rice

Manish Kumar Maurya, SK Singh, SN Rahul, VP Dubey, Vikash Kumar Yadav, SP Vishwakarma and Shyam Babu Gautam

Abstract
Rice false smut caused by *Ustilaginoidea virens* (Cke.) Tak. is an emerging threat now a days. It causes both qualitative and quantitative yield losses. The present study is carried out to evaluate the efficacy of five fungicides against *Ustilaginoidea virens*. The result revealed that the complete inhibition was observed under treatment Propineb, Propiconazole, Carbendazim 63% + Mancozeb 12% and Tebuconazole 50% + Trifloxystrobin 25% while in Kresoxim methyl, inhibition per cent is 57.69 and 69.98 at concentration 0.1% and 0.2% respectively in *in vitro* condition.

Keywords: Rice, false smut, fungicides, *in vitro*, *U. virens*

Introduction
False smut disease caused by *Ustilaginoidea virens* (Cke.) Tak. (teleomorph form: *Villosiclava virens*) is a destructive disease of rice all around the world. The disease was first reported from Tirunelveli district of Tamil Nadu staffe of India (Cooke, 1878) [4]. False smut was recognized as a symbol of a more yield and due to its sporadic occurrence, it is considered as a minor disease. It is also known as Lakshmi (goddess of wealth and prosperity) disease. Now a day, it has become a main constraint in a rice production in many rice growing regions of India (Ladhalakshmi *et al*., 2018) [8] due to use of high input (large application of nitrogenous fertilizer) large scale use of hybrid varieties and climate change (Rani *et al*., 2015) [12]. The False smut pathogen (*U. virens*) infect the plant during flowering stage where an individual healthy grains converts firstly into whitish, yellowish orange to green velvety spores which later turns into greenish black in colour (Baite *et al*., 2014) [1].

False smut causes a qualitative and quantitative loss and in northern Indian states, disease incidence (per cent of infected tillers) varied from 2 to 75 per cent. In Uttar Pradesh, a yield loss was recorded up to 5-85 per cent (Singh *et al*., 2014) [13]. Over all, the loss in yield due to false smut disease in India has been varied between 0.2–49%, depending on disease incidence and rice varieties (Dodan and Singh, 1996) [3]. Various researchers reported different effective fungicide from time to time, carbendazim (Hegde *et al*., 2000) [6], trifloxystrobin + tebuconazole and propiconazole (Ladhalakshmi *et al*., 2014), Kresoxim methyl, Tebuconazole and Azoxystrobin + Difenconazole (Banasode and Hosagoudar, 2020) [2], Copper oxychloride and copper hydroxide, Hexaconazole (Bhargava *et al*., 2018) [5]. Therefore, present investigations were conducted to know the appropriate and effective combination group of fungicides to inhibit the pathogen *in vitro*.

Materials and Methods
The experiments were conducted in the laboratory of Department of Plant Pathology, Acharya Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya, UP.

Isolation of pathogen
False smut infected panicles were collected from the NSP-6 farm of the university. The smut balls was brought to the laboratory and isolates them on a PDA (Potato Dextrose Agar) medium as described by Ladhalakshmi *et al*., 2012 [8]. The smut balls were thoroughly washed repeatedly in tap water. Surface sterilized in a mercuric chloride (1% $NaOCl_2$) solution for 30 seconds followed by three times rinsing in sterilized distilled water. The false smut balls were cut into two halves, the inner layer containing spores was then streaked on PSA medium which was supplemented with 100ppm streptomycin to avoid bacterial contamination. The inoculated Petri-plates were incubated in a BOD incubator at 25+1 ^{0}C.

In the present investigation twenty locally isolated microorganisms including nineteen *Trichoderma spp.* and one *Penicillium spp.* were tested for their antagonistic property against three different species of the *Fusarium viz. Fusarium oxysporum* f. sp. *Lycopersici, Fusarium oxysporum* f. sp. *Cicero, Fusarium fujikuroii.* Antagonistic activities results showed that Tharz-6, Tviri-1, Thama-1, and Tviri-5, Tpoly -2 were suppressed higher mycelia growth of *F. o.* f. sp. *ciceri* at 48 hrs and Tharz-1 and Tpoly-1 were superior inhibitor of mycelia growth of pathogen at 96 hrs, time interval. Likewise, Thama-1 and Tpoly-2 were suppressed higher growth of *F. o.* f. sp. *lycopersici* at 48 hrs and Tpoly-1 and Thama-1 were superior inhibitor of mycelia growth of this pathogen at 96 hrs. It indicates the Tpoly and Thama were effective at every time interval. Though, the antagonistic activity of Tharz-2, Tviri-1, Tvire-2 and Tharz-6 were suppressed higher mycelia growth of *F. fujikuroii* at 48 hrs and Tharz-1, Tpoly-1, Tviri-4, and Tvire-2 were superior inhibitor of mycelia growth of this pathogen at 96 hrs, its indicates the Tharz and Tviri were effective at every time interval.

Trichoderma spp., Fusarium spp. and Bio-control

Introduction

Soil borne plant pathogens are the major problem among the disease causing agents. *Fusarium spp.* are the one of most important soil borne fungal pathogen of plants it causes economic loss to more than 200 host plants.

The *Fusarium spp.* used in the present investigation are soil borne which caused wilt and rot in various crop (Chakraborty, 2005 and Chakraborty and Chatterjee 2008). Therefore, it is for reach to control by chemical or fungicides as soil and seed application. The alternative approach, for the control these pathogens is the use of bio-agents. Though, the biocontrol agent is necessary to control effectively of such soil borne plant pathogens.

In the present communication, an attempt was made to study the antagonistic activity of these fungal antagonist of *Trichoderma spp* and *Penicillium spp.* against soil borne pathogen *fusarium spp* which caused wilt and rot in various crop.

Scenarios of biological control of soil-borne plant pathogens using most encouraging bio-control agent, the genus *Trichoderma* has

Ustilaginoidea virens (Cooke) Takah.

Abstract

Ustilaginoidea virens (Cooke) Takah. causing false smut of rice is a destructive disease which causes an economic yield loss ranges from 0.2-49%. The present study is carried out to check inhibitory effect of botanicals and bioagents against *U. virens*. Among botanicals, neem oil at both concentration, i.e., 5 per cent and 10 per cent was found highly effective and inhibit the growth by 66.97% and 70.14%, respectively followed by onion (62.89%, 67.64%), garlic (58.82%, 64.25%), ginger (55.88%, 63.57%) and tulsi (46.40%, 54.98%). Among bioagents, maximum inhibition (53.55%) was observed in *Bacillus subtilis* followed by *Pseudomonas fluorescence* (41.87%), *Trichoderma viride* (40.35%) and *Trichoderma harzianum* (36.29%) in *in vitro* condition.

1. Introduction

Rice (*Oryza sativa* L.) being the most staple cereal food crop, grown in India, providing one third of calories requirement for more than 70 per cent of Indian population. More than 90 per cent of world's rice is grown and consumed in Asia, known as rice bowl of the world. To focus attention on the importance of rice in global food security and necessity into increased rice production and productivity, United Nation General Assembly in 2002, declared to celebrate the year 2004 as "International year of rice.

In India, it is cultivated in an area of 43.77 Mha with a production of 169.14 Mt and has an average productivity 3.86 t/ha (Anonymous, 2019). The major rice producing states are West Bengal, Punjab, Uttar Pradesh, Andhra Pradesh, Bihar and Tamil Nadu. In Uttar Pradesh, it is cultivated in an area of 5.81 Mha with production of 19.91 Mt and average productivity 3.42 t/ha (Anonymous, 2019).

Rice crop is affected by number of biotic and abiotic factors. Among biotic factors, diseases caused by fungi, bacteria, virus and others are the major one. False smut is one of the most calamitous fungal diseases of rice and its occurrence is reported from every corner of the world wherever rice is growing (Ladhalakshmi *et al.*, 2018). Initially, the disease was of minor importance and commonly known as "Welcome/Lakshmi disease" because the disease was considered as an indicator of vigorous crop resulting into good harvest but due to continuous use of high dose of nitrogenous fertilizer extensively, cultivation of hybrid cultivars and climatic change, the disease becomes major one (Jehan *et al.*, 2019). The disease was first reported from Tirunelveli district of Tamil Nadu state of India (Cooke, 1878). The false smut pathogen *U. virens* infect the plant during flowering stage where an individual healthy grain converts firstly into whitish, yellowish orange to green velvety spores which later turns into greenish black in colour (Biate *et al.*, 2014).

In Uttar Pradesh, a yield loss was recorded ranges from 5-85 per cent (Singh *et al.*, 2014). Continuous use of fungicides has resulted in accumulation of toxic compounds which is hazardous to humans, animals and environment and also build-up resistance in the pathogens. So, botanicals and bioagents are the best alternative and economical way to manage the disease. Management of diseases and pests by the use of plant-based products was practiced over time until synthetic pesticides were developed (Mahmood *et al.*, 2016). Various researchers reported different effective botanicals from time-to-time. Neem and garlic was found effective as reported by Mahmud *et al.* (2017). Different bioagents are normally dominant components of the soil microflora in extensively varying habitats and are very effective against the *U. virens* (Xiaoli.e *et al.*, 2011; Kannahi *et al.*, 2016; Nath and Das, 2020). Therefore, the present investigation was carried out to know the appropriate and effective botanicals and bioagents against *U. virens in vitro*.

2. Materials and Methods

The experiments were conducted in the laboratory of Department of Plant Pathology, Acharya Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya, U.P. during 2020-21.

2.1 Isolation of pathogen

Panicles infected with false smut were collected from the NSP-6 farm of the University. The smut balls were brought to the laboratory

Abstract

In this study, the effect of different botanicals in combination with *Trichoderma harzianum* were used to observe plants mortality and yield affected by collar rot of chickpea. The effect of different treatments on germination at 20 days after sowing and vigour index I (germination × plant height), vigour index 2 (germination × dry weight), 45, 60, 75 days after sowing (DAS) and also yield parameter like (yield per plot and yield in q/h) were evaluated at after harvesting of chickpea. Significant variant in germination of chickpea seeds were recorded under different treatments. The lowest germination was recorded in the control plot (T9) (85.89%) and maximum in (T8) with (97.33%) at 20 days after sowing. Highest vigour index 1 (2019.59) and vigour index 2 (147.94) were recorded in T8, maximum plant height in T8 (20.75, 25.25, 33.38 cm.), highest total number of branches per plant in T8 (5.47, 6.27, 7.67), maximum fresh weight in T8 (6.42, 17.50, 20.72 gm.), maximum dry weight in T8 (1.52, 4.26, 5.09), minimum plant mortality in T8 (3.55, 7.47, 14%) and maximum plant mortality in control (9.73, 15.07, 21%) were recorded at 45, 60, 75 DAS, and maximum yield per plot in T8 (1.68 kg) and also the yield parameter and plants mortality was best observed in T8 followed by in botanical T2 (Neem oil 2.5%) with combination of *Trichoderma harzianum*, respectively.

1. Introduction

Chickpea (*Cicer arietinum* L.) is, a self-pollinated, diploid (2n = 2x = 16) annual legume of family Fabaceae and known as various names, viz., Gram, Bengal gram, Garbanzo and Egyption pea. It was first cultivated in south eastern region of the world, but now it is also cultivated in semi-arid regions (Agarwal *et al.*, 2012). Pulses contain higher proportions of protein (17%-30% by dry weight) in comparison to other plant foods. With the protein, chickpea is a good source of carbohydrates has comparison to other pulses, according to Wallace *et al.* (2016). There are various biotic and abiotic factors that affect the production of the chickpea in the world as well as in India too. The biotic factor includes insect pests and a number of devastating diseases caused by fungi, bacteria, viruses, and nematodes. The fungal diseases such as fusarium wilt (*Fusarium oxysporum* f.sp. *ciceris*), Ascochyta blight (*Ascochyta rabiei*), collar rot (*Sclerotium rolfsii*), Verticillium wilt (*Verticillium dahliae*), black root rot (*Fusarium solani*), Phytophthora root rot (*Phytophthora megasperma*) and seed rot (*Aspergillus flavus*), *etc.* Among all of the diseases collar rot disease, caused by *Sclerotium rolfsii Sacc.*, is a serious threat to chickpea that may cause 55-95% mortality of the crop at seedling stage under favourable environmental conditions (Gurha and Dubey, 1982).

2. Materials and Methods

2.1 Preparation of botanicals

Fresh parts of the test plants (*Lantana camara*, *Eucalyptus* spp. *Ocimum sanctum* and *Azadirachta indica*) were collected and washed thoroughly in clean water. Hundred grams of each washed samples were grinded in mortar and pestle by adding equal amount (100 ml) of sterilized distilled water (1:1 W/V) and boiled at 80ºC for 10 min in a hot water bath. The grinded material was filtered through muslin cloth followed by filtering through sterilized Whatman No. 1 filter paper and treated as standard 100 per cent plant extract (Nene and Thapliyal, 1982) and required concentrations of five per cent of each plant extract were prepared.

2.2 Treatments details

All the treatments were used as seed treatments. (T1) Seeds treated with combination of *Trichoderma harzianum* (10 gm/kg seed) and *Pseudomonas* spp. (10 gm/kg seed). (T2) Seeds treated with combination of *Trichoderma harzianum* (10 gm/kg seed) and Neem oil (2.5%). (T3) Seed treated with combination of *Trichoderma harzianum* (10 gm/kg seed) and Jeevamrit (5%). (T4) Seed treated with combination of *Trichoderma harzianum* (10 gm/kg seed) and *Lantana camara* extract (5%). (T5) Seed treated with combination of *Trichoderma harzianum* (10 gm/kg seed) and *Eucalyptus* spp. extract (5%). (T6) Seed treated with combination of *Trichoderma harzianum* (10 gm/kg seed) and *Ocimum sanctum* extract (5%). (T7) Seed treated with combination of *Trichoderma harzianum* (10 gm/kg seed) and Neem leaf extract (5%). (T8) Seed treated with combination of *Trichoderma harzianum*(10 gm/kg seed) and Carbendazim (3 gm/kg seed).

To study the response of salicylic acid on growth, physiological traits, yield and yield components of wheat varieties on timely and late sown conditions

Prashansha Singh, Vinaya Kumar Yadav, AH Khan and Ram Kalap Yadav

Abstract
The present investigation entitled "Effect of salicylic acid on growth, physio-chemical changes and yield of wheat (*Triticum aestivum* L.) under high temperature at anthesis" was conducted at Students Instructional Farm of the Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) during *rabi* seasons of 2014-15 and 2015-16. The experiment was planned under RBD (Randomized Block Design) with three replications. The treatment consisted of two date of sowing viz;25th November and 25th December with two varieties NW-5054 and NW-2036 with six salicylic acid treatment. Results indicated that growth attributes such as plant height, number of tillers per plant and dry weight per plant influenced with the date of sowing. When late sown variety was planted timely all the growth attributes showed drastic reduction with respect to late sowing (25th December). However, NW-5054 showed comparatively good performance in terms of growth attributes at timely sown (25th November). Performance of NW-5054 was very good as compared to NW-2036 due to delayed sowing on 25th December. Among SA treatments,T10(Seed soaking in (0.75mM) salicylic acid + Foliar spray of (0.75mM) salicylic acid at 30 DAS) resulted in highest increase in these traits while T9 (Foliar spray of (0.75mM) salicylic acid at 30 DAS)over control. Proline content in leaves increased with the age of the crop up to 90 DAS in both the date of sowing. The highest amount of proline content was recorded at 90 DAS in both the varieties under both the date of sowing. Date of sowing influenced the membrane injury index (MII). Both the varieties had higher MII at 60 DAS. SA treatment significantly decreased the MII at all the growth stages. The activity of antioxidant enzymes viz: catalase, superoxide dismutase and peroxide in leaves increased with the age of the crop up to 90 DAS under both the date of sowing in both the varieties.SA treatments increased the activities of catalase, superoxide dismutase and peroxide enzyme. However, maximum increase in the activity of these enzymes was observed with T10 (Seed soaking in (0.75mM) salicylic acid + Foliar spray of (0.75mM) salicylic acid at 30 DAS). Time of sowing decreased substantially almost in all the yield components measured viz; number of ear per plant, ear length, number of grains per plant, test weight, biological yield and harvest index which caused severe reduction in yield. Overall, T10 (Seed soaking in (0.75mM) salicylic acid + Foliar spray of (0.75mM) salicylic acid at 30 DAS) treatment showed best result and T2 Seed soaking in (0.25mM) salicylic acid gave least. All the salicylic acid treatments reduced the detrimental effect of heat stress on both the varieties by improving physiological traits which ultimately helped in obtaining higher yield.

Introduction
Wheat (*Triticum aestivum* L.) is the most important cereal crop belongs to family poaceae. It is staple diet for more than one third of the world population. Wheat crop occupies 21.8% of the total area under food grains. It constitutes the staple food for at least 43 countries including China, India, USA, France, Russia, Canada, Australia and a member of European countries. Wheat is an important crop of India. It is grown over 26 million hectares. Wheat production in 2016-17 is forecast at 93.5 million tonnes (Source: International Grains Council (IGC).India ranks second in area (12.5%) and production (12.05%) of wheat in the world which is next to China (Anonymous, 2013)[13]. India has about 29.25 mha area with the production of 85.93mt and productivity of 29.38 q/ha. The northern and western part of India has maximum area and production under wheat cultivation. In Uttar Pradesh, area, production and productivity are 9.67 mha, 33.97 mt and 31.13q/ha, respectively Uttar Pradesh ranks first in area (36.58% of India) and production (36.27% of India) of wheat in the country.

Introduction
Wheat (*Triticum aestivum* L.) is the most important cereal crop belongs to family poaceae. It is staple diet for more than one third of the world population. Wheat crop occupies 21.8% of the total area under food grains. It constitutes the staple food for at least 43 countries including China, India, USA, France, Russia, Canada, Australia and a member of European countries. Wheat is an important crop of India. It is grown over 26 million hectares. Wheat production in 2016-17 is forecast at 93.5 million tonnes (Source: International Grains Council (IGC) India ranks second in area (12.5%) and production (12.05%) of wheat in the world which is next to China (Anonymous. 2017) [1]. India has about 29.25 mha area with the production of 95.9 mt and productivity of 29.38 q/ha. The northern and western part of India has maximum area and production under wheat cultivation. In Uttar Pradesh, area, production and productivity is 9.67 mha, 33.97 mt and 31.13 q/ha, respectively Uttar Pradesh ranks first in area (25.58% of India) and production (36.27% of India) of wheat in the country.

There are number of constraints which affect wheat production and decrease the economic value of wheat. Among them increase in temperature due to global warming is one major factor. Most of the world crops including wheat have an optimal range of temperature. Exposure to higher than optimal temperature reduced yield and decreased quality of subject grain. Over 7 million hectares of wheat grown in approximately 30 countries are subjected to continual heat stressing environment and adversely affects wheat growth in many important production regions and is a major limitation to wheat productivity worldwide. Heat stress is a function of the magnitude and rate of temperature (Wahid *et al*., 2007) [20]. At present,

Effect of fertilizers and cutting schedule on growth and quality of dual purpose barley crop (*Hordeum vulgare* L.)

Vishuddha Nand, R Yadav, Rajesh Kumar, RK Doharey, SK Verma, Neeraj Yadav and RK Yadav

Abstract
A field experiment was carried out at Agronomy Research Farm,Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.) during Rabi season 2016-17.The experiment was laid out in Split Plot Design with three replications. Main plot were treated with fertilizer levels, F_1 (60 kg N+ 30kg P_2O_5 ha^{-1}), F_2(80 kg N+40 kg P_2O_5 ha^{-1}), F_3 (100 kg N+50 kg P_2O_5 ha^{-1}) and F_4 (120 kg N+60 kg P_2O_5 ha^{-1}) and sub plot were treated with cutting schedule as 45 DAS, 55 DAS, 65 DAS and 75 DAS. The results revealed that the growth parameters like, plant height, dry weight of plant, leaf area index (LAI) and no. of tillers at first cutting and at harvest were recorded maximum with the application of 120 kg N + 60 kg P_2O_5 ha^{-1} followed by 100 kg N + 50 kg P_2O_5 kg ha^{-1} and 80 kg N + 40 kg $P_2O_5ha^{-1}$ respectively and significantly higher over the application of 60 kg N +30 kg P_2O_5 ha^{-1}. The maximum plant height (77.28 cm) was recorded when barley crop cut as 75 DAS which was higher tune to the 12.6%, 17.57% and 32.51% over 65, 55 and 45 days after sowing. The dry matter accumulation, leaf area index and no. of tillers were also maximum in the same cutting. However, the quality parameters viz. crude protein (12.88%), crude fiber (31.87%),TDN (65.93%), WSC(10.40%), ADF (31.34%), NDF (52.49%) and Ash (13.34%) were recorded maximum with the application of 120 kg N + 60 kg P_2O_5 ha^{-1} while in case of cutting schedule the maximum crude fiber (31.49%), WSC (10.80%), ADF (33.58%), NDF (54.02%) and Ash (15.20%) were found at first cut (75 DAS) where as crude protein (13.13%) and TDN (65%) obtained at first cut (45 DAS).

Keywords: growth, LAI, fresh weight, plant height, P_2O_5 Barley and cutting schedule

Introduction

India is the largest milk producing country in the world with livestock population of 529 million and milk production 133 mt. It contributes nearly 7% in the global cereal production. Barley grain largest use as animal feed in all over the world and in India also, a major share of barley grain is used as animal feed either alone or mixture with fodder crops. Barley has tremendous potential and variation for production of very high amount of digestible dry matter as well as protein yield per hectare. It is grown successfully in a wider range of climatic conditions than any other cereals. Barley has such morpho-physiological traits that make it suitable for dual purpose cultivation for fodder and grain production than other cereals. It is highly efficient in the utilization of water and nutrients in limiting conditions. It is high capacity of crop for tillering and regenerate after cutting and additional capacity for large accumulation of biomass. It sets seed rapidly after re-growth, thus escaping terminal stress due to high temperature and warm winds often experienced in the region. Thus, as a dual purpose (green forage and feed/grain) crop it provides a welcome boost to the confidence of forage growers and fits well for crop diversification in the integrated crop-livestock farming system. Area under barley in world is 47.5 mha with 123.7 mt production and 2.68 t/ha Productivity. Russian federation holds first position in all over the world in terms of area and production with 4.94 mha and 8.35 mt respectively.

In India, barley crop was grown over an area of 695.0 thousand hectare with a production of 1743.2 thousand tones and productivity of 2.51 t ha^{-1} during 2012-13 (Anonymous, 2013) [1]. Uttar Pradesh is one of the most important barley growing states of India. In Uttar Pradesh, the area under cultivation of barley is about 168.0 thousand ha^{-1} with a production of 441.0 thousand tonnes and productivity of 2.63 t ha^{-1} (Anonymous, 2013) [1]. Dual purpose barley is an excellent alternate crop for fodder purpose. The nutritive value of green fodder is highest at 50% flowering stage and decreases after flowering stage in most of the crops. In dual purpose barley crop, stage of harvesting also determine the regenerative potential of the crop, the regeneration capacity is adversely affected by the higher stage of harvesting for green fodder.

Effect on foliar application of potassium nitrate on morpho-physiological and yield potential in different wheat [*Triticum aestivum* L.] cultivars under drought and irrigated conditions

Vinaya Kumar Yadav, Anil Kumar Singh, Prashansha Singh, Rajnish Kumar, Shubham Kumar Srivastav, Vikas Yadav and Ram Kalap Yadav

Abstract
The field experiments were conducted at Student Instructional Farm of CSAUAT Kanpur, during Rabi 2016-17 and 2017-18. The objective of investigation was to study the effect of foliar applied thio-urea with different doses on plant traits (morphological, yield and its components) of two wheat varieties under drought and irrigated condition. It was designed in split-split plot design with three replications. The two conditions *i.e.*, drought (I_0) and irrigated (I_1) conditions were allocated in the main plots and two wheat varieties *i.e.*, V_1 (K-1006) and V_2 (K-307) in sub plot and for each five chemical treatments were applied as foliar spray at heading stages by 500 ppm (T_2) and 1000 ppm thio-urea (T_4), along with control (T_0) in sub-sub plots. The significantly higher grain yield (5.30 & 5.26 gm) with best morpho-physiological. Next to this were 500ppm thio-urea (T_3) *i.e.*, 5.12 & 5.08, 1000ppm thio-urea (T_4) *i.e.*, 5.08 & 5.03 as compare to control (T_0) *i.e.*, 4.39 & 4.35 gm. Among cultivars, maximum responsive was K-1006 (V_1) in most of traits and gave significantly higher grain yield (5.26 & 5.30) and and minimum in K--307 (V_2) *i.e.*, 5.08 & 5.12 gm with both concerning experimental years.

Keywords: Growth parameter, yield parameter, foliar spray on thio-urea, drought and irrigated conditions

Introduction
Wheat [*Tritium aestivum* L.] is one of the most important cereal crops of the world. Bread wheat is the major staple food source for a large part of global population. It is second most important cereal crop after maize and plays an important role in national food security. It has originated from the Levant region of the New East and Ethiopian Highlands, but now cultivated worldwide. Wheat is the world's most outstanding crop that excels all other cereals both in area and production, known as king of cereals. It is also one of the most nutritious cereals and its contribution to human diet puts it in the first rank of plants that feed the world (Costa *et al.*, 2013) [4]. Wheat consumption worldwide is estimated to 817 million tons by 2030 and production would need to increase at 22.6-43.6% in different countries at the current production level to meet the estimated consumption demand. It gives me immense pleasure to bring out the
current issue of Wheat & Barley Annual Report. I am also very delighted to share that during (Anonymous, 2017-18) [2], once again, the country has achieved a highest record wheat production of 99.70 mt which is very close to the magical figure of 100 mt from an area of 29.58 mha thereby registering an all-time high productivity of 3371 kg/ha. Similarly, in barley also the country harvested a record production of 1.77 mt from an area of 0.66 mha achieving a record average productivity of 2679 kg/ha. *Inter alia*, coordinated research, conducive environmental conditions, governments pro-farmers' policies and farmers hard work contributed towards achieving good productivity in both the crops across regions facilitating the farmers to be on the track of "Doubling the Farmers Income by 2022" as envisioned by the Hon'ble Prime Minister of India.
Drought is the most prevailing problem and the factor known to be serious for its impacts on crop limitations (Souza *et al.*, 2004) [10]. This kind of abiotic stress often occurred as consequence of the reduction of the water level that reaches earth due to extreme atmospheric

The response of salicylic acid on growth, yield and yield components of wheat varieties on timely and late sown conditions

Prashantha Singh, Vinaya Kumar Yadav, Afif Khan and Ram Kalap Yadav

Abstract
The present investigation entitled "Effect of salicylic acid on growth, physio-chemical changes and yield of wheat (*Triticum sectivum* L.) Under high temperature at anthesis" was conducted at Students instructional Farm of the Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) during rabi seasons of 2014-15 and 2015-16. The experiment was planned under RBD (Randomized Block Design) with three replications. The treatment consisted of two date of sowing viz.25th November and 25th December with two varieties WW-3054 and WW-2036 with six salicylic acid treatment viz. (T1)Control, (T2)Seed soaking in (0.25mM) salicylic acid, (T3)Foliar spray of (0.25mM) salicylic acid at 30 DAS, (T4)Seed soaking in (0.25mM) salicylic acid + Foliar spray of (0.25mM) salicylic acid at 30 DAS, (T5)Seed soaking in (0.5mM) salicylic acid, (T6)Foliar spray of (0.5mM) salicylic acid at 30 DAS, (T7) Seed soaking in (0.5mM) salicylic acid + Foliar spray of (0.5mM) salicylic acid at 30 DAS, (T8)Seed soaking in (0.75mM) salicylic acid, (T9)Foliar spray of (0.75mM) salicylic acid at 30 DAS, (T10) Seed soaking in (0.75mM) salicylic acid + Foliar spray of (0.75mM) salicylic acid at 30 DAS. Results indicated that growth attributes such as plant height, number of tillers per plant and dry weight per plant influenced with the date of sowing. When late sown variety was planted timely all the growth attributes showed drastic reduction with respect to late sowing (25th December) However, WW-3054 showed comparatively good performance in terms of growth attributes at timely sown (25th November). Performance of WW-3054 was very good as compared to WW-2036 due to delayed sowing on 25th December. Application of salicylic acid significantly increased all growth attributes in both varieties under both timely and late sown. Time of sowing decreased substantially almost in all the yield components measured *viz*. number of ear per plant, ear length, number of grains per plant, test weight, biological yield and harvest index which caused severe reduction in yield. Overall, T10 (Seed soaking in (0.75mM) salicylic acid + Foliar spray of (0.75mM) salicylic acid at 30 DAS) treatment showed best result and T2 Seed soaking in (0.25mM) salicylic acid gave least. Overall growth attributes physiological traits and yield as well as yield components of wheat crop were adversely affected by time of sowing due to onset of high temperature during crop growth and particularly grain filling. All the salicylic acid treatments reduced the detrimental effect of heat stress in both the varieties by improving physiological traits which ultimately helped in obtaining higher yield.

Keywords: Growth, conditions, yield and yield parameter

Introduction
In India, wheat production has been stagnant around 70-72 million tonnes since 1999-2000, to meet the increasing demand of the growing population till 2020, it is estimated that around 9 million tonnes wheat grain production will be required. It is consumed in the form of chapattis, puris, naji or rawa. Wheat grain has relatively high content of niacin and thiamine that's why wheat proteins are especially important in human diet. Beside their significance in nutrition they are principally concerned in providing the "gluten" which provides spongy cellular texture of bread and baked product. Wheat straw is good source of feed for a large population of cattle in our country.

There are number of constraints which affect wheat production and decrease the nutritive value of wheat. Among them increase in temperature due to global warming is an important factor. Most of the world crops including wheat have an optimal range of temperature. Exposure to higher than optimal temperature reduced yield and decreased quality of wheat grain. Over 7 million hectares of wheat grown in approximately 50 countries are subjected to continual heat stressing environment and adversely affects wheat growth in many important

The present investigation entitled "Foliar Response of Chemicals on Yield and Yield Attributing Characters of rice (*Oryza sativa* L.) Under Rain fed Condition" was conducted during the *Kharif* season in 2016 at the Student Instructional Farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad-224 229 (U.P.). Experiment was conducted in randomized block design with three replications and nine treatments on rice variety (Sahbhagidhan) under rainfed condition. Chemicals *viz*., foliar spray of 0.5 and 1.0%KCl, 1.0 and 2.0% $MgSO_4$, 0.3 and 0.6% Boric acid and 0.25 and 0.5% Salicylic acid at two growth stages(15 DAT and milky stage) along with untreated control (distilled water spray). Yield and yield attributing characters *viz*., Number of panicle bearing tiller plant^{-1}, Number of grains panicle^{-1}, Number of sterile grains panicle^{-1}, Grain yield (kg ha^{-1}), Straw yield (kg ha^{-1}) and Test weight (g)were improved by different chemical concentrations. On the basis of results obtained foliar application of various chemicals enhanced yield as compare to control under rain fed condition. The effects of 1.0 % $MgSO_4$ were more pronounced fallowed by salicylic acid 0.25 and 0.5% as well as 1% KCl over other treatments.

Introduction

Rice (*Oryza sativa* L.) as one of most important cereals worldwide is considered as the major food of more than 2 billion of peoples across the world (Akhgary, 2004). The rice is one of economically important crops in the world (Bajaj and Mohanty, 2005; Harkamal *et al*., 2007) which is cultivated in 114 countries (FAO, 2004).

Rice is staple food of a millions of people in the world particularly in developing countries. About 90 per cent of rice grown in the world is produced and consumed in Asian countries (Patel *et al*., 2016). India rank first in respect of area (44.50 million ha) second in production (102.75 million tonnes), but the productivity of rice is very low (2.20 t ha^{-1}) (Verma *et al*., 2015).

Rice has the evolutionary particularity of being semi-aquatic. The conventional system for irrigating rice is to flood, which provides water and nutrient supply under anaerobic conditions and uses large amounts of water.

2Chandrashekhar Azad University of Agriculture and Technology, Kanpur-208 002 (U.P.)

Abstract

The investigation entitled "Effect of salicylic acid and cycocel on biochemical and phenology change of mustard(*Brassica juncea* L. Czern & Coss)" was conducted during *rabi* season, 2016-17 at the Instructional Farm of Narendra Deva University of Agriculture & Technology, Kumarganj, Ayodhya (U.P.) in randomized block design with 7[th] treatments, three replications and variety Narendra rai (NDR-8501). Various concentrations of (T_1) Control, (T_2) Salicylic acid (50ppm), (T_3) Salicylic acid (100ppm), (T_4) Salicylic acid (200ppm) and (T_5) Cycocel (100ppm) , (T_6) Cycocel (150ppm), (T_7) Cycocel (200ppm). Observations were recorded at 30, 60, 90 DAS and at maturity. The observations were taken on biochemical and phenology parameters like Chlorophyll content, Oil content (%), Days to 50 % flowering. The maximum chlorophyll 'a' and 'b' content was observed in salicylic acid 200ppm followed salicylic acid 100ppm at 60 DAS and 80 DAS over the control and maximum oil content was recorded in salicylic acid 200ppm followed by salicylic acid 100ppm and lowest increase was recorded in cycocel 200ppm among all treatments & Maximum increase in number of flowers plant^{-1} was observed with the treatment of salicylic acid 200ppm followed by salicylic acid 100ppm and lowest increase was recorded in control among ten treatments.

Keyword: Biochemical, phenology, salicylic acid, cycocel

Introduction

Oilseed crops play an important role in agricultural economy of India. Rapeseed-mustard is the third important oilseed crop in the world after soybean (*Glycine max*) and palm oil (*Elaeisguineensis*Jacq.). Mustard is an important *rabi*crop of Rajasthan, Gujarat, Madhya Pradesh, Uttarakhand, Uttar Pradesh, Bihar, West Bengal and Assam. India is one of the largest rapeseed-mustard growing countryin the World, occupying the first position in area and third position in production after China and Canada. India occupies the second position in area after China and third position in production of rapeseed-mustard in the world after China and Canada. In India, it is the second most important edible oilseed crop after groundnut sharing 25-30 percent Indian oilseed economy. The share of oilseeds is 14.1 % out of the total cropped area, in India, rapeseed-mustard accounts for 3% of it. Mustard seed is the second largest produced oilseed in the world with an area of 37.0 m ha, with the production of 63.09 m tones and productivity of 11.90 q ha^{-1}. India contributes 28.3 % and 19.8 % in world acreage and production. India produced around 7.4 mt of rapeseed-mustard next to China (11-12 mt) and EU (10-13 mt) with significant contribution in world rapeseed industry. Among the entire oilseed crops producing states in India, in U.P. the area under cultivation was 6.39 lakh ha with production of 7.9 lakh metric tonnes and productivity of 12.36 q ha^{-1} (Anonymous,2015).In India, mustard is mostly cultivated for use as edible oil. It is used as condiments and spices to improve the flavour of pickles and also as fodder for livestock. There is an increasing interest in crop as source of erucic acid for chemical industry. Rapeseed and mustard cake is used as a protein supplement in livestock and poultry feed. The cake has minerals like, S, P, Co, K, Mg, Zn and vitamins like niacin, thiamine, riboflavin, and vitamin E. The Indian mustard possesses oil content ranging from 31-48 per cent in air dried seeds. PGRs are extremely important agent and play an important role from germination up to senescence of the plant. Plant growth regulators (PGRs) can play an important role in increasing its yield by making the plants photosynthetically more effective. Use of growth regulators increased. Salicylic acid is ortho-hydroxyl benzoic acid and is a secondary metabolite acting as analogous of growth regulating substances. It helps in protection of nucleic acids and prevention of protein degradation. The salicylic acid is also known to induce many genes coding for parthenogenesis and proteins in response to biotic and abiotic stresses (Enyedi *et al*., 1992). Foliar application of salicylic acid increased the IAA content in broad bean leaves. Foliar application of salicylic acid exerted a significant effect on plant growth metabolism when applied at physiological concentrations, and thus acted as one of the plant growth regulating substances (Kalarani *et al*., 2001). Cycocel (2-Chloro ethyl three methyl ammonium chloride) is the most usual anionic plant growth, regulator. There are reports that anionic compounds treated plants were tolerant to drought conditions compared to untreated plants. Moreover, they had higher net photosynthesis potential. From a biochemical point of view, CCC prevents ent-kaurene synthesis in GA3 biosynthetic cycle leading to GA3 deficiency and the subsequent reduced vegetative growth reported that any yield increase by CCC was related to the enhanced dry matter accumulation. Cycocel foliar application increased cytokinin translocation from roots to shoots, leading to prolonged aboveground parts life-span and hence increased yield

Materials and Methods

The experimental site is situated at the student Instructional Farm of the university on the Ayodhya, Raibareli road, at a distance of 42 km from Faizabad city and 23 km away from Jagdishpur. In the present study, Variety Narendra rai (NDR-8501) Various concentrations of (T_1) Control, (T_2) Salicylic acid (50ppm), (T_3) Salicylic acid (100ppm), (T_4) Salicylic acid (200ppm) and (T_5) Cycocel (100ppm) , (T_6) Cycocel (150ppm), (T_7) Cycocel (200ppm). Observations were recorded at 30, 60, 90 DAS and at maturity. The observations were taken on growth parameters like Chlorophyll content, Oil content (%), Days to 50 % flowering.

Results and Discussion

Biochemical:

Chlorophyll content

The data presented in Table 1. clearly indicate that the foliar application of plant growth regulators improved the chlorophyll contents in leaf up to 60 DAS and after 60 DAS the decline trend was recorded in chlorophyll content. The maximum increase in chlorophyll content was registered in T_4 (salicylic acid @ 200ppm) at 40 DAS (2.31), 60 DAS (2.97), 80 DAS (1.98) followed by T_3(salicylic acid @ 100ppm) at 40 DAS (2.24), 60 DAS (2.88),80 DAS (1.92) and minimum increase in T_7 (cycocel @200ppm) at 40 DAS (1.95), 60 DAS (2.51), 80 DAS (1.67) and over control at 40 DAS (1.89), 60 DAS (2.43),and 80 DAS (1.62). Bekheta 2004 and Bekheta *et al*., 2006.

Table-1: Effect of salicylic acid and cycocel on chlorophyll of mustard at different growth stages

QUALITY PARAMETERS OF TOMATO (*LYCOPERSICON ESCULENTUM* MILL.) STRAINS / VARIETIES AT RIPENING STAGE GROWN IN EASTERN U. P.

Brijesh Kumar*, Pratibha Singh, R. N. Kewat, R. K. Yadav and S. K. Vishwakarma
Department of Agril. Biochemistry, Narendra Deva University of Agriculture and Technology Kumarganj, Ayodhya- 224 229 (U.P.) India

Abstract

Ten germplasms of tomato namely NDTH-90, NDTH-101, NDTH-108, Kalyanpur Selection-2, Kalyanpur Selection-3, Kalyanpur Selection-6, IIVR Selection-2, CO-3, Arka vikas and Pusa Early Dwarf were analysed at ripening stage.

The data obtained in the experiment showed the highest fruit size length and diameter (4.83, 7.17 cm) at ripening stage was found in variety Pusa Early Dwarf & Arka vikas. Maximum fruit weight (95.33g.) and specific gravity (1.28 ml/cc) at ripening stage in variety CO-3 & Pusa Early Dwarf .Whereas maximum ascorbic acid (27.67 mg/100) at ripening stage was found in variety NDTH-101 and total mineral (0.80 mg/100g) at ripening stage was found in variety Arka vikas. Total acidity (0.50 %) at ripening stage was found in variety Pusa Early Dwarf. Maximum lycopene (4.93 mg/100g) at ripening stage was found in germplasms Kalyanpur Selection-6 and β carotene (1.50 mg/100g) at ripening stage was found maximum in germplasms Kalyanpur Selection-3. Whereas, total chlorophyll (1.77 mg/100g)at ripening stage was found maximum in germplasms NDTH-90 chlorophyll a & b (1.27, 0.58 mg/100g) at ripening stage was found maximum in variety/germplasms NDTH-108 & Pusa Early Dwarf .Whereas Polyphenol oxidase (35.87 unit/mg) and Peroxidase enzyme (1.80 unit/mg) were found maximum in variety /germplasms Arka vikas & NDTH-108. have highest total sugar (6.40 %) and non-reducing sugar (1.80 %) at ripening stage was found maximum in variety CO-3, T.S.S. content (4.83 %) at ripening stage was found highest in germplasms NDTH-101 and reducing sugar (4.77 %) was found maximum in germplasms Kalyanpur Selection-6, Total free amino acid (12.73 mg/100g) as found maximum in germplasms Kalyanpur Selection-6. Maximum lycopene (4.93 mg/100g) at ripening stage was found in germplasms Kalyanpur Selection-6.

Key words:- Fruit size, weight, specific gravity, colour, lycopene, β carotene, chlorophyll a and b , ascorbic acid, total mineral, titrable acidity Polyphenol oxidase, Peroxidase. T.S.S., total sugar, non-reducing sugar, reducing sugar, lycopene and total free amino acid.

Introduction

The tomato (Lycopersicon esculentum Mill.) is one of the most widely consumed and most popular fresh vegetable in the industrialized world. Tomato belongs to the family Solanaceae having diploid chromosome number (2n=24). It is the world's largest vegetable crop after potato and sweet potato but it tops the list of canned vegetables. It is an important condiment in most diets and a very cheap source of vitamins and antioxidents. It also contains a large quantity of water and calcium and Niacin which are of great importance in the metabolic activities. Tomato is a good source of vitamins A, C, E and minerals that are very good for body and protect the body against diseases (Taylor, 1987).

Tomato is the second most widely grown vegetable crop in the world other than potato (**Hanson et al., 2001**). Canada is the second larger producer of tomato next to Mexico. Total area of world under tomato cultivation is 4.50 million ha and total production is 240.51 million tonnes with 31.8 tonnes /ha productivity whereas, in India total area is 0.767 million ha and production is 16.385 million tonnes with 21.353 million tonnes /ha productivity. In U.P., total area is 0.010 million ha, production is 0.413 million tonnes with 39.488 million tonnes /ha productivity. (**NHB, 2014-15**). Tomato crop is adapted to a wide variety of climates ranging from the tropics to within a few degrees of the Arctic Circle. However, in spite of its broad adaptation, production is concentrated in few warm and rather dry areas. Though, it is a perennial plant in tropical climates, it is grown as an annual in North America. Tomatoes find numerous uses in both fresh and processed forms that include ketchup, sauces, pastes and juice. Tomato is considered as an important cash generating crop for small holders and medium scale commercial farmers providing employment opportunity in the production and processing industries (**Naikaet al., 2005**).

Tomatoes commonly consumed in daily diets are a major source of antioxidants. Tomatoes being an important source of potassium, phosphorus, magnesium, iron, so necessary to the normal activity of nerves and muscles. Vitamins as A, B and C tomatoes is the third source of vitamin C in our diet and the fourth for vitamin A, through its content in beta-carotene or pro vitamin A. Phytosterols, compounds that help to keep cholesterol under control folic acid, which helps eliminate homocysteine, an amino acid whose metabolism is dependent on the metabolism of vitamins from B complex, especially that of folic acid. Compositionally, the tomato has a unique nutritional and phyto-chemical profile. The major phyto-chemicals in tomato are the carotenoids consisting of 60 to 64% lycopene, 10 to 12% phytene, 7 to 9% neurosporene, and 10 to 15% carotenes. Tomatoes based foods are the world rich sources of lycopene (**Sgherri et al., 2008**). Based on a fresh weight basis, tomato (on average) contains about 35 mg/kg of lycopene, with red cultivars containing in average 90 mg/kg of lycopene and yellow ones only 5 mg/kg Processed tomatoes (sauce, paste, juice, and ketchup) contain 2- to 40-fold higher lycopene than fresh tomatoes.

Materials and Methods

The experiment was conducted in the department of vegetable science at MES of vegetable farm, Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya (U.P) during the Rabi season 2016-2017. The climate of Ayodhya comes under the category of semi-arid.

The fruit size has been taken by varnier callipors and specific gravity by water displacement methods. Total chlorophyll, total free amino acid and chlorophyll a and d were analysed by Jayraman (1981). TSS and acidity have been done by Rangana (1986) Reducing sugar have been analysed by Miller (1959) and Total sugar by the Dubois,et.al method. Lycopene have been done by Adsule etal.1979 and β carotene by Collumn method, 1953.Total mineral content have done by hort and Fischer, 1971 method and ascorbic acid by AOAC,1970 method. Polyphenol oxidase have been determined by Farkas *etal*. 1962 and Peroxidase was analysed by MaCune and Galston 1959.

Results and Discussion

The fruit length varied from 3.90-4.83 cm at ripening stage was respectively. These results are nearly corresponding with **Chattopadhyay *el al.* (2013)**. The fruit size decreases at ripening stage is attributed to the loss of moisture and carbohydrates in accordance with **Karki (2005)**. The fruit diameter varied from 4.80-7.17 cm at ripening stage. These results are nearly corresponding with **Chattopadhyay *el al.* (2013)**. The fruit size decreases at ripening stage is attributed to the loss of moisture and carbohydrates in accordance with **Karki (2005)**.

In the present investigation, average fruit weight of tomato varieties / strains at ripening stage was ranged from 46.97-95.33 g, the similar data was found by Leonardi ***et al.* (2000)**. The fruit weight decreases within excepted of weight loss per cent, the mean weight loss at ripening stage was varied weight loss 11.16 per cent are in accordance with **Getinet *et al.* (2008)**.

Abstract
The field experiments were conducted at Student Instructional Farm of CSAUAT Kanpur, during Rabi 2016-17 and 2017-18. The objective of investigation was to study the effect of foliar applied potassium nitrate and thio-urea with different doses on plant traits (physiological, biochemical, yield and its components) of two wheat varieties under drought and irrigated condition. It was designed in split-split plot design with three replications. The two conditions *i.e.* drought (I_0) and irrigated (I_1) conditions were allocated in the main plots and two wheat varieties *i.e.*, V_1 (K-1006) and V_2 (K-307) in sub plot and for each five chemical treatments were applied as foliar spray at heading stages by 500 ppm (T_3) and 1000 ppm thio-urea (T_4), along with control (T_0) in sub-sub plots. The significantly higher grain yield (5.30 & 5.12 gm) with best morpho-physiological, phenological and biochemical traits can be obtained by foliar application of 500ppm thio-urea (T_3) with both condition of *i.e.*, drought (I_0) and irrigated (I_1) of wheat crop. Next to this were 500ppm thio-urea (T_3) *i.e.* 5.30 & 5.26, 1000ppm thio-urea (T_4) *i.e.*, 5.12 & 5.08 as compare to control (T_0) *i.e.* 4.30 & 4.13 gm. Among cultivars, maximum responsive was K-1006 (V_1) in most of traits and gave significantly higher grain yield (5.30 & 5.23) and minimum in K--307 (V_2) *i.e.*, 5.12 & 5.08 gm with both concerning experimental years.

Keywords: Physiological, biochemical, yield attributes, foliar spray of thio-urea on drought and irrigated conditions

Introduction

Wheat consumption worldwide is estimated to 817 million tons by 2030 and production would need to increase at 22.6-43.6% in different countries at the current production level to meet the estimated consumption demand. India is the largest wheat producing country in the world after China. Wheat consumption worldwide is estimated to 817 million tons by 2030 and production would need to increase at 22.6-43.6% in different countries at the current production level to meet the estimated consumption demand. It gives me immense pleasure to bring out the current issue of Wheat & Barley Annual Report. I am also very delighted to share that during (Anonymous, 2017-18) [3], once again, the country has achieved a highest record wheat production of 99.70 mt which is very close to the magical figure of 100 mt from an area of 29.58 mha thereby registering an all-time high productivity of 3371 kg/ha. Similarly, in barley also the country harvested a record production of 1.77 mt from an area of 0.66 mha achieving a record average productivity of 2679 kg/ha. It may be recalled that the total wheat production of the country during 1947-48 was just 5.6 million tons with average productivity of less than one t/ha. The wheat production has increased manifold from 6.60 million tonnes at the time of independence to 97.44 million tons in (Anonymous. 2016-17) [3]. The productivity has witnessed an increase by 473 per cent *i.e* from 670 kg/ha to 3172 kg/ha during the above period. Despite delayed sowing, the country recorded 30.71 million hectares. The clearly indicates the strength of systematic and planned wheat research in the country. Wheat consumption in India estimated to surpass 110 million tons of wheat will be needed by 2020. Drought is the most prevailing problem and the factor known to be serious for its impacts on crop limitations (Souza *et al*., 2004) [17]. This kind of abiotic stress often occurred its consequence of the reduction of the water level that reaches earth due to extreme atmospheric conditions which frequently cause water loss via transpiration and evaporation. Generally, water scarcity resulted from either drought or soil salinity influenced crop plant's morphology, physiology and could lead to cellular and organelles deformation. Drought specific impacts on biochemical and molecular processes lead to stomata closure with consecutive decrease in

Effect of seed priming with plant growth regulators on physiological changes of Indian mustard (*Brassica juncea* L. Czern & Coss.)

Tulsi Ram Yadav, Pradip Kumar Saini, Sanjay Kumar Tripathi, RK Yadav, Raj Bhahadur

Abstract
The investigation entitled "Effect of seed priming with plant growth regulators on physiological changes of Indian mustard (*Brassica juncea* L. Czern & Coss.)" was conducted during *rabi* season, 2016-17 at the Instructional Farm of Narendra Deva University of Agriculture & Technology, Kumarganj Faizabad (U.P.) in randomized block design with eight treatments, three replications and variety Narendra rai (NDR-8501).Various concentrations of GA_3 (100ppm, 150ppm, 200ppm) and SA (50ppm, 100ppm, 200ppm) were taken along with untreated control. Seed was soaked before 6 hrs of sowing. Observations were recorded at 40, 60, 80 DAS and at maturity. Biochemical parameters like, chlorophyll content, in green leaves, oil content (%) in dry seeds were taken. Seed soaking of different concentrations of GA_3 and SA influenced on all characters of mustard crop.

Keywords: SA, GA_3, mustard, chlorophyll, oil content, etc.

Introduction

Oilseeds crops are the second most important determinant of agricultural economy, next only to cereals. Today, the demand for vegetable oils is out pacing the supply with more than half of its annual requirements being met mainly through imports. India is the 5th largest vegetable oil economy in the world next to USA, China, Brazil and Argentina accounting for 7.4% world oilseed output, 6.1 % of oil meal production, 3.9% world oil meal export 5.8% vegetable oil production, 11.2% of world oil import and 9.3% of the world edible oil consumption (DRMR, 2013, Vision 2020). Rapeseed-mustard (Brassica spp.) is one of the most important oilseed crops of the world where India is ranking third in area and production in the world (DRMR, 2015). Among the seven edible oilseeds cultivated in India, rapeseed mustard contributes 28.6% in the total oilseeds production and ranks second after groundnut sharing 27.8% in the India's oilseed economy (Shekhawat *et al.* 2012) [27] however due to more oil content (ranging from 35-45%) rapeseed-mustard ranks first in terms of oil yield among all oilseeds crops. Its seed contains 37 to 49 percent edible oil (Singh *et al.*, 2009) [24]. Demand of edible oil has increased with increasing population and improvement in the living standard of the people, resulting thereby in short supply of edible oils which is being met with imports of edible oil worth 44,000 crores per annum. Thus, there is need to boost the oilseed production through area expansion and productivity enhancement.

Indian mustard (*Brassica juncea* L. Czern) belongs to family Cruciferae, genus Brassica and species juncea popularly known as rai. Mustard is cultivated mostly under temperate climate. It is also cultivated in certain tropical and subtropical region as a cold weather crop. In India, rapeseed-mustard occupy 5.99 million ha area with production and productivity of 6.31 million tones and 1053 kg/ha respectively (India stat 2015-16). Indian mustard (*Brassica juncea* L.) is an important rabi crop of Haryana. In Haryana, rapeseed and mustard is one of the major growing crop occupying 0.56 million ha of area, with production and productivity of 0.699 million tones and 1248kg/ha respectively (India stat 2015-16).

Priming of seed is a physiological pre- conditioning which is widely used in various crops. Which includes subjective of seeds to cycle of wetting, drying and incubation at low temperature. Seed priming is normally practiced with water and can be improved further by selection of inorganic chemicals and growth regulators. Material used in seed priming are

Abstract: The present investigation was carried out under field condition at main experiment station (MES) of Narendra Deva University of agriculture & Technology, Narendra Nagar, Kumarganj, Faizabad U.P. during Rabi season 2010-11. The experiment was executed in completely randomized block design (factorial) with three replications. Six treatments comprised of zinc application i.e. (control 1%, 1.5% $ZnSO_4$ seed soaking, 15 kg and 25 kg $ZnSO_4$ ha^{-1} basal application and 1% $ZnSO_4$ +2.5% urea foliar spray and three wheat verities (Raj-3077, NW-1014, UP-2425). Seed soaking, basal application and foliar spray of $ZnSO_4$ increased growth characters in all varieties of wheat. Wheat variety UP-2425 responded better in comparison to NW-1014 and Raj-3077. Variety UP-2425 performed maximum plant height number of tiller, Leaf area, dry weight plant^{-1} as compared to Raj-3077 and NW-1014 at the crop growth stages. A control sets was also maintained. Seed soaking, basal application and foliar spray of $ZnSO_4$ increased growth characters and biochemical changes in all varieties of wheat. Application of 25kg $ZnSo_4$ha^{-1} in soil significantly increased in chlorophyll content, carbohydrate content obtained. Wheat variety UP-2425 responded better in comparison to NW-1014 and Raj-3077. It is concluded from the results that basal application of 25 kg $ZnSo_4$/ha^{-1} was found superior and economical in comparison to other treatments.

INTRODUCTION

Wheat (*Triticum aestivum* L.) a crop of poaceae family which is a major staple food crop of the world after rice. It is primarily grown in temperate region at higher altitude and medium altitude of tropical climate. However, it is cultivated widely around the world due to wide adoption and greater role in human nutrition as well as agricultural economy. With shrinking of arable land due to urbanization and industrialization, the wheat cultivation is also being pushed to marginal lands including salt affected soils. Sodic soil are widespread in the world and in India it occurs mainly in Indo-Gangetic alluvial plains, where it is estimated to cover about 2.8mha in India, salt affected soils are spread 7.0mha of which 1.29mha exists in U.P. alone (Abrol and Bhumbla 1971). However information of salts affected area in India indicates for 13.0mha. (Yadav and Gupta 1984).Salt affected soil contain excessive concentration of chloride and sulphate of sodium, calcium and magnesium (saline soil) or and excess of exchangeable sodium (alkaline or sodic soil) along with carbonate and bicarbonates. Excessive exchangeable sodium, high pH and poor physical properties of soils are known to adversely affect the growth, yield, chemical composition and nutrients uptake of plant. The adverse effect of soil sodicity is also mediated through the unavailability of certain micronutrients like zinc and iron. The available zinc in Indian soil ranges between 0.08-20.5ppm. Application of zinc have been found to boost the growth and yield of crops to a great extent (Zaid et al. 1977) Zinc deficiency includes rosting and poor tillring leading to decreased productivity in crop plants, since zinc is co-factor of carbonic anahydrase and sithse there fore it may adversely affect enzyme activities and carries corresponding metabolic reaction when zinc is deficient in soil. Zinc is also involved in synthesis of protein tryptophan (amino acid), superoxide dismutase (SOD) activity is much lower but can be restured in vitro by resupplying zinc to the assay medium (Vaugh an et al. 1982).

MATERIALS AND METHODS

The present study was conducted to investigate the response of wheat genotypes Raj-3077, NW-1014, UP-2425, to different treatmentT_1, Control,T_2, Seed soaking- .0% ZnSo4 (Soaking for 4 hours and drying in shade for 24 hours before sowing). T_3, Seed soaking-1.5% ZnSo4 (Soaking 4 hours and drying in shade for 24 hours before sowing). T_4,ZnSo4-15 Kg/ha basal application. T_5, ZnSo4-25 Kg/ha basal application. T_6, Foliar Spray at tillring and booting stage-1.0%ZnSo4+2.5%Urea.Wheat genotypes was collected from seed resource centre of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (U.P.). Seed soaking with respectively $ZnSo_4$ solution was done for four hours and then soaked seed were dried in shade for 24-

Effect of different levels and sources of phosphorous on biochemical changes of wheat (*Triticum aestivum* L.) under sodic soil

Pradeep Saini, RK Yadav, Nikita Nehal and Nitish Sharma

Abstract
The present investigation entitled "Effect of different levels and sources of phosphorous on biochemical changes of wheat (*Triticum aestivum* L.) under sodic soil" was carried out at the Main Experimental Station (MES), Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.) during *rabi* season of 2015-16. The experiment was laid down in randomized block design with three replications on wheat variety NW 1014 and pH of the soil is 9.4. Seven treatments were given and are comprised of T1: Control T2: 60 kg /ha through SSP, T3: 60 Kg Phosphorus /ha. through DAP. T4: 80 Kg Phosphorus /ha. through SSP, T5:80 Kg Phosphorus /ha. Through DAP, T6:100 Kg phosphorus/ha. through SSP, T7:100 Kg Phosphorus /ha. through DAP. Observations were recorded on chlorophyll, carbohydrate and protein content in leaves at 30, 60, 90 DAS.. All the levels and sources of phosphorus positively influenced biochemical changes positively however, the effect of T4: 80 Kg Phosphorus /ha. Through DAP was found most effective and significantly increased chlorophyll, carbohydrate and protein content in leaves of wheat.

Keywords: Wheat, Sodic soil, Carbohydrate, Chlorophyll, Protein.

Introduction
Wheat (*Triticum aestivum* L.) is the important crop of India. It is consists second position in both area and production after rice in India as well as world after china. The Northern and Western part of India has maximum area and production under wheat cultivation. The record production in the country during last few years has enabled India to attain the position of being second largest producer of wheat in the world.

Sodic soil are widespread in the world and in India. It occurs mainly in Indo-Gangetic alluvial plains, where it is estimated to cover about 2.8 mha. In India, salt affected soils are spread 7.0 mha of which, 1.29 exists in U. P. alone (Abrol and Bhumbla 1971) [5]. However, information on salt affected area in India indicates for 13.0 mha (Yadav and Gupta, 1984). Salt affected soils contain excessive concentration of chloride and sulphate of sodium, calcium and magnesium (Saline soil) or excess of exchangeable sodium (alkaline or sodic soil) along with carbonate and bicarbonate. These affected soils are extensively distributed in arid and semi arid parts of Haryana, Punjab, Uttar Pradesh, Rajasthan, Gujrat, and Maharastra. The soil affected soil in U. P. are spread over several districts including Sultanpur, Raibarreilly, Azamgarh, Etawah, Pratapgarh, Ballia, Mau, Mainpuri, Hardoi, Kanpur, Faizabad, Jaunpur and Fatehpur (Singh and Tyagi 1980) [8].

Phosphorus is critical in the metabolism of plant, playing a role in cellular energy transfer, respiration and photosynthesis. It is also a structural component of the nucleic acid of gens and chromosome it works as many coenzymes, phosphoproteins and phospholipids, early season limitation in phosphorus availability can result in restriction in crop growth, from which the plant will not recover even when phosphorus supply of is increased to adequate level. An adequate supply of phosphorus is essential from the earliest stage of plant growth (Betaerd, *et al.* 2003). Beside many other factor, fertilizer play a vital role in increasing the crop yield. Commonly used fertilizer are nitrogen, phosphorus and potash. Phosphorus is the second major nutrient after nitrogen for plant growth which play a fundamental role in large number of enzymatic reaction that depend upon the energy transfer or phosphorylation (20). Recovery of applied Phosphorus reported in the literature is low (0.02-0.5%) in alkaline calcareous soil

An experiment was conducted with six wheat varieties K 911, PBW 343, Raj 3765, K 9006, AAU 11 and HD 2733 for evaluation for heat tolerance at grain growth stage. Heat treatment was given by delayed sowing of 60 days from normal date (15 November) so that wheat varieties could experience severs heat stress (37-39^{0}C) at reproductive stage. Agronomic practices were followed as per recommendation for wheat crops. Wheat varieties were screened on the basis of membrane stability index (MSI), chlorophyll stability index (CSI) and canopy temperature depression (CTD) at grain growth stage. K 911, Raj 3765 and AAU 11 had high MSI, CSI, and CTD and also showed less percent reduction in yield and yield components over PBW 343, K 9006 and HD 2733. Fifteen RAPD markers were tested for genetic variability for heat tolerance. Out of fifteen markers only three molecular markers showed variation for heat tolerance. Therefore, MSI, CSI and CTD can be used as major criteria for heat tolerance in wheat.

Heat stress, MSI, CSI, CTD, Molecular marker, Tolerance and Wheat

Introduction

Wheat (*Triticum aestivum* L.) is the important crop of India. It is consists second position in both area and production after rice in India as well as world after china. The Northern and Western part of India has maximum area and production under wheat cultivation. There are number of constraints which affect the wheat production and decrease the nutritive value of the wheat. Now a day's heat stress in wheat is becoming major constrain in wheat at grain filling stage. Heat stress is often defined as the rise in temperature beyond a threshold level (26^{0}C) for a period of time sufficient to cause irreversible damage to plant growth and development. In general, a transient elevation in temperature, usually 10-15^{0}C ambient is considered heat stress. However heat stress is a complex function of intensity (temperature in degree) duration and rate of increase in temperature. According to a report of the Intergovernmental Panel on climatic change (IPCC) global mean temperature will rise 0.3^{0}C per decade (Jones *et al.*, 1999) reaching to approximately 1 and 3^{0}C above the present value by years 2025 and 2100, respectively and leading to global warming.

ABSTRACT

A field experiment was conducted during winter season of 2014-15 on wheat at Instructional Farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (UP). The soil of the experimental field was silt loam having pH 8.25, EC 0.35 dSm^{-1}, organic carbon 4.4 g/Kg^{-1} available nitrogen 195 Kg ha^{-1}, available P 12 Kg ha^{-1} and available K 240 Kg^{-1} the experiment was consisted of 8 treatments viz. T_1 (control), T_2 (100 % RDF), T_3 (75 % RDF), T_4 (75 % RDF + 25 % N-FYM), T_5 (75% RDF + *Azotobacter*), T_6 (50 % RDF + 50 % N-FYM) 7- (50 % RDF + 50 %N-FYM + PSB) and T_8 (50 % RDF + *Azotobacter* + PSB) were laid in the randomized block design with three replication. The highest values of yield and yield attributes were recorded with treatment T_7 (50% RDF + 50% N- FYM + PSB) which was significantly superior over control as well as T_2 (75% RDF), T_5 (75% RDF + *Azotobacter*) and T_6 (50% RDF + *Azotobacter* + PSB) and statistically at par with rest of the treatments.

Introduction

Wheat (*Triticum aestivum* L.) is one of the most important cereal crops of the world. Among the world's most important food grains, it ranks next to rice. It is eaten in various forms by more than one billion in the world. Millions of farmer in developing countries need adequate resource for augmenting crop. productivity and sustainability of soil. Therefore to maintain fertility and productivity of soil at sustainable level for long duration, there is need to adopt the concept of integrated nutrient management. Organic manure such as farm yard manure, vermin-compost, crop residues, biofertilizer, green manure and chemical fertilizer are considered to be an integral component of integrated nutrient management and may help to recover soil health in cropping system. As they improve soil fertility and physical properties such as soil structure, aeration, porosity, infiltration rate and water holding capacity and decrease soil crusting, organic matter in soil improve physical condition of the soil for better performance of micro-organism and physical status of soil. Organic matter affects crop

Abstract
The investigation entitled "Effect of seed priming with plant growth regulators on physiological changes of Indian mustard (*Brassica juncea* L. Czern & Coss.)" was conducted during *rabi* season, 2016-17 at the Instructional Farm of Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.) in randomized block design with eight treatments, three replications and variety Narendra rai (NDR-8501).Various concentrations of GA_3 (100ppm, 150ppm, 200ppm) and SA (50ppm, 100ppm, 200ppm) were taken along with untreated control. Seed was soaked before 6 hrs of sowing. Observations were recorded at 40, 60, 80 DAS and at maturity. Biochemical parameters like, chlorophyll content, in green leaves, oil content (%) in dry seeds were taken. Seed soaking of different concentrations of GA_3 and SA influenced on all characters of mustard crop.

Keywords: SA, GA_3, mustard, chlorophyll, oil content, etc.

Introduction

Oilseeds crops are the second most important determinant of agricultural economy, next only to cereals. Today, the demand for vegetable oils is out pacing the supply with more than half of its annual requirements being met mainly through imports. India is the 5th largest vegetable oil economy in the world next to USA, China, Brazil and Argentina accounting for 7.4% world oilseed output, 6.1 % of oil meal production, 3.9% world oil meal export 5.8% vegetable oil production, 11.2% of world oil import and 9.3% of the world edible oil consumption (DRMR, 2013, Vision 2020). Rapeseed-mustard (Brassica spp.) is one of the most important oilseed crops of the world where India is ranking third in area and production in the world (DRMR, 2015). Among the seven edible oilseeds cultivated in India, rapeseed mustard contributes 28.6% in the total oilseeds production and ranks second after groundnut sharing 27.8% in the India's oilseed economy (Shekhawat *et al*., 2012) [27] however due to more oil content (ranging from 35-45%) rapeseed-mustard ranks first in terms of oil yield among all oilseeds crops. Its seed contains 37 to 49 percent edible oil (Singh *et al*., 2009) [24]. Demand of edible oil has increased with increasing population and improvement in the living standard of the people, resulting thereby in short supply of edible oils which is being met with imports of edible oil worth 44,000 crores per annum. Thus, there is need to boost the oilseed production through area expansion and productivity enhancement.

Indian mustard (*Brassica juncea* L. Czern) belongs to family Cruciferae, genus Brassica and species juncea popularly known as rai. Mustard is cultivated mostly under temperate climate. It is also cultivated in certain tropical and subtropical region as a cold weather crop. In India, rapeseed-mustard occupy 5.99 million ha area with production and productivity of 6.31 million tones and 1053 kg/ha respectively (India stat 2015-16). Indian mustard (*Brassica juncea* L.) is an important rabi crop of Haryana. In Haryana, rapeseed and mustard is one of the major growing crop occupying 0.56 million ha of area, with production and productivity of 0.699 million tones and 1248kg/ha respectively (India stat 2015-16).

Priming of seed is a physiological pre- conditioning which is widely used in various crops. Which includes subjective of seeds to cycle of wetting, drying and incubation at low temperature. Seed priming is normally practiced with water and can be improved further by selection of inorganic chemicals and growth regulators. Material used in seed priming are aqueous solution of salts (sodium chloride, sodium sulphate, potassium nitrate etc.) growth

Impact of integrated nutrient management (INM) on growth of Berseem (*Trifoliumalexandrinum* L.) at various cutting stages

Vishuddha Nand, RK Gupta, RS Yadav, KD Singh, RK Yadav and AK Srivastav

Abstract
An experiment was conducted during winter season of 2016-17 on Berseem (cv. Mescavi). The experiment comprised of twelve treatments *viz.* T_1 (control), T_2 (100% RDF, 20 kg N + 80 kg P_2O_5 ha^{-1}), T_3 (100% N through Farm Yard Manure (FYM), T_4 (100% N through Poultry Manure), T_5 (50% RDF +50% N through FYM), T_6 (50% RDF +50% N through Poultry Manure). T_7 (50% N through FYM+50% N through Poultry Manure), T_8 (50% RDF +25%N through FYM +25% N through Poultry Manure), T_9 (75% RDF +25% N through FYM), T_{10} (75% RDF +25% N through Poultry Manure). T_{11} (25% RDF +75% N through FYM) and T_{12} (25% RDF +75% N through Poultry Manure) were tested in Randomized Block Design with three replications. the results revealed that the maximum plant height, fresh weight of leaf and stem, dry weight of leaf and stem, shoot : root ratio $plant^{-1}$ and number of nodules $plant^{-1}$ were observed with the application of 100% RDF (20 kg N + 80 kg P_2O_5 ha^{-1}) fallowed by 75% RDF +25% N through poultry manure and 75% RDF +25% N through FYM.

Keywords: FYM, Poultry manure, INM, growth, RDF, plant height, and leaf

Introduction
Berseem (*Trifoliumalexandrinum* L.) is one of the most important winter forage crop of India, due to high forage yield, palatability and nutritive value. It has become a very popular as *rabi* forage in irrigated areas or all most all over the country. Berseem belongs to one of the largest and most useful plant family leguminaceae and sub family faboideae. Berseem is known as king of fodder crops and it is popular among the world. It is one of the oldest cultivated crops, domesticated in Egypt and later introduced into many other parts of the world. Berseem was introduced in India in 1903 (Roy *et al*., 2009) [5]. It is now widespread in the irrigated regions of west and south Asia. Most of the farmers conserved the berseem as hay to get cheap, palatable and nutritive forage during scarcity periods or early winter and summer. Berseem is a cheapest source of increasing milk production as well as improving soil fertility. Berseem can be sown in early autumn and can thus provide feed before and during the colder months but the optimum conditions are 18-25 °C. If the winter temperature falls to 6-8° C the crop growth is severely affected. This is nutritious, succulent and palatable fodder available for fairly long period during winter, spring and early summer (Chaterjee and Das, 1989) [2]. Grazing is possible though less common than cutting. The most important cultural practices that need to be carefully adjusted to achieve maximum benefit from the forage grass-legume mixtures. The ability to fix atmospheric nitrogen and convert it to a useable form for plant growth is the main trait to these legumes (Allen and Allen, 1981) [1].

Poultry manure is an excellent soil amendment that provides nutrients for growing crops and also improves soil quality when applied widely, because it has high organic matter content combined with available nutrients for plant growth (Ryssen *et al.*, 1993) [7]. The application of FYM with chemical fertilizers and composted with rock phosphate to improve crops yield is very well established (Shafi *et al*., 2012) [8]. Fertilizers play an important role in enhancing forage productivity. Chemical fertilizers are soluble and immediately available to the plants: therefore, the effect is usually direct and fast, the price is lower and they are quite high in

Abstract

The present investigation entitled "Effect of plant growth regulators on growth and yield of Indian mustard [*Brassica juncea* (L.) Czern. & Coss.] under drought stress condition" was conducted during *Rabi* season, 2013-14 at the Student Instructional Farm (SIF) of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (U.P.), India. Experiment was setup in randomized block design with twelve treatments, *viz.* and three replications on mustard variety Narendra rai under normal and drought conditions. PGRs were applied on the foliage of plant at 30 DAS. Drought was imposed for 30 days by curtailing irrigation at 30 DAS and normal condition plots were irrigated at 30 DAS. Normal and drought conditions plots were irrigated at 60 DAS. On the basis of results obtained foliar application of plant growth regulators improved all the growth (plant height and number of branches plant^{-1}) and biochemical parameters (chlorophyll and proline content in leaves) as well as the yield and yield attributing characters under normal and drought conditions. But the effect of PGRs were more pronounced under drought condition and they minimize the detrimental effect on mustard.

Key words : Mustard, GA_3, SA, ABA, Morphological traits and Grain yield

Introduction

Rapeseed-mustard is the third important oilseed crop in the world after soybean (*Glycine max*) and palm oil (*Elaeis guineensis* Jacq.). India is the fourth largest oilseed economy in the world. Among the seven edible oilseeds cultivated in India, rapeseed-mustard contributes 28.6% in the total oilseeds production and ranks second after groundnut sharing 27.8% in the India's oilseed economy. The share of oilseeds is 14.1% out of the total cropped area in India, rapeseed-mustard accounts for 3% of it. The global production of rapeseed-mustard and its oil is around 38-42 and 12-14MT, respectively. India contributes 28.3% and 19.8% in world acreage and production. India produces around 6.7MT of rapeseed-mustard next to China (11-12MT) and EU (10-13MT) with significantly contribution in world rapeseed-mustard industry.

*Author for correspondence : E-mail : nikitanehal1989@gmail.com

Rapeseed and mustard occupy an important position among oilseed. In world the total area under rapeseed-mustard during 2012-2013, was 34.19 M ha with the production of 63 m t and productivity was 1850 kg/ha. In India, the total area under rapeseed-mustard during 2012-13 was 6.3 M ha with the production of 7.4 MT and productivity of 1176 kg/ha. During 2011-12 in Uttar Pradesh, the total area of rapeseed was 0.64 M ha with the production of 0.79 MT and productivity of 1256 kg/ha (Anonymous, 2013).

Drought is a major environmental cue impairing many physiological and metabolic processes in plants, which may lead to suppressing plant growth and development, reducing crop productivity and promote plant death. Across plant species drought imposes various physiological and biochemical limitations and adverse effects (Chaves *et al*., 2004 and Wang *et al*., 2003). For example, drought stress elevates generation of reactive oxygen species,

Abstract

The investigation entitled "Effect of salicylic acid and cycocel on growth and yield attributes of mustard (*Brassica juncea* L. Czern&Coss)" was conducted during *rabi* season, 2016-17 at the Instructional Farm of Narendra Deva University of Agriculture & Technology, Kumarganj Faizabad (U.P.) in randomized block design with 7th treatments, three replications and variety Narendra rai (NDR-8501). Various concentrations of (T_1) Control, (T_2) Salicylic acid (50ppm), (T_3) Salicylic acid (100ppm), (T_4) Salicylic acid (200ppm) and (T_5) Cycocel (100ppm) , (T_6) Cycocel (150ppm), (T_7) Cycocel (200ppm). Observations were recorded at 30, 60, 90 DAS and at maturity. The observations were taken on growth parameters like Plant height (cm), Total number of branches plant^{-1}, Dry matter partitioning plant^{-1}, Leaf area plant^{-1} and yield parameters like Number of siliquae plant^{-1}, Number of seeds plant^{-1}, Test weight (1000 seed weight), Seed yield plant^{-1} (g), Biological yield (q ha^{-1}), Seed yield (q ha^{-1}), Harvest index (%). Plant growth regulators influenced plant height, a number of branches plant^{-1}, dry matter partitioning^{-1} and leaf area^{-1}. The effect of salicylic acid 200ppm was more pronounced followed by salicylic acid 100ppm and cycocel 200ppm and all yield attributing characters like a number of siliquae plant^{-1}, a number of seeds plant^{-1}, total dry weight plant^{-1}, seed yield plant^{-1} and test weight showed positive response with plant growth regulators. Maximum increase was observed in salicylic acid 200ppm.

Keyword: Salicylic acid, Growth, Cycocel, Yield

Introduction

Oilseed crops play an important role in the agricultural economy of India. Rapeseed-mustard is the third important oilseed crop in the world after soybean (*Glycine max*) and palm oil (*Elaeis guineensis* Jacq.). Mustard is an important *rabi* crop of Rajasthan, Gujarat, Madhya Pradesh, Uttarakhand, Uttar Pradesh, Bihar, West Bengal, and Assam. India is one of the largest rapeseed-mustard growing countries in the World, occupying the first position in the area and third position in production after China and Canada. Brassica (rapeseed-mustard) is the second most important edible oilseed crop in India after groundnut and accounts for nearly 30 percent of the total oilseeds production and 13 percent of the country's gross cropped area. When compared to other edible oils, the rapeseed-mustard oil has the lowest amount of harmful saturated fatty acid. It also contains an adequate amount of the two essential fatty acids (*i.e* linoleic and linolenic acids) which are not present in many of the other edible oils. Rapeseed-mustard seed was primarily used for human consumption because of low *erucic acid* and thus, becoming desirable edible oil. With the invention of steam power, it was found that the oil could be used as a lubricant that would be used for cleaning water steam-washed metal surfaces better than any other lubricant.

India occupies the second position in the area after China and third position in the production of rapeseed-mustard in the world after China and Canada. In India, it is the second most important edible oilseed crop after groundnut sharing 25-30 percent Indian oilseed economy. The share of oilseeds is 14.1 % out of the total cropped area, in India, rapeseed-mustard accounts for 3% of it. Mustard seed is the second largest produced oilseed in the world with an area of 37.0 m ha, with the production of 63.09 m tones and productivity of 11.90 q ha^{-1}. India contributes 28.3 % and 19.8 % in world acreage and production. India produced around 7.4 mt of rapeseed-mustard next to China (11-12 mt) and EU (10-13 mt) with significant contribution in world rapeseed industry. Among the entire oilseed crops producing states in India, in U.P. the area under cultivation was 6.39 lakh /ha with a production of 7.9 lakh metric tonnes and productivity of 12.36 q ha^{-1} (2012-2013) (Anonymous, 2013). Rajasthan ranks first both in area and production and Gujarat has the highest productivity of mustard. In Uttar Pradesh, mustard is grown on 0.82-million-hectare area with the production of 0.90 million tonnes and productivity of 1141 kg ha^{-1}.

Salicylic acid is ortho-hydroxyl benzoic acid and is a secondary metabolite acting as analogous of growth regulating substances. It helps in protection of nucleic acids and prevention of protein degradation. The salicylic acid is also known to induce many genes coding for parthenogenesis and proteins in response to biotic and abiotic stresses (Enyedi *et al*., 1992). Foliar application of salicylic acid increased the IAA content in broad bean leaves. Foliar application of salicylic acid exerted a significant effect on plant growth metabolism when applied at physiological concentrations, and thus acted as one of the plant growth regulating substances (Kalarani *et al*., 2001).

Cycocel (2-Chloro ethyl three methyl ammonium chloride) is the most usual anionic plant growth, regulator. There are reports that anionic compounds treated plants were tolerant to drought conditions compared to untreated plants. Moreover, they had higher net photosynthesis potential. From a biochemical point of view, CCC prevents ent-kaurene synthesis in GA3 biosynthetic cycle leading to GA3 deficiency and the subsequent reduced vegetative growth reported that any yield increase by CCC was related to the enhanced dry matter accumulation. Cycocel foliar application increased cytokinin translocation from roots to shoots, leading to prolonged aboveground parts life-span and hence increased yield

Materials and Methods

The experimental site is situated at the student Instructional Farm of the university on the Faizabad Raibareli road, at a distance of 42 km from Faizabad city and 23 km away from Jagdishpur. In the present study, Variety Narendra rai (NDR-8501) Various concentrations of (T_1) Control, (T_2) Salicylic acid (50ppm), (T_3) Salicylic acid (100ppm), (T_4) Salicylic acid (200ppm) and (T_5) Cycocel (100ppm), (T_6) Cycocel (150ppm), (T_7) Cycocel (200ppm). Observations were recorded at 30, 60, 90 DAS and at maturity. The observations were taken on growth parameters like Plant height (cm), Total number of branches plant^{-1}, Dry matter partitioning plant^{-1}, Leaf area plant^{-1} and yield parameters like Number of siliquae plant^{-1}, Number of seeds plant^{-1}, Test weight (1000 seed weight), Seed yield plant^{-1} (g), Biological yield (q ha^{-1}), Seed yield (q ha^{-1}), Harvest index (%).

Statistical Analysis

Data recorded on various growth and yield attributes were subjected to statistical analysis by Fisher method of analysis of variance (Fisher and Yates 1949).

Results and Discussion

Plant height (cm)

All the treatments influenced plant height at all stages of observations. However, all the concentration of salicylic acid increased plant height while all the concentration of cycocel reduced plant height as compared to control at all stages of observation. However, maximum plant height was noted in T4 (salicylic acid @200ppm) at all the stages of observation i.e. 40 DAS (24.42cm), 60DAS (96.80cm), 80 DAS

ABSTRACT

A field experiment was conducted with wheat genotypes Halna, PBW 343, NW 1014, DBW 16, K 911 and AAI 11 during rabi 2015-16 at the student instructional farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (U.P). Heat treatment was given by delayed sowing of 65 days (25 January) than normal date of sowing (23 November 2015). So, that wheat genotypes could experience severe heat stress at grain filling stage. The screening of wheat genotypes was done on the basis of plant height, tiller number per plant, days to 100% flowering, days to 100% maturity, stay green duration, number of spikes per plant, spike length, number of grain per spike, test weight and yield plant^{-1} at grain filling stage. The wheat genotypes Halna, NW 1014, DBW 16, K 911, and AAI 11 had high membrane stability index (MSI) and stay green duration also showed less percent reduction in yield and yield components comparatively PBW 343 and DBW 16. Therefore, MSI and stay green duration can be used as physiological screening indices for heat tolerance genotypes at grain filling stage.

Key world: *MSI, Stay green duration, Wheat, Heat stress, Yield components.*

INTRODUCTION

Wheat (*Triticum aestivum* L) is an important winter season cereal crop in India as well as in the many parts of the world. India has second position in both area and production after China. Wheat crop faces a number of abiotic stresses among which heat stress at grain filling is importance one. Heat stress may be defined as an increase in temperature above threshold level (> 30°C) and cause considerable damage to growth, development and finally yield of plant[1]. High temperature (> 30°C) at the time of grain filling is one of the major constraints in increasing productivity of wheat in tropical and sub-tropical countries[12].

ABSTRACT

The present investigation was carried out to study the physical and biochemical properties of Pearl millet (Pennisetum glaucum L.) genotypes. The kernel husk ratio in Pearl millet germplasm was found in the range of 64:36 to 80:20.The colours of Pearl millet were very attractive with Pale yellow and light gray. The colour plays an important role as far as consumer's acceptance is concerned. The average test weights of grain sample taken for the study were noticed between 5.35 to 12.98 of Pearl millet germplasm, respectively. The various biochemical parameters such as Carbohydrate content NDBH-2 (64.24g/100g), crude fibre content in Pearl millet-4 (2.30g/100g), Total mineral content in Pearl millet-3 (2.26 g/100g) were also noticed in present investigation.

Key word: Pearl millet, total mineral, carbohydrate, crude fibre and seed colour of seeds.

Received 21.09.2017 Revised 24.10.2017 Accepted 03.11.2017

INTRODUCTION

Pearl millet (*Pennisetum glaucum*L.) is also known as spiked millet, candle millet or dark millet in Europe; cattail, pecilaria in USA; bulrish millet or dukhn in Africa; bajra, combo or sajje in India. Pearl millet is originated in central Africa. Pearl millet crop is grown in tropical semi-arid region of the world primarily in Africa and Asia. Pearl millet is well adapted to production system characterized by low rainfall (200-600 mm), low soil fertility and high temperature. Pearl millet belongs to the family gramineae (Poaceae, Grass family). The height of the pearl millet plant may range from 0.5 – 4.0 meter. The grains color may be nearly white, pale yellow, brown, grey, salt blue or purple. The grains of the pearl millet are about 3 to 4 mm long much longer than those of other millets. The weight of seeds usually ranges from 1.4 to 2.5g with a typical mean of 0.8gram [1]. India is the largest producer of pearl millet covering about 8.7 million ha of marginal and sub marginal lands. Rajasthan, Gujarat, Haryana, Uttar Pradesh and Maharashtra are the fifth important states cultivar of these crops. Total cultivated area of Pearl millet in Uttar Pradesh is around 0.84 million ha and production 0.95 metric tonns. [2]. People affected by gluten related disorders, such as celiac, non-celiac gluten sensitivity and wheat allergy suffers, who need gluten free diet can replaced gluten containing cereal in their diet. 100 gram pearl millet are provided 378 kcal energy, protein 11 percent, Carbohydrate 73 per cent, fat 4 percent, Several vitamin B, minerals such as calcium 8 mg, iron 3 mg, magnesium 114 mg and some other nutrients like selenium 2.7 micro gram (USDA).

MATERIALS AND METHODS

Ten germplasm of Pearl millet were collected from different districts of Uttar Pradesh namely Balrampur, Sultanpur, Faizabad, Jaunpur, Gazipur, Bahraich and Lakhimpur were used as experimental materials. Samples of Pearl millets were brought to Biochemistry laboratory of Narendra Deva University of Agriculture & Technology, Kumarganj Faizabad (U.P.) after collection. They were analyzed for various physical and biochemical parameters. The collected Pearl millet was cleaned, dried and dried seed was then crushed by a pestle and mortar. Finally, the product was the desired Pearl millet powder. The chemical properties of the Pearl millet powder were analyzed and the results are summarized. The milling per cent of Pearl millet grain include the dehusking and determining by traditional method using wooden pestle and mortar determining hand operated wooden pestle mortar steel persist. One hundred gram Pearl millet germplasm were weight on balance and their husk was remove with hand operated okhali finally the husk and kernel weight were recorded and there ratio was calculated.1000 grains of Pearl millet were randomly selected from threshed crop of each plot and their weight recorded on balance to obtain test weight of

ABSTRACT

The experiment was conducted in Randomized Block Design with three replications, wheat variety NW-1014. The experiment was laid out in field condition with seven treatments *viz.* T_1 (control), T_2 (60 kg SSP ha^{-1}), T_3 (60 kg DAP ha^{-1}), T_4 (80 kg SSP ha^{-1}), T_5 (80 kg DAP ha^{-1}), T_6 (100 kg SSP ha^{-1}), T_7 (100 DAP ha^{-1}). The different levels and sources of phosphorous were applied in field basal before sowing of seeds. Observations were recorded as germination percentage, (15 DAS after sowing) growth parameters, biochemical changes at 30, 60, 90 DAS and maturity after sowing. Yield and yield attributes traits were also recorded at harvest stage of crop. All the treatments increased the germination percentage, growth characters and biochemical changes superior over control. The maximum germination percentage was recorded with 80 kg DAP ha^{-1} over other treatments including control. Growth characters as plant height (cm) was found significantly superior, number of tillers plant^{-1}, dry matter plant^{-1}, total chlorophyll content (mg g^{-1} fresh weight), carbohydrate (mg g^{-1} dry weight) and protein content (%) in leaves were found significantly superior with basal application of 80 kg DAP ha^{-1} followed by 100 kg SSP ha^{-1} over control. Yield and yield contributing traits viz length of spike (cm), number of spike plant^{-1}, grains spike^{-1}, number of grains plant^{-1}, yield (g plant^{-1}), 1000 grains weight (g), yield (q ha^{-1}) and harvest index (%) were also found statistically superior with basal application 80 kg DAP ha^{-1} followed by basal application of 100 SSP ha^{-1} over control.

Wheat (*Triticum aestivum* L.) is the important crop of India. It is consisting second position in both area and production after rice in India as well as world after china. The Northern and Western part of India has maximum area and production under wheat cultivation. Indian wheat can be classified into four type (1) Emmer wheat (*Triticum dicoccum Schub L.*), (2) Macroni wheat (*Triticum durum Desf.*) (3) Common bread wheat (*Triticum aestivum L.*) and (4) Indian dwarf wheat (*Triticum spherococcum Mihi.*). Uttar Pradesh, Madhya Pradesh, Punjab, Bihar, Rajasthan, Haryana, Maharashtra and Gujarat are major wheat growing state in our country; of these U.P occupies a first place in terms of both area and production. Wheat is one of the important cereals due to its relatively higher niacin and thiamine content. In addition, it is also rich in "gluten" which provides spongy cellular texture of bread and baked product with shrinking of arable land due to urbanization and industrialization, the wheat cultivation is also being pushed to marginal lands including salt affected soil.

Sodic soil is widespread in the world and in India. It occurs mainly in Indo-Gangetic alluvial plains, where it is estimated to cover about 2.8 mha. In India, salt affected soils are spread 7.0 mha. of which, 1.29 exists in U.P. alone (Abrol and Bhumbla 1971). However, information on salt affected area in India indicates for 13.0 mha (Yadav and Gupta, 1984). Salt affected soils contain excessive concentration of chloride and sulphate of sodium, calcium and magnesium (Saline soil) or excess of exchangeable sodium (alkaline or sodic soil) along with carbonate and bicarbonate. These affected soils are extensively distributed in arid and semi arid parts of Haryana, Punjab, Uttar Pradesh, Rajasthan, Gujrat, and Maharastra. The soil affected soil in U. P. are spread over several districts including Sultanpur, Raibarreilly, Azamgarh, Etawah, Pratapgarh, Ballia, Mau, Mainpuri, Hardoi, Kanpur, Faizabad, Jaunpurand Fatehpur (Singh and Tyagi 1980).

The detrimental effect of sodicity on biomass production is attributed to osmotic as well as toxic effect of the ions on the physiological and biochemical function of the cells. The increasing level of soil sodicity resulted reduction in plant growth, tiller production, root and shoot (Dargan *et al.* 1976). Soil sodicity has been found to deforess protein synthesis and accelerate its degradation in plants. In general, the level of reducing sugar and starch decreased in chloroplast, while those of non reducing sugar increased under saline condition. Salinity reduced growth and productivity in crop species due to excessive amount of salts, especially sodium cloride in the soil. Sodium cloride induces osmotic and ionic effects, leading to changes in plant metabolism (Qadir *et al.*, 2008) and reduced plant growth and development in many crop science (Sing *et al.*, 2007).

Abstract

The investigation entitled "Effect of plant growth regulators (PGRs) on growth, biochemical changes & yield of mustard [*Brassica juncea* (L.) Czern.& Coss.]" was conducted during *rabi* season, 2013-2014 at the Instructional Farm of Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.), India in randomized block design with ten treatments, three replications and variety Narendra rai (NDR-8501). The treatments were comprised of foliar spray of 3 plant growth regulators (PGRs) of different concentrations *viz.*, Salicylic acid (0.1 mM, 0.3 mM, 0.5 mM), GA_3 (25 ppm, 50 ppm, 100 ppm) and kinetin (25 ppm, 50 ppm, 100 ppm) along with untreated control (distilled water spray) & spraying was done at 30 DAS. Observations were recorded at 60, 90 DAS and at maturity. The observations were taken on growth parameters like plant height, number of branches plant^{-1}, biochemical parameters like chlorophyll a & b content, oil content, yield characters like no. of siliquae plant^{-1}, no. of seeds plant^{-1}, setting percentage of siliquae. All the PGRs *viz.*, salicylic acid (0.1 mM, 0.3mM, 0.5mM), GA_3 (25 ppm, 50 ppm, 100 ppm) and kinetin (25 ppm, 50 ppm, 100 ppm) induced positive influence on the growth characters and chlorophyll content in plants but the foliar spraying of GA_3 50 ppm at 30 DAS was found more profound among all treatments. All the treatments enhanced the yield and yield contributing characters at all the doses in mustard. On the basis of above investigation it may be concluded that foliar spray of PGRs at 30 DAS may be used as a potential tool to improve growth and yield of mustard.

Key words : Mustard, GA_3, SA, kinetin, morphological traits and grain yield

Introduction

Oilseed crops play an important role in agricultural economy of India. Rapeseed-mustard is the third important oilseed crop in the world after soybean (*Glycine max*) and palm oil (*Elaeis guineensis* Jacq.). Mustard is an important *rabi* crop of Rajasthan, Gujarat, M.P, Uttarakhand, Uttar Pradesh, Bihar, West Bengal and Assam. India is one of the largest rapeseed-mustard growing countries in the world, occupying the first position in area and second position in production after China.

Brassica (rapeseed-mustard) is the second most important edible oil seed crop in India after groundnut and accounts for nearly 30 per cent of the total oilseeds production and 13 per cent of the country's gross cropped area. When compared to other edible oils, the rapeseed-mustard oil has the lowest amount of harmful saturated fatty acid. It also contains adequate amount of the two essential fatty acids (*i.e.* linoleic and linolenic), which are not present in many of the other edible oils. Rapeseed-mustard seed was primarily used for human consumption because of low erucic acid and thus, becoming desirable edible oil. With the invention of steam power, it was found that the oil could be used as a lubricant that would be used for cleaning water steam-washed metal surfaces better than any other lubricant.

PGRs are organic compound other than nutrients that modify plant physiological process. PGRs are called bio-stimulants / bio-inhibitors act inside the plant cell to

Plant Hormones: Their nature occurrence and functions: A chapter

RK Yadav[1], Pradip Kumar Saini[2]
[1-2] Department of Crop Physiology, N.D. University of Agriculture & Technology, Uttar Pradesh, India

Abstract
Plant hormones are a class of organic substances which are synthesized during the plant metabolism. They have an obvious physiological effect on plant growth at very low concentrations. Generally, plant hormones are mainly divided into five categories: Auxins, Gibberellins (GAs), Cytokinins, Ethylene, and Abscisic acid (ABA). With the deepening of research, some novel plant hormones such as Brassinosteroid, Salicylates, Jasmonates, Polyamines, and Signal Peptides have been found and identified. The plant hormone products are mainly obtained through plant extraction, chemical synthesis as well as microbial fermentation.

Keywords: gibberellins, ethylene, brassinosteroid, occurrence, biosynthesis

Introduction

Plant hormones are *a group of naturally occurring, organic substances which influence physiological processes at low concentrations*. The processes influenced consist mainly of growth, differentiation and development, though other processes, such as stomatal movement, may also be affected. Plant hormones have also been referred to as 'phytohormones' though this term is infrequently used. In their book *Phytohormones* Went and Thimann in 1937 define a hormone as a substance which is transferred from one part of an organism to another. Its original use in plant physiology was derived from the mammalian concept of a hormone. This involves a localized site of synthesis, transport in the bloodstream to a target tissue, and the control of a physiological response in the target tissue via the concentration of the hormone. Auxin, the first-identified plant hormone, produces a growth response at a distance from its site of synthesis, and thus fits the definition of a *transported* chemical messenger. However this was before the full range of what we now consider plant hormones was known. It is now clear that plant hormones do not fulfil the requirements of a hormone in the mammalian sense. The synthesis of plant hormones may be localized (as occurs for animal hormones), but it may also occur in a wide range of tissues, or cells within tissues. While they may be transported and have their action at a distance this is not always the case. At one extreme we find the transport of cytokine's from roots to leaves where they prevent senescence and maintain metabolic activity, while at the other extreme the production of the gas ethylene may bring about changes within the same tissue, or within the same cell, where it is synthesized. Thus, transport is not an essential property of a plant hormone. The term 'hormone' was first used in medicine about 100 years ago for a stimulatory factor, though it has come to mean a transported chemical message. The word in fact comes from the Greek, where its meaning is 'to stimulate' or 'to set in motion'. Thus the origin of word itself does not require the notion of transport *per se*, and the above definition of a plant hormone is much closer to the meaning of the Greek origin of the word than is the current meaning of hormone used in the context of animal physiology. Plant hormones2 are a unique set of compounds, with unique metabolism and properties, that form the subject of this book. Their only universal characteristics are that they are natural compounds in plants with an ability to affect physiological processes at concentrations far below those where either nutrients or vitamins would affect these processes.

The discovery, identification, plant hormones

The plant hormone concept probably derives from observations of morphogenic and developmental correlations by Sachs between 1880 and 1893. He suggested that "Morphological differences between plant organs are due to differences in their material composition" and postulated the existence of root-forming, flower forming and other substances that move in different directions through the plant. At about the same time Darwin was making his original observations on the phototropism of grass coleoptiles that led him to postulate the existence of a signal that was transported from the tip of the coleoptile to the bending regions lower down. After further characterizations by several workers of the way in which the signal was moved, Went in the Netherlands was finally able to isolate the chemical by diffusion from coleoptile tips into agar blocks, which, when replaced on the tips of decapitated coleoptiles, resulted in the stimulation of the growth of the decapitated coleoptiles, and their bending when placed asymmetrically on these tips. This thus demonstrated the existence of a growth promoting chemical that was asymmetrically resulted in a bending of the coleoptile away from the side with the higher concentration. This substance was originally named *Wuchsstoff* by Went, and later this was changed to *auxin*. After some false identifications the material was finally identified as the simple compound indoleacetic acid, universally known as IAA.

Effects of plant hormones, nature & occurrence

Abstract
The field experiments were conducted at Student Instructional Farm of CSAUAT Kanpur, during Rabi 2016-17 and 2017-18. The objective of investigation was to study the effect of foliar applied potassium nitrate and thio-urea with different doses on plant traits (physiological, biochemical, yield and its components) of two wheat varieties under drought and irrigated condition. It was designed in split-split plot design with three replications. The two conditions *i.e.*, drought (I_0) and irrigated (I_1) conditions were allocated in the main plots and two wheat varieties *i.e.*, V_1 (K-1006) and V_2 (K-307) in sub plot and for each five chemical treatments were applied as foliar spray at heading stages by 500 ppm (T_3) and 1000 ppm thio-urea (T_4), along with control (T_0) in sub-sub plots. The significantly higher grain yield (5.30 & 5.12 gm) with best morpho-physiological, phenological and biochemical traits can be obtained by foliar application of 500ppm thio-urea (T_3) with both condition of *i.e.*, drought (I_0) and irrigated (I_1) of wheat crop. Next to this were 500ppm thio-urea (T_3) *i.e.*, 5.30 & 5.26, 1000ppm thio-urea (T_4) *i.e.*, 5.12 & 5.08 as compare to control (T_0) *i.e.*, 4.30 & 4.13 gm. Among cultivars, maximum responsive was K-1006 (V_1) in most of traits and gave significantly higher grain yield (5.30 & 5.23) and minimum in K–307 (V_2) *i.e.*, 5.12 & 5.08 gm with both concerning experimental years.

Introduction

Wheat consumption worldwide is estimated to 817 million tons by 2030 and production would need to increase at 22.6-43.6% in different countries at the current production level to meet the estimated consumption demand. India is the largest wheat producing country in the world after China. Wheat consumption worldwide is estimated to 817 million tons by 2030 and production would need to increase at 22.6-43.6% in different countries at the current production level to meet the estimated consumption demand. It gives me immense pleasure to bring out the current issue of Wheat & Barley Annual Report. I am also very delighted to share that during (Anonymous, 2017-18) [3], once again, the country has achieved a highest record wheat production of 99.70 mt which is very close to the magical figure of 100 mt from an area of 29.58 mha thereby registering an all-time high productivity of 3371 kg/ha. Similarly, in barley also the country harvested a record production of 1.77 mt from an area of 0.66 mha achieving a record average productivity of 2679 kg/ha. It may be recalled that the total wheat production of the country during 1947-48 was just 5.6 million tons with average productivity of less than one t/ha. The wheat production has increased manifold from 6.60 million tonnes at the time of independence to 97.44 million tons in (Anonymous, 2016-17) [3]. The productivity has witnessed an increase by 473 per cent *i.e.* from 670 kg/ha to 3172 kg/ha during the above period. Despite delayed sowing, the country recorded 30.71 million hectares. The clearly indicates the strength of systematic and planned wheat research in the country. Wheat consumption in India estimated to surpass 110 million tons of wheat will be needed by 2020.

Drought is the most prevailing problem and the factor known to be serious for its impacts on crop limitations (Souza *et al.*, 2004) [17]. This kind of abiotic stress often occurred as consequence of the reduction of the water level that reaches earth due to extreme atmospheric conditions which frequently cause water loss via transpiration and evaporation. Generally, water scarcity resulted from either drought or soil salinity influenced crop plant's morphology, physiology and could lead to cellular and organelles deformation. Drought specific impacts on biochemical and molecular processes lead to stomata closure with consecutive decrease in

Techniques of seed priming in field crops

RK Yadav, Pradip Kumar Saini, Mayank Pratap and Sanjay Kumar Tripathi

Abstract
Priming in botany and agriculture is a form of seed planting preparation in which the seeds are pre-soaked before planting. Farmers do not have sufficient resources to meet the requirement of seedbed preparation for sowing and they are at more risk as compared to progressive farmers. On the other hand good establishment increases competitiveness against weeds, increases tolerance to drought period, increase yield and avoids the time consuming, need for re-sowing that is costly too. It is well accepted fact that priming improves germination, reduces seedling emergence time and improves stand establishment. A method to improve the rate and uniformity of germination is the priming or physiological advancement of the seed lot. The general purpose of seed priming is to partially hydrate the seed to a point where germination processes are begun, but they would exhibit rapid germination when re-imbibed under normal or stress conditions. A lot of work has been done on seed priming and results of these studies indicate well the importance of priming to get a good crop stand in many crops of tropical region such as rice, sorghum and maize.

Keywords: Seed priming, germination

1. Introduction
Various studies have been carried out to reduce the period between sowing to emergence as this play a key role in crop production. One of the important developments in this area has been the seed priming technique. The theory of seed priming was first proposed by Heydecker (1973) [21]. Seed priming is an effective technology to enhance rapid and uniform emergence and to achieve high vigour, leading to better stand establishment and yield. It is a simple and low cost hydration technique in which seeds are partially hydrated to a point where pre-germination metabolic activities start without actual germination, and then re-dried until close to the original dry weight. Seed priming is employed for better crop stand and higher yields in a range of crops. Harris *et al.*, (2007) [20] reported that seed priming led to better establishment and growth, earlier flowering, increase seed tolerance to adverse environment and greater yield at maize. The beneficial effects of seed priming have been demonstrated for many field crops such as wheat, sweet corn, mung bean, barley, lentil, cucumber, etc. (Sadeghian and Yavari, 2004) [40]. Rehman *et al.*, (2011) reported that seed priming is a cost effective technology that can enhance early crop growth leading to earlier and more uniform stand with yield associated benefits in many field crops including oilseeds.
Hormonal priming is the pre - seed treatment with different hormones like GA_3, kinetin, ascorbate etc., which promotes the growth and development of the seedlings. Ashraf *et al.*, (2005) found that GA_3 treatment enhanced the vegetative growth of two wheat cultivars. It enhanced the deposition of Na^+ and Cl^- in both root and shoots of wheat plant. It also caused a significant increase in photosynthetic at the vegetative stage of the crops.
Afzal *et al.*, (2006) reported that wheat cultivar Auqab-2000 was treated with different priming agents i.e. Abscisic acid (ABA), Salicylic acid (SA) and ascorbic acid and were sown under normal and saline condition (15 dSm^{-1}), and showed that under saline conditions these treatment reduced the time for 50% germination, increased final germination count, and significantly increased the fresh and dry weight but ascorbic acid did not show such results. Hormonal priming has reduced the severity of the effect of salinity but the amelioration was better due to 50ppm SA and 50ppm ascorbic acid treatments as these showed the best results on seedling growth, fresh and dry weights under non-saline and saline conditions whereas hormonal priming with ABA as not effective under present experimental material and conditions (Afzal *et al.*, 2006).

The response of salicylic acid on growth, yield and yield components of wheat varieties on timely and late sown conditions

Prashanika Singh, Vinaya Kumar Yadav, Ali Khan and Ram Kalap Yadav

Abstract
The present investigation entitled "Effect of salicylic acid on growth, physio-chemical changes and yield of wheat (*Triticum sestivum* L.) Under high temperature at anthesis" was conducted at Students Instructional Farm of the Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) during rabi seasons of 2014-15 and 2015-16. The experiment was planned under RBD (Randomized Block Design) with three replications. The treatment consisted of two date of sowing viz.25th November and 25th December with two varieties WH-3056 and WH-2036 with six salicylic acid treatment viz. (T1)Control, (T2)Seed soaking in (0.25mM) salicylic acid, (T3)Foliar spray of (0.25mM) salicylic acid at 30 DAS, (T4)Seed soaking in (0.25mM) salicylic acid + Foliar spray of (0.25mM) salicylic acid at 30 DAS,(T5)Seed soaking in (0.50mM) salicylic acid, (T6)Foliar spray of (0.50mM) salicylic acid at 30 DAS, (T7) Seed soaking in (0.50mM) salicylic acid + Foliar spray of (0.50mM) salicylic acid at 30 DAS,(T8)Seed soaking in (0.75mM) salicylic acid, (T9)Foliar spray of (0.75mM) salicylic acid at 30 DAS, (T10) Seed soaking in (0.75mM) salicylic acid + Foliar spray of (0.75mM) salicylic acid at 30 DAS. Results indicated that growth attributes such as plant height, number of tillers per plant and dry weight per plant influenced with the date of sowing. When late sown variety was planted timely all the growth attributes showed drastic reduction with respect to late sowing (25th December).However, WH-3056 showed comparatively good performance in terms of growth attributes at timely sown (25th November). Performance of WH-3056 was very good as compared to WH-2036 due to delayed sowing on 25th December. Application of salicylic acid significantly increased all growth attributes in both varieties under both timely and late sown. Time of sowing decreased substantially almost in all the yield components measured viz. number of ear per plant, ear length, number of grains per plant, test weight, biological yield and harvest index which caused severe reduction in yield. Overall, T10 (Seed soaking in (0.75mM) salicylic acid + Foliar spray of (0.75mM) salicylic acid at 30 DAS) treatment showed best result and T2 Seed soaking in (0.25mM) salicylic acid gave least. Overall growth attributes physiological traits and yield as well as yield components of wheat crop were adversely affected by time of sowing due to onset of high temperature during crop growth and particularly grain filling. All the salicylic acid treatments reduced the detrimental effect of late sown on both the varieties by improving physiological traits which ultimately helped in attaining higher yield.

Keywords: Growth, conditions, yield and yield parameter

Introduction
In India, wheat production has been stagnant around 70-72 million tonnes since 1999-2000, to meet the increasing demand of the growing population till 2020, it is estimated that around 9 million tonnes wheat grain production will be required. It is consumed in the form of chapattis, puris, suji or rawa. Wheat grain has relatively high content of niacin and thiamine that's why wheat proteins are especially important in human diet. Beside their significance in nutrition they are principally concerned in providing the "gluten" which provides spongy cellular texture of bread and baked product. Wheat straw is good source of feed for a large population of cattle in our country.

There are number of constraints which affect wheat production and decrease the nutritive value of wheat. Among them increase in temperature due to global warming is an important factor. Most of the world crops including wheat have an optimal range of temperature. Exposure to higher than optimal temperature reduced yield and decreased quality of wheat grain. Over 7 million hectares of wheat grown in approximately 30 countries are subjected to continual heat stressing environment and adversely affects wheat growth in many important

Impact of stocking density on gait score and mortality in broiler chickens

KD Singh, PS Pramanik, Subodh Kumar, Rajesh Kumar, AK Srivastav and MK Verma

Abstract
The research was conducted to investigate the impact of stocking density (i.e. I.C.A.R., Venky's and Amrit recommendations) on gait score & mortality in broiler chickens. A 500 day-old straight run commercial broiler strain "VENCOB" chicks were divided in two batches. Each batch was subdivided in 3 equal groups namely Gr 1 (I.C.A.R.), Gr 2 (Venky's) and Gr 3 (Amrit). All the birds were reared on pucca floor with saw dust as litter material providing equal managemental practices. Walking ability was accessed at weekly interval up to 6 weeks of observation. The gait scoring system followed in the present study was Modified gait scoring system developed by Garner *et al.* (2002). Daily mortality of birds was recorded in morning hours &mortality rate was calculated weekly. The lowest and highest% of birds showing GS 0 under I.C.A.R. recommendation of stocking density have been found to be 85.35±0.64% (week 4) and 92.86±0.40% (week 6) respectively. Similarly the corresponding proportion of birds showing GS 1 were 6.07±0.78% (week 1) and 13.93±0.64% (week 4, respectively. Comparatively lesser % of birds show GS 2 and the lowest and highest L.S. means % of this were 0.00±0.40% (week 5) and 3.21±0.82% (week 3) respectively. Venky's & Amrit's observation were also similar as I.C.A.R. recommendation has been observed. Overall it has been observed that% of birds showing GS 1 was significantly more in I.C.A.R. followed by Amrit and Venky's during this study. However, highest% of birds showing GS 1 was recorded in Venky's recommendation followed by Amrit and I.C.A.R. Whereas, less than 5% birds exhibited GS 2 in this study in respective of stocking densities. There was no significant difference regarding% of birds with GS 2 in three stocking densities during all the weeks except at week 4. The overall mortality (%) was less than 5% over weeks under each placement densities. No significant difference was observed among mortality rates of broiler chickens under these three stocking densities during all the weeks studied. From present study, this can be concluded that leg health and walking ability was comparatively better under I.C.A.R. recommendation followed by Amrit and Venky's. However, effect of stocking density on mortality was non significant among three stocking.

Keywords: gait score, foot pad lesions, stocking density, mortality and walking ability

Introduction
The total poultry population in India is 729.2 million, which is 12.39 percent higher than numbers in the previous census (Livestock Census, 2012) [21]. Poultry is one of the fastest growing sectors of Indian agriculture today, with annual growth rates of 5.67 percent and 11.44 percent in egg and broiler production, respectively. The value of output from the poultry sector was US$10 billion in 2014 (Rajendran *et al.*, 2014) [25]. Broiler production has been more vibrant than layer production within the poultry sector, with an annual growth rate of 11.44 percent, production of 3.725 million tons and employment of 4.29 million people (Index Mundi, 2015) [15]. India is the fourth largest producer of poultry meat in the world, valued at US$ 6.6 billion. Poultry production accounts for about 0.66 percent of India's GDP and 7.72 percent GDP from the livestock sector (Rajendran *et al.*, 2014) [25]. Poultry meat production increased from 0.069 million tons in 1961 to 3.725 million tons in 2014. The per capita availability of poultry meat is 2.8 kg; against recommended level of 11 kg (Rajendran *et al.* 2014 [25]; Index Mundi, 2015 [15]). The main reasons for improved broiler poultry production (Kalamkar, 2012; SAPPLPP, 2009) [17, 29] are: modernization of production practices; import of pure lines/grandparent stock; least-cost feed formulation; vaccines against major diseases; provision of EAS and other input services; improved quality breeder management; developments in poultry processing; and private sector partnerships through Contract Broiler Farming. It is estimated that 37 percent of broiler production in India is under contracts, and about 78 percent of those contracts are concentrated in southern India (Rajapwani, 2012) [26].
Gait scores (GS), a parameter used to evaluate walking ability (Kestin *et al.*, 1992, Garner *et*

Abstract

The present study was carried out to evaluate the influence of Moringa oleifera leaf extracts on carcass traits and mortality of broiler chickens. A total of 250-day-old broiler chicks (Vencobb-430) were randomly distributed into five groups with 5 replicates of 10 birds in each. Different dietary treatments were; basal diet with no supplement (NC- negative control) and basal diet supplemented with antibiotics (PC-positive control), aqueous extract of 1.5% Moringa powder (MOAQE), ether extract of 1.5% Moringa powder (MOEE) and alcoholic extract of 1.5% Moringa powder (MOALE). Percent weight of various cut parts, eviscerated weight and drawn yield were evaluated after 35 days of experiment. The results showed significantly higher eviscerated weight and drawn yield percentage in Moringa extracts supplemented groups compared to PC group. PC and MOAQE group recorded significantly ($P<0.05$) higher drumstick % compared to NC, MOEE and MOALE group. Moringa extracts group recorded significantly ($P<0.05$) lower mortality than PCand NC group birds. From above results it was concluded that supplementation of Moringa extract of 1.5% Moringa oleifera leaf powder improved the carcass traits and reduced the mortality of birds.

Key words: *Broiler, Extract, Carcass, Mortality and Moringa (words in alphabetical order)*

Introduction

Major cost involved for poultry enterprise is in the form of feed. Various approaches such as feed supplements and additives are being used to obtain more net return and to minimize expenditure on feed (Agasheet *al.*, 2017). *Moringa oleifera* leaf (MOL) has fascinated great attention as a non-traditional feed component because of its unique qualities. Moringa oleiferagrows fast, drought-tolerant tree native belonging to sub-Himalayan tracts of northern India, Pakistan, Bangladesh and Afghanistan. Moringa is currently cultivatedglobally in the tropics and subtropics (Faheyet *al.*, 2001). Crude protein content in Moringa varies from 25% to more than 30% on a dry matter basis (Melesse et al., 2013), with a high proportion of essential amino acids (Lu *et al.*, 2016). Moringa leaves, flowers and Pods are used as good sources of vitamins A, B and C, riboflavin, nicotinic acid, folic acid, pyridoxine, ascorbic acid, beta-carotene, calcium, iron and alpha-tocopherol (Dahot M.U., 1988). Moringa leaves are the preferred part of tree for use in animal diets as leaf meal due to high nutritional and medicinal properties (Abbas, 2013). The meat obtained from broiler chickens is an excellent source of protein, vitamins, mineralsand lower in fat content, so having a great demand among non-vegetarians(Naji *et al.*, 2013).Addition of*Moringa oleifera* leaf meal in broilers diet resulted significant increase in dressed weight, eviscerated weight and dressing percentage (Ayo-Ajasa *et al.* 2016). Dietary supplementation of Moringa leaves would be a potential strategy to improve the meat quality in broilers due to its antioxidant potential. It was further reported that phytosterols could lower malondialdehyde content and increase glutathione concentration in the breast muscle of broiler chickens (Naji *et al.*, 2013).

This study was carried out to evaluate the effect of different extracts (1.5%) of *Moringa oleifera* leaves powder as feed supplement in broiler diets on carcass characteristicsand mortality of broiler birds.

(Please correct red marks)

Materials and Methods

The present experiment was conducted after an approval from "Institutional animal ethical committee (IAEC)" was obtained vide reference number IAEC/CVSc/P-36/2019. A total of 250 one-day old Vencobb-430 strain chicks were randomly allocated into five dietary treatment groups with 5 replicates of 10 chicks in each. The chicks were kept on five dietary treatments which includes a basal diet without any additive in negative control (NC) or that supplemented with antibiotics (Positive control-PC), aqueous extract of 1.5% Moringa powder (MOAQE), ether extract of 1.5% Moringa powder (MOEE) and alcoholic extract of 1.5% Moringa powder (MOALE) in basal diet. Birds were fed *ad libitum* in different phases of experimental trial. The composition of formulated experimental diets as per BIS (2007) has been given in Table 1.

The chicks were kept on deep litter system under uniform standard management conditions with availability of clean, fresh and wholesome drinking water. Mortality was recorded during the entire research period. At the end of trial one bird per replicate (5 birds/treatment) were selected randomly for the carcass evaluation and sacrificed after 12 hours pre-slaughter fast though drinking of water was allowed. After complete bleeding carcass were dipped in hot water (58°C) for 1-2 minutes and feather were removed. Evisceration was done by making a slit from tip of breast bone up to the area around the cloaca. Thorough washing and cleaning were done after evisceration. After that the carcass were kept hanging on the special racks for 5-10 minutes. The visceral organs were removed by supporting the bird with one hand via the incised abdomen. Eviscerated carcasses were weighed and cut parts like thigh, drumstick, breast, wings, back, head, neck and shank were also weighed.The relative weight of dressed, drawn yield and different edible cuts were calculated as percentage of live weight.

The data were analysed under completely randomized (CRD) by employing one way analysis of variance (Snedecor and Cocran, 1994) and means of different dietary treatments were compared with Duncan multiple range test. The P value lower than 0.05 was thought-out significant.

(Please correct red marks)

Results and Discussion

Carcass characteristics:

The data pertaining to the carcass traits of broilers presented in Table 2. The results showed that the dressed weight and thigh weight of different groups was similar and showed no significan ($P>0.05$) effect of various Moringa extracts. The eviscerated weightof aqueous extract (72.24), ether extract (73.10) and alcoholic extract (73.09) supplemented group broilers were simila to NC (72.05) group, however significantly ($P<0.05$) higher than PC (70.39). The drawn yield of MOAQE, MOEE, MOALE and NC also significantly ($P<0.05$) higher than PC group. Leg and drumstick weight % of PC group was significantly ($P<0.05$) highe than MOEE and MOALE group. However, leg weight wa

ABSTRACT

An experiment was conducted on "Effect of land configuration and moisture regimes on productivity of hybrid maize (*Zea mays* L.) in summer season." during 2018-19 at Agronomy Research Farm, ANDUA and T, Kumarganj, Ayodhya (U.P.). The experiment accomplished of 12 treatment combinations and laid out in split plot design, replicated three times. The Experiment consisted of three land configuration *viz.* flat bed planting (P_1), ridge planting (P_2) and paired row planting on raised bed (P_3) were kept in main plots and four moisture regimes *viz.*0.5 IW/CPE ratio, 0.7 IW/CPE ratios, 0.9 IW/CPE ratios and 1.1 IW/CPE ratios were allotted in sub plots. The experimental results revealed that growth parameters, such as plant height, leaf area index, dry matter accumulation, days to 50 percent ear emergence and days to50 percent maturity and yield were obtained maximum with the paired row planting methods followed by ridge planting and flat bed planting and yield attributes such as number of cobs plant^{-1} , number grains row^{-1}, number of grains cob^{-1}, cob length (cm), cob girth (cm), grains weight cob^{-1}(g), cob weight (g), shelling percentage (%), grain yield (q ha^{-1}), stover yield (q ha^{-1}), and biological yield (q ha^{-1}) were also increased similarity in same treatment. In case of moisture regimes, the same trends were observed maximum when applied irrigation at 1.1 IW/CPE ratios as compared to other moisture regimes.

Abstracts

The present study was conducted to investigate the effect of different litter materials on growth performance of Kadaknath chicks. 300 Kadaknath chicks were raised on three litter treatments viz. Sand, rice hulls and rice hulls plus chopped paddy straw (1:1) con of two replicates in each treatment. The result showed that chicks reared on paddy straw + rice hulls litter had significantly high weight, lower feed intake and better FCR($P<0.05$). The body weight of chicks raised under sand and rice hull litter did n significantly, however the average daily feed intake of chicks under rice hulls was significantly higher than that of under sand li performance index of the earlier study period was significantly higher in paddy straw + rice hulls followed by sand and ri respectively.

Key words: *Kadaknath, feed, body weight, sand, rice hulls, litter materials*

Introduction

Desi fowls are cheaply reared as scavenging flocks by feeding household left over and their meat and egg taste are preferred over those of exotic chickens (Dessie and Ogle, 2001).Wood shaving has been standard choice for poultry litter for many years. Rice hulls appear to be a favourable alternative to wood shavings (Grimes *et al.*, 2007).Various types of litter materials like sand (shields *et al.*, 2005), gypsum (Grimes *et al.*, 2007), rice and wheat straw (Srechari Sharma 2010), ground corn cob and soyabean straw(De Avila *et al.*, 2008) have been utilised as bedding materials for rearing of poultry birds. Sand has shown good potential as an alternate litter for more reuse quality and very less caking.

Pine shavings and saw dust are the most desirable and most widely used litter materials for broiler production in the United States. About 60% of farmers used saw dust as litter materials, 16.7% used wood shaving, 20% used both wood shaving and saw dust while 3.3% of farmers do not use bedding materials. The types of litter used by farmer depend on locality and availability (Kalu E. 2015) . Paddy husk is most commonly used litter material in northern India.Sigroha et al., (2017) used saw dust, wheat straw, rice husk, river bed sand and sandy soil as litter materials and found higher weight of birds at 42 days of age in wheat straw followed by sandy soil, saw dust, river bed sand and rice husk. As far as seen in literature there is no concert conclusion for litter type and thickness for various regions and climates. In view of above a study was undertaken with following objectives-

To investigate the effect of litter material on the growth perf of kadaknath fowls

To study the feed conversion efficiency of kadaknath fow various bedding materials

Materials and Methods:

The present investigation was carried out to study the different litter materials on growth performance, feed gain Kadaknath fowl. The study was carried out at the poultry Teaching Livestock and Poultry farm of the College of V science and Animal Husbandry, N.D.U.A.T. Kumarganj, U.P., situated at a distance of 42 km away from Faizabad cit km away from Jagdishpur Industrial area at an altitude o above sea level and latitude of 26° 47' North and longitude East and it falls in Eastern plain Zone of Middle Gange region of India.

Experimental period and climatic conditions

The experiment was conducted in the months of Nove February which comprised winter season of this region. Du period, the climatic parameters have been shown in table average minimum temperature recorded during study per 12.54°C, while the average maximum temperature was There were a few showers of rain, ranging from 62 to 123 average was 92.5 cm during this period. The topography o almost even and most of the farm area remains dry round Parasitic infestation was moderate.

Climatological parameters recorded during experiment period

S.No	Climatological Parameters	Average Value	Average Max	Average Min
1.	Environmental temperature(°C)	18.7	24.86	12.54
2.	Relative humidity (%)	70.35	77.68	57.86

Experimental animals

To carry out present investigation, 300 straight run day old Kadaknath Chicks, from college hatchery were got issued. These 300 kadaknath chicks were divided into two batches; each batch consisted of 150 Kadaknath Chicks. Each batch was subdivided in three equal groups of 50 chicks viz. Group1 (sand), Group2(rice hulls), Group3(paddy straw + rice hulls) randomly distributed among three pens. Each pen was equipped with fresh litter, feeder and waterer. All the birds were raised on pukka floor with sand, rice hulls and paddy straw + rice hulls (50:50) as litter materials. Chicks were reared under standard uniform managemental practices up to the age of 42 days and observations for different parameters were recorded simultaneously. Thereafter, a replication was made with the next batch of chicks.

Brooding and rearing of chick

Brooder house

The cold room brooding method was applied for brooding an of Kadaknath Chicks in the brooder house. Brooding was pukka floor using deep litter system. Each group of Kadakna placed in separate pens which were visually isolated from e along with provision of adequate ventilation and artificial lig brooder house.

Preparation of brooder house to receive Kadaknath chicl

Brooder house was properly scrubbed and cleaned at leas before the trail began. After the house, equipments were cleaned. The house was allowed to dry out thoroughly. The h equipments were fumigated using 1% formalin. Three inches litter were made on the floor. Few days before the chicks equipments were arranged in brooder house and the elect were started to adjust temperature and light. The temperatu the brooder house was slightly above 35°C. The corners of space were made rounded off with cardboard and metal chi to prevent chicks from piling up in the corner. All these pre

STUDY THE PHYSIO-HEMATOLOGICAL RESPONSE BEFORE AND AFTER DISBUDDING IN CALVES

Shiv Swaroop[1], P.S. Pramanik[1], K.D. Singh[2*], A.K. Verma[2], Vishuddha Nand[2] and A.K. Srivastav[2]

[1]Department of Livestock Production Management, College of Veterinary Science and Animal Husbandry NDUAT, Kumarganj, Faizabad- 224229, Uttar Pradesh, India [2]Department of Livestock Farm Complex, College of Veterinary Science and Animal Husbandry NDUAT, Kumarganj, Faizabad- 224229, Uttar Pradesh, India

Abstract

The aim of the present investigation was to examine the effect on Physio-haematological profile before and after disbudding in calves. The study was carried out at Livestock Farm Complex, College of Veterinary Science and Animal Husbandry, NDUAT, Kumarganj, Faizabad and nearby villages. Twenty four cattle calves were utilized to study Physio-haematological parameters that are Respiration Rate (RR), Pulse Rate (PR), Rectal Temperature (RT), Haemoglobin (Hb (gm/dl), Neutrophil (%), Basophil (%), PCV (%), Lymphocyte (%), Monocyte (%), TLC (10^3/ µl), Eosinophil (%) and N:L ratio) before and after disbudding in to four groups viz. control (T_0), lignocaine (T_L), tremadol (T_T) and lignocaine+tremadol (T_{L-T}). After medication calves were disbudded by hot iron method. The physiological parameters recorded just before (0h) and after disbudding on 1h, 6h and 24h. The blood samples were collected for haematological parameters just before (0h) and after disbudding on 6h, 24h and 72h. The results showed that, at 0h, 1h, 6h and 24h RR were significantly different among treatment groups. Only at 0h PR was significantly different among different treatment groups and during rest of the period up to 24h there is no significant different among groups. There was significant difference for RT only at 24h among different treatment groups. At 24h, T_0 group showed significantly lowest Hb (10.66±0.49%) which was statistically similar to T_T and T_{L-T} groups. At 0h, 6h and 72h means of PCV% were significantly different among treatment groups. There was no significant different in eosinophil, neutrophil and TLC among different treatment groups during the whole period of study, The lowest lymphocytes (64.00±1.00) was observed in T_T group at 6h. The T_0 group showed significantly lowest basophil (0.00±0.00) which was statistically similar to T_T and T_{L-T} groups but significantly different from T_L group at 6h. At the same interval, T_0 group showed significantly lowest monocytes (4.66±0.61) which was significantly different with T_L, T_T and T_{L-T} groups. At 6h, T_0 group showed significantly lowest N/ L ratio (0.15±0.01) which was statistically similar to T_T and T_{L-T} groups but significantly different from T_L group. It may be concluded that generally physiological responses like RR, PR and RT were higher in control groups than treatment groups before and after disbudding. No significant difference was observed in eosinophil%, TLC, neutrophil% and monocyte% counts between control and treatment groups. However Hb%, basophil%, PCV% and lymphocyte% were significantly different between control and treatment groups. N/L ratio was significant only at 6h. Most of the cases T_{L-T} group showed comparatively better performance.

Introduction

Disbudding is painful yet common husbandry practice in the cattle industry, especially on dairy farms, because hornless cattle are safer (ALCASDE, 2009) and injuries to cattle and other animals are reduced (Prayaga, 2007). Dehorned cattle are safer to handle and cause fewer injuries to workers, other cattle, and farm animals (Stafford and Mellor, 2005). Cattle are also dehorned to reduce bruising and hide damage and to meet transport requirements (Gooneewardene and Hand, 1991; Faulkner and Weary, 2000; Prayaga, 2007). Several disbudding methods exist, including cautery, the use of caustic paste, and hot iron. All of these methods involve tissue damage and have been described as painful (Stafford and Mellor, 2005; 2011). The *Model Code of Practice for the Welfare of Animals: Cattle*, however, strongly advises against caustic disbudding (PISC, 2004).

Despite this knowledge, dehorning is commonly performed without pain relief because of the costs and impracticalities associated with researched methods (Petherick, 2005). The breeding of polled cattle eliminates the need for dehorning and because horns are inherited as an autosomal recessive with polledness being dominant (Long and Gregory, 1978), The legislation pertaining to dehorning and disbudding differ between countries like in Sweden, disbudding without local anaesthesia and sedation was banned in the 1992 Animal Rights Act (Bengtsson *et al.* 1996), but calves may be dehorned in Denmark without local anaesthesia until they are 4 weeks of age (Grondahl-Nielsen *et al.* 1999). The Council of Europe recommends the use of anesthesia for the dehorning of calves over 4 wk of age (Oliver, 2009). Pain control is also required for all calves under the *Canadian Code of Practice for the Care and Handling of Dairy* Cattle (NFACC, 2009). Furthermore, the Australian *Model Code of Practice for the Welfare of Animals: Cattle* recommends the use of local analgesics for dehorning calves over 6 month of age (PISC, 2004). Thus, the need to meet industry standards and the availability of suitable dehorning pain relief regimens for commercial production remain a challenge. Very little work has been done on the disbudding distress in Indian dairy animals particularly in indigenous animals.

Materials and Methods

The aim of the present investigation was to examine the Physio-hematological response before and after disbudding in calves. Study was carried out at the Instructional Livestock Farm Complex of the college of Veterinary Science and Animal Husbandry, NDUAT, Kumarganj, Faizabad and around the campus. Twenty four (24) farm born cattle calves of 2 to 3 weeks were randomly divided into four groups within each comprising of 3 males and 3 females, Control (T_0), Lignocaine hydrochloride (2%) @ 1 ml/ bud (T_L) (Tramadol @ 0.25 mg/ kg body weight I/M) (T_T) and Lignocaine + Tramadol at above dose rate (T_{L-T}). Medication was done 5-10 minutes before disbudding. Two doses of ligocaine per bud were injected for cornual nerve block in calves.

(a) Physiological responses

Physiological responses recorded before and after disbudding were as follows-

Respiration rate (no./ minutes)	Pulse rate (no./ minutes)	Body temperature (^{0}F)

(b) Haematological parameters

Haematological responses recorded before and after disbudding were as follows

a) Hb (gm/dl)	d) Neutrophil (%)	g) Basophil (%)
b) PCV (%)	e) Lymphocyte (%)	h) Monocyte (%)

Impact of integrated nutrient management (INM) on growth of Berseem (*Trifoliumalexandrinum* L.) at various cutting stages

Vishuddha Nand, RK Gupta, RS Yadav, KD Singh, RK Yadav and AK Srivastav

Abstract
An experiment was conducted during winter season of 2016-17 on Berseem (cv. Mescavi). The experiment comprised of twelve treatments *viz.* T_1 (control), T_2 (100% RDF, 20 kg N + 80 kg P_2O_5 ha^{-1}), T_3 (100% N through Farm Yard Manure (FYM), T_4 (100% N through Poultry Manure), T_5 (50% RDF +50% N through FYM), T_6 (50% RDF +50% N through Poultry Manure), T_7 (50% N through FYM+50% N through Poultry Manure), T_8 (50% RDF +25%N through FYM +25% N through Poultry Manure), T_9 (75% RDF +25% N through FYM), T_{10} (75% RDF +25% N through Poultry Manure), T_{11} (25% RDF +75% N through FYM) and T_{12} (25% RDF +75% N through Poultry Manure) were tested in Randomized Block Design with three replications. the results revealed that the maximum plant height, fresh weight of leaf and stem, dry weight of leaf and stem, shoot : root ratio $plant^{-1}$ and number of nodules $plant^{-1}$ were observed with the application of 100% RDF (20 kg N + 80 kg P_2O_5 ha^{-1}) fallowed by 75% RDF +25% N through poultry manure and 75% RDF +25% N through FYM.

Keywords: FYM, Poultry manure, INM, growth, RDF, plant height, and leaf

Introduction
Berseem (*Trifoliumalexandrinum* L.) is one of the most important winter forage crop of India, due to high forage yield, palatability and nutritive value. It has become a very popular as *rabi* forage in irrigated areas or all most all over the country. Berseem belongs to one of the largest and most useful plant family leguminaceae and sub family faboideae. Berseem is known as king of fodder crops and it is popular among the world. It is one of the oldest cultivated crops, domesticated in Egypt and later introduced into many other parts of the world. Berseem was introduced in India in 1903 (Roy *et al.*, 2009) [5]. It is now widespread in the irrigated regions of west and south Asia. Most of the farmers conserved the berseem as hay to get cheap, palatable and nutritive forage during scarcity periods or early winter and summer. Berseem is a cheapest source of increasing milk production as well as improving soil fertility. Berseem can be sown in early autumn and can thus provide feed before and during the colder months but the optimum conditions are 18-25 °C. If the winter temperature falls to 6-8° C the crop growth is severely affected. This is nutritious, succulent and palatable fodder available for fairly long period during winter, spring and early summer (Chaterjee and Das, 1989) [2]. Grazing is possible though less common than cutting. The most important cultural practices that need to be carefully adjusted to achieve maximum benefit from the forage grass-legume mixtures. The ability to fix atmospheric nitrogen and convert it to a useable form for plant growth is the main trait to these legumes (Allen and Allen, 1981) [1].
Poultry manure is an excellent soil amendment that provides nutrients for growing crops and also improves soil quality when applied widely, because it has high organic matter content combined with available nutrients for plant growth (Ryssen *et al.*, 1993) [7]. The application of FYM with chemical fertilizers and composted with rock phosphate to improve crops yield is very well established (Shafi *et al.*, 2012) [8]. Fertilizers play an important role in enhancing forage productivity. Chemical fertilizers are soluble and immediately available to the plants; therefore, the effect is usually direct and fast, the price is lower and they are quite high in

GENETIC STUDIES ON REPRODUCTIVE TRAITS OF HARIANA COWS

***Ashish Kumar Srivastava, Jaswant Singh and V.K. Singh**
*Assistant Professor, Department of LFC
College of Veterinary Sciences and Animal Husbandry
N.D.U.A.T., Kumarganj- Faizabad (U.P.)

Abstract

performance records of 211 Hariana cows, progeny of 27 sires, born during the year 1966 to 1985 having at least records up to second ing were utilized in this study. These cows were maintained at D.D.D. farm, Mathura and livestock farm, Madhurikund (Mathura). The 'age post partum oestrus interval was estimated to be 185.43± 11.18, the heritability estimate of post partum oestrus interval was estimated e 0.021±0.175. The magnitude of the effect of sires was non significant and the variation in post partum oestrus accounted due to sires very small (8.7%) in total variation. The least squares means and their standard errors of number of service per conception were estimated e 2.19±0.26. The heritability estimate of the number of service per conception was estimated to be 0.294±0.210. The contribution of sires 21.8% in the total variation of the trait.

roduction

cow is an efficient machine for converting farm crops into useful nan food like milk and milk products, which are the main source of mal protein in the diet of a large vegetarian population of the ntry. Hariana breed of zebu cattle has been well established dual-pose breed known for its milk yield as well as for draught ability. e breed has reduced significantly and is continuing to decline at an rming rate. Apart from the declining population, Hariana cattle ve also deteriorated in their productivity (Joshi et al., 1995).

aterials and Methods

e present study was undertaken on Hariana cows. All the animals ten into consideration were farm bred. The data used in this vestigation were collected from the pedigree sheets, milking register d breeding record of Hariana cows maintained at DDD Farm, athura. The performance record of 211 cows, having at least record to second calving were collected for genetic studies. The statistical alysis of the data was carried out by using the LSMLMW (Least quares and Maximum Likelihood Method)- Harvey (1990) PC-2 rsion computer programme and Henderson (1953) model were used.

esults and Discussion

ne least squares mean of the post-partum oestrus interval along with eir standard errors have been presented in table 1. The average post-rtum interval was estimated to be 185.43±11.18 days. The equency of animal in various PPO groups (class interval of 40 days) about 23.69% animals had post-partum oestrus interval below 90 ys. The maximum frequency of animals was in 90 to 130 days group 6.54%). Present observation is comparatively higher than the verage of post-partum interval reported by Luktuke and ubramanium (1961), Singh et al., (1964), Arora et al., (1971), charya et al. (1971) and Khanna (1998) for Hariana cows. Whereas, ohli and Suri, 1957, Kohli and Suri, 1960 and Tomar and Arneja, 972 have reported comparatively higher post-partum oestrus in lariana cattle.

east squares analysis of variance was performed to study the effect f farm, period and session of calving are present in table 2. The erusal of the table revealed that the effect of farm was found to be on-significant on post-partum oestrus interval in Hariana cows, lthough the contribution of farm was highest (83.5%) in total ariation. However, Ashraf et al., (2000) observed highly significant arm effect on post-partum oestrus interval. The effect of period and eason of calving were found non-significant. However, Mahmoud et l., (1991) observed a significant effect of month of calving.

Heritability estimate of post-partum oestrus interval was estimated to be 0.021±0.175. The magnitude of the effect of sires was non-significant and the variation in PPO accounted for due to sires was very small (8.7%) in total variation. The findings were indicative of zero heritability for this trait in these animals. Similar observations were reported by Prasad (1958) for Tharparkar cattle and Singh et al., (1964) for Hariana cattle.

Conclusion

Any selection programme based on post-partum oestrus interval will not prove beneficial in these cattle because the genetic variability for this character in these animals does not seem to exist. In view of the above observations, improvement in managemental practices may lead improvement in this trait.

Abstract
To assess the associations among body condition score at calving (BCSC), BCS during lactation (BCSL), production performance and udder health status of dairy cows, 50 cows (HF cross) at 2nd parity were selected randomly. The animals after random distribution into 3 groups i.e. group I (BCS<3.0, thin), group II (3.0<BCS>3.5, moderate), group III (BCS>3.5, fat) kept in observation for 120 days. The BCS of group-III cows were significantly (P<0.05) higher than group I. The FCM, fat and SNF was positively correlated with BCSC and negative with BCSL. The somatic cell score (SCS) was correlated negatively with BCSC and positively with BCSL.
Key words- BCS, Milk, Milk composition, Udder health, SCS

Introduction

Milk quality is as significant as the milk quantity in dairy animals. High yielding dairy cows had higher incidence of mastitis that can be assessed by somatic cell count (SCC) of milk (Kadarmideen and Bryce, 2001). Optimal body condition of dairy cow is important for obtaining elite herd and quality milk. Low or higher body reserves may pose a risk of lower milk yield and higher SCC in milk respectively (Berry et al., 2007). High yielding dairy cows exhibit negative energy balance after calving which may influence both immune and metabolic system of the individual that predispose the animals to mastitis. Body condition score had a favourable correlation with SCC, but it was not strong (Berry *et al* Loc. cit.). Dang et al., (2010) reported non-significant relationship between BCS and SCC. Hence, it is postulated that there are no consistent results regarding the relationship between body condition score and somatic cell counts of the dairy animals. Therefore, the present study was carried out to investigate the association among body condition score, production performance and udder health status of dairy cows.

Materials and Methods

This study was carried out in the area under subtropical zone of Indo-Gangetic plane. Fifty lactating dairy cows (HF cross) of second parity available at the Teaching Livestock Farm in the College of Veterinary Science and Animal Husbandry, N.D.U.A.T., Kumarganj, Faizabad (U. P.) and in the small dairy farms of the surrounding villages were selected. Observations were recorded for 4 months. The animals in farm and field conditions were maintained under loose housing system and the stanchion system, respectively. The data collected at fortnightly intervals were, the Body Condition Score (BCS), Production performances and Somatic cell count (SCC). Milk yield of selected animals in the farm and the field were recorded on the observation days both morning and evening. Milk samples were collected directly from the animal during milking to assess the milk composition such as fat, SNF (solid not fat), CLR (corrected lactometer reading) by EKO milk ultra, milk analyser (Milkana KAM98-2A). The milk yield was further corrected on 4% fat basis (Fat corrected milk, FCM) according to the formula given by Gaines (1928) as under-

FCM = 0.4 × milk yield (l) + 15 × milk fat (kg).

Body condition score of animals after calving were assessed in the morning milking by the chart formulated by Prasad (1994) having 1-6 scale with 1 indicating under body condition and 6 representing over body condition of the dairy cows. 1 to 6 scales were further splitted in to half or quarter point increment (e.g., 2.5 or 3.25). For the better interpretation of BCS effect on the milk yield, milk composition and udder health status, the animals were divided in to three groups on the basis of BCS at calving i.e. group-I (BCS <3.0, thin), group-II (3.0≤BCS≥3.5, moderate) and group-III (BCS > 3.5, fat). The udder health status was determined by somatic cell count (SCC) of milk immediately after collection as per methodology of IDF (1984). The SCC was log-transformed into the fortnightly test day observation SCS (Somatic cell score) as SCS=$\log_{10}$SCC (Mrode and Swonson, 1996).

The collected data were analyzed by SPSS (version 11.5). The means of various measurements were compared by Duncan's Multiple Range test (Duncan, 1955). The Pearson's correlation coefficient was estimated to find relationships among observations.

Results and Discussion

Out of 50 animals, 13 cows were classified as thin (group–I), 20 as moderate (group–II) and 17 as fat (group–III) at parturition. BCS of cows at calving was 2.83±0.06, 3.38±0.03 and 4.22±0.11, in group I, II and III, respectively (Table-1). BCSC differ significantly (P<0.05) among the three groups of cows. The BCS during calving to 15 days were significantly (P<0.05) higher than rest period of lactation. The declining BCS might be due to mobilization of body fat reserves to cover milk production during early lactation (Buckley *et al*., 2000, Friggens *et al*.,

Abstracts

The present study was conducted to investigate the effect of different litter materials on growth performance of Kadaknath chicks. A total 300 Kadaknath chicks were raised on three litter treatments viz. Sand, rice hulls and rice hulls plus chopped paddy straw (1:1) comprising of two replicates in each treatment. The result showed that chicks reared on paddy straw + rice hulls litter had significantly higher body weight, lower feed intake and better FCR($P< 0.05$). The body weight of chicks raised under sand and rice hull litter did not differ significantly, however the average daily feed intake of chicks under rice hulls was significantly higher than that of under sand litter. The performance index of the earlier study period was significantly higher in paddy straw+ rice hulls followed by sand and rice hulls respectively.

***Key words**: Kadaknath, feed, body weight, sand, rice hulls, litter materials*

Introduction

Desi fowls are cheaply reared as scavenging flocks by feeding household left over and their meat and egg taste are preferred over those of exotic chickens (Dessie and Ogle, 2001).Wood shaving has been standard choice for poultry litter for many years. Rice hulls appear to be a favourable alternative to wood shavings (Grimes *et al.*, 2007).Various types of litter materials like sand (shields *et al.*, 2005), gypsum (Grimes *et al.*, 2007), rice and wheat straw (Sreehari Sharma 2010), ground corn cob and soyabean straw(De Avila *et al.*, 2008) have been utilised as bedding materials for rearing of poultry birds. Sand has shown good potential as an alternate litter for more reuse quality and very less caking.

Pine shavings and saw dust are the most desirable and most widely used litter materials for broiler production in the United States. About 60% of farmers used saw dust as litter materials. 16.7% used wood shaving, 20% used both wood shaving and saw dust while 3.3% of farmers do not use bedding materials. The types of litter used by farmer depend on locality and availability (Kalu E. 2015) . Paddy husk is most commonly used litter material in northern India.Sigroha et al., (2017) used saw dust, wheat straw, rice husk, river bed sand and sandy soil as litter materials and found higher weight of birds at 42 days of age in wheat straw followed by sandy soil, saw dust, river bed sand and rice husk. As far as seen in literature there is no concert conclusion for litter type and thickness for various regions and climates. In view of above a study was undertaken with following objectives-

To investigate the effect of litter material on the growth performance of kadaknath fowls

To study the feed conversion efficiency of kadaknath fowls under various bedding materials

Materials and Methods:

The present investigation was carried out to study the effect of different litter materials on growth performance, feed gain ratio of Kadaknath fowl. The study was carried out at the poultry unit of Teaching Livestock and Poultry farm of the College of Veterinary science and Animal Husbandry, N.D.U.A.T. Kumarganj, Faizabad U.P., situated at a distance of 42 km away from Faizabad city and 38 km away from Jagdishpur Industrial area at an altitude of 113 m above sea level and latitude of 26^0 47' North and longitude of 82^0 12' East and it falls in Eastern plain Zone of Middle Gangetic Plain region of India.

Experimental period and climatic conditions

The experiment was conducted in the months of November to February which comprised winter season of this region. During this period, the climatic parameters have been shown in table 3.1. The average minimum temperature recorded during study period was 12.54^0C, while the average maximum temperature was 24.86^0C. There were a few showers of rain, ranging from 62 to 123 cm and average was 92.5 cm during this period. The topography of land is almost even and most of the farm area remains dry round the year. Parasitic infestation was moderate.

Climatological parameters recorded during experiment period

S.No	Climatological Parameters	Average Value	Average Max	Average Min
1.	Environmental temperature(^{0}C)	18.7	24.86	12.54
2.	Relative humidity (%)	70.35	77.68	57.86

Experimental animals

To carry out present investigation, 300 straight run day old Kadaknath Chicks, from college hatchery were got issued. These 300 kadaknath chicks were divided into two batches: each batch consisted of 150 Kadaknath Chicks. Each batch was subdivided in three equal groups of 50 chicks viz. Group1 (sand), Group2(rice hulls), Group3(paddy straw + rice hulls) randomly distributed among three pens. Each pen was equipped with fresh litter, feeder and waterer. All the birds were raised on pukka floor with sand, rice hulls and paddy straw + rice hulls (50:50) as litter materials. Chicks were reared under standard uniform managemental practices up to the age of 42 days and observations for different parameters were recorded simultaneously. Thereafter, a replication was made with the next batch of chicks.

Brooding and rearing of chick

Brooder house

The cold room brooding method was applied for brooding and rearing of Kadaknath Chicks in the brooder house. Brooding was done on pukka floor using deep litter system. Each group of Kadaknath chicks placed in separate pens which were visually isolated from each other along with provision of adequate ventilation and artificial light in the brooder house.

Preparation of brooder house to receive Kadaknath chicks

Brooder house was properly scrubbed and cleaned at least a week before the trail began. After the house, equipments were properly cleaned. The house was allowed to dry out thoroughly. The house and equipments were fumigated using 1% formalin. Three inches depth of litter were made on the floor. Few days before the chicks arrived, equipments were arranged in brooder house and the electric bulbs were started to adjust temperature and light. The temperature under the brooder house was slightly above 35^0C. The corners of brooding space were made rounded off with cardboard and metal chick guards to prevent chicks from piling up in the corner. All these preparations

ASSOCIATIONS AMONG BODY CONDITION SCORE, PRODUCTION PERFORMANCE AND UDDER HEALTH STATUS IN DAIRY COWS

Abstract

The present study was conducted to investigate the effect of different litter materials on behavior of Kadaknath chicks. A total 300 Kadaknath chicks were raised on three litter treatments viz. Sand, rice hulls and rice hulls plus chopped paddy straw (1:1) comprising of two replicates in each treatment. The results indicate that Kadaknath chicks reared on sand and rice hull litter had significantly higher proportion of time in activities like drinking, dust-bathing and perching than paddy straw+rice hulls. The behavioral activities like drinking, dust bathing, stretching, standing and perching in sand litter, dust-bathing, peaking, stretching, walking, lying and perching in rice hulls and peaking, stretching and standing in straw+rice hulls were seemed to be significantly differed in morning, noon and evening hour interval.

Key words: Kadaknath, feed, behavior, sand, rice hulls, litter materials

Introduction

Desi fowls are cheaply reared as scavenging flocks by feeding household left over and their meat and egg taste are preferred over those of exotic chickens (Dessie and Ogle, 2001). Wood shaving has been standard choice for poultry litter for many years. Rice hulls appear to be a favourable alternative to wood shavings (Grimes *et al.*, 2007). The present investigation was carried out to study the effect of different litter materials on growth performance, feed gain ratio of Kadaknath fowl. The study was carried out at the poultry unit of Teaching Livestock and Poultry farm of the College of Veterinary science and Animal Husbandry, N.D.U.A.T. Kumarganj, Faizabad U.P., situated at a distance of 42 km away from Faizabad city and 38 km away from Jagdishpur Industrial area at an altitude of 113 m above sea level and latitude of 26^0 47' North and longitude of 82^0 12' East and it falls in Eastern plain Zone of Middle Gangetic Plain region of India.

Experimental period and climatic conditions

The experiment was conducted in the months of November to February which comprised winter season of this region. The average minimum temperature recorded during study period was 12.54^{0}C, while the average maximum temperature was 24.86^{0}C. There were a few showers of rain, ranging from 62 to 123 cm and average was 92.5 cm during this period. The topography of land is almost even and most of the farm area remains dry round the year. Parasitic infestation was moderate.

Experimental animals

To carry out present investigation, 300 straight run day old Kadaknath Chicks, from college hatchery were got issued. These 300 kadaknath chicks were divided into two batches; each batch consisted of 150 Kadaknath Chicks. Each batch was subdivided in three equal groups of 50 chicks viz. Group1 (sand), Group 2(rice hulls), Group3 (paddy straw + rice hulls) randomly distributed among three pens. Each pen was equipped with fresh litter, feeder and waterer. All the birds were raised on pukka floor with sand, rice hulls and paddy straw + rice hulls (50:50) as litter materials. Chicks were reared under standard uniform managemental practices up to the age of 42 days and observations for different parameters were recorded simultaneously. Thereafter, a replication was made with the next batch of chicks.

Brooding and rearing of chick

Brooder house

The cold room brooding method was applied for brooding and rearing of Kadaknath Chicks in the brooder house. Brooding was done on pukka floor using deep litter system. Each group of Kadaknath chicks placed in separate pens which were visually isolated from each other along with provision of adequate ventilation and artificial light in the brooder house.

Preparation of brooder house to receive Kadaknath chicks

Brooder house was properly scrubbed and cleaned at least a week before the trail began. After the house, equipments were properly cleaned. The house was allowed to dry out thoroughly. The house and equipments were fumigated using 1% formalin. Three inches depth of litter were made on the floor. Few days before the chicks arrived, equipments were arranged in brooder house and the electric bulbs were started to adjust temperature and light. The temperature under the brooder house was slightly above 35^{0}C. The corners of brooding space were made rounded off with cardboard and metal chick guards to prevent chicks from piling up in the corner. All these preparations were completed for Kadaknath chicks before they were procured to brooder house. A chick guard of about 15 cm height was used at a distance of 30 to 40 cm away from the brooder and was moved away for the every day. It was completely removed after two weeks.

Litter materials

For the present experiment three litter materials namely sand, rice hulls and paddy straw + rice hulls (50:50) were used for rearing the Kadaknath chicks. Rice hulls were procured from the nearby rice mill, paddy straw taken from village shivnathpur and sand was taken from kumarganj market. These litters were clean, dry and free from fungal growth. The thickness of litter was 3.0 cm. After spreading this litter on the floor with proper thickness was covered with newspaper up to 4 days of brooding.

Parameters recorded

Behaviour

The behaviours in the Kadaknath recorded in this study were chosen from preliminary observations and defined as a list of 12 states which have given here.

1. Eating
2. Drinking

ABSTRACT

The present study was carried out on 172 lactation records of Murrah buffalo maintained at Livestock farm, NDUAT, Kumarganj, Faizabad under Network Project on Buffalo Improvement (AICRP) from 2002-2011. The four weekly test day milk yield were used to develop the best lactation curve for the 305 days lactation milk yield in Murrah buffaloes using four models viz. Gamma type function (Wood, 1967), Exponential function (Wilmink, 1987) and Quadratic model (Dave, 1971). The average weekly test day milk yield increased from 7.11 kg in 1st week to a peak yield of 9.91 kg in 8th week, and subsequently to 4.17 kg in 40th week according to Exponential function for overall records. The average weekly test day milk yield increased from 8.77 kg in 1st week to a peak yield of 11.55 kg in 8th week, and subsequently to 5.81 kg in 40th week as per Quadratic model for overall records. The gamma type function was observed slightly higher test day yield in first lactation than the least squares mean. However it was observed lower value in other lactations than the least square mean. The different lactation curve of lactation wise showed gamma function type gave the best fit results in all the lactations.

Key Words: *Lactation curve, Four weekly test day milk yield, ascending phase and descending phase.*

Introduction: There is different trends of milk secretion throughout the lactation of an animal, which can be invariably represented mathematically in the form of the lactation curve. In simple term the lactation curve can be defined as the graphical representation of milk yield against the time (Broody *et. al.*, 1923). There are three different stages of lactation curve. The ascending phase indicates the initial steep rise in the milk yield, which is usually linear. The peak yield along with persistent phase is the largest phase of the lactation, which represent the inherent capacity of animal for suitable milk production. The third phase is the decline phase, which is comparatively short. This phase is usually associated with the drying off stage of the animal. Various lactation curve models have been tried by different workers to fit the lactation curve in different cattle breeds (Singh *et. al.*, 2002; Cilek and Keskin, 2008; Rashia, 2010). The three models (Gamma function, Exponential Function and Quadratic function model) have been used for modeling of lactation curve in present study. The lactation curve models are also used to predict the yield of lactation at any point of the lactation. This property of the model can prove beneficial in case of incomplete records. Getting the test day information from field is not easy and there is every chance of missing the data due to certain inevitable reasons. In such cases these lactation models may prove very beneficial for prediction of these incomplete records. Lactation curve is a valuable tool in designing suitable breeding and managemental strategies for lactating animals. Hence, the present study is carried out on the four weekly test day milk yield data of Murrah buffalo maintained at NDUAT, Kumarganj, Faizabad under Network Project on Buffalo Improvement (AICRP) with objective to identify the best fit lactation curve model to test day milk yield data of Murrah buffalo.

Material and Method: the data utilized in present study was spread over a period of nearly 10 years from 2002 to 2011. The data of 172 four weekly test day milk yield (1st weekly test day milk yield-WTDY 1; 4th weekly test day milk yield-WTDY 2; 8th weekly test day milk yield-WTDY 3; 12th weekly test day milk yield-WTDY 4; 16th weekly test day milk yield-WTDY 5; 20th weekly test day milk yield-WTDY 6; 24th weekly test day milk yield-WTDY 7; 28th weekly test day milk yield-WTDY 8; 32th weekly test day milk yield-WTDY 9; 36th weekly test day milk yield-WTDY 10 and 40th weekly test day milk yield-WTDY 11) distributed in different parities as given as first lactation (44 records), 2nd lactation (29), 3rd lactation (34), 4th lactation (32) and 5th lactation (32). Selection of models were selected and fitted to the lactation curves for the five parities to determine the best model for each of the parity. The models used were as follows-

1. Gamma function model - Model 1 (Wood, 1967)
   $Yt = at^b e^{-ct}$
2. Exponential Function model –Model 2 (Wilmink, 1987)
   $Yt = a + bt + c\exp^{(-0.05t)}$
3. Quadratic model –Model 3 (Dave 1971)
   $Yt = a + bt + ct^2$

   Where,
   Yt = average test day milk yield in the t^{th} week
   a = appropriate initial milk yield just after calving
   b = incline slope parameter upto peak yield
   c = decline slope parameter
   t = time of test day yield

the above mentioned models were fitted to milk yield for different parities. The most suitable model for different parities was identified on the basis of highest coefficient of determinant (R^2) value.

Result and Discussion: the 172 WTDY of different lactation were used to predict different WTDY by these above mentioned lactation curve models. The results are presented in table 2 for different lactation. The average four weekly test day milk yield increased from 6.17 Kg in 1st week (WTDY 1) to a peak yield of 8.91 Kg in 8th week (WTDY 3) and subsequently to 3.30 Kg in 40th week (WTDY 11) by Gamma function model (Model 1). The average four weekly test day milk yield increased from 7.11 Kg in 1st week (WTDY 1) to a peak yield of 9.91 Kg in 8th week (WTDY 3) and subsequently to 4.17 Kg in 40th week (WTDY 11) by Exponential function model (Model 2). The average four weekly test day milk yield increased from 8.77 Kg in 1st week (WTDY 1) to a peak yield of 11.55 Kg in 8th week (WTDY 3) and subsequently to 5.81 Kg in 40th week (WTDY 11) by Quadratic model (Model 3) for overall records presented in table 1.

The Gamma function (Model 1) was observed slightly higher WTDY in first lactation as compare to the least squares mean of actual observations. However it was observerd lower value in all other lactations than the least squares mean of actual observations. Quadratic model (Model 3) gave the highest value in all the lactation than the least square mean of actual observations. The Gamma function (Model 1) gave the best fit results in all the lactation with higher R^2 value. Similaraly Dongare *et. al.*, 2012, Cilek, and Keskin., 2008, singh and bhat., 1978, pande, 1983, olori *et. al.*, 1999, Yadav *et. al.*, 1977 and Kellong *et. al.*, 1977 found good fit Model l in different breeds of

Impact of blue and green monochromatic light in comparison to white LED on the stress reaction and mortality rate of broiler chickens

P Gautam, PS Pramanik, KD Singh, MK Verma, S Gautam, AK Verma, VN Gupta and B Singh

Abstract
The present experiment was conducted to investigate the impact of blue and green monochromatic light in comparison to white LED on the stress reaction and mortality rate of broiler chickens. For a period of 42 days study two hundred forty day old Vencobb 400 straight run commercial broiler chicks were randomly divided into three groups with 2 replicates of 40 in each at the poultry unit of livestock farm complex, College of veterinary sciences and animal husbandry, A.N.D.U.A.T. Kumarganj, Ayodhya, (U.P). In first green-blue group (T_{GB}), the birds were kept on green LED light (GL) and blue LED light (BL) from 1-21days and 22-42 days, respectively. The broiler birds of Group Tw and Tc were kept in white and incandescent LED lights for 42 days, respectively. The findings revealed that the heterophil % differed significantly ($P<0.05$) at 6th week of age when broiler finished their light treatment duration (after shifting from green LED to blue LED at 4th week of age). The ratio of blood heterophil to lymphocyte was also significantly differed ($P<0.05$) at the 6th week of age. The H/L ratio was higher in T_C group (0.37±0.008) whereas, it was lowest in T_{GB} group (0.33±0.456) than Tw group (0.35±0.120) birds at 6th of age. This study indicated that birds were minimum stress level in T_{GB} group than other treatment groups. The mortality rate of broiler chicks was highest in Tw group (6.25%) and lowest in T_{GB} group (3.75%) than T_C group (5%) birds. The results of the present study concluded that, broiler birds under green-blue (1-21d in GL and 22-42d in BL) LED bulb treatment group had significantly ($p<0.05$) lower stress as drawn by a ratio of Heterophil: Lymphocyte, which was highest in incandescent bulb treatment groups followed by white LED groups.

Introduction
For the large section of poultry meat consumers, the comprehensive mechanization of the poultry segment has made the broiler meat available in the recent years. Now the broiler meat is far most globally famous animal food product due to its nutritional, sensory and economical properties. It has a high potential to generate foreign exchange earnings through export of poultry products to neighboring countries. The Poultry industry has emerged as the fastest growing segment of the livestock sector both globally as well as in India (Iisa Augustine and Ruchira Shukla, 2015) [6]. Broiler production is one of the most dynamic and fastest growing animal husbandry sub-sectors in India. The total poultry population has increased by 16.81% over in the recent census and the total poultry in the country is 851.81 million. However, in previous census 2012, it was 729.21 million in numbers (Livestock census, 2019) [14]. Due to increasing population growth, urbanization and rising income there is an increasing demand of animal protein source so that chicken meat has shown its fastest growth in last two decades.
Lighting is an important environmental cause in poultry production that is known to affect performance and behavior. Chickens are visually well equipped, and therefore light plays very important role in their wellbeing and productivity. Light is constituted of a wide spectrum of electromagnet (EM) waves. The visible part of the electromagnetic (EM) spectrum is relatively small and is formed of wavelengths from approximately 350 to 800 nm. The eyes of broilers seem to be more sensitive to the broader spectrum than humans and these can perceive ultraviolet and infrared as well.

Components of Light in Poultry Management
Artificial light can be described by distribution of light (photoperiod), colour (wave length)

EFFECT OF NEEM LEAVES FEEDING ON SERUM BIOCHEMICAL PARAMETERS OF COMMERCIAL BROILER CHICKENS

Abstract

The experiment was conducted at the nearby poultry farm of the College of Veterinary Science and Animal Husbandry, NDUAT, Kumarganj, Faizabad, UP, India. A total of 200 unsexed Vencob commercial broiler chicks were distributed to four treatment groups each made of 50 chicks in a 4-brooder rooms. All the fifty chicks from each treatment were divided to form 5 replicates of 10 chicks each in a Completely Randomized Design (CRD).The four treatment groups were supplemented with neem leaf powder @ 0g, 1g, 2g and 3g / kg of broiler ration respectively. The glucose levels in serum of different broiler groups were affected by NLP feeding and were ranged from 12.91 to 17.55 (mmol/l) and there was significant differences found in all the groups. The lowest glucose level was observed in T_2, followed by T_1, T_3 and T_0. The mean serum total protein concentration was significantly higher in T_2 followed by T_0, T_1 and T_3. The values of albumin in T_2 and T_3 were significantly lower than those of T_0 and T_1. Among the groups, globulin was ranged between 23.55 and 31.81 g/l. The Highest globulin value was recorded in T_2 followed by T_0, T_1 and T_3. The data of albumin: globulin ratio revealed that T_2 group birds had the lowest ratio among the groups. The serum cholesterol concentrations of all the treated groups were non-significant but significantly ($p<0.05$) lower than that of control group. The ALT level in T_2 group was significantly lower than that of other groups. The AST concentration in the different groups of broilers serum was ranged between 126.31 and 134.79 U/L and the T_2 group showed significantly lower AST value than that of other groups. There was significant difference observed in various serological parameters studied in different group of birds.

Key words- ALT, AST, Cholestrol, Serum and Neem leaf powde

Introduction

Many synthetic drugs and growth promoters are supplemented to the broilers for their rapid growth but their uses have shown many disadvantages like high cost, adverse side effect on health of birds and long residual properties (Nayaka *et al.*, 2012). Exploring new antibiotics and growth promoters from the medicinal plants is a priority in this era of antibiotics resistance to increase the production of broilers. Consequently, there is considerable research interest in the possible use of natural products such as essential oils, extracts of edible plants, herbs and spices, for the development of new additives in animal feeding. Scientists are concentrating on the use of our ancient medicinal system to find beneficial herbs and plants which can be safely used to increase the production of animals. Many plants such as garlic, cloves, neem fruits and leaves, cinnamon, ginger, peppermint, thyme, mustard, and fenugreek etc. produce secondary metabolites such as phenolic compounds, essential oils and sarasaponins. Blood profiles are important indices of the physiological state of animal. The serum biochemical and hematological features have attracted many workers to look at their indices in order to make clinical predictions of the health status of a particular animal or a bird. The blood picture varies with certain conditions such as stress, infectious and toxicity (Khan and Zafar, 2005). Blood constituents provide valuable media for clinical investigations and nutritional evaluations of an animal (Aderemi, 2004).

Materials and Methods

To carry out the present investigation, 200-day old straight run, commercial broiler strain "VENCOB" chicks were procured from a commercial hatchery. These 200 chicks were divided in four groups, i.e. Group 1, 2, 3, 4, each group having 50 chicks. All the chicks from each group were divided equally to form 5 replicates of 10 chicks each in a completely randomized design (CRD). Water and starter diet for the four respective treatments were offered *ad libitum*. The four treatment groups were supplemented with neem leaf powder @ 0g, 1g, 2g and 3g/kg of broiler ration respectively. The litter of each treatment group was mixed weekly with dry neem leaves @ 0g, 2g, 4g and 6g/sq. ft. area.

Feeding schedule and treatments

Just after arrival of chicks, glucose water @ 10g /l water was provided in each group of birds. *Ad-lib* feeding of pre-starter, starter, and finisher ration of commercial feed was provided according to their age. Feed was provided in morning, afternoon and night hours in each group after proper weighing. Proper medication was done each and every sick bird as per their need. Prophylactic treatment and supportive therapy was done in each group equally. Fresh and clean palatable drinking water was provided *ad-lib* in each group. Vitamin and other medicines were provided in the drinking water as per dose rate recommended.

Blood collection and analysis

Blood samples were collected from individual bird at the end of experiment and analysed for various serum biochemical parameters.

Collection and processing of blood samples

Blood samples were collected aseptically from wing vein of each bird using sterilized disposable syringe and placed in two sets of sterile glass tubes, first set with anticoagulant, ethylene diamine tetra acetate (EDTA) (@1 mg/ ml of blood) for haematological purposes and second set without anticoagulant for serum separation. Separate the clot from the inner surface of the tubes and centrifuge at 2500 rpm for 10 minutes and collected the supernatant serum. Then serum samples were stored in labelled vials at-20°C for further analysis to assess the biochemical profile of birds.

Biochemical profiles

Serum Glucose

Glucose in the serum was determined by o-toluidine method (Hultman, 1959), where glucose forms a green coloured complex with o-toluidine in hot acetic acid, the intensity of which is read photo metrically at 630nm.

Total protein

Total protein in serum was estimated by the biuret method (Hiller *et al., 1948*).

Proteins bind with copper ions in the alkaline medium of the biuret reagent and produce a purple coloured complex, whose absorbance is proportional to the protein concentration when read at 555 nm.

Albumin and globulin

Albumin in the serum was estimated by bromocresol green (BCG) dye binding method of Gustafsson (1976). Albumin in a buffered medium bind with bromocresol green and produces a green coloured complex whose absorbance is proportional to the albumin concentration, when read sprectrophotometrically at 630 nm. Globulin was determined as the difference between total protein and albumin concentration in the serum.

Total cholesterol

ABSTRACT

The experiment was conducted at the nearby poultry farm of the College of Veterinary Science and Animal Husbandry, NDUAT, Kumarganj, Faizabad, UP, India. A total of 200 unsexed Vencob commercial broiler chicks were distributed to four treatment groups each made of 50 chicks in a 4-brooder rooms. All the fifty chicks from each treatment were divided to form 5 replicates of 10 chicks each in a Completely Randomized Design (CRD). Drinking water and broiler diet for the four respective treatments were offered ad libitum. The litter of each treatment group was mixed weekly with dry neem leaves @ 0g, 2g, 4g and 6g / sqft area. The nitrogen%, moisture% and pH of litter from each treatment groups were analyzed to determine quality of litter at the end of experiment. The performance index was calculated at 7th, 21st and 42nd day. The application of 4g dry neem leaves in the poultry litter significantly ($p<0.05$) reduced the values of pH, moisture % and nitrogen % than those of other treatment and control group of birds. The highest PI value was obtained in the birds of T_2 group followed by T_0, T_1 and T_3 in a descending manner at 42nd day.

Introduction

There is a saying "As the litter goes, so goes the flock!" This saying has a lot of truth as it relates to managing litter and the subsequent effect it has on air quality. For the most part, litter management has often more to do with managing the systems that influence litter quality rather than managing the litter. Litter conditions are often a reflection of how well one has done in managing litter. So, the litter management is very important in case of poultry because bad litter can create a lot of problems. Improper litter management leads to NH3 gas accumulation in the poultry shed. NH3 is a toxic, color, odorous and corrosive gas which pollutes the air. In addition, it creates few diseases such as conjunctivitis, immune suppression, lung congestation, impaired kidney function leading to problems like nephritis & urolithiasis. Neem (*Azadirachta indica*) a large evergreen fast growing perennial tree, is native to India and inhabitant of South Asian countries. Among the all plant parts the processed leaves play the most significant role inlivestock health (Sharma and Reddy. 2002). Neem leaves have some medicinal properties like antibacterial, antifungal, antimalarial, antiviral, anti

Effects of Neem leaves powder supplementation on performance and water intake of broiler chicken

Gaurav Panday, PS Pramanik, AK Verma, Mukesh Kumar, Amit Tiwari, Abhishek Mishra, Awadhesh Kumar Yadav and Vijay Gautam

Abstract
To carry out the present investigation, 200 day old straight run, commercial broiler strain "VENCOB" chicks were procured from a commercial hatchery. These 200 chicks were divided in four groups, i.e. Group 1, 2, 3, 4, each group having 50 chicks. All the chicks from each group were divided equally to form 5 replicates of 10 chicks each in a completely randomized design (CRD).Water and starter diet for the four respective treatments were offered *ad libitum*. The four treatment groups were supplemented with neem leaf powder @ 0g, 1g, 2g and 3g/kg of broiler ration respectively. There was significant difference in water intake of birds among the treatment groups in all the weeks on the trial. The highest water was observed in T_1 followed by T_2, T_0 and T_3 groups in the whole experiment period. Average final live weight (kg/bird) and the daily weight gain gm/day/bird) were significantly higher in T_3 followed by T_1, T_0 and T_2 groups. The lowest FCR was found in the groups of T_2 birds whereas the average daily water intake ml/bird was significantly higher in T_1 followed by T_0, T_2 and T_3.

Keywords: Neem leaves powder, performance, water intake, FCR, water: feed, broiler chicken

Introduction
It was established that water is an important factor in poultry raising because a bird can survive several weeks without food, but only a few days without water. Broilers drink a great amount of water and a critical fact that producers may not be aware of that feed and water consumption are very closely related (Tabler, 2003) [8], for example a 2.3kg broiler will consume about 8.2kg of water, compared to approximately 4.6kg of feed (Lacy,2002) [6]. Water consumption can be affected by the number of interacting parameters: birds, water quality feed quality and poultry house environmental issues (Manning, 2007) [7]. It was estimated that the correlation between feed and water consumption was at 0.98; it means that when water consumption changes, in 98% of the cases feed consumption changes as well. Best on this fact, daily feed consumption can be established by accurate monitoring of daily water intake. Monitoring water intake on daily basis has been shown to be a reliable measure of broiler performance (Defra, 2002) [2]. Water consumption both during a day and during the entire raising period is a key indicator reflecting the state of the birds' health. Therefore, the present study has been undertaken to evaluate the performance and water intake of broiler chickens supplemented with neem leaves powder.

Materials Methods
To carry out the present investigation, 200 day old straight run, commercial broiler strain "VENCOB" chicks were procured from a commercial hatchery. These 200 chicks were divided in four groups, i.e. Group 1, 2, 3, 4, each group having 50 chicks. All the chicks from each group were divided equally to form 5 replicates of 10 chicks each in a completely randomized design (CRD).Water and starter diet for the four respective treatments were offered *ad libitum*. The four treatment groups were supplemented with neem leaf powder @ 0g, 1g, 2g and 3g/kg of broiler ration respectively.

A B S T R A C T

The aim of the present investigation was to examine the man-power utilization pattern of milking operation in dairy animals. The present study was conducted on 23 selected milch animals at Instructional Livestock Farm Complex, College of Veterinary Science and Animal Husbandry, N.D.U.A.T., Kumarganj, Faizabad, U.P. The loose housing system was followed in the farm and animals were maintained within the enclosure having covered area on and around the feed manger. Hand methods of milking were performed in separate milking byre in two shifts following single row system. Man-min required under hand milking operations were recorded by a stop watch and observations were taken for 30 days. The results showed that, that time required in unit operation (sec/ Litre milk) decreased with increase in milk yield of animals. Man-second utilized for unit operation of 0-2, 2-4 and 4-6 litre milk yield group was 166.94, 90.59, and 75.80 second respectively. The average total milking time required for milk yield groups of 0-2, 2-4, and 4-6 litre was 268.77±11.10, 307.09±9.23 and 390.4±10.95 second respectively. These groups had an average yield of 1.61, 3.39 and 5.15 litre milk respectively. Similarly, for evening milking, milk yield group studied were 0-2, 2-4 and 4-6 litre which has an average production of 1.52, 3.25 and 5.08 litre milk respectively. The time required for the milking of per litre of milk for these groups was 188.76, 94.21 and 65.51 second respectively. It was observed with increase in milk yield the time required in unit operation was observed to be in decreasing order. The total time required in milking operation increased from 286.92±9.73, 306.17±12.13 and 332.8±11.84 second respectively. From the present study it may be concluded that total average time spent in hand milking operation of animals was found maximum in morning milking followed by evening milking.

Introduction

The dairy farming is a two-stage production system, i.e., cultivation of fodder crops and management of milch animals, currently contributes about 132.4 million tones (Department of Animal Husbandry, Dairying & Fisheries, Ministry of Agriculture, GOI) of milk and acts as a substrate to channelize energies of 143 million men and 35 million women farm workers to participate in the production process in India (Patel and Mehla, 1988). Man-power is the most critical resources

Keywords

Eggs, Fertility, Hatchability, Kadaknath and Aseel

A B S T R A C T

The present study was conducted to compare the fertility and hatchability of Kadaknath and Aseel fowls. For this purpose 50 birds from each breeds comprising of 45 females and 5 males were selected and kept in two different pens at poultry unit of Teaching Livestock and Poultry Farm of the College of Veterinary Science and Animal Husbandry, N.D.U.A.T. Kumarganj Faizabad (U.P.). Fertility was found higher in Kadaknath (86.18) than Aseel (81) with significant difference among them. Both hatchability on set egg and hatchability on fertile eggs were significantly differed among two breeds being higher in Kadanath. Average chick weight was found higher in Aseel than Kadaknath. Normal chick % was found highest in Kadaknath followed by Aseel. This result indicates that Kadanath are superior to Aseel in relation to fertility, hatchability and related traits.

Introduction

Indian poultry industry has made a tremendous and remarkable progress evolving from small scale backyard venture to the status of commercial, full-fledged, self sufficient and most progressive agro based industry. Poultry accounts for more than 30% of all animal protein consumption worldwide (Permin and Pedersen, 2000).Fertility and hatchability are the main factor which affects the profitability in the hatchery enterprise (Peters *et al.*, 2008).These parameters appears to be very important as for as parent stocks are kept to produce final hybrids. Hatchability is a major complex age dependent traits. Egg production and hatchability of broiler eggs can be influenced considerably by age of flock (Elibol *et al.*, 2002). Kadaknath (KN) is an important Indian reared poultry breed which is well known for poor egg production, slow growth rate, smaller body size as well as late sexual maturity. Aseel is noted for its Pugnacity, high stigma, and majestic gait and dogged fighting qualities.

The present experiment was designed –

1. To find the fertility, hatchability and associated traits in Kadaknath and Aseel.
2. To find out the correlation among hatchability traits in Kadaknath and Aseel.

Study the Haematological parameters and Oxidative stress before and after disbudding in Calves

Abstract

The aim of the present investigation was to examine the haematological profile and oxidative stress before and after disbudding in calves. The study was carried out at Livestock Farm Complex, College of Veterinary Science and Animal Husbandry, ANDUAT, Kumarganj, Ayodhya and nearby villages. Twenty four cattle calves were utilized to study haematological parameters that are Haemoglobin (Hb (gm/dl), Neutrophil (%), Basophil (%), PCV (%), Lymphocyte (%), Monocyte (%), TLC (10^3/ µl), Eosinophil (%), N/L ratio) and oxidative stress before and after disbudding in to four groups viz. control (T_0), lignocaine (T_L), tremadol (T_T) and lignocaine+tremadol (T_{L-T}). After medication calves were disbudded by hot iron method. The blood samples were collected for haematological parameters & for estimation of LPO (lipid peroxides) as per method described by [1] just before (0h) and after disbudding on 6h, 24h and 72h. The results showed that, at 24h, T_0 group showed significantly lowest Hb (10.66±0.49%) which was statistically similar to T_T and T_{L-T} groups. At 0h, 6h and 72h means of PCV% were significantly different among treatment groups. The lowest lymphocytes (64.00±1.00) was observed in T_T group at 6h. The T_0 group showed significantly lowest basophil (0.00±0.00) which was statistically similar to T_T and T_{L-T} groups but significantly different from T_L group at 6h. At the same interval, T_0 group showed significantly lowest monocytes (4.66±0.61) which was significantly different with T_L, T_T and T_{L-T} groups. At 6h, T_0 group showed significantly lowest N/ L ratio (0.15±0.01) which was statistically similar to T_T and T_{L-T} groups but significantly different from T_L group. At 0h, 6h and 24h LPO was significantly different among groups. At 0h, T_0 group showed significantly highest (106.59±0.63) which was significantly different from T_L, T_T and T_{L-T} groups. It may be concluded that no significant difference was observed in eosinophil%, TLC, neutrophil% and monocyte% counts between control and treatment groups. However, Hb%, basophil%, PCV% and lymphocyte% were significantly different between control and treatment groups. N/L ratio was significant only at 6h. Most of the cases T_{L-T} group showed comparatively better performance. At 0h, 6h and 24h LPO was significantly different among groups. At 0h, T_0 group showed significantly highest (106.59±0.63) which was significantly different from T_L, T_T and T_{L-T} groups.

Influence of Fortifying Graded Levels of *Moringa oleifera* Leaf Powder on Growth Performance and Haemato-biochemical Indices of Broiler Chickens

Ajeet K. Verma[1]*, Partha S. Pramanik[1], Manoj K. Verma[2], Sachin Gautam[3], Rajesh Kumar[4], Saurabh[4]

Abstract

The study was conducted to evaluate the influence of *Moringa oleifera* leaf powder (MOLP) on the growth and haemato-biochemical indices of broiler chickens. A total of 250-day-old broiler chicks (Vencobb-430) were randomly distributed into five groups with 5 replicates of 10 birds in each. Different dietary treatments were; basal diet with no supplement (NC- negative control) and a basal diet supplemented with antibiotics (PC-positive control), 1% MOLP (MOLP1), 1.5% MOLP (MOLP1.5), and 2% MOLP (MOLP2). Bodyweight gain (BWG), feed intake (FI), feed conversion ratio (FCR), haemato-biochemical parameters, and economics were assessed in 35 days of the experiment. The results showed that BWG of birds was significantly ($p < 0.05$) higher in all Moringa supplement groups than NC group, but similar to PC group birds. Feed intake and FCR of Moringa supplemented and PC groups were significantly ($p < 0.05$) lower than the NC group, except MOLP2, which showed no difference in FI compared with the NC group. MOLP1.5 group birds recorded the best value of FCR among different groups. The highest profit per broiler was recorded in MOLP1.5 followed by MOLP1 and MOLP2 than NC, similar to the PC group. Hb and PCV values of the MOLP1.5 group were significantly ($p < 0.05$) higher than the NC group but comparable to the PC group. Platelet and WBC count were significantly ($p < 0.05$) lower in Moringa supplemented groups than NC and PC groups. A significant ($p < 0.05$) reduction was observed in blood glucose, SGPT, SGOT, cholesterol, and triglyceride levels of Moringa supplemented groups as compared to broilers of PC and NC groups. From the results, it was concluded that supplementation of 1.5% *Moringa oleifera* leaf powder improved the performance of birds without any detrimental effect on their health.

Ind J Vet Sci and Biotech (2021): 10.21887/ijvsbt.17.3.7

Introduction

A very strong demand for animal protein for human beings has expanded, consolidated, and globalized in countries of all income levels. The poultry industry in India is one of the fastest-growing livestock sectors, with a growth rate of 8.51 and 7.52 % in egg and broiler production, respectively (BAHS, 2019). Antibiotic feed additives in food-producing animals have been used to meet the increasing demand for animal protein, including improved feed utilization, promotion in growth, and prevention from pathological micro-organisms. However, usage of antibiotic feed additives as growth promoters leads to harmful effects on consumer's health due to augmentation of microbial resistance and residual effect. Considering microbial resistance builds-up forces to reduce antibiotic feed additives in livestock and poultry production (Cheng *et al.*, 2019). Investigating safe and natural antibiotics alternatives is a tremendous challenge for animal scientists and veterinarians to meet the increased demand for providing wholesome meat at a low cost. Dietary inclusion of herbal plants and their extracts have been used as an alternative to antibiotic growth-promoter in poultry production (Movahhedkhah *et al.*, 2019).

SHORT COMMUNICATION

Evaluation of Body Weight and Body Measurements of Lesser-known Gang-Fatehpuri Sheep of Uttar Pradesh, India

Manoj K. Verma[1]*, Vindhyavashini K. Singh[1], Jaswant Singh[1], Ajeet K. Verma[2]

Abstract

The present study was aimed to evaluate morphometric characteristics of lambs of less known native sheep of Gang-Fatehpuri of Fatehpur district of Uttar Pradesh during different growth stages in its breeding tract for breed recognition and registration with NBAGR, Karnal, India. A total of 365 lambs of either sex of different age groups (94, 102, 95, and 74 heads of 3, 6, 9, and 12 months of age, respectively) were surveyed in 15 villages of Fatehpur district. The overall values of body weight and body measurements, *viz.*, body length, height at withers, chest girth, tail length, and ear length recorded at 12 months of age (sexual maturity) were 29.62 ± 0.46 kg, 73.47 ± 0.46 cm, 73.54 ± 0.51 cm, 77.63 ± 0.43 cm, 40.08 ± 0.23 cm, and 18.29 ± 0.13 cm, respectively. The mean values of all the traits, except ear length, of male lambs, were significantly ($p < 0.05$) higher/larger than female lambs. The differences gradually increased significantly ($p < 0.01$) with advancing age from 3 months to 12 months. The values were generally comparable with the earlier known sheep breeds like Muzaffarnagari, and Kajali of the region.

Keywords: Body measurements, Body-weight, Gang-Fatehpuri, Mutton type breed.

Ind J Vet Sci and Biotech (2021): 10.21887/ijvsbt.17.4.17

Introduction

India has vast biodiversity of ovine genetic resources with multipurpose utility for wool, mutton, milk, skin, and manure. The livestock population develops through unique adaption to their agro-climatic environments and their survival over a prolonged duration. Sheep rearing is a valuable component of the rural economy of India's arid, semi-arid and hilly areas. A systematic attempt to characterize and conserve animal breeds were started after establishing the National Bureau of Animal Genetic Resources (NBAGR) at Karnal, India. In addition to 44 well-recognized sheep breeds, many unrecognized, uncharacterized, and lesser-known sheep genetic populations are disseminated in the entire country. The biometric measurements of different body parts have a significant relationship with the body-weight of animals (Nayak *et al.*, 2008; Mishra *et al.*, 2016; Dass *et al.*, 2019).

The body measurements (body length, height at withers, chest girth) and body weight are used as an indicator of adult size, feeding requirements, and physiological maturity of animals. Furthermore, based on body measurements, an association can be established between body conformation and functionality of animals. Thus, body measurements can assist in the evaluation of growth performance as well as the meat production potential of Gang-Fatehpuri sheep. In view of the facts above, the present study aimed to evaluate the body weights and body morphometric measurements during the growth period of one year of this breed, as part of its recognition and registration with the Animal Genetics Bureau.

Abstract

The present study was carried out to evaluate the influence of Moringa oleifera leaf extracts on carcass traits and mortality of broiler chickens. A total of 250-day-old broiler chicks (Vencobb-430) were randomly distributed into five groups with 5 replicates of 10 birds in each. Different dietary treatments were; basal diet with no supplement (NC- negative control) and basal diet supplemented with antibiotics (PC-positive control), aqueous extract of 1.5% Moringa powder (MOAQE), ether extract of 1.5% Moringa powder (MOEE) and alcoholic extract of 1.5% Moringa powder (MOALE). Percent weight of various cut parts, eviscerated weight and drawn yield were evaluated after 35 days of experiment. The results showed significantly higher eviscerated weight and drawn yield percentage in Moringa extracts supplemented groups compared to PC group. PC and MOAQE group recorded significantly (P<0.05) higher drumstick % compared to NC, MOEE and MOALE group. Moringa extracts group recorded significantly (P<0.05) lower mortality than PCand NC group birds. From above results it was concluded that supplementation of Moringa extract of 1.5% Moringa oleifera leaf powder improved the carcass traits and reduced the mortality of birds.

Key words: *Broiler, Extract, Carcass, Mortality and Moringa (words in alphabetical order)*

Introduction

Major cost involved for poultry enterprise is in the form of feed. Various approaches such as feed supplements and additives are being used to obtain more net return and to minimize expenditure on feed (Agasheet *al*., 2017). *Moringa oleifera* leaf (MOL) has fascinated great attention as a non-traditional feed component because of its unique qualities. Moringa oleiferagrows fast, drought-tolerant tree native belonging to sub-Himalayan tracts of northern India, Pakistan, Bangladesh and Afghanistan. Moringa is currently cultivatedglobally in the tropics and subtropics (Faheyet *al*., 2001). Crude protein content in Moringa varies from 25% to more than 30% on a dry matter basis (Melesse et al., 2013), with a high proportion of essential amino acids (Lu *et al*., 2016). Moringa leaves, flowers and Pods are used as good sources of vitamins A, B and C, riboflavin, nicotinic acid, folic acid, pyridoxine, ascorbic acid, beta-carotene, calcium, iron and alpha-tocopherol (Dahot M.U., 1988). Moringa leaves are the preferred part of tree for use in animal diets as leaf meal due to high nutritional and medicinal properties (Abbas, 2013). The meat obtained from broiler chickens is an excellent source of protein, vitamins, mineralsand lower in fat content, so having a great demand among non-vegetarians(Naji *et al*., 2013).Addition of*Moringa oleifera* leaf meal in broilers diet resulted significant increase in dressed weight, eviscerated weight and dressing percentage (Ayo-Ajasa *et al.* 2016). Dietary supplementation of Moringa leaves would be a potential strategy to improve the meat quality in broilers due to its antioxidant potential. It was further reported that phytosterols could lower malondialdehyde content and increase glutathione concentration in the breast muscle of broiler chickens (Naji *et al*., 2013).

This study was carried out to evaluate the effect of different extracts (1.5%) of *Moringa oleifera* leaves powder as feed supplement in broiler diets on carcass characteristicsand mortality of broiler birds.

(Please correct red marks)

Materials and Methods

The present experiment was conducted after an approval from "Institutional animal ethical committee (IAEC)" was obtained vide reference number IAEC/CVSc/P-36/2019. A total of 250 one-day old Vencobb-430 strain chicks were randomly allocated into five dietary treatment groups with 5 replicates of 10 chicks in each. The chicks were kept on five dietary treatments which includes a basal diet without any additive in negative control (NC) or that supplemented with antibiotics (Positive control-PC), aqueous extract of 1.5% Moringa powder (MOAQE), ether extract of 1.5% Moringa powder (MOEE) and alcoholic extract of 1.5% Moringa powder (MOALE) in basal diet. Birds were fed *ad libitum* in different phases of experimental trial. The composition of formulated experimental diets as per BIS (2007) has been given in Table 1.

The chicks were kept on deep litter system under uniform standard management conditions with availability of clean, fresh and wholesome drinking water. Mortality was recorded during the entire research period. At the end of trial one bird per replicate (5 birds/treatment) were selected randomly for the carcass evaluation and sacrificed after 12 hours pre-slaughter fast though drinking of water was allowed. After complete bleeding carcass were dipped in hot water (58°C) for 1-2 minutes and feather were removed. Evisceration was done by making a slit from tip of breast bone up to the area around the cloaca. Thorough washing and cleaning were done after evisceration. After that the carcass were kept hanging on the special racks for 5-10 minutes. The visceral organs were removed by supporting the bird with one hand via the incised abdomen. Eviscerated carcasses were weighed and cut parts like thigh, drumstick, breast, wings, back, head, neck and shank were also weighed.The relative weight of dressed, drawn yield and different edible cuts were calculated as percentage of live weight.

The data were analysed under completely randomized (CRD) by employing one way analysis of variance (Snedecor and Cocran, 1994) and means of different dietary treatments were compared with Duncan multiple range test. The P value lower than 0.05 was thought-out significant.

(Please correct red marks)

Results and Discussion

Carcass characteristics:

The data pertaining to the carcass traits of broilers presented in Table 2. The results showed that the dressed weight and thigh weight of different groups was similar and showed no significant (P>0.05) effect of various Moringa extracts. The eviscerated weightof aqueous extract (72.24), ether extract (73.10) and alcoholic extract (73.09) supplemented group broilers were similar to NC (72.05) group, however significantly (P<0.05) higher than PC (70.39). The drawn yield of MOAQE, MOEE, MOALE and NC also significantly (P<0.05) higher than PC group. Leg and drumstick weight % of PC group was significantly (P<0.05) higher than MOEE and MOALE group. However, leg weight was

ABSTRACT

A field experiment was conducted during *kharif season* of 2014-15 at N.D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) in sandy loan soil. The experiment consisted of 9 treatment combinations comprised of three transplanting dates *viz*., July 5 (D_1), July 15 (D_2) and July 25 (D_3) and three varieties viz., Sarjoo-52 (V_1), NDR-359 (V_2) and Swarna (V_3). It was observed that different phenophases of rice markedly varied with not only dates of transplanting but also different weather variables which ultimately creates the different crop growing environment to harvest the yield accordingly. Among the three varieties, it was also observed that different phenophases has taken higher days in V_1 as compare to V_2 and in different days of transplanting higher linear growth rate (LGR) was recorded in D_2than D_1 and D_3.Crop growth rate (CGR) in V_3 recorded highest CGR as compare to V_1 & V_2. V_3 maintained the superiorly of RGR and possess highest growth rate 0.40 mg/g/day over V_2 (0.36 mg/g/day) and V_1 (0.29 mg/g/day).

Introduction

Rice yields have been increasing since the 1960s, but since the 1990s, growth in rice production has been slower than population growth Indeed, it is anticipated that rice production will need to increase by 30% by 2025 in order to sustain those who need it for sustenance. However, climate change, especially access to water, soil erosion and other problems threaten rice yields. The impact of air temperature on rice growth would be specific because of the different sensitivity of different locations with regard to temperature. In tropical regions, the temperature increase due to the climate change is probably near or above the optimum temperature range for the physiological activities of rice (Baker *et al*., 1992). Such warming will thus reduce rice growth. In addition, higher temperatures will cause spikelet sterility owing to heat injury during panicle emergence. In temperate regions, increased air temperatures should hasten rice development, thereby shortening the time from transplanting (or direct seeding) to harvesting and reducing the total time for photosynthesis yield development (Neue and Sass, 1994). Rice is very sensitive to higher temperature during reproductive stage especially flowering and anthesis. It is necessary to identify genetic donors for heat stress from high temperature rice growing environments. Temperature stress affects at

LIVESTOCK PRODUCTION AND MANAGEMENT IN RELATION TO CLIMATIC VARIABILITY IN EASTERN INDIA

Anil Kumar Singh
Department of Agricultural Meteorology, N.D.University of Agriculture & Technology, Kumarganj, Faizabad-224 229
aksmausam@gmail.com,

ABSTRACT

A bench mark survey pertaining to Livestock production and management in relation to climate variability was done during 2005-2007 in Eastern India. In the present study the temperature, humidity, air movement, solar radiation and rainfall are major climatic parameters affected the nutritional plan of animals through the amount of crops and pastures. The milk yield of all mammalian species undergoes seasonal variations. In cattle, the yield was relatively unaffected within the temperature range of 5 to 21°C. At temperature lower than 5°C as well as from 21-27°C, the yield decreased slowly whereas above 27°C the decline was much faster. Milk production decreased approximately by 1 kg for each degree rise in rectal temp. In Eastern U.P. the livestock population in high rainfall and low lying area (Gorakhpur & Siddharthnagar) and low rainfall and undulated area of Mirzapur division is very interesting that in Gorakhpur during 1988-2003, percentage increase of Buffalo was 37% followed by Goat 21%.While in Mirzapur, the population of all livestocks increased unexpectedly. Pig increase was 166% followed by Buffalo and Sheep 78% and 77% respectively. Goat percent was also increased by 56% i.e. rural masses more depend on livestock may be due to poor socio-economic status, undulated topography, erratic rainfall and drought prone region of the eastern U.P. Within the range of environmental temp. 9°C to 29°C egg production in the domestic fowl was not reduced. Thermal stress especially sharp changes in temp. adversely affected both egg weight and shell quality. 24 hrs. exposure to 380 resulted in sudden temporary drop in egg production of some strains. RH and Photoperiod hampered the Sheep rearing in Jharkhand as increased humidity retards wool growth. Lactating animals present in Eastern U.P., Bihar and Jharkhand, in 2004-05 declined by around 40.90%, 35.16% and 25.35% respectively as compared to that in 1981-82. Scanty availability of round the year fodder production due to undulant rainfall patterns has made the specific changes in the animal rearing in these three states.Almost all farmers fed green fodders (Berseem, Bajra, Maize and Jowar) as well as chaffed Dry fodder (Wheat straw, Paddy straw & kadbi of Bajra, Maize & Jowar) to their animals. Concentrate mixture was provided to animal mostly at time of milking (98.2%, 98.6% and 97.6%) respectively in these three states. In Bihar the concentrate feeding to the animals is found to be maximum whereas in Jharkhand grazing pastures available are maximum probably due to high rainfall pattern during last 15 years. The scarcity fodder availability was also maximum in Jharkhand state.The majority of the farmers of eastern U.P. prefers stall feeding to their animals as compared to the farmers of Bihar & Jharkhand states. In all three states the animal diseases like FMD, BQ, H.S., Pneumonia, Diarrhoea, Bloat, Mastitis and Protozoal diseases like Theileriosis, Surra and other Parasitic diseases were more frequent in last one decade. Weather Based Disease Forecast (WBDF) is to be provided at regional levels to sustain various diseases to increase reproductive efficiency in livestock species. As per the livestock census of 2003 the population of sheep in Jharakhand state has declined by about 31% as compared to that of in 1981-82. Therefore, rectified methods to be evolved for maintaining and breeding of sheep production as a lucrative business as per the present climate change in Eastern India. Also the alternative sources of fodder crops such as subabool, peepal leaves and ber leaves for sustainable meat production for marginal farmers is to be suggested.

Climate change is frequently considered a major conservation threat to the country. The Earth's climate has already warmed by 0.5°C over the past century and recent studies show that it is possible to detect the effects of a changing climate on ecological systems. Changes in climate in recent decades are apparent all over the globe at all levels of ecological organization: population and life-history changes in species composition of communities and structure and functioning of ecosystems. Although it is impossible to prove that climate change is the cause of ecological effects. It is no longer safe to assume that all of species historic range remains suitable. Importance of climate change as a current threat to species emphasize the need for current conservation efforts to consider climate change in both insitu conservation and reintroduction efforts. These studies can contribute to preparations for future challenges by providing valuable input to models. The temperature, humidity, air movement, solar radiation and rainfall are major climatic parameters affecting the nutritional plan of animals through the amount of crops and pastures.

RESULTS AND DISCUSSION

In Eastern U.P. the livestock population in high rainfall area (Gorakhpur) and undulated low rainfall area of Mirzapur division is very interesting that in high rainfall area of Gorakhpur percentage increase of Buffalo is 37%

Yield Gap Analysis and total Rainfall of Rice crop of Onset of Monsoon in Different Sectors of U.P

Ajit Singh*, A.K. Singh, Smita Gupta and U.P. Shahi

Abstract

The onset date of south west monsoon in eastern U.P./ central U.P. shifted to 19th/20th June from normal date 15th June. Total rainfall in relation to onset of monsoon decreased by 6% if monsoon reaches on 19th June in eastern U.P. as compare to rainfall of normal date (15th June) and 9.5 %if monsoon reaches on 25th June. Consequent upon length of rainy season was also decreased from normal 108 days to 99 days in eastern U.P. whereas reduction in length of rainy season in other sectors of U.P. ranged between 12-13 days. Rainy day and rainfall intensity both reduced in all sectors of U.P. In eastern U.P. rainfall intensity reduced from 25 mm/day (1971-1990) to 17.2 mm/day (1992-2011), i.e. 32 % reduction hence crop planning may be made accordingly in respective sectors. Yield gap of crop has been calculated at particular amount of rainfall over the year of data with difference of maximum yield and minimum yield at same amount of rainfall. Variability of seasonal rainfall in different sectors of U.P. was also in same order and magnitude as that of total rainfall.

Keywords
Yield gap, onset of monsoon.

Introduction

Rice is the country's most important crop economically and culturally. The total area under rice is estimated to be about 11 million ha occupying 55% of the total cropped land. The climate of Ping River Basin is dominantly affected by Monsoon. The Monsoon (rainy season), winter and summer. Rainy season or Southwest Monsoon Season (May to Mid-October) is dominated by the southwest monsoon, during which time rainfall in the north is at its heaviest. India climatology exhibits a strong trend and inter-decadal variability. The variability in recent decades (Post-1980) seems to be strongly ENSO and it is the main cause of many of the disastrous Inter annual climate fluctuations affecting tropical and sub-tropical countries . Assessment of the adverse effects of climate variability on agriculture might help to properly anticipate and adapt farming to optimize agricultural production (James, 2008). In this article, three major issues related to climate variability, impacts of climate variability on rain -fed rice production and adaptation strategies in the face of varying climate are addressed. The weather and its variability are well known to the farming community and have great impact on crop production. The economy of the farmers is well influenced by weather. The greatest risk to crop yields in Indian agriculture is attributed to the variability of seasonal rainfall and the uncertainty in the amount and its distribution in a given season. Hence, rainfall is one of the prime meteorological factors which control the water balance of a particular area. Therefore, its amount, time of occurrence and spatial variability controls the agricultural practices adopted in the region (Baweja 2011).

The rainfall process exhibits a high degree of variability of space and time and its relation determine the environment and development of particular region. It is not only crucial agroclimatic parameter to the agricultural activities but also one of the design for ground water recharge (Ramos, 2001). The challenges of global agriculture have been analysed exhaustively and the need has been established for sustainable improvement in agricultural production aimed at food security in a context of increasing pressure on natural resources (Cassman 2012, Connor and Minguez 2012). Of a total global land area of 13,000 Mha, arable land and permanent crops account for by 12%, permanent meadows and pastures for 26%, forests for 30% whereas 32% of this land is unsuitable for agriculture (FAO 2011). Analysis that accounts for suitability of remaining land for cropping and alternative land uses concludes that expansion of cropping land to 2050 is likely to be small. Globally, 15% of arable land is irrigated and currently accounts for 42% of all crop production; 7100 km3 of water are consumed annually to produce food globally whereas feeding the world population of around 9 billion by 2050 would require an additional 2100 km3 year (Sumberg 2012, Rockstrom *et al*. 2012).

Materials and Methods

The rainfall data of 20 years (1992-2011) of Uttar Pradesh received from Department of Agriculture statistics, Directorate of Agriculture Uttar Pradesh, Lucknow has been analyzed to evolve the rainfall based planning the farm operations, crop management and cropping system with minimum risk to utilize the rainfall efficiently for increased production.

Uttar Pradesh is the most populous state in India with a population of over 199.5 million people, geographical area of 2,40,928 square km as of 1 March 2011. It is situated at 27°40'N Latitude & 80° 00' E Longitude. The latitude & longitude of districts of U.P. Study districts has been show in Fig 1

Onset of SW monsoon

The guidelines to be followed for declaring the onset of monsoon over Kerala/over country are enlisted is below:

Rainfall

If after 10th May, 60% of the available stations in the state the rainfall of 2.5 mm or more for two consecutive day, the onset over Kerala be declared on the 2nd day, provided the following criteria are also in concurrence;

i) ***Wind field***

Depth of westerlies should be of magnitude maintained upto 600 hPa, in the box equator to lat. 10°N and Long. 55°E to

Abstract : The present investigations were on five varieties and tried in randomized block design with four replications. Five varieties namely Yellow gold, Parasmani, SCM-565, Varuna and SRM-777 were used in experiment. The soil of experimental plot was loamy sand in texture, low in organic carbon and available nitrogen, phosphorus and available potassium. The result of the present investigation indicated that the maximum germination, flowering and maturity was recorded in varieties SRM-777 and minimum in Yellow gold. The maximum number of pod development was noted in varieties SRM-777 and minimum in Parasmani. The weather parameter was recorded in average range to all varieties.

Key words : Tmax, Tmin, Mean temperature, Temperature range, Morning and evening RH, BSS, Physiological stages.

1. Introduction

Brassica is a winter season crop and its physiological as well as morphological developments are markedly influenced by temperature conditions during different physiological stages. Indian mustard [*Brassica juncea* (L.)] is a crop of tropical as well as temperate zones requiring somewhat cool and dry weather for satisfactory growth and development. High temperature at flowering stage causes reduction in seed yield as it may lead to pollen sterility [Malarkadi (2007)]. Although mustard is a long day plant requiring 16 h of light period in 24 h cycle, it can be made to flowering, if it is provided with a cycle of 8 h of light period with 4 h of dark period (short night). Mustard can be made to flower in about 50 days under 16/8 h light/dark period. Due to its hardy nature and capacity to thrive well under poor conditions of fertility and moisture, it is generally raised as rainfed crop due to which its average yield is low. Mustard is the crop of tropical as well as temperate zone. The temperature requirement varies from 0.5-3.0°C (min.) to 35-40°C (max.) with an optimum of temperature regime of 20-35°C. Cool temperature, dry weather with good amount of bright sunshine increases the oil yield. Mustard needs high temperature for vegetative growth (*i.e.* 20-32 °C) and cool temperature with clear sky during reproductive growth and maturity. Significant response of oilseed to the tune of 30-40% was recorded due to the use of secondary major nutrients and micronutrients and with significant residual effect in cropping system. In tropical environment of central plane zone Indian conditions [Srivastava (2003), Nanda (1996)], mustard sowing usually start from mid-October but in some parts of this region, sowing is delayed due to the late harvest of transplanted rice. The average yield of mustard is only 999 kg/ha in India, which is very low compared to other mustard growing countries of the world [Anonymous (2002-2003)].

2. Materials and Methods

The five cultivars of mustard *viz.*, Yellow gold, Parasmani, SCM-565, Varuna and SRM-777 were sown at 25th October during the year 2013- 14 with recommended package of practices Agrometeorological weather station farm, School of forestry and environment, SHIATS Allahabad. The size of the each plot was 2m × 2m with a row-to-row spacing of 30 cm and plant-to plant spacing of 10 cm. Thinning was done manually at 25 days after sowing to maintain plant population of 30/m². The soil of the experimental

Impact assessment of climate change on rice yield using simulation model

Ashish Singh, AK Singh and AN Mishra

Abstract
Rice crop yield prediction using normalized yield difference analysis on seasonal basis reveal that maximum temperature may cause the reduction in yield of rice in Eastern U.P. by 1% to 1.2% / ha during 2020 to 2080. Minimum temperature may decrease the yield of rice by 1.5% to 1.8% / ha. South-West monsoon rainfall will remain the major factor for controlling the yield of rice by the end of 2080. Increase of yield in Eastern U.P. may increase to the extent of 28% to 30% / ha. Future prediction of Tmax & Tmin scenario on monthly basis predicts that the month of December and January will be hotter than November contrary to normal trends. For T minimum the prediction in Eastern U.P., increase of temperature will be during month of December and January for 2020 to 2080. The rate of increase of Tmax those during months in Eastern U.P. will be higher during 2050-2080 (2 to 4 °C) as compared to 2020 to 2050(1 to 2 °C). During 2020, the rainfall will be lower in Eastern U.P. Terminal drought (60 DAT -75 DAT) at 50% flowering to milking stage is more severe to reduce the rice yield as compared to drought at early tillering (15 to 25 DAT) and vegetative stage (45 to 60 DAT). Simulated yield of rice reduced from average 2020 to 2080 in the tune of 15.13%, 11.19%, and 14.09% under July 5th, July 15th, July 25th transplanting of rice variety Sarjoo-52 respectively. The Rate of decrease of simulated yield of rice Sarjoo-52 variety under 2020 to 2080 was faster under delayed transplanting of July 25th. Integrated crop management emphasized in future besides developing short duration, drought tolerant varieties responsive to low inputs.

1. Introduction
Crop simulation models can integrate knowledge of physiological process and morphological traits to help explain yield formation in environments varying in physical, biological and agronomic factors. These simulations can be used to evaluate key interactions quickly and identify traits with the greatest impact on yield potential (Aggarwal *et al.*, 1997) [1] and for assessing the relationship between crop productivity and environmental factors.
Crop simulation models can predict responses to large variations in weather. At every point of application weather data are the most important input. The main goal of most applications of crop models is to predict commercial output like grain yield, fruits, root, biomass for fodder, etc. Crop simulation models are used in USA and in Europe by farmers, private agencies and policy makers to a great extent for decision making. Under Indian climatic condition, these applications have an excellent role to play. Rice is mainly grown as rainfed crop in Uttar Pradesh but Uttar Pradesh is highly risk prone in respect of rainfall either due to delayed monsoon, intermittent drought or terminal drought and even floods in north Eastern part of Uttar Pradesh causing great loss of rice production. Therefore, prediction of rice production not only in state as a whole but also at district level is rather uncertain due to vagaries of monsoon. Hence, modeling approach can be adopted for prediction in the state at macro or micro level. Simulation models which help in predicting the yield of a crop is therefore is the need of the day. It is essential to have pre-harvest estimate of production for Uttar Pradesh due to its importance on state as well as national economy. Hence present investigation was undertaken.

Materials and Methods
Collection of daily historical weather data of last (20 years), crop data & soil data were made. Minimum data set for Rice crop for last three years was required for operation and evaluation of simulation model. Calibration of simulation model was made with the historical data of kharif rice 2013 and 2014. Validation of the model was done with the experimental data of kharif rice 2015 and 2016. For impact assessment of climate change on Rice yield of Future prediction of Rice crop under Agro-climatic conditions of Eastern U.P., Prediction of

ABSTRACT

An experiment was conducted during kharif 2015 and 2016 at Agro met Research Farm of NDUAT as to basis the yield forecast Yield Forecast of rice crop in Eastern U.P. using simulation Model. The genetic coefficients were determined by the Decision Support System for Agro Technology Transfer (DSSAT) model using the identical management and other conditions as in the field experiment for three varieties of rice (Sarooj-52, NDR-359 and Swarna). These determined coefficients were used in the subsequent in calibration on validation and other applications. Results reveal that observed value of grain yield of rice in July 5th transplanted rice was higher over simulated value. Due to higher number of days taken to anthesis and physiological maturity over simulated value. Due to delay in transplanting, the grain yield of rice decreased in accordance with observed value too. This shows the better sensitivity of DSSAT model.

Introduction

An Agricultural model contains many simple, empirically derived relation-ships that do not completely represent actual plant processes. When models are adequately tested against observed data (calibration and validation process), the results represent agricultural output under current climate conditions. The agricultural models simulate the current range of agricultural technologies available worldwide.

They do not include potential improvements in such technology, but can be used to test the effects of some potential improvements, such as improved varieties and irrigation schedules. A range of agricultural models are used widely by scientists, technical extension services, commercial farmers and resource managers to evaluate agricultural alternatives in a given location under different conditions. Decision Support System for Agro Technology Transfer (DSSAT) includes a basic set of tools for the preparation of the input data, as well as application programmes for seasonal, crop rotation and spatial analysis. (Anonymous, 2007 and Aggarwal *et al.*, 1997) In simulation of systems, carbon from canopy assimilation forms the essential core of most simulations that deal with the growth of vegetation. Change in weather to warm and humid may lead to the more rapid development of a plant disease, a loss in yield

Water requirement of wheat crop for optimum production using CROPWAT model

Krishna Deo, SR Mishra, AK Singh, AN Mishra and Ashish Singh

Abstract
A field experiments was conducted during *rabi* seasons of 2014-2015 and 2015-2016 at the Agro met Farm, N.D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) The treatment comprised of four levels of irrigation schedule *Viz*.. I_1 (critical stages), I_2 (0.6 IW: CPE ratio), I_3 (0.8 IW: CPE ratio), and I_4 (1:0 IW: CPE ratio). The findings of present investigation indicated that the growth and yield attributes of wheat were significantly influence due to different irrigation schedule. The results, further revealed that growth attributes such as plant height (cm) and Leaf area index (LAI) were found significantly higher under I_1 (critical stages) treatment. The highest grain yield (52.3 and 52.2 q/ha) and straw yield (65.8 and 66.9 q/ha) recorded under I_1 (critical stages) treatment. The lowest grain yield (51.2 and 51.9 q/ha) and straw yield (64.4 and 65.3 q/ha) was recorded under I_2 (0.6 IW: CPE ratio).Water requirement of wheat crop simulated by CROPWAT model was 237.8 and 266.9 mm for the whole crop season during 2014-15 and 2015-16 respectively. In initial stage minimum water requirement was simulated by model. The highest crop water requirement (130.7& 136.7 mm / decade) recorded in the late stage of growth which was 45.0 and 48.7% of total water requirement of wheat crop during the years 2014-15 and 2015-16. The phase wise reduction in Etc, yield and cumulative yield reduction was less in I_1 (critical stages) as compared to other treatments.

Keywords: cropwat model, yield reduction, leaf area index, grain yield, straw yield, water requirement.

Introduction
CROPWAT is a computer program for irrigation planning and management, developed by the Land and Water Development Division of FAO (FAO, 1992) [3]. Its basic functions include the calculation of reference evapotranspiration, crop water requirements, and crop scheme irrigation. Through a daily water balance, the user can simulate various water supply conditions and estimate yield reductions and irrigation and rainfall efficiencies. Typical applications of the water balance include the development of irrigation schedules for various crops and various irrigation methods, the evaluation of irrigation practices, as well as rainfed production and drought effects. There are two new versions of the CROPWAT: one is CROPWAT v 7.0 that contains a completely version in Pascal, developed with the assistance of the Agricultural College of Velp, Netherlands. It overcomes many of the shortcomings of the original 5.7 version. CROPWAT 7.0 is a DOS-application, but it runs without any problem in all MS-WINDOWS environments. Another one is CROPWAT for Windows that is written in Visual Basic and operates in the Windows environment. It has been developed with the assistance of the International Irrigation & Development Institute (IIDS) of the University of Southampton, UK. Both versions use the same FAO (1992) [3] Penman-Montieth method for calculating the reference crop evapotranspiration. These estimates are used in crop water requirements and irrigation scheduling calculations. Some of the interpolation methods used in CROPWAT for Windows are slightly different (up to 2%) to those used in CROPWAT 7.0.

Materials and Methods
Model input data
The CROPWAT model version 8.0 was calibrated for wheat crop for different irrigation regimes. Daily weather data (minimum temperature, maximum temperature, relative humidity, sunshine hours) have been given as input for computation of ETO. Similarly rainfall was also given as input for calculation of effective rainfall. The crop characteristic such as planting date, phase wise Kc values, stage duration, rooting depth were given. In soil file soil characteristics Total available soil moisture (mm/meter), rain infiltration rate (mm/day),

Determination of suitable irrigation schedule for optimum water use efficiency of wheat crop.

Krishna Deo, SR Mishra, AK Singh, AN Mishra, Ashish Singh and Sanjay Kumar

Abstract
A field experiments was conducted during *rabi* seasons of 2014-2015 and 2015-2016 at the Agromet Farm, N.D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) The treatment comprised of four levels of irrigation schedule *Viz*., I_1 (critical stages), I_2 (0.6 IW: CPE ratio), I_3 (0.8 IW: CPE ratio), and I_4 (1.0 IW: CPE ratio). The findings of present investigation indicated that the grain and straw yields as well as most of the growth and yield attributes of wheat were significantly influence due to different irrigation schedule. The results, further revealed that growth attributes such as plant height (cm), number of shoots m^{-2} and Leaf area index (LAI) were found significantly higher under I_1 (critical stages) treatment during both year 2014-15 and 2015-16. The total number of effective tillers m^{-2}, length of spike (cm), harvest index (%) and test weight (gm) were found higher under I_1 (critical stages) and I_4 (1.0 IW: CPE ratio) treatment during both years. The highest grain yield (52.3 and 52.2 q/ha) and straw yield (65.8 and 66.9 q/ha) recorded under I_1 (critical stages) treatment during the both years of 2014-15 and 2015-16. The lowest grain yield (51.2 and 51.9 q/ha) and straw yield (64.4 and 65.3 q/ha) was recorded under I_2 (0.6 IW: CPE ratio) during both years. The highest WUE (16.42 and 16.70 kg ha^{-1} mm^{-1}) was recorded under I2 (0.6 IW: CPE ratio) treatment and lowest (14.69 and 14.96 kg ha^{-1} mm^{-1}) under I_1 treatment.

Keywords: irrigation schedule, leaf area index, water use efficiency, grain yield, straw yield, harvest index.

Introduction
Wheat *(Triticum aestivum* L.*)* is one of the most important cereal crop in large number of countries in the world. It provides about 20% of total food calories for the human race. It is widely grown through the temperate zone and in some tropical and sub-tropical areas at higher elevation. The major wheat growing countries in the world are USSR, USA, China, India, Canada, Australia, France, Turkey and Pakistan. It ranks first (Anonymous, 2013) [2] in the world among the cereals both in respect of area (225.43 mha) and production (708.0 mt). Water is essential at every developmental phase starting from seed germination to plant maturation for harvesting the maximum potential yield of wheat. There is a positive correlation between grain yield and irrigation frequencies (Bajwa *et al.*, 1987) [3]. Availability of adequate amount of moisture at critical stages of plant growth not only optimizes the metabolic process in plant cell but also increases the effectiveness of the mineral nutrients applied to the crop (Bajwa *et al.*, 1993) [4]. Water deficit imposed after planting significantly reduces the plant growth and yield (Harold, 1986).Normal irrigations are essential for bumper crop production, but when there is scarcity of water, it becomes imperative to differentiate the critical growth stages of the crop where irrigation could be missed, without reducing the grain yield significantly (Timsina *et al.*, 1998) [16]. Irrigation missing at some critical growth stage sometime drastically reduces grain yield (Chauhan *et al.*, 2008) [7] due to lower test weight (Bajwa*et al.*, 1993) [4]. However, number of productive tillers per unit area remains unaffected (Rana, 1976) [12]. Similarly, over irrigation also sometimes tends to decrease grain yield instead of increasing yield (Kahlown and Azam, 2002) [8]. Among the various factors responsible for poor productivity of wheat, the irrigation scheduling is one of the major is play a vital role among them

ABSTRACT

An experiment was conducted during the two consecutive seasons of Kharif 2015 and Kharif 2016 in the silty loam soil at Agronomy Research Farm of N.D.U.A.T., Kumarganj, Faizabad, (UP). The experiment was conducted in Randomized Block Design which comprised of ten treatment combinations viz T_1 - Pendimethalin (PRE) fb Bispyribac - Na (POE) (1000 fb 25g ha^{-1}), T_2 - Oxadiargyl (PRE) fb Bispyribac - Na (POE) (100 fb 25 ha^{-1}), T_3 - Pendimethalin (PRE) fb Fenoxaprop (POE) (1000 fb 67 ha^{-1}), T_4 - Oxadiargyl (PRE) fb Fenoxaprop (POE) (100 fb 60 ha^{-1}), T_5 - Pendimethalin (PRE) fb 2, 4-D Na (POE) (1000 fb 60 ha^{-1}), T_6 - Butachlor (PRE) fb Bispyribac Na (POE) (1500 fb 25 ha^{-1}), T_7 - Butachlor (PRE) fb 2, 4 -D Na (POE) (1500 fb 60 ha^{-1}), T_8 - Butachlor (PRE) fb Fenoxaprop (POE) (1500 fb 67 ha^{-1}), T_9 - Weed free (25 and 45 DAS) and T_{10} - Weedy check (PRE and POE application at 3 DAS and 25 DAS). Rice variety 'NDR-359' was seeded in rows spacing 20 cm apart using seed drill. Results reveals that at 60 DAS, among the weed management practices, Pendimethalin (PRE) 1.0 kg ha^{-1} fb bispyribac-Na (POE) 0.025 kg ha^{-1} (4.25) was recorded significantly lower weed density which was at par with T_2 and T_6 while significant as compare to rest of the herbicide treatment. Significantly superior weed management under weed free plots were recorded as comparison to overall treatments with weedy check. Higher weed control efficiency was recorded under treatment with Pendimethalin (PRE) 1.0 kg ha^{-1} fb bispyribac-Na (POE) 0.025 kg ha^{-1} (62.46 %) followed by T_2 (61.22 %) and T_6 (59.89 %) as compare to rest of the herbicidal treatment while its highest value were recorded in weed free treatment. The significantly maximum grain yield was found in Pendimethalin (PRE) 1.0 kg ha^{-1} fb bispyribac - Na (POE) 0.025 kg ha^{-1} (3.83 q ha^{-1}) which was at par with T_2, T_5 and T_6 as compared to rest herbicidal treatment while treatment T_7 and T_3 recorded significantly higher value over T_4, T_8 and weedy check. Significantly highest grain yield was found in weed free plots. Consequently, the highest benefit : cost ratio were recorded under Pendimethalin (PRE) 1.0 kg ha^{-1} fb bispyribac - Na (POE) 0.025 kg ha^{-1} (Rs. 1.77 per Re. invested) followed by T_2 and T_6. Lowest benefit cost ratio were found in weed free and weedy check.

INTRODUCTION

Rice is the staple food crop of India. It is grown in an area of 43.95 million ha with total production of 104.32 million tonnes and with an average productivity of 2.40 t ha^{-1}. Uttar Pradesh ranks 2nd in total rice production. Weed infestation is the major constraints in direct seeded rice causing severe yield losses. Success adoption of direct seeded rice (DSR) depends largely on weed control especially with chemical methods as mechanical weed control is labour intensive and not cost effective. Various herbicides have been used for controlling weeds in DSR but efficiency of chemical methods based on single herbicide treatment may be non significant because of their narrow spectrum of weed control. Application of several herbicides in sequence can be more useful (Chauhan and Yadav 2013). Hence keeping above facts in view the present investigation was under taken.

METHODOLOGY

An experiment was conducted during the two seasons of *Kharif* 2015 and *Kharif* 2016 at Agronomy Research Farm of N.D.U.A.T., Kumarganj, Faizabad, (UP). The experiment was conducted in Randomized Block Design and replicated three times. The experiment comprised of ten treatment combinations viz T_1 - Pendimethalin (PRE) *fb* Bispyribac - Na (POE) (1000 *fb* 25g ha^{-1}), T_2 - Oxadiargyl (PRE) *fb* Bispyribac - Na (POE) (100 *fb* 25 ha^{-1}), T_3 - Pendimethalin (PRE) *fb* Fenoxaprop (POE) (1000 *fb* 67 ha^{-1}), T_4 -

ABSTRACT

The field experiment was conducted during winter season of 2015-16 at Agronomy Research Farm of N.D. University of Agriculture & Technology, Narendra Nagar (Kumarganj), Faizabad. The experiment consisted of treatment viz, T_1 (Control), T_2 (Inorganic source of nitrogen), T_3 (100% RDF + 25% N through FYM), T_4 (100% RDF + 25% N through Vermicompost), T_7 (75% RDF through inorganic sources (120N: 60P : 40K), T_8 (75% RDF through inorganic sources +25% N through FYM), T_9 (75% RDF through inorganic sources + 25%N through Vermicompost), T_{10} (75% RDF through inorganic sources + 25% N through FYM + Azotobactor) and T_{11} (75% RDF through inorganic sources 25% N through Vermicompost + Azotobactor) were conducted in Randomized Block Design with three replications. Results revealed that growth parameters such as plant height, number of shoots m^{-2}, total dry matter accumulation m^{-2} were significantly higher in 100% recommended dose of fertilizers and 25% N through Vermicompost + Azotobactor over other treatments. Yield attributes viz., spike length and number of grains spike $^{-1}$ were increased significantly with 100% recommended dose of fertilizers through inorganic source and 25% N through Vermicompost + Azotobactor which was at par with all treatments excepted T_1, T_7,T_8 . Grain and straw yields and nutrient (NPK) uptake were maximum with 100% recommended dose of fertilizers and 25% N through Vermicompost + Azotobactor. Application of 100% of recommended dose of nitrogen through inorganic source + 25 % N Vermicompost + Azotobactor - improved available N P and K content in soil as compared to other treatments. Protein content was maximum with T_6 (100% recommended dose of fertilizers and 25% N through Vermicompost + Azotobactor). Highest gross returns were obtained with 100% recommended dose of fertilizers + 25% N through Vermicompost followed by T_5.The highest B: C ratio (1.78) were calculated with T_6 followed by T_5 (1.73) and lowest T_1 (1.10).

INTRODUCTION

Wheat (*Triticum aestivum* L.) belongs to the family Poaceae is a staple food of the world. The important and economic consideration for increasing wheat productivity is the effective use of nitrogen fertilization. Nitrogen fertilization is the most important factor in front of wheat agronomist for achieving high yield targets. Previous research reviewed that number of tillers, spikes m^{-2}, plant height, spike length, number of spikelet's, grains spike^{-1}, grain yield and straw yield of wheat increased with increased nitrogen level (Sobhoel *et al.*, 2000). Sufficient supply of nitrogen at optimum planting time also resulted good quality and vigorous seed. The use of organic manure as a renewable source of plant nutrients is assuming importance. In this endeavor proper blend of organic and inorganic fertilizer is important not only for increasing yield but also for sustaining soil health (Weber *et al.* 2007 and Pullicinoa *et. al.* 2009).

The vermicomposting is bio oxidation and stabilization of organic material involving joint action of earthworm and micro organisms. Although, microbes are responsible for the biological degradation of the organic matter, earthworms are the important drivers of the process, conditioning the substrate and altering biological activity (Aira *et. al.* 2002). Farmyard manure by adding organic matter improves the physical condition of soil by increasing water holding capacity for maximum utilization of water. Application of FYM and inorganic N in integration improved the productivity and monetary returns of wheat and also maintained soil fertility (Sharma *et al.* 2007). Application of farmyard manure (FYM) to soil have been practiced for many centuries and its application to soil have increased crop yield, improved soil fertility, increased soil organic matter, increased microbiological activities and improved

ABSTRACT

The recurrence frequency of fog events on annual, decadal, seasonal and fortnightly basis of eastern Uttar Pradesh, Faizabad district were made from long period average data of 1986-2015. From 2012 onwards in December and January months the fog frequency increased exponentially. In terms of percentage of fog frequency during second fortnight (1986-2014), 37% frequency of occurrence of fog above the normal was recorded in November, 48 % in December and 44% in January and in month of February it was 68%.Total 33% fog occurrence was recorded in first decade (1986-1995) 38 % in 2nd decade (1996-2005) i.e. 5% increase as compared to first decade then after decreased to 29% in 3rd decade (2006-2015) hence indicated that fog occurrence was osolllating between 29% to 38%. December and January months were recorded higher days of fog occurrence in each decade. In the decade 1986-95, out of total, 32% fog days occurred in December, and 30% in January. While in 2nd decade (1996-2005) it was 29.5 and 42% in December and January respectively and in 3rd decade it was further increased in December to 36 % but decreased from 42% to 38 % in January. In Monthly variation December and January months were recorded higher days of fog occurrence in each decade.

Introduction

Possible impact of climate change on frequency and severity of weather extremes can have a significant impact on agriculture production, but their effect is often unclear, this may be due to interaction with other factors that affect yield and due to lack of precise definitions of relevant weather extremes (Vanoort, 2012). The Climate variability and weather extremes are principal sources of fluctuations of annual productivity of many crops in arid and semi-arid environments. Of the total annual crop losses in world agriculture, many are due to direct weather and climatic effects such as drought, flash floods, untimely rains, frost, hail, and storm. Temperature and precipitation are the major weather variables that determine the variability of crop yields (Bannayan and Sanjani, 2011). Under the impact of future scenario of climate change and global

Effect of nutrient management and moisture regime on growth and yield of wheat (*Triticum aestivum* L.)

Ajit Kumar, Anil Kumar Singh, Sanjay Kumar, Dinesh Kumar, Tarun Gopal, Deepak Pandey and Vinay Kumar Pandey

Abstract
The field experiment was conducted at Agronomy Research Farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) during *Rabi* season of 2014-15 and 2015-16. Comprised whitsixteen treatments combination formed Viz; four moisture regime, and four nutrient management which were allocated in split plot design with three replications. The four moisture regime I_1; 0.6 IW/CPE ratio I_2; 0.8 IW/CPE ratio I_3; 1.0 IW/CPE ratio and I_4; 1.2 IW/CPE ratio were as main plot and four nutrient management 100% RDF through inorganic fertilizers (120:60:40 kg NPK ha^{-1}). 75% NPK+ 25% N through FYM (90:45:30 kg NPK ha^{-1}). 50% NPK+ 50% N through FYM (60:30:20 kg NPK ha^{-1}) (d) 25% NPK+75% N through FYM (30:15:10 kg NPK ha^{-1}) were kept as sub plots. The growth attributes *viz*; number of shoots, plant height, dry matter accumulation and yield attributing characters *viz*, number of grains $spike^{-1}$, number of spike m^2, length of spike, test weight, grain and straw yield, harvest index, nutrients uptake by crop was significantly increased 75% RDF (90:45:30 kg NPK/ha +25% N through FYM along withI_4; 1.2 IW/CPE ratio moisture regimewhich was at par with 100% RDF(120:60:40 kg NPK/ha)along with I4; 1.2 IW/CPE ratio moisture regimeand significantly higher over rest of the treatment as well as economics of various treatments were recorded. Moisture regime of 1.0 IW/CPE ratio (5-6irrigations) was found suitable for achieving higher yield of wheat with 75% RDF (90:45:30 kg NPK/ha +25% N through FYM followed by 100% RDF (120:60:40 kg NPK/ha) was found suitable higher growth and yield of wheat crop. On the basis of results obtained, application of 75% RDF (90:45:30 kg NPK/ha +25% N through FYM, nutrient supply system and I4; 1.2 IW/CPE ratio moisture regimefound to be more suitable for higher yield of wheat variety Malviya 234.

Introduction
Wheat (Triticumaestivum L.) is a staple food of the world and falls under Poaceae family. It is primarily grown in temperate regions and also at higher altitude under tropical climatic areas in winter season. It is the single most important cereal crop that has been considered as integral component of the food security system of the several nationsWheat is the single, most important cereal crop that has been considered as integral component of the food security system of the several nations. It ranks first in the world among the cereals both in area with 225.43 mha and production with 708.0 mt. In India, total area under wheat is 29.90 mha with the production and productivity of 93.90 mt and 3.14 t ha-1 respectively (Anonymous, 2014).
The normal time for sowing of dwarf wheat in irrigated tracts starts in the beginning of November. Medium to long duration varieties taking 135-145 days to mature should be sown in the first fortnight of November while, short duration varieties (120-125 days) may be sown in the second fortnight of November.The productivity of wheat in eastern U.P. is very low (25 q ha-1) and it might be due to adoption of cereal-cereal (Rice-Wheat) cropping system, poor management in balanced fertilization, etc. Increasing level of production can be achieved by increasing level of fertilizer, but continuous use of chemical fertilizers alone may lead diminishable yield even with the recommended dose of fertilizer application. Besides chemical fertilizer alone may also lead to same detrimental effect on physical and chemical properties of soil and may not be so remunerable unless the fertility of soil is maintained at sustainable level by application of organic manures. Therefore to maintain fertility and productivity of soil at sustainable level for long duration, there is a need to adopt the concept of integrated nutrient management. Organic manures such as farmyard manure are to be considered and integral component and may help to recover soil health in cropping system (Ranwa and Singh, 1999) as they improve soil fertility and physical properties. Organic matters in soil improve physical

Effect of energy requirement on growth and yield at Rabi maize (*Zea mays* L.) on various moisture regimes

Purusharth Katiyar, AK Singh, SR Mishra, Rajan Chaudhari, RK Aryan, Nitish Kumar and Anil Nishad

Abstract
A field experiment was carried out at Agronomy Research Farm, Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj), Faizabad (U.P.) during Rabi season of 2016-17 to study the "Effect of energy requirement on growth and yield at Rabi maize (*Zea mays* L.) on various moisture regimes." The experiment comprised of nine treatment combinations and conducted in Split plot design and replicated four time. Experiment consisted of three crop growing environment viz. 60x 20 cm spacing, 60 x 25 cm and 60 x 30 cm spacing were kept in main plots with three moisture regimes Viz. 0.6 IW/CPE ratio, 0.9 IW/CPE ratio and 1.2 IW/CPE ratio were kept in sub plot. Result reveal that Crop growing Environment of 60x20 cm spacing (83,333 plants/ha) was found suitable for optimum growth and yield of Rabi maize. Among crop growing environment, sowing done at 60x20 cm spacing recorded higher days taken from sowing to maturity while among moisture regime 1.2 IW/CPE ratio recorded higher days taken from sowing to maturity. Moisture regimes of 1.2 IW/CPE ratio was found suitable for higher growth and yield of Rabi maize. Crop growing Environment of 60x20 cm spacing and Moisture regimes of 1.2 IW/CPE ratio recorded higher heat use efficiency from sowing to maturity of Rabi maize.

Keywords: Maize, dry matter GDD, HUE, yield

Introduction
Maize (*Zea mays* L.) is an ideal crop owing to its quick growing habit, high yielding ability, palatability and nutritious ness. It can be grown in any season and is one of the most important cereal crop of the world human and feed for animals. Maize is very efficient utilizer of solar energy and has immense potential for higher yield. Each climatic zone has its own characteristics and as such different hybrids, composites and local varieties maturing in 60 to 150 days are being grown (Jain *et al.*, 1981) [3]. It can be fed to cattle at any stage, as there is no problem of poisoning to cattle with HCN or oxalic acid in plant unlike sorghum and therefore it is called as Queen of cereals and King of fodder. The father of green Revolution Renowned Nobel Laureate Dr. Norman E. Borlaug, has mentioned maize as the crop of future. In future maize can play vital role in ensuring food security as well as nutritional security by use of quality protein maize for the country as well as world as a whole. In Maharashtra, maize is principally a rainy season crop but the climatic variability and eco-physiological limitations are the major constraints to achieve potential yield of maize in traditional rainfed *kharif* season in the state. Recent studies conclusively proved that maize is a potential winter season crop having three times higher yield potential than *kharif* crop (Desai and Deore, 1980; Nayak *et al.*, 1987) [2, 5]. Water and nutrient is the key factor to increase the productivity of this crop. In India, maize is grown in diverse environments-from the dry area of Chitradurga, Karnataka to the warm wet plateau of Chindwara, (M.P). Since maize is largely grown under rainfed conditions during the rainy season, the crop is sown with the onset of the monsoon. Sowing window of maize occurs during Ist fortnight of June to the Ist fortnight of July depending upon the onset of the monsoon. Maize yields during the winter season are higher than during the rainy season. During winter, maize enjoys a favorable environment of cool temperatures, clear sky and higher solar radiation interception with less nutrient losses; less infection of insect pests and thereby better yields (Joshi *et al.*, 2005) [4]. Winter maize crop which makes the best use of low temperature and sunshine hours has longer growth duration of about 150-170days than 100-120 days under *Kharif* crop. As such in winter it synthesizes more food material resulting in higher yields. Yield obtained in *Rabi* season is invariably higher (>6t/ha) than the *Kharif* season yield (2-2.5t/ha). In the world, maize occupies an area of 185.12 million

A field experiment was conducted during *kharif season* of 2017-18 on the topic entitled "Effect of growing environment on growth and development of rice (*Oryza sativa L.*) cultivars." in sandy loam soil of N.D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P.). The experiment consisted of nine treatment combinations comprised of three transplanting dates *viz.* July 5th, July 15th and July 25th and three varieties viz., NDR-97, NDR-3112 and BPT-5204. Results reveal that different phenophases of rice markedly varied with only dates of transplanting but also different weather variables which ultimately create the different crop growing environment to harvest the yield accordingly. Highest Growing Degree days (GDD) was recorded in growing environment of July 5th due to occurrence of long duration. Highest heliothermal and photothermal unit was recorded in 1st date of transplanting on July 5th at vegetative stage.

Introduction

Rice (*Oryza sativa* L.) is the paramount cereal crop after wheat belonging to the grass family, poaceae, extensively cultivated in most parts of the world and is the major staple food for more than half of the global population (FAO, 2013). Rice is a staple food of more than 50 per cent of the world's population (Anonymous, 2011) During 2013-14 in India, rice is cultivated in an area of 46 million ha with a production of 106.5 million tonnes and yield 2424 kg ha1(Agricultural statistics at a glance, 2014). However, productivity of rice in India is much lower than that of other rice producing countries. The impact of air temperature on rice growth would be location-specific because of the different sensitivity of different locations with regard to temperature. In tropical regions, the temperature increase due to the climate change is probably near or above the optimum temperature range for the physiological activities of rice [Baker *et al.*, 1992]. Such warming will thus reduce rice growth. Rice productivity is highly dependent upon

Agriculture is one of the most important sectors and plays a vital role in the development of the Indian Economy. A large part of the Indian agriculture depends on monsoon rains and agriculture production and essential commodity market shows fluctuation due to early/delayed arrival of monsoon. Any change in rainfall pattern impacts agriculture and hence the country's economy and food security. Climate change is one of the most important global environmental challenges with implications for food production. For India, the IPCC predicts 10-40 percent loss in crop production by the year 2080-2100. Increased heat stress associated with global climate change may, however, cause distress to dairy animals and possibly impact milk production. Dairy sector may lose 1.8 million tons of milk by 2020 due to climate stresses in different parts of the country.

Selection of village Banpurwa was done under jurisdiction of K.V.K, Bahraich (U.P) and then selected 60 farmers from the village comprised of 20 marginal farmers 20 small farmers and rest 20 rich farmers. Benchmark survey was made with respect to village profile, Individual farmer profile, Perception/ knowledge of farmers about climate change and its impact on agriculture/farmers assessment of weather parameters, Exposure and vulnerability of agricultural crops to climate change., Adverse effect on agriculture crop stages, Adaptation strategies/measure taken up by farmers; i. Crop adaptation strategies. ii. Soil and water conservation measures. iii. Adaptation strategy by means of crop insurance. iv. Farmers expectations to mitigate the ill effects of climate change and Individual farmer's perception on Agro met advisory services.

The farming household and the number of farmers are presented in table 1. It is evident from the survey that total Farming households in the village was 1602 in which marginal were 614; small 788 and rest 200 farmers were under rich category. Total population was recorded 6414, out of which male population were 3605 and female population were 2809. SC population in the village was recorded 1062 in which male population were 610 and female population were 452. ST population was totally nil in the village. Total irrigated area in the village was recorded 3492 ha. The number of households engaged in crop production was recorded 1223.

Farmers of 3 group's i.e. Marginal, Small and Rich farmers were categorized on the basis of Family size, Age group and Education as shown in table 2. It is quite evident from the data presented in table 2 that highest percentage of farmers of each group belonged to family size between 5-8 members, while above 8 family members were found in lowest percentage. An examination over data revealed that in both Small farmers and rich farmers the highest percent were of >60 years age old farmers. Highest 80% of marginal farmers were illiterate while lowest % of farmers (20%) were up to 10th passed. Highest % of Small and rich farmers were graduate in the selected village of study. Similar results have been reported by Nagaratna, *et al*. 2012.

Perception of farmers on changes in the precipitation is presented in table 3. Perusal of data presented in table 3 reveal that the No. of rainy day was more than normal during before the year 2000 while beyond 2000 its value showed less than normal while amount of rainy days during recent past was found medium. As per survey report of farming, onset of rainfall was found irregular during all the years. Rainfall was changed during crop growing period (July-Oct.) as per opinion given by selected farmers but change in the rainfall pattern have less variation during recent past as compared to high variation before the year 2000. Crop growing period reduced during the year 2000 and also in very recent past i.e. since last 5 years. Similar results have

The field experiment was conducted at Agronomy Research Farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) during *Rabi* season of 2014-15 and 2015-16. Sixteen treatments comprised of four levels of moisture regime (a) I1; 0.6 IW/CPE ratio (b) I2; 0.8 IW/CPE ratio (c) I3; 1.0 IW/CPE ratio and (c) I4; 1.2 IW/CPE ratio and four levels of fertilizers ((a) 100% RDF through inorganic fertilizers (120:60:40 kg NPK ha-1) (b) 75% NPK+ 25% N through FYM (90:45:30 kg NPK ha-1) (c) 50% NPK+ 50% N through FYM (60:30:20 kg NPK ha-1) (d) 25% NPK+75% N through FYM (30:15:10 kg NPK ha-1) were tested in a split plot design with three replications. The growth attributes *viz.*, number of shoots, plant height, dry matter accumulation and yield attributing characters *viz.*, number of grains spike^{-1}, number of spike m^{2}, length of spike, test weight, grain and straw yield, harvest index, nutrients uptake by crop was significantly increased 75% RDF (90:45:30 kg NPK/ha +25% N through FYM along with I4; 1.2 IW/CPE ratio moisture regime which was at par with 100% RDF(120:60:40 kg NPK/ha)along with I4; 1.2 IW/CPE ratio moisture regime and significantly higher over rest of the treatment as well as economics of various treatments were recorded. Moisture regime of 1.0 IW/CPE ratio (5-6irrigations) was found suitable for achieving higher yield of wheat with 75% RDF (90:45:30 kg NPK/ha +25% N through FYM followed by 100% RDF (120:60:40 kg NPK/ha) was found suitable higher growth and yield of wheat crop. On the basis of results obtained, application of 75% RDF (90:45:30 kg NPK/ha +25% N through FYM, nutrient supply system and I4; 1.2 IW/CPE ratio moisture regime found to be more suitable for higher yield of wheat variety Malviya 234.Wheat cultivar Malviya 234accrued the maximum net return with B:C ratio of 2.76 under 1.0 IW/CPE moisture regime (I3) with 100% RDF through inorganic fertilizers (120:60:40 kg NPK ha-1).

Introduction

Wheat (*Triticum aestivum* L.) is a staple food of the world and falls under Poaceae family. It is primarily grown in temperate regions and also at higher altitude under tropical climatic areas in winter season. It is the single most important cereal crop that has been considered as integral component of the food security system of the several nations Wheat is the single, most important cereal crop that has been considered as integral component of the

The analysis of climatic variability/weather trends (past and future) in eastern U.P.

Ajit Singh, AK Singh, UP Sahai, SP Singh and Smarpal Singh

Abstract
Underneath these trends is that of decadal scale variability in the Pacific basin at least induced by the Interdecadal Pacific Oscillation (IPO), which causes decadal changes in climate averages. On interannnual timescales El Ni˜no/Southern Oscillation (ENSO) causes much variability throughout many tropical and subtropical regions and some mid-latitude areas. During the course of the 21st century global-average surface temperatures are very likely to increase by 2 to 4.5 ^{o}C as greenhouse gas concentrations in the atmosphere increase. By concentrating on changes in climate means, the full impacts of climate change on biological and human systems are probably being seriously underestimated. Here, we briefly review the possible impacts of changes in climate variability and the frequency of extreme events on biological and food systems, with a focus on the developing world. We present new analysis that tentatively links increases in climate variability with increasing food insecurity in the future. Climatic variability & weather trend analysis were made for past and future based on the historical data results reveal that. Future rainfall scenario of eastern U.P. Showed much varying trends in monthly rainfall and was observed that in eastern U.P. rainfall will increase during south west monsoon period up to 2080 but the month of August will face sharp decline in rainfall. Projected trends in temperature and rainfall over eastern U.P. reveal that rainfall will not significantly affect the yield of rice crop as compared to temperature. The rate of increase of maximum temperature in eastern U.P. will be higher during 2050 to 2080 (2-4 ^{o}C) as compared to 2020-2050 (1-2 ^{o}C).

Keywords: Climatic Variability, Weather Trends, Past and Future, Eastern U.P

Introduction
Climate change has many elements, affecting biological and human systems in different ways. The considerable spatial heterogeneity of climate change impacts has been widely studied; global average temperature increases mask considerable differences in temperature rise between land and sea and between high latitudes and low; precipitation increases are very likely in high latitudes, while decreases are likely in most of the tropics and subtropical land regions (IPCC, 2007).

It is widely projected that as the planet warms, climate and weather variability will increase. Changes in the frequency and severity of extreme climate events and in the variability of weather patterns will have significant consequences for human and natural systems. Increasing frequencies of heat stress, drought and flooding events are projected for the rest of this century, and these are expected to have many adverse effects over and above the impacts due to changes in mean variables alone (IPCC, 2012). The cooler period of climate in the 19th century and rapid global warming during the late 20th century. Over the last millennium climate has varied by as much as 1 ^{o}C globally. Key questions of any future impacts of global warming are the effects on human society and economics, and in particular, on agriculture and forestry. History can provide very valuable lessons on effects of climatic variability on the human dimensions. The multidecadal cooling of the late 16th century in Europe resulted in one of the peak cooling excursions of the so called Little Ice Age epoch of Europe. This example of climate variability provides impacts of a mere 0.5 ^{o}C cooling in annual mean temperature on society. Increases were observed in surface global temperatures during the 20th century, and interannual climate variability has been observed in many regions of the globe. The 1982/83 and 1997/98 El Ni˜nos and the 1991 Mt. Pinatubo volcanic eruption. Caused considerable variability in the interannual climate of tropical regions in the late 20th century.

Climate variability and trends have significant environmental and socioeconomic impacts. Global challenges such as food security, biodiversity loss, water scarcity and human health are affected by reference evapotranspiration, temperature, solar radiation, and precipitation together, but nonlinear dynamics of these four climatic factors have not been assessed simultaneously at the national scale.

Performance of growth and yield on under variable moisture regimes at wheat (*Triticum aestivum* L.) cultivars

RK Aryan, AK Singh, SR Mishra, Rajan Chaudhari, Purusharth Katiyar, Nitish Kumar and Jeetendra Pandey

Abstract
A field experiment was carried out at Agrometeorology Research Farm, Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj), Faizabad (U.P.) during Rabi season 2017 to study the "Performance of growth and yield on under variable moisture regimes at wheat (*Triticum aestivum* L.) cultivars." The experiment consisted of 9 treatment combinations and tested in Randomized block design with three replications. Experiment consisted of three moisture regimes viz. 0.8 IW/CPE ratio, 1.0 IW/CPE ratio and 1.2 IW/CPE ratio and three wheat cultivars Viz. HUW-234, PBW-343 and NW-1012. Wheat cultivar PBW-343 was found suitable for optimum growth and yield of wheat. Highest Consumptive use (67.7 cm) was found in moisture regime of 1.2 IW/CPE ratio and highest water use efficiency (81kg ha^{-1} cm^{-1}) was computed under 0.8 IW/CPE ratio. Among wheat cultivars highest water use efficiency of 74 kg ha^{-1} cm^{-1} was computed in PBW-343 cultivar of wheat.

Keywords: wheat, water use efficiency, light interception yield

Introduction
Irrigated wheat is grown in rotation with rice on 2.6 Mha in the intensive rice–wheat system in north India (GOP, 2006) [6]. However, the sustainability of the rice–wheat system is threatened by declining soil fertility and ground water depletion (Humphreys *et al.*, 2010; Ladha *et al.*, 2007) [7, 8]. Nearly 60% of arable land worldwide is dedicated to cereal production. Fertilizers are constrain factor limiting crop productions such as wheat (Chamara *et al.*, 2003, Derksen *et al.*, 2002, Mohammaddoust *et al.*, 2006) [2, 4, 9]. The demand for wheat by 2020 has been projected to be between 105-109 million tonnes. Most of this increase in production will have to manage from increase productivity as the land area under wheat is not expected to expand. About one third of the developing world's wheat (*Triticum aestivum* L.) area is located in environments that are regarded as marginal for wheat production because of drought, heat and edaphic factors. Despite these limitations, the world's dry and difficult cropping environments are increasingly crucial to food security in the developing world. For example, it has been reported that 32% of the 99 million hectares of wheat grown in developing countries experiences varying levels of drought stress (Rajaram *et al.*, 1996) [11]. It is well known that water management is one of the major factors responsible for achieving better harvest in crop production. As more than 90% of the water is used for irrigation. Priority should be fixed for higher WUE in the field. Since water is a precious and scare input and hence it must be judiciously used. It plays a vital role for assured crop production. Without water either through irrigation or rain, plant growth and development will be adversely affected. Since it is essential for the maintenance to turgidity, absorption of nutrients and the metabolic process of the plants. Therefore, it becomes imperative to find out appropriate irrigation schedule in order to maintain the availability of soil moisture throughout the growing season for exploiting yield potential. Among the several recognized criteria of irrigation scheduling, the climatological approach is very scientific and has been identified widely among the scientists and research workers throughout the world. It is well known that evapo-transpiration by a full crop cover is closely associated with the evaporation from an open pan (Dastane, 1967) [3]. Parihar *et al.* (1974) [10] suggested a relatively more practical meteorological approach of IW/CPE, the ratio between a fixed amount of irrigation water (IW) and cumulative pan evaporation minus rains

Importance of under variable moisture regimes on wheat (*Triticum aestivum* L.) cultivars

RK Aryan, AK Singh, SR Mishra, Rajan Chaudhari, Purusharth Katiyar, Nitish Kumar and Anil Nishad

Abstract
A field experiment was carried out at Agrometeorology Research Farm, Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj), Faizabad (U.P.) during Rabi season 2017 to study the "Importance of under variable moisture regimes on wheat (*Triticum aestivum* L.) cultivars.". The experiment consisted of 9 treatment combinations and tested in Randomized block design with three replications. Experiment consisted of three moisture regimes viz. 0.8 IW/CPE ratio, 1.0 IW/CPE ratio and 1.2 IW/CPE ratio and three wheat cultivars Viz. HUW-234, PBW-343 and NW-1012. Result reveal that moisture regimes of 0.8 IW/CPE ratio was found suitable for higher growth of wheat crop.

Keywords: wheat, moisture regimes, dry matter, LAI

Introduction
Wheat (*Triticum aestivum* L.) is a staple food of the world and belongs to family Poaceae. It is most important staple food of about two billion people (36% of the World population). About 55% of the world population depends on wheat for intake of about 20% of food calories. Wheat is self-pollinated crop and it has been described as the 'King of cereals'. In India, it is grown in an area of 30.47 million hectare, production 95.85 million tone's with a productivity of 3.15 tonnes per hectare. Uttar Pradesh having first rank in respect of both area (9.95 million hectare) and production (30.24 million tone's) with a productivity of 3.10 tone's per hectare in 2015 (Anonymous 2015) [1]. Irrigation in wheat can be scheduled mainly by three approaches *viz.*, soil moisture depletion approach, climatic approach (IW/CPE ratio) and physiological growth stage. Among them the climatological approach is very scientific and useful which has been widely recognized among the scientists and research workers throughout the world. It is well known that evapo-transpiration by a full crop cover is closely associated with evaporation from an open pan (Dastane, 1967) [2]. (Parihar *et al.* 1974) [3] Suggested a relatively more practical meteorological approach of IW/CPE. The ratio between fixed amount of irrigation water (IW) and CPE are a basis for irrigation scheduling of crops. Temperature below or above normal alter plant functions and productivity. In late sown wheat, low temperature prevailing during germination substantially affects the germination and seedling emergence. Germination is a critical process, as temperature below 12 °C result in poor and uneven emergence (Timmermans *et al.*, 2007) [6]. Therefore, the rate of emergence and final emergence percentage are important factors in determining the crop potential in various temperature of wheat production. In late sowing season, temperature of soil can be expected to be below 10 °C, which affects the seed germination and stand establishment. However mid-season sowing of winter wheat for any locality is usually most favourable, whereas late sown wheat suffers more winter injury, which produces fewer tillers and may ripen in lower grain weight and number of grains per plant (Razzaq *et al.*, 1986) [4]. The genotypic response of wheat to planting dates varies for yield contributing characters due to different genetic potential. The decline becomes prominent in the cultivars requiring more days for heading under normal planting. Increase in temperature cause shortens of heading period (Tashiro & Wardlaw, 1999) [5]. Similarly, cultivars matured earlier when planted late, indicating the forced maturity due to high temperature.

Materials and Methods
An experiment was conducted during Rabi 2017 at the Agrometeorology Research Farm of N.D. University of Agriculture& Technology, Kumarganj, Faizabad (U.P.) on the topic entitled "Importance of under variable moisture regimes on wheat (*Triticum aestivum* L.) cultivars." The experimental site is located in the main campus of NDUA&T, Kumarganj

Effect of energy requirement on growth and yield at Rabi maize (*Zea mays* L.) on various moisture regimes

Purusharth Katiyar, AK Singh, SR Mishra, Rajan Chaudhari, RK Aryan, Nitish Kumar and Anil Nishad

Abstract
A field experiment was carried out at Agronomy Research Farm, Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj), Faizabad (U.P.) during Rabi season of 2016-17 to study the "Effect of energy requirement on growth and yield at Rabi maize (*Zea mays* L.) on various moisture regimes." The experiment comprised of nine treatment combinations and conducted in Split plot design and replicated four time. Experiment consisted of three crop growing environment viz. 60x 20 cm spacing, 60 x 25 cm and 60 x 30 cm spacing were kept in main plots with three moisture regimes Viz. 0.6 IW/CPE ratio, 0.9 IW/CPE ratio and 1.2 IW/CPE ratio were kept in sub plot. Result reveal that Crop growing Environment of 60x20 cm spacing (83,333 plants/ha) was found suitable for optimum growth and yield of Rabi maize. Among crop growing environment, sowing done at 60x20 cm spacing recorded higher days taken from sowing to maturity while among moisture regime 1.2 IW/CPE ratio recorded higher days taken from sowing to maturity. Moisture regimes of 1.2 IW/CPE ratio was found suitable for higher growth and yield of Rabi maize. Crop growing Environment of 60x20 cm spacing and Moisture regimes of 1.2 IW/CPE ratio recorded higher heat use efficiency from sowing to maturity of Rabi maize.

Keywords: Maize, dry matter GDD, HUE, yield

Introduction
Maize (*Zea mays* L.) is an ideal crop owing to its quick growing habit, high yielding ability, palatability and nutritious ness. It can be grown in any season and is one of the most important cereal crop of the world human and feed for animals. Maize is very efficient utilizer of solar energy and has immense potential for higher yield. Each climatic zone has its own characteristics and as such different hybrids, composites and local varieties maturing in 60 to 150 days are being grown (Jain *et al.*, 1981) [3]. It can be fed to cattle at any stage, as there is no problem of poisoning to cattle with HCN or oxalic acid in plant unlike sorghum and therefore it is called as Queen of cereals and King of fodder. The father of green Revolution Renowned Nobel Laureate Dr. Norman E. Borlaug, has mentioned maize as the crop of future. In future maize can play vital role in ensuring food security as well as nutritional security by use of quality protein maize for the country as well as world as a whole. In Maharashtra, maize is principally a rainy season crop but the climatic variability and eco-physiological limitations are the major constraints to achieve potential yield of maize in traditional rainfed *kharif* season in the state. Recent studies conclusively proved that maize is a potential winter season crop having three times higher yield potential than *kharif* crop (Desai and Deore, 1980; Nayak *et al.*, 1987) [2, 5]. Water and nutrient is the key factor to increase the productivity of this crop. In India, maize is grown in diverse environments-from the dry area of Chitradurga, Karnataka to the warm wet plateau of Chindwara, (M.P). Since maize is largely grown under rainfed conditions during the rainy season, the crop is sown with the onset of the monsoon. Sowing window of maize occurs during Ist fortnight of June to the Ist fortnight of July depending upon the onset of the monsoon. Maize yields during the winter season are higher than during the rainy season. During winter, maize enjoys a favorable environment of cool temperatures, clear sky and higher solar radiation interception with less nutrient losses; less infection of insect pests and thereby better yields (Joshi *et al.*, 2005) [4]. Winter maize crop which makes the best use of low temperature and sunshine hours has longer growth duration of about 150-170days than 100-120 days under *Kharif* crop. As such in winter it synthesizes more food material resulting in higher yields. Yield obtained in *Rabi* season is invariably higher (>6t/ha) than the *Kharif* season yield (2-2.5t/ha). In the world, maize occupies an area of 185.12 million

Keywords: maize, phenophases, LAI, yield attribute

Introduction

Maize (*Zea mays* L.) belongs to family poaceae is one of the most important cereal crop in the world after wheat and rice. The importance of maize lies in its wide industrial applications besides serving as human food and animal feed. Maize is called 'queen of cereal' as it grown throughout year due to its photo-thermo-insensitive character and highest genetic yield among the cereals. Being a C_4 plant, it is very efficient in converting solar energy in to dry matter. Over 85% of maize produced in the country is consumed as human food. Green cobs are roasted and consumed by people with great interest. Maize seed contains 10% protein, 4% oil and 2-3% crude fiber. Several food dishes including chapaties are prepared out of maize flours and grains. Green maize plants are used as succulent fodder. Popping the corn is a method of starch cookery. Maize is a raw material for a number of products viz., starch, glucose, dextrose, sorbitol, dextrine, high fructose syrup, maltodextrine, germ oil, germ meal, fiber rand gluten products which have application in industries such as alcohol, textile, paper, pharmaceuticals, organic chemicals, cosmetics and edible oil. Maize has got very high yield potentiality and wide adaptability under various agro climatic conditions than any other cereal crops (Singh, 2013) [6]. The cultivation of winter maize was started in 1983-84 with the introduction of cold resistant varieties (Khehra and Dhillon 1984) [1]. The main idea was to give impetus to maize production because winter maize had high yield potential due to low incidence of insect-pest and diseases, lodging tolerance as compared to kharif season crop (Lal *et al* 2000) [3]. However, the practice of growing winter maize also could not catch up with the farmers due to its variable response to suboptimal temperatures, chilly winds and frequent incidences of frost in early period of growth in different areas of Punjab. Therefore, the Punjab Agricultural 2 University has also recommended maize sowing in the month of August. August sown maize has significantly lower maize borer attack, higher monetary returns (Srinivasulu *et al* 2008, Lal 1973) [7, 2], higher values of grain yield, stover yield, gross returns, net returns, benefit: cost ratio and per day gross returns as compared to sown in June and July (Panchanathan *et al* 1992) [4]. Maize responds relatively better to management factors especially irrigation and nitrogen (Prasad *et al* 1987) [5]. Assured irrigation is an important

Effect of energy requirement on growth and development of mustard [*Brassica juncea* (L.)] cultivars at different phenological stages

Amrendra Yadav, AK Singh, Rajan Chaudhari, SR Mishra and Ramanand Patel

Abstract
A field experiment was conducted during *Rabi season* of 2014 on the topic entitled "Effect of energy requirement on growth and development of mustard [*Brassica juncea* (L.)] cultivars at different Phenological stages" in sandy loam soil of N.D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P.). The experimental comprised of three planting geometry *viz.*, 40×15cm, 40×20cm, 40×25cm and three varieties *viz.*, Varuna, Vardan and NDR-8501. Highest Thermal use efficiency was recorded when sowing was done on 40×15cm planting geometry, followed by sowing done on 40×20cm. NDR-8501 variety was found more conducive for growth development, grain yield and thermal use efficiency. Thermal unit (1659.4^{0}days), Photo thermal index (129.64), from sowing to maturity produced the high yield of Indian mustard.

Keywords: GDD, TUE, APAR, RUE, PTI

Introduction
Indian mustard (*Brassica juncea* L.) is an important oilseed crop belong to family cruciferae. The oilseed crop play an important role in agriculture economy of India. Our country is the largest oil economy in the world after the U.S., China and Brazil in term of vegetable oil. India occupies the second position in area after China and third position in production in the world after China and Canada. In India, during year 2012-2013, the area of Rapeseed-mustard was 67.17 lakh ha. With the production of 72.62 lakh mt. and productivity of 10.81 quintal/ha. In U.P during the year 2013-14 the area of rapeseed-mustard was 6.5 lakh ha. With the production of 7.8 lakh mt. and productivity of 12.08 quintal/ha (Anonymous, 2013-14) [1]. An option of suitable crop management practices are important factors for improving crop productivity. Sowing time has profound effect on growth and yield of mustard (Pawar *et al.*, 1976) [8]. Sowing dates and crop geometry are the two foremost non-monetary inputs of production can be manipulated to increase the crop productivity. Since information on sowing dates and crop geometry of Indian mustard. Climate change has increased the intensity of heat stress and heat stress due to increased temperature is an agricultural problem in many areas in the world as well as in India (Beck *et al.*, 2007) [2]. Transitory or constantly high temperatures cause an array of morphological, physiological and biochemical changes in plants (Serraj *et al.*, 1999, Moradshahi *et al.*, 2004) [9, 7].

Materials and Methods
The present investigation entitled "Effect of energy requirement on growth and development of mustard [*Brassica juncea* (L.)] cultivars at different Phenological stages" was conducted at Instructional Farm of Narendra Deva University of Agriculture and Technology Kumarganj, Faizabad (U.P.) during *Rabi* season of 2014. The farm is located 42 Km away from Faizabad city on Faizabad- Raebareily road at 26°47 N latitude and 82°12 E longitude and about 113 meters above the mean sea level. The experiment was conducted in Randomized Block Design (RBD). The different growth parameters studied were measured as Heat unit/ Thermal unit (GDD), Thermal use efficiency (g/m^{-2}/^{0}days), APAR (MJ/m^2), Radiation use efficiency (g/MJ), Photo thermal Index.

Results
Heat unit/ Thermal unit (GDD) of Indian mustard at different Phenophases as affected by planting geometry and varieties have been presented in Table-1. The maximum heat Unit

Effect of heat use efficiency and thermal unit at different phenophases of rice (*Oryza sativa* L.) cultivars

Anil Nishad, AN Mishra, SR Mishra, AK Singh, Rajan Chaudhari, Nitish Kumar and RK Aryan

Abstract
A field experiment was conducted during kharif season of 2017 on the topic entitled "Effect of heat use efficiency and thermal unit at different phenophases of rice (*Oryza sativa* L.) cultivars." in sandy loam soil of N.D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P.). The experiment consisted of nine treatment combinations comprised of three transplanting dates viz., July 5th, July 15th and July 25th and three varieties viz., NDR-97, NDR-3112 and BPT-5204. Results reveal that Highest Heat use efficiency (HUE) was recorded in growing environment of July 25th transplanting at all the stage followed by July 15th and July 5th transplanting while among the variety NDR-3112 recoded highest HUE followed by BPT-5204and NDR-97.

Keywords: Phenophases, HUE, thermal units

Introduction

Rice (*Oryza sativa* L.) is one of the important foods for most people living in India. It is being grown under diverse agro-climatic condition at wide range of latitudes. It is essential to human diet in India as it is a richest source of carbohydrates and adds the proteins component in human diet too. Generally 6.8% protein, 78.2% carbohydrates, 0.5% fat and 0.6% mineral matters are found in rice hence it is primarily used as a staple food crop. Rice production is influenced by a set of meteorological variables such as temperature, rainfall etc Ji, B. *et al.* (2007) [4]. The climate extremities, particularly high temperatures affect the plant growth and reduce the rice yield significantly Satake, T. and Yoshida, S. (1978) [7]. The crop growth response is influenced largely by the microclimate environment in the crop. Microclimate in the crop varies from top of the canopy to the soil surface and affects crop development and yield. Various environmental factors influencing crop growth are interception of photosynthetically active radiation, air and leaf temperatures, relative humidity, prevailing wind speed, CO2 concentration and soil moisture availability. Temperature and light play a key role in influencing the crop production. Thermal time is an independent variable to describe plant development Dwyer, L.M. and Stewart, D.W. (1986) [3]. It can be used as a tool for characterizing thermal responses in different crops. Knowledge of accumulated GDD can provide an estimate of harvest date as well as crop development stage Ketring, D.L. and Wheless, T.G. (1989) [5]. Heat use efficiency (HUE), i.e., efficiency of utilization of heat in terms of dry matter accumulation, depends on crop type, genetic factors and sowing time and has great practical application Rao *et al.* (1999) [6]. Initiation as well as duration of crop phenophases is an essential component of weather based dynamic crop growth and yield simulation models. Crop phenology can be used to specify the most appropriate date and time of specific development process. The duration of each phenophase determines the accumulation and partitioning of dry matter in different organs Dalton, L.G. (1967) [2]. Wang, J.Y. (1960) [8] reported that the duration of a particular stage of growth was directly related to temperature and this duration of particular species could be predicted using the sum of daily air temperature. Temperature is an important environ- mental factor influencing the growth and development of crop plants. It influences the crop phenology and yield of crop Bishnoi *et al.* (1995) [1]. Plants have a definite temperature requirement to attain phenological stages. Hence, it becomes imperative to have knowledge of the exact duration of phenological stages in a particular crop-growing environment and their impact on yield of crop. In the present study, an attempt is made to predict the growth and yield of rice (*Oryza sativa* L.) with agroclimatic indices viz. growing degree days (GDD), heliothermal units (HTU), photothermal

Studies on production and potential yield of wheat in eastern plain zones of UP

Vivesh Singh, SR Mishra, AK Singh, Rajan Chaudhari, Nitish Kumar and AN Mishra

Abstract
The experimental site is located at the main campus of university on the left side of Faizabad-Raibareilly road at a distance of 43 km away from Faizabad district headquarter. The local of experimental site lies between a latitude of 24^{0}47' and 26^{0}56' N and longitude of 82^{0}12' and 83^{0}98' E and an altitude of 113 m mean sea level, in the genetic alluvium of eastern Uttar Pradesh. Comparisons were made between simulated data of various parameters viz., yield, total dry matter, LAI, soil moisture, test weight, harvest index, grain weight and their corresponding observed data through regression analysis. Measures of accuracy were worked out with coefficient of determination (R^2).The crop yield data for the respective districts as obtained from the reports of The Directorate of Agriculture, Government of U.P. were considered as actual yield for the respective district which was nothing but the average of the district yield data collected from farmers' fields in the district concerned.

Keywords: wheat, LAI, PI, yield component

Introduction
Wheat (*Triticum aestivum* L.) is one of the most important staple food crop cultivated in at least 43 countries and provides 20% of food calories to the mankind, covering 223.6 million hectares area and producing 690.0 million tones with an average productivity of 3.08 t/ha (Anon., 2010). The major wheat growing countries are USSR, USA, China, India, Canada, Australia, France, Turkey and Pakistan. In India, wheat is next to paddy in area and production and grown over an area of 27.75 million hectares with an annual production of 80.68 million tones. India rank second after China in wheat growing countries. It is considered to be the backbone of the food security in India. Wheat is cultivated in almost all the states of India, but its extensive cultivation is confined to Uttar Pradesh, Punjab, Haryana, Rajasthan, Madhya Pradesh and Gujarat. In semiarid and arid regions, there is increasing competition for water resources between agricultural irrigation and other ecological water uses due to a growing population (Molden, 1997) [15]. Efficient management of water resources in agriculture is needed to balance water supply and demand (Ines *et al.*, 2002) [10]. In the last 20 yr, irrigation planning methods have switched from the allocation approach, e.g., based on socio-political considerations, to quantitative management (Raman *et al.*, 1992) [16]. The development of mathematical models is a fundamental step to guide quantitative irrigation. Th e accurate estimation of temporal and spatial variations in soil moisture, evaporation, and transpiration is crucial to determine the availability of water resources (Aggarwal, 1995; Addiscott *et al.*, 1995) [3, 2] and sustainable management of limited water resources in arid and semiarid regions (e.g., Garatuza-Payan *et al.*, 1998) [8]. Simulation models of crop physiological growth are widely accepted tools for field study of efficient and sustainable water use in agricultural production in various agro-ecological zones. Such models can aid in understanding the interactions between crops and environments (Kropff and Goudriaan, 1994; Yin *et al.*, 2004) [13, 17] and provide optimal agricultural management strategies under uncertain weather conditions and climatic change (Meinke *et al.*, 2001; Booltink *et al.*, 2001; Kersebaum í 2002) [14, 6, 12]. Several crop physiological growth models (e.g., Simple and Universal Crop Growth Simulator [SUCROS] and ORYZA [Goudriaan and van Laar, 1994] [9]; World Food Studies [WOFOST; Boogaard *et al.*, 1998]; Decision Support System for Agrotechnology Transfer [DSSAT; Jones *et al.*, 2003] [11] have been developed from photosynthesis modeling based on the complex biochemical approach (Farquhar *et al.*, 1980) [7], the constant light use efficiency

Simulation of wheat (*Triticum aestivum* L.) yield using WOFOST model under different management levels

Vivesh Singh, SR Mishra, AK Singh, Rajan Chaudhari, Nitish Kumar and AN Mishra

Abstract
A field experiment was conducted at Agrometeorology Research Farm, Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj), Faizabad (U.P.) during Rabi season 2012 and 2013 to study the "Simulation of wheat (*Triticum aestivum* L.) Yield using WOFOST model under different management levels". The experiment consisted of 12 treatment combinations in tested Split plot design with three replications. Experiment consisted of three irrigations at different stage i.e. First Irrigations (CRI+ Tillering+ Ear Head Emergence +Milking, Second irrigation (CRI+ Ear Head Emergence + Milking) and Third irrigation (CRI+ Milking) and two date of sowing i.e. first is normal sowing (15 November) and second is delayed sowing (15 December) and two fertilizer doses higher dose (150:75:75 NPK kg ha^{-1}) and optimum dose (120:60:60 NPK kg ha^{-1}). Sensitivity of WOFOST model simulated grain yield to incremental units of maximum air temperature showed a gradual decrease in yield while, the down scaled maximum temperature increased the yield. The wheat yield increased due to decreased temperature ranged 5.7 to 25.4. While the reduction of yield due to increase of temperature from -8.8 to 26.3.Every 1^0C decrease in the minimum temperature increased the grain yield of wheat was 5.6, 12.1, 19.4, 23.9 and 26.8 respectively while increase in temperature from 1^0C to 5^0C wheat yield decrease from -11.0 to 37.9 percent.

Keywords: Wheat, WOFOST model, irrigation levels, CO_2 levels

Introduction

In crop growth modeling schemes, the various components of the water balance in an agro ecological system are the most important physical and physiological factors for calculations (Aggarwal, 1995; Addiscott *et al.*, 1995) [2, 1]. Spatial and temporal variation of soil moisture is one of the main causes of crop production variation (Shepherd *et al.*, 2002; Anwar *et al.*, 2003; Patil and Sheelavantar, 2004) [9]. Meanwhile, actual evaporation and transpiration, which determine the soil moisture profile, are the main processes for water loss in a soil–plant system (Burman and Pochop, 1994; Monteith and Unsworth, 1990) [3, 7]. Crops can only absorb the soil moisture present within reach of their roots. These processes could be represented in hydrologic models. Therefore, the coupling of hydrologic and crop growth models connects hydrology and agronomy quantitatively and provides a bridge across the boundaries of the two subjects. In the last several years, numerous studies have been conducted to understand the complex interactions between ecological systems and the hydrologic cycle, resulting in the development of ecohydrologic models and soil–plant–atmosphere models (Smettem, 2008) [10]. Simulation modeling can be used to understand the relationships among crop production, groundwater recharge, soil evaporation, and crop transpiration (Engel and Priesack, 1993) [5]; used a numerical model to evaluate groundwater recharge in an irrigated cropland. By coupling hydrologic and crop growth models, (Eitzinger *et al.* 2004) [4] studied soil water movement during crop growth stages and concluded that the coupled modeling approach was better than a single-model method. A few studies have been conducted to investigate the effects of the soil moisture distribution along a vertical soil profile during crop transpiration (e.g., Varado *et al.*, 2006) [11]. The model coupling studies have generally focused on the effect of crop growth on soil moisture, and much less attention has been paid to improving crop growth models by properly modelling the root growth algorithm and root water uptake. In this study, we developed a modeling approach to simultaneously estimate crop production, soil moisture dynamics, evaporation, and transpiration by coupling HYDRUS with WOFOST. The soil moisture dynamic movements are simulated through the Richards equation (in the HYDRUS model), while root water uptake and transpiration are calculated according to the

Field experiment was conducted at Agronomy Research Farm, Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj), Faizabad (U.P.) during Rabi 2016-2017 on silty loam soils to study the "Consumptive use, Water use efficiency and Economics of Rabi Maize as Influenced by Planting geometry and Moisture regimes". The experiment was laid out in split plot design with four planting geometriesviz., 60× 10 cm, 60 × 15 cm, 60 × 20 cm, 60 × 25 cm and four moisture regimes viz., 0.6 IW/CPE ratio, 0.9 IW/CPE ratio, 1.2 IW/CPE ratio, 0.9 IW/CPE ratio up to silking and 1.2 IW/CPE ratio for rest of the crop season which were replicated thrice. Results showed that Consumptive use (cm) was more in 60 x 10 cm spacing and 1.2 IW/CPE ratio. Maximum WUE was recorded in 60 × 25 cm spacing and 1.2 IW/CPE ratio. The highest gross return, net return and benefit-cost ratio were recorded with60 × 25 cm planting geometry and 1.2 IW/CPE ratio.

Introduction

Maize (*Zea mays* L.) belongs to family poaceae is one of the most important cereal crop in the world after wheat and rice. Maize is called 'queen of cereal' as it is grown throughout the year due to its photo-thermo-insensitive character and highest genetic yield among the cereals. Being a C_4 plant, it is very efficient in converting solar energy in to dry matter. Importance of maize lies in its wide industrial applications besides serving as human food and animal feed. In the world, maize occupies an area of 185.12 million hectares with a production of 872.06 million tonnes and with a productivity of 4.9 t ha^{-1}. In India, maize is cultivated in an area of 8.49 million hectares, with a production of 21.28 million tonnes and with a productivity of 2.5 tha^{-1}.*Rabi* maize is grown in an area of 1.2 million hectares with the production of 5.08 million tonnes, with an average productivity of 4.00 t/ha.

It is traditionally a rainy season crop in India and is extensively grown as an important *kharif* crop under rainfed or irrigated condition, but *Kharif* crop suffers due to vagaries of monsoon, excessive rainfall leading to water stagnation, poor drainage, erratic and insufficient rainfall leading to moisture stress condition, severe infestation of

ABSTRACT

A field experiment was conducted during *rabi* 2016-2017 on silty loam soils at Agronomy Research Farm, Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj), Faizabad (U.P.) to study the "Agro-physiological attributes of maize as influenced by Planting geometry and Moisture regimes". The experiment was laid out in split plot design with four planting geometries *viz*., 60× 10 cm, 60 × 15 cm, 60 × 20 cm, 60 × 25 cm and four moisture regimes *viz*., 0.6 IW/CPE ratio, 0.9 IW/CPE ratio, 1.2 IW/CPE ratio, 0.9 IW/CPE ratio up to silking and 1.2 IW/CPE ratio for rest of the crop season which were replicated thrice. Results showed that higher plant height (cm) and leaf area index (LAI) at harvest was recorded with 60 × 10 cm planting geometry and 1.2 IW/CPE ratio which was statistically at par with 60 × 15 cm and 0.9 IW/CPE ratio up to silking and 1.2 IW/CPE ratio for the rest of the crops season. Dry matter accumulation (g m^{-2}), stem girth (cm) at harvest was higher in 60 × 25 cm and 1.2 IW/CPE ratio which was at par with 60 × 20 cm and 0.9 IW/CPE ratio up to silking and 1.2 IW/CPE ratio for the rest of the crop season. Number of days taken for 75% tasselling, silking and maturity was lower with 60 × 25 cm and 1.2 IW/CPE ratio while higher with 60 × 10 cm and 0.6 IW/CPE ratio. Interactive effect of planting geometry and moisture regimes on Agro-physiological attributes under study were found to be non-significant.

Introduction

Maize (*Zea mays* L.) belongs to family poaceae is one of the most important cereal crop in the world after wheat and rice. Maize is called 'queen of cereal' as it is grown throughout the year due to its photo-thermo-insensitive character and highest genetic yield among the cereals. Being a C_4 plant, it is very efficient in converting solar energy in to dry matter. Importance of maize lies in its wide industrial applications besides serving as human food and animal feed. In the world, maize occupies an area of 185.12 million hectares with a production of 872.06 million tonnes and with a productivity of 4.9 t ha^{-1}.

In India, maize is cultivated in an area of 8.49 million hectares, with a production of 21.28 million tonnes and with a productivity of 2.5 tha^{-1}. *Rabi* maize is grown in an area of 1.2 million hectares with the production of 5.08 million tonnes, with an average productivity of 4.00 t/ha.

Water productivity of *rabi* maize (*Zea mays* L.) as influenced by planting geometry and moisture regimes

KKK Reddy, AK Singh and RS Singh

Abstract
A field experiment with maize was conducted during *rabi* 2016-2017 on silty loam soils at Agronomy Research Farm, Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.). The experimental design was split plot design with three replicates. The objective of this study was to determine the effect four planting geometry *viz.*, 60 × 10 cm, 60 × 15 cm, 60 × 20 cm, 60 × 25 cm and four moisture regimes *viz.*, 0.6 IW/CPE ratio, 0.9 IW/CPE ratio, 1.2 IW/CPE ratio, 0.9 IW/CPE ratio up to silking and 1.2 IW/CPE ratio for rest of the crop season on water productivity of *rabi* maize. Among the planting geometry, highest irrigation water productivity (1.01 kg/m^3), input water productivity (0.98 kg/m^3) and real water productivity (1.29 kg/m^3) was recorded in 60 × 25 cm, while the lowest irrigation water productivity (0.88 kg/m^3), input water productivity (0.85 kg/m^3) and real water productivity (1.00 kg/m^3) was recorded in 60 × 10 cm. With respect to different moisture regimes tried highest irrigation water productivity (1.36 kg/m^3), input water productivity (1.30 kg/m^3) and real water productivity (1.40 kg/m^3) was recorded in 0.6 IW/CPE ratio, while the lowest irrigation water productivity (0.83 kg/m^3), input water productivity (0.81 kg/m^3) and real water productivity (1.01 kg/m^3) was recorded in 1.2 IW/CPE ratio.

Keywords: Water productivity, *rabi* maize, planting geometry, IW/CPE ratio, moisture regimes

Introduction
Maize (*Zea mays* L.) is the third most important grain crop in India after rice and wheat with respect to area and productivity. Globally maize is cultivated in an area of 177 million hectares with a production and productivity of 989 and 5.5 metric t ha^{-1}, respectively (Commodity profile-maize, 2015) [1]. In India it is grown in an area of 9.43 million hectares with production of 24.35 Mt and 2562 kg ha^{-1} productivity (CMIE, 2016) [5]. It has wide ecological adaptability and is grown in extreme semi-arid to sub-humid and humid regions as a staple crop for human beings, feed for animals and as a basic raw material for production of starch, oil, protein, alcoholic beverages, food sweeteners and more recently bio-fuel (Dass *et al.*, 2008) [2]. The average grain yield of maize is not only substantially lower compared with other important maize growing countries but also less than the production potential of existing genotypes. Traditionally maize is a rainy/*kharif* season crop in India and is extensively grown under rainfed conditions, but *kharif* crop suffers due to vagaries of monsoon, excessive rainfall leading to water stagnation, poor drainage, erratic and insufficient rainfall leading to moisture stress condition, severe infestation of pests and diseases, fertilizer losses, greater weed menace and high temperature throughout the growth period which tend to reduce grain yield. On the contrary, the risk of damage to the crop from excessive rainfall, water stagnation, inadequate soil moisture, pest and disease infestation during winter/*rabi* season is less. The average grain yield of maize is not only substantially lower compared with other important maize growing countries but also less than the production potential of existing genotypes. Low yield of maize is due to many constraints but among them, cultivation of local genotypes, imbalanced use of fertilizers, traditional sowing methods, improper water management, lack of optimal crop stand and optimum planting geometry are the factors of prime importance. Planting geometry and water management play an important role in enhancing the crop productivity. Planting geometry *i.e.* plant population per unit area have immense role since it is a non tillering crop. Sub optimal plant stand *i.e.* wider spacing leads to poor yield per unit area. While higher plant populations have greater competition for growth resources and leads to poor yield. In order to produce higher yields of maize, optimum soil moisture should be maintained as it is susceptible to both water logging and water deficit. Among the different approaches for scheduling, the climatological approach based on IW/CPE ratio (IW - irrigation water, CPE - cumulative pan evaporation) has been found most appropriate as it integrates all weather

Research Paper

Bio-efficacy of pre-and post-emergence herbicides for weed management in Japanese mint (*Mentha arvensis*)

A.K. SINGH[1], JAIDEV SHARMA[2], A.N. MISHRA[3] AND R.P. SINGH[4]

Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya, Uttar Pradesh 224 229

Received : March 2017; Revised accepted : May 2019

ABSTRACT

A field experiment was conducted during the summer season of 2014 and 2015 at Kumarganj Faizabad, Uttar Pradesh, to evaluate the effect of different herbicides on growth and yield of Japanese mint (*Mentha arvensis* L.) and associated weeds. The experiment was conducted in a randomized block design with 3 replications. There were 10 treatments, comprising pendimethalin 1,000 g/ha, oxyfluorfen 200 g/ha, oxyfluorfen 250 g/ha, pendimethalin 1,000 g followed by (fb) clodinafop 60 g/ha, pendimethalin 1,000 g fb imazethapyr 50 g/ha, pendimethalin 1,000 g fb clodinafop 60 g fb imazethapyr 50 g/ha, metribuzin 490 g/ha, metribuzin 700 g/ha, weed-free, weedy check. The soil was silt loam in texture with low in organic carbon, nitrogen, phosphorus and medium in potash. The Japanese mint variety 'Kashi' was used @ 400 kg/ha in rows, 45 cm apart. Application of pre-emergence (PE) pendimethalin 1,000 g/ha and post-emergence (PoE) of clodinafop 60 g/ha followed by imazethapyr 50 g/ha resulted in the highest weed-control efficiency (83.69%) at harvesting stage. Post-emergence application of imazethapyr 50 g/ha resulted in 80–90% control of broad-leaf weeds, but it produced toxic effect on the crop. Among the weed-control treatments, pendimethalin 1,000 g/ha as a PE fb PoE of clodinafop 60 g/ha, exhibited higher benefit: cost ratio 2.60 over the other treatments, which proved to be more remunerative and economical to the farmers.

Key words: Bioefficacy, Herbicides, Japanese mint, Post-emergence, Pre-emergence

Japanese mint is grown for medicinal and aromatic purposes. It is a long-lasting, quick-growing, hairy leaved herb that can even attain a height of 1.5 m if favourable condition are provided. The oil of this plant is extremely useful in various industries, viz. food industry, pharmaceutical industry and also in a perfumery and flavouring industries. Japanese mint oil is often required by the medicine industry and, it is used in balm, cough drops, inhalers, toothpaste, mouthwash etc. With the steam-distillation process, mint oil is extracted from the fresh plant foliage. Major growing countries of mint are India, China, and Brazil. In India, the major mint-producing states are Uttrakhand, Punjab, Haryana, Bihar and Uttar Pradesh etc. India contributes about 73% of total mint oil production of the world and rest by China and Brazil.

Yield per unit area as well as oil content in herb of Japanese mint are much lower in India as compared to other countries. One of the major factor responsible for low yield is improper control of weeds. The crop is infested with a number of weeds, viz. *Cyperus rotundus, Cynodon dactylon, Chenopodium album, Solanum nigrum, Euphorbia hirta, Anagallis arvensis, Echinochloa colonum, Eleusine indica* etc. These weeds caused 78 and 81% losses in first and second harvest of Japanese mint oil yield (Singh *et al.*, 1993; Kumar *et al.*, 2011). The crop requires frequent irrigations for quick sprouting and better growth which encourage the growth of weeds. The crop is planted in the end of January or beginning of February and remain in the field till September and provide 2 cuttings. Thus, the crop is affected with weeds of both winter and summer seasons. Due to poor initial growth rate, field is usually dominated by the weeds, resulting in poor quality and quantity of oil. The weeds can be controlled by cultural, mechanical and chemical methods. Due to timely unavailability of labours and their higher wages it becomes quite difficult to manage the weeds manually and hence use of the herbicides in controlling associated weeds becomes imperative. A number of herbicides, e.g. Pendimethalin, Oxyfluorfen and Metribuzin are being used to control the weeds in Japanese mint (Brar *et al.*, 2000). Now-a-days a number of high-potency herbicide

Evaluation of crop simulation modeling in chickpea crop using DSSAT model ver4.6

Sarvesh Baranwal, AN Mishra, AK Singh, SR Mishra, SK Sharma and DP Singh

Abstract
A field experiment was conducted during the *Rabi* season of 2017-18 to access the "Evaluation of crop simulation modeling in chickpea crop using DSSAT model ver4.6" in silty loam soil at student's instructional Farm, N.D. University of Agriculture & Technology, Kumarganj, Faizabad. The experiment was conducted with Randomized block design and replicated four times with nine treatment combinations consisted of three dates of sowing viz. D_1 (5th November), D_2 (15th November) and D_3 (25th November) and three cultivars *viz.* V_1 (BG-372), V_2 (KPG-59) and V_3 (Pant G-186). The historical crop data of year 2015-16 and 2016-17 were used for calibration of the model. The yield and yield attributes, phonological stages, test weight, harvest index as simulated by model were compared with the observed data. The result revealed that the model underestimated the test weight, LAI, first pod initiation, physiological maturity and overestimated rest of the parameters.

Keywords: Crop growth model, DSSAT, chickpea, simulation, calibration validation

Introduction

Chickpea (Cicer arietinum L.) is the premier pulse crop of Indian sub continent. India is the largest chickpea producer as well as consumer in the world. In UP its total area is 0.27 million hectare, production 0.22 million ton and productivity is 805kg/ha. The UN declared 2016 the 'international year of pulses'. (Agriculture Statistics, 2016-17).

It has the highest nutritional compositions in the form of fiber and mincrals. It can fix atmospheric nitrogen up to 140 kg/ha through its symbiotic association with Rhizobium and meets its 80 % requirement. It also helps in enhancing the soil quality for subsequent cereal crop. In India, acid exudates from the leaves were used medicinally for bronchitis, cholera, constipation, diarrhea, dysentery, snakebite, sunstroke and warts. The productivity of chickpea is curtailed due to biotic and abiotic stresses. Weather is one of the important factor, which affects all stages of chickpea growth and finally the yield (Abbo et al. 2005) [1]. The crop growth simulation models show considerable potential to evaluate crops, crop varieties, cropping pattern and genetic potential pattern for yield (Boote et al., 1987) [4]. In this paper attempt has been made to calibrate and validate to genetic coefficient of chickpea cultivar using DSSAT model.

Materials and Methods

Geographically the experimental site is situated at 26°47′ N latitude, 82°12′ E longitude and at an altitude of 113 meters above sea level in the Indo genetic alluvium of eastern Uttar Pradesh. The site comes under the subtropical climate and often subjected to extreme weather condition i.e. cold winter and hot summer. The experimental data (2017-18) of chickpea crop at Agro meteorological Research farm in the main campus of NDUA&T, Kumarganj, (Faizabad). Comprising three date of sowing (D_1-5 Nov, D_2-15 Nov, D_3-25 Nov) and three varieties (V_1-BG-372, V_2- KPG-59, V_3- Pant G-186). The package and practices for cultivation was followed as per the recommendation of crop parameters such as yield and yield attributes, LAI, harvest index and phenology were used for calibration of the DSSAT ver4.6 model. The genetic coefficient of chickpea were estimated by repeated interactions until a close match between simulated and observed phenology and yield was obtained in respective treatments. The values of genetic coefficients as derived from calibration of the model are the presented in Table1.

Study the effect of crop weather interaction on the growth and development of rice genotypes

Sandeep Kumar Sharma, SR Mishra, AK Singh, AN Mishra, Sarvesh Baranwal and SK Shukla

Abstract
From a morphological point of view, we attempted to estimate rice (*Oryza sativa* L.) yields by multiplication of three yield components considering seasonal changes in meteorological conditions. A field experiment was conducted during *kharif season* of 2017-18 in sandy loam soil of N.D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P.). The experiment consisted of nine treatment combinations comprised of three transplanting dates *viz.* July 5th, July 15th and July 25th and three varieties viz., NDR-97, NDR-3112 and BPT-5204. Results reveal that different phenophases of rice markedly varied with only dates of transplanting but also different weather variables which ultimately create the different crop growing environment to harvest the yield accordingly. Highest crop growth rate (CGR) was recorded in growing environment of July 5th due to occurrence of long duration. Highest Leaf are index and Plant height was recorded in Ist date of transplanting on July 5th at vegetative stage.

Keywords: LAI, plant height, CGR, RGR, harvest index

Introduction

The productivity of rice is largely affected by a set of weather variables among which rainfall, solar radiation and temperature play a significant role. Rice is one of the major crops feeding the world population and is most important ingredient in food composition in South Asia. It is most important cereal crop belong to the family Poaceae. It is the staple food for half of the world's population. Rice deserves a special status among cereals as world's most important wetland crop. (Gorantla *et al.,* 2005) [2].

Rice is an excellent source of carbohydrates and also rich in magnesium, thiamine, niacin, phosphorus, vitamin B_6, zinc and copper. Some varieties have iron, potassium and folic acid. Some varieties may provide 14g of protein per 100g. It is used for sweet dishes, for *risotto* in Italy, and many rice dishes, such as *arròsnegre*, in Spain. The challenge, above anything else, is to produce this additional rice with less land, less water, and less labour, in more efficient, environmentally-friendly production systems that are more resilient to climate change, among other factors. Uttar Pradesh is largest rice growing state after West Bengal in the country. Rice area with salt problem in state is estimated to be ≤ 2%. Inland salinity areas are mainly concentrated in Raibareilly, Azamgarh, Sultanpur, Faizabad, Lucknow, Unnao and Pratapgarh district. The area and production of rice in this state is about 5.87 million hectare and 12.22 million tonnes, respectively and productivity of 2082 kg per hectare (Anonymous, 2015-16) [1]. Among the crop production tools, proper time and method of sowing are the prerequisites that allow the crop to complete its life phase timely and successfully under a specific agro-ecology. In rice, the optimum leaf areas for seedlings, optimum leaf shapes to maximize photosynthetic efficiency, deep, well-developed root systems, leaf area index (LAI) at flowering and crop growth rate (CGR) during panicle initiation have been identified as the major determinants of yield. In environments with large temperature amplitudes, this effect should be considered when water-saving measures are applied in lowland rice fields. (Sun *et al.*, 1999) [4]. Climate change and its impact would emerge as a new challenge in near future, in addition to many challenges that are already present to achieve higher productivity in rice crop (Krishnan *et al.*, 2011) [3]. According to Zacharias *et al.* (2010), high temperature stress caused reduction in total dry matter, tiller mortality, reduced the number of panicles, grain per panicle, floret sterility and grain weight thus reducing the grain yield of rice. According to Waraich *et al.* (2012) [5] proper plant nutrition is one of the good strategies to alleviate the temperature stress

Studies on extreme weather events of eastern plain zone of Uttar Pradesh

Arpita SN, AK Singh, AN Mishra, Sachin Kumar Shukla and Manoj Kumar

Abstract
The historical daily data of rainfall and temperature were collected for the period of last 30 years (1985-2015) for the various extreme weather events *viz*, Dry spell, Wet spell, Heat waves, Cold waves, and frost as to identify the impact of various extreme weather events. Based on the historical data results reveal that. In EPZ of U.P, the dry spell showed an increasing trend in recent years. The wet spell of 10mm for 7 days, 25mm for 3 days showed decreasing trend in recent years. S-W monsoon rainfall of EPZ of UP declined over the normal in recent years. Maximum days of heat waves were recorded in May (1.6 days) followed by June (1.5days).During the month of September there was no any heat waves, while during the month of March followed by August recorded lowest frequency of heat waves. Maximum days of cold waves (1.6 days) were recorded during the month of January followed by February and December month. The month of October and March have no cold wave in EPZ of U.P. The trend of extreme minimum temperature and extreme maximum temperature showed decreasing trend against the normal value of 3°C and 44°C respectively.
The number of frost events increased from 29 days to 57 days, against the normal of 44 days. The total increasing trend of frost occurrence over the decades in the area will force to make strategy on contingent plan for major crops and adoptive measures from frost protection as to harvest highest genetic potential yield. Probability % of maximum frost occurrence during the month of January showed the decreasing trend of variation from 69% (1986-1995), 85% (1996-2005) and 63% (2005-2015) over the normal value of 72 %. Frost occurrence in the month of Dec- Jan will coincides with active tuber bulking phase in potato its effect is to bring about yield losses, and frost, foggy weather in winter months and occasional rains favours the late blight disease of potato in this region. So the decreasing tendency of frost days in January month in recent decades have beneficial impact on the growth of rabi crops in the region.

Keywords: Extreme, dry spell, wet spell, heat wave, cold wave, contingent plan, frost, tendency

Introduction
India being mainly an agricultural country, the economy and further its growth purely depends on the vagaries of the weather and in particular weather events. The weather and its variability are well known to the farming community. Possible impact of climate change on frequency and severity of weather extremes. They also referred that weather extremes can have a significant impact on agriculture and food security but their effect is often unclear, this may be due to interaction with other factors that affects yield and due to lack of precise definitions of relevant weather extreme. Extreme weather, in the most obvious sense, is weather that lies outside a locale's normal range of weather intensity. It is therefore by definition, infrequent or rare. Failures of rains and occurrence of natural disasters such as floods and droughts could lead to crop failures, food security, famine, loss of property and life, mass migration and negative national economic growth. Both the extremes of maximum and minimum temperatures cause stress to plant productivity (Ramakrishna, 2013) [2]. Extreme weather events like drought, flood, heat wave, cold wave, fog, thunder storm, dust storm, and hail storm causes considerable loss in crop productivity in the EPZ region. Use of improved climate and weather information and forecast along with efficient early warning systems contribute to the preparedness for extreme weather events to reduce loss of life and crop damage. For an instance, Providing forecasts and warnings of severe weather like extreme temperature, extreme cold, frost occurrence, and drought or flood in a timely manner contributes to preparedness. Better Agromet Advisories helps in minimizing the impact of extreme weather events in the region. Keeping above facts in view the present investigation was undertaken.

Validation of DSSAT model of rice cultivars under different growing environment of Eastern plain zone of U.P.

Sachin Kumar Shukla, AN Mishra, AK Singh, Arpita SN and Manoj Kumar

Abstract
A field experiment was conducted during Kharif 2016 to generate the ground truth data of rice crop at Agrometeorological Research Farm of N.D.U.A&T, of Kumarganj, Faizabad as to assess the "Validation of DSSAT model of rice cultivars under different growing environment of Eastern plain zone of U.P." The experiment was conducted in Randomized Block Design. The treatment comprised of three dates of Transplanting *viz.* 5th July (D_1); 15th July (D_2) and 25th July (D_3) with three varieties *viz.* NDR-80 (V_1); Pant Dhan-4 (V_2) and Swarna (V_3). The historical field crop data of year 2014 and 2015 were used for calibration and its validation was made from field crop data of year 2016.
Result reveals that crop growth simulation model was Model simulated the days taken to Panicle Initiation, Anthesis, Physiological Maturity, and Yield. And yield was closed in Accordance to Observed value and model overestimated the V_1 and V_2 Underestimated in 2016. And maturity was closed in Accordance to Observed value and model overestimated the V_3D_3 except D_1D_2 and V_1, V_2 Underestimated in 2016 and in Anthesis V_2, V_3 were overestimated and D_1V_1 were underestimated. Lowest error % was recorded in timely Transplanting crop of rice (5th July) with Swarna variety (D_2V_3) and error % increased with delay in Transplanting. DSSAT crop growth simulation model in rice crop depicted well the variation in yield due to varying crop growth environment. The simulated grain yield and phenological events were overestimated to observed values in timely transplanting suggested that the simulated yield were well within the accepted limits, therefore the model can be used for predicting rice yield and phenological events in eastern U.P.

Keywords: DSSAT, calibration, growing environment, anthesis and phenology

Introduction
Climate change and occurrence of extreme climate events are major concern for productivity of crop, and researchers are engaged in understanding its impact on various soil and crop processes, delineating vulnerable regions through growth and yield of crops and identifying suitable adaptation strategies to sustain systems productivity. Historic analysis of seasonal temperature indicates mixed trend of heating as well as cooling in various agro-climatic regions. There is a need to isolate the effect of other biophysical and socio-economic aspects, in order to work out the impact of climate change, which can be effectively done through use of mechanistic/dynamic simulation models.
The crop growth models are helpful to assess the impact of climate change on the stability of crop production under different management options. Crop growth simulation models provide means to quantify the effect of climate on soil, crop growth, productivity and sustainability of agriculture production. These tools can reduce the need for expensive and time consuming field experimentation and can be used to analyze yield gaps in various crops including wheat. Crop simulation model is quite useful as it forms a bridge between crop process analysis and performance assessment in which process operation are in their natural context.
The Decision Support System for Agro-technology Transfer (DSSAT) was originally developed by an International network of scientists. It is decision support system that encompasses process based computer models that predict growth development and yield as a function of a local weather soil condition, crop management scenarios and genetic information and also includes a basic set of tools to prepare the input data, as well as application programs for seasonal, crop rotation and spatial analysis. Hence the present investigation was undertaken.

Effect of accumulated heat unit, heat use efficiency and solar radiation interception on mustard cultivars under different growing environment (*Brassica juncea* L.)

Gajendra Singh, AN Mishra, AK Singh, SR Mishra, Rovit Kumar and Manoj Kumar

Abstract
A field experiment was conducted during the *Rabi* season of 2018-19 to access the "Effect of different growing environment on growth and yield of mustard cultivars (*Brassica juncea* L.)" in silty loam soil at Agro-meteorological Research Farm of N.D. University of Agriculture & Technology, Kumarganj, Ayodhya. The experiment was conducted with RBD (Factorial) and replicated four times with nine treatment combinations consisted of three growing environment viz. 20th October, 30th October and 09th November and three cultivars *viz.* Varuna, Narendra rai-1 (NDR-8501) and Kranti. Results revealed that 20th October sown mustard crop produced significantly higher growth and yield due to fulfilment of optimum heat unit requirement, heat use efficiency and solar light interception for various processes of plant. Among the different cultivars of mustard, Varuna was recorded maximum heat unit (1660.6 °C days), heat use efficiency (0.50 g/m²/°days) and Solar radiation interception (589 MJ/m²) from sowing to maturity produced the high yield of Indian mustard.

Keywords: Heat unit, heat use efficiency, solar radiation interception, mustard, growing environment

Introduction
Mustard (*Brassica juncea* L.) belonging to family cruciferae is the third important oilseed crop in the world after soybean (*Glycine max*) and palm oil (*Elaeis guineensis jacq*). The important mustard growing countries of the world are India, Canada, China, Pakistan, Poland, Bangladesh and Swedan. India is one of the important country among the oilseeds producing countries of the world. Mustard is the second most important edible oil seed crop after groundnut in India. India occupies the second position in area after China and third position in production in the world after China and Canada. Indian mustard is also grown where annual precipitation of 500 to 1200 mm, temperature of 6 °C to 27 °C and soil pH of 6.5 to 8.3. Mustard is the crop of tropical as well as temperate zone. The temperature requirement varies from 0.5-3.0 °C ($T_{Min.}$) to 35-40 °C ($T_{Max.}$) with an optimum temperature regime of 20-35 °C. Cool temperature, dry weather with good amount of bright sunshine increases the oil yield. Mustard needs high temperature for vegetative growth (20-32 °C) and cool temperature. If the mustard is sown late, duration is reduced due to the high temperature during the reproductive phase with concomitant reduction in yield (Kumari *et al.*, 2004) [6]. The growth phase of the crop should synchronize with optimum environmental conditions for better expression of growth and yield. It is a fact that specified genotypes does not exhibit the same phenotypic characteristics in all environmental conditions. Bora (1997) [1] has reported that the yield potential of different mustard varieties may differ under different agro-climatic conditions because of their inherent capacity.

Materials and methods
An experiment was conducted at Agro-meteorological Research Farm of Narendra Deva University of Agriculture & Technology, Kumarganj, Ayodhya (U.P.) during Rabi season 2018-19. The farm is located 42 km away from Ayodhya city on Ayodhya - Raibareily road at 26°47' N latitude and 82°12' E longitude and at an attitude of about 113 meter above the mean sea level. The experiment was conducted in R.B.D. (Factorial).

Studies on crop growing environment of mustard (*Brassica juncea* L.) varieties of eastern plain zone

Pankaj Jaiswal, AN Mishra, AK Singh, SR Mishra, Gajendra Singh, Rovit Kumar and Manoj Kumar

Abstract
A field experiment was conducted during rabi season of 2018-19 entitled "Studies on crop growing environment of mustard (*Brassica juncea* L.) varieties of Eastern Plain Zone" at Agromet Research Farm of Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj), Ayodhya (U.P.). The experiment was conducted in spilt plot design which consisted of nine treatment combinations comprised of three crop growing environments viz. Oct. 20th, Oct. 30th and Nov. 9th and three varieties viz. Varuna, NDR-8501 and Kranti. Results reveal that higher dry matter accumulation was recorded in crop growing environment Oct. 20th which was at par with crop growing environment Oct. 30th while significant over crop growing environment Nov. 9th. Among the varieties, higher dry matter accumulation was recorded in Varuna variety which was at par with NDR-8501 while significant over Kranti variety recorded lowest dry matter accumulation at all the growth stages.
Maximum thermal sensitivity Index from sowing to maturity was recorded in Varuna variety while minimum thermal sensitivity index was obtained in Kranti variety from sowing to maturity of Indian mustard. Higher GDD was recorded in crop growing environment Oct. 20th followed by crop growing environment Oct. 30th and crop growing environment Nov. 9th. Among the varieties, higher GDD was recorded under Varuna followed by NDR-8501 at all the stages of Indian mustard.

Keywords: Dry matter accumulation, thermal sensitivity index, GDD, Growing environment, mustard

Introduction
Indian mustard belongs to cruciferae family. Rapeseed is locally called sarson, toria, yellow toria, whereas, mustard is called rai or laha. Among the oilseeds *Brassica*, is the most important member of groups because more than 80 per cent of the area under rapeseed-mustard is followed by *toria, yellow sarson, gobhisarson, brown sarson and taramira.* Oilseeds, the second largest agricultural commodity after cereals in India, plays a significant role in India's agrarian economy, as more than 85 per cent of country's vegetable oil supply depend upon seven edible oilseeds (groundnut, rapeseed-mustard, soybean, sesame, sunflower, Niger and safflower) and two non-edible oilseeds (linseed and castor). Among the seven edible oilseed cultivation in India, rapeseed-mustard (*Brassica* spp.) contributes 28.6% in the production of oilseeds. Rapeseed-mustard is the major *rabi* oilseed crop of the country. India occupies the third position in rapeseed and mustard production in world after Canada and China. In India during year 2017-18, the area of Rapeseed-mustard was 6.4 million ha. with the production of 6.4 million tonnes and productivity of 987 kg/ha. In India, it is mainly cultivated in Rajasthan, Gujrat, Maharashtra, Haryana, Uttar Pradesh, Madhya Pradesh, Bihar, Assam, and West Bengal in varied situation. (Anonymous, 2017-18). Neoget *et al.*, (2005) revealed that as growing degree days (GDD) increased from 1270 to 1684 °C day in Pusa Jaikisan and Varuna, the seed yield -also increased and with the further increase in GDD accumulation, there was a decline in the seed yield of mustard. Change in sowing dates led to change in thermal environments of the cultivars with respect to different growth and development stages leading to variation in completion of life cycle (Roy *et al.*, 2005) [4]

Phenophasic study of rice varieties under different crop growing environment

Rovit Kumar, AK Singh, AN Mishra, SR Mishra, Gajendra Singh and Manoj Kumar

Abstract
A field experiment was conducted during kharif season of 2018 entitled "Phenophasic study of rice varieties under different crop growing environment" at N.D. University of Agriculture and Technology, Kumarganj, Ayodhya (U.P.). The experiment consisted of nine treatment combinations which comprised of three crop growing environment *viz.* July 15th, July 25th and August 04th and three varieties viz., NDR-97, NDR-2064 and BPT-5204. Results reveal that higher days taken to all phenophases from tillering to physiological maturity were recorded in crop growing environment of July 15th followed by July 25th. Among the varieties, BPT-5204 recorded higher days taken to physiological maturity followed by NDR-2064. Variety NDR-2064 followed by BPT-5204 were found suitable for higher growth, yield attributes and yield of rice. Crop growing environment of 15th July and variety NDR-2064 possess congenial weather and harvested maximum growth, yield attributes and yield of rice.

Keywords: Phenophasic duration, yield attributes, yield, growing environment, rice

Introduction

Rice is one of the most important cereal crop belong to the family *Poaceae.* It is the staple food for half of the world's population Temperature regimes greatly influenced not only the growth duration, but also the growth pattern and the productivity of rice crops. Extreme temperatures whether low or high cause injury to the rice plant. In tropical regions, high temperatures are a constraint to rice production. The most damaging effect is on grain sterility, just 1 or 2 hours of high temperature at anthesis (about 9 days before heading and at heading) result in a large percentage of grain sterility. Studies on rice productivity under global warming also suggest that the productivity of rice and other tropical crops will decrease as global temperature increases. Mohandrass *et al.* (1995) [3]. Such warming will thus reduce rice growth. In addition, higher temperatures will cause spikelet sterility owing to heat injury during panicle emergence. In temperate regions, increased air temperatures should hasten rice development, there by shortening the time from transplanting (or direct seeding) to harvesting and reducing the total time for photosynthesis yield development (Nguyen, 1994) [4]. Rice is very sensitive to higher temperature during reproductive stage especially flowering and anthesis. The elevated temperature at the time of flowering and maturity determines the yield per seed of the genotypes. Under high temperature stress, the response of genotypes depended on developmental stage, but highest sensitivity was recorded at reproductive stage. The time of sowing, days to flowering (duration group), heat escape (early morning flowering) and inbuilt tolerance were the crucial factors in determining the performance of genotypes to varying temperature. Hence, it is necessary to select genotypes by keeping in view the above factors for different temperature stress within and across the environment (Raju *et al.* 2013) [5]. Hence, present investigation was under taken.

Materials and Methods

A field experiments was conducted at N. D. University of Agriculture & Technology, Kumarganj, Ayodhya (U.P.) during *kharif* season of 2018 which lies at latitude 26° 47'North longitude 82° 12' East and altitude of 113 meter from mean sea level in the Indo-genetic alluvium of Eastern Uttar Pradesh. The experiment was carried out in Randomized Block Design (Factorial), and replicated four times. The experiment comprised of three crop growing environment i.e. 15th July, 25th July and 04th August with three varieties i.e. NDR-97, NDR-2064 and BPT-5204. Fertilizers were applied @120:60:60 N: P_2O_5: K_2O kg/ha 1/3rd of

Studies on accumulated thermal unit and thermal use efficiency at different phenophases of rice varieties under different crop growing environment

Rovit Kumar, AK Singh, AN Mishra, Gajendra Singh and Manoj Kumar

Abstract
A field experiment was conducted during kharif season of 2018 entitled "Studies on accumulated thermal unit and thermal use efficiency at different phenophases of rice varieties under different crop growing environment" at N.D. University of Agriculture and Technology, Kumarganj, Ayodhya (U.P.). The experiment consisted of nine treatment combinations viz. three crop growing environment *viz.* July 15th, July 25th and August 04th and three varieties viz., NDR-97, NDR-2064 and BPT-5204. Results reveal that maximum accumulated thermal unit (2203.1°C days) was recorded in crop growing environment of July 15th followed by the July 25th (2089.8°C days). Among the varieties, maximum accumulated thermal unit in variety BPT-5204 (2367.2°C days) followed by NDR-2064 (2113.7°C days). Maximum thermal use efficiency of (0.51g/m²/°C days) was recorded in July 15th at Physiological Maturity followed by July 25th (0.475g/m²/°C days). NDR-2064 possess maximum TUE of 0.535g/m²/°C days at Physiological Maturity followed by BPT-5204 (0.505g/m²/°C days).

Keywords: Thermal unit, thermal use efficiency, growing environment, rice

Introduction
Rice is one of the most important cereal crop belong to the family *Poaceae*. It is the staple food for half of the world's population. Among the crop production tools, proper time of transplanting is the prerequisites that allow the crop to complete its life phase timely and successfully under a specific agro-ecology. In rice, the optimum leaf areas for seedlings, optimum leaf shapes to maximize photosynthetic efficiency, deep, well developed root systems, leaf area index (LAI) at flowering and crop growth rate (CGR) during panicle initiation have been identified as the major determinants of yield. Growth and grain yield reductions have been widely observed when traditionally flooded rice fields were subjected to water saving irrigation measures, where a continuous flood water layer is avoided.

Rice is very much sensitive to photo thermal regimes and the crop growth is influenced largely by the growing environmental conditions. Among them temperature plays a significant role in physiological, chemical and biological processes of plants. It is an important environmental factor influencing the growth and development of crops. During growth and development of a cereal, several growth stages are distinguishable in which important physiological processes occur. Influence of temperature on phenology and yield of crop plants can be studied under field condition through accumulated heat units. Plants have a definite temperature requirement for attainment of certain phenological stages. The duration of each phenophase determines the accumulation and partitioning of dry matter in different parts as well as crop responses to environmental and external factors. The occurrence of different phenological events during crop growth period in relation to temperature can be estimated by using accumulated heat units or growing degree days (GDD).

Growing degree days are based on the concept that the real time to attain a phenological stage is linearly related to temperature in the range between mean temperature and base temperature. A degree day or heat unit is the departure from the mean daily temperature above the minimum threshold temperature. The heat unit concept assumes that a direct and linear relationship between growth and temperature is advantageous for the assessment of yield potential of a crop in different weather conditions. Keeping above facts in view present investigation was under taken.

Studies on mustard (*Brassica juncea* L.) varieties under various crop growing environment in eastern plain zone

Pankaj Jaiswal, AN Mishra, AK Singh, SR Mishra, Rovit Kumar, Gajendra Singh and Kapil Dev Sharma

Abstract
A field experiment was conducted during rabi season of 2018-19 entitled "Studies on mustard (*Brassica juncea* L.) varieties under various crop growing environment in Eastern Plain Zone" at Agromet Research Farm of Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj), Ayodhya (U.P.). The experiment was conducted in spilt plot design which consisted of nine treatment combinations comprised of three crop growing environments viz. Oct. 20th, Oct. 30th and Nov. 9th and three varieties viz. Varuna, NDR-8501 and Kranti. Results reveal thattaller plants (146.6 cm) were recorded in growing environment20th October. Shorter plants (116.8 cm) were recorded under 09th November. Among the varieties, taller plant height (143.8 cm) was recorded in Varuna. Significantly higher leaf area index at 60 DAS (4.67) was recorded in 20th October. Among the varieties, highest leaf area index (4.3) was recorded in Varuna variety. The maximum number of primary branches plant^{-1} was recorded on 20th October at 30, 60, 90 days and at harvest after sowing. Among the varieties, maximum number of primary branches plant^{-1} was recorded in Varuna variety. Significantly higher number of secondary branches plant^{-1} was recorded 20th October at 30, 60, 90 DAS and at harvest. Among the varieties, maximum number of secondary branches plant^{-1} was recorded with Varuna at 30, 60, 90 DAS and at harvest. The higher number of siliquae/plant, length of siliqua, Number of seeds/siliqua were recorded on 20th October date of sowing. Among the varieties, maximum numbers of siliquae/plant, length of siliqua, number of seeds/siliqua were recorded in Varuna variety of mustard. Maximum Seed yield (20.9 q/ha), Stover yield (74.3 q/ha), Biological yield (95.28 q/ha) were recorded on 20th October crop growing environment. Among the varieties, maximum Seed yield (20.2 q/ha), Stover yield (70.3 q/ha), Biological yield (90.6 q/ha) were recorded with Varuna.

Studies on accumulated thermal unit of rice (*Oryza sativa* L.) cultivars under varying crop growing environment

Kapil Dev Sharma, SR Mishra, AN Mishra, AK Singh, Gajendra Singh, Rovit Kumar and Vishesh Kumar

Abstract
A field experiment was conducted during *kharif season* 2018 entitled "Studies on accumulated thermal unit of rice (*Oryza sativa* L.) cultivarsunder varying crop growing environment." in sandy loam soil of N.D. University of Agriculture and Technology, Kumarganj, Ayodhya (U.P.). The experiment consisted of nine treatment combinations comprised of three transplanting dates *viz.* July 15th, July 25th and August 04th and three varieties viz., NDR-97, NDR-2064 and BPT-5204. Results reveal that different phenophases of rice markedly varied with only dates of transplanting but also different weather variables which ultimately create the different crop growing environment to harvest the yield accordingly. Accumulated thermal unit was recorded in crop growing environment on July 15th (2158.5 ^{0}C days) at all the phenophases followed by July 25th (2059.7 ^{0}C days) and August 04th (1934.5 ^{0}C days) transplanting while among the cultivars BPT-5204 (2223.5 ^{0}C days) was recorded maximum thermal unit due to occurrence of long duration variety.

Keywords: Thermal unit, growing environment, growing degree days (GDD), rice

Introduction
Rice (*Oryza sativa* L.) being the staple cereal food crop, grown in India, providing one third of calories requirement for more than 70% of Indian population. More than 90% of world's rice is grown and consumed in Asia, known as rice bowl of the world. To focus attention on the importance of rice in global food security and necessity rice production and productivity, United Nation General Assembly in 2002, first time declared to celebrate the year 2004 as International year of rice with the name of "Rice is Life". Theheat unit concept assumes that a direct and linear relationship between growth and temperature is advantageous for the assessment of yield potential of a crop in different weather conditions. Reaumur was the first to suggest that duration of particular stages of growth is directly related to temperature summation. Knowledge of accumulated GDD can provide an estimate of harvest date as well as crop development stage. However, the impact of temperature, bright sunshine hour as well as day length on the growth habits of this crop are not well documented. The present experiment has been undertaken to address this lacunae (Malo *et al.*, 2018) [7]. The extreme climatic conditions, particularly high temperature, reduce the plant growth and yield significantly (Satake and Yoshida, 1978) [8]. The crop growth response is mainly influenced by the microclimate of crop canopy. Microclimatic environment in the crop refers to the interception of photo synthetically active radiation, prevailing wind speed, soil moisture availability, relative humidity and concentration of CO2.
Temperature and light radiation are key factors affecting crop production. During crop growth period, the occurrence of various phenological events can be estimated by computing accumulated growing degree days (Gouri *et. al.*, 2005) [4]. Accumulated growing degree days (GDD) provides an estimate of harvest date as well as development stages of crop (Ketring and Wheless, 1989) [6]. Various developmental stages as well as harvest date of crop can be estimated from the knowledge of accumulated GDD. Thermal time can be used as a tool for characterizing thermal responses in different crops as it is an independent variable to describe plant development (Dwyer and Stewart, 1986) [2]. Hence, the study was taken up to find out the thermal heat units requirement for different rice varieties, viz. NDR-97, NDR-2064 and BPT-5204.

Studies on thermal use efficiency, heliothermal unit and photothermal unit of rice (*Oryza sativa* L.) cultivars under varying crop growing environment

Kapil Dev Sharma, SR Mishra, AK Singh, AN Mishra, Gajendra Singh, Vineet Kumar and Pankaj Jaiswal

Abstract
A field experiment was conducted during *kharif* season2018 entitled "Studies on thermal use efficiency, heliothermal and photothermal unitof rice (*Oryza sativa* L.) cultivarsunder varying crop growing environment." in sandy loam soil of N.D. University of Agriculture and Technology, Kumarganj, Ayodhya (U.P.). The experiment consisted of nine treatment combinations comprised of three transplanting dates *viz*. July 15th, July 25th and August 04th and three varieties viz., NDR-97, NDR-2064 and BPT-5204. Results reveal that different phenophases of rice markedly varied with only dates of transplanting but also different weather variables which ultimately create the different crop growing environment to harvest the yield accordingly. Highest thermal use efficiency (TUE) was recorded in crop growing environment on July 15that all the stage, followed by July 25th, among the cultivars highest thermal use efficiency was recorded with BPT-5204, followed by NDR-2064.Maximum heliothermal unit was recorded in crop growing environment on July 15th at both the stages vegetative and reproductive stage followed by July 25th. Maximum photothermal unit was recorded in crop growing environment on July 15th at both the stages, followed by July 25th at vegetative and reproductive stage and among the cultivars in BPT-5204.

Keywords: Thermal use efficiency, heliothermal unit, photothermal unit, rice

Introduction
Rice is the most consumed cereal grain in the world constituting the dietary staple food of more than half of the world population. Apart from food rice is intimately involved in the culture as well as economy of many societies. Rice a member of the family *Poaceae* originated from South East Asia and in Asia where more than 90 per cent of world's rice is produced and consumed with two countries, China and India, growing more than half of the total crop. Thus rice is immensely important to food security of Asia. Crops sown on different dates are exposed to different solar duration during the season and this may influence Radiation use efficiency through its effect on radiation transmission (Khichar *et al.*, 2000) [2]. The duration of growth stage of any particular species was directly related to temperature and it could be predicted using the sum of daily air temperature. Temperature is an important environmental factor that influences the growth and development, phenology and yield of crops (Bishnoi *et al.*, 1995) [1]. Heat use efficiency (HUE), i.e., efficiency of heat utilization in terms of dry matter accumulation, depends on genetic factors, crop type and sowing time and has great practical application (Rao *et al.*, 1999) [3]. The effects of meteorological factors on crop production and yield can be assessed in two different ways (Van Keulen 1987) [4].

Materials and Methods
The field experiments was conducted at N. D. University of Agriculture & Technology, Kumarganj, Ayodhya (U.P.) during *kharif* season of 2018 situated at a distance of about 40 km. away from Ayodhya district headquarter on Ayodhya Raibarelly road. The geographical situation of experimental site lies at latitude 26° 47'North longitude 82° 12' East and altitude of 113 meter from mean sea level in the Indo-genetic alluvium of Eastern Uttar Pradesh. The experiment was carried out in Randomized Block Design (Factorial) and replicated four times. The experiment comprised of three crop growing environment i.e. 15th July, 25th July and 04th August with three varieties i.e. NDR-97, NDR-2064 and BPT-5204.

Larval fluctuation of *Helicoverpa armigera* with reference to environmental factors in chickpea crop

Vineet Kumar, SR Mishra, AN Mishra, AK Singh, RB Singh, Vishesh Kumar and Kapil Dev Sharma

Abstract
A field experiment was conducted during rabi season of 2017-18 entitled "Larval fluctuation of *Helicoverpa armigera* with reference to environmental factors in chickpea crop." in sandy loam soil of Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj), Ayodhya (U.P.). The experiment consisted of nine treatment combinations comprised three varieties and three date of sowing viz., sowing on Nov. 5th with temperature 23.8 °C, Nov 15th with temperature 20.8 °C and Nov. 25th with temperature 16.8 °C and three varieties Uday (V_1), Pusa-362 (V_2) and Radhey (V_3). Results reveal that the all three varieties under three date of sowing Peaks larval population of pod borer were recorded during 8th to 9th standard week. Highest larval population (5.50 larvae/plant) was recorded in crop sown at November 25th followed by November 15th sown crop while lowest in sown on November 05th, larval population increased with increase in temperature, maximum temperature from 25°C to 35°C increases the larval population, while minimum temperature from 10 °C to 14 °C indicate that larval population increased with increase in minimum temperature in all varieties.

Keywords: Chickpea, population dynamics, *Helicoverpa armigera*

Introduction
Chickpea, (*Cicer arietinum* L.) is one of the most important legume crop in the world and in the Asia region. Chickpea is the premier pulse crop of Indian sub continent. India is the largest chickpea producer as well as consumer in the world. Pulse occupies an unique position in Indian agriculture by virtue of its high protein content and its capacity to enrich the soil fertility through the mechanism of symbiotic nitrogen fixation. It is a super energy umbrella for the people as dietary protein for the livestock as green nutritious fodder and feed and for the soil as a mini nitrogen plant and green manure (Ali, 1988) [1]. Chickpea is a good source of protein (21.1%), Carbohydrates (61.5%), Minerals (Ca, P and Fe) and Vitamins (C). Among the various insects that attack chickpea crop, pod borer (*Helicoverpa armigera*) is the most damaging insect. It is quite prevalent in Asia, Africa, Australia and some other chickpea growing regions. As pod borer is a polyphagous insect that attacks on more than 182 plant species, the development of cultivars resistant or tolerant to *H. armigera* could be integrated in the pest management strategy particularly in the developing countries (Fitt 1989). Among different insect-pests of -chickpea in field gram pod borer *(H. armigera)* is serious pest which cause damage upto 20-50 % pod damage throughout the country (Anonymous, 1978), 16-18% at Almora in Uttaranchal, 16-22% in Orissa and it causes serious damage to the crop every year in Punjab (Atwal, 1991). The young larvae feed on the tender portion of leaves and shoots by scratch them. Grown up larvae consume leaf buds, whole leaf and flowers under severe infestation, the whole plant may get defoliated with the availability of pods, the third instars larvae make a hole in the pods and move inside to feed on grains, where as fully grown larvae feed after making a hole in the pods and thrusting its head, there in while keeping hind parts of the body outside. A single larva destroys about 30-40 % pods (Reed and Pawar, 1982) [5].

Materials and Methods
The experiment was conducted during Rabi season 2017-2018 at Student's Instructional Farm of N.D.U.A.&T., Kumarganj, Ayodhya (U.P.). Geographically, the experimental site is situated at 26°47 N latitude, 82°12 E longitude and at an attitude of 113 meters above mean sea

Effect of changing environment on growth and yield of chickpea (*Cicer arietinum* L.)

Ajeet Kumar, SR Mishra, AK Singh, RK Aryan and Anil Nishad

Abstract
A field experiment was conducted during *rabi season* of 2016 on the topic entitled "Study the crop-weather interaction on chickpea (*Cicer arietinum* L.) Cultivars" in sandy loam soil of N.D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P). The experimental consisted of nine treatment combinations comprised of three growing environment *viz.*, sowing on Oct.25th with temperature 24.2 ^{0}C, Nov.4th with temperature 22.5 ^{0}C and Nov.14th with temperature 22.2 ^{0}C and three varieties viz. Radhey, Pusa-372, and BG-256. Results revealed that plant height Taller plants were obtained at sowing temperature 32.5 ^{0}C (exist on October 25th) which was significant higher over rest sowing dates. Shorter plants were recorded under sowing date November 14th. higher leaf area index was obtained at sowing temperature 32.5 ^{0}C (existed on Oct.25th) as compared to sowing done on Nov.4th and Nov.14th in which later sown i.e. Nov.14th proved lowest LAI at all the stages of crop. Higher leaf area index was obtained in Radhey followed by BG-256 while significantly superior over Pusa-372 cultivar at all the successive stages of chickpea. Maximum plant population (32plant m^{-2}) was recorded under sowing done on Oct.25th with sowing temp. 32.5 ^{0}C followed by Nov.4th sowing of chickpea. Delay in sowing recorded lowest no. of initial plant population of chickpea Radhey cultivar exhibited maximum initial plant population (32) followed by Pusa-372 (30). Number of branches plant^{-1} shows that different growing environment had significant influence on the number of branches plant^{-1} at all the stages. Crop sown on Oct.25th with temperature 32.5 ^{0}C produced significantly higher number of branches plant^{-1} was significantly superior over both sowing done on Nov.4th with temperature 30.5 ^{0}C and Nov.14th with temperature 31 ^{0}C. Number of branches plant^{-1} was affected significantly by varieties at all the stages.

Keywords: chickpea, plant height, LAI, number of branches/plant, initial plant population

Introduction
Chickpea (*Cicer arietinum* L.) is one of most important pulse crop of India. Chickpea probably originated in south-eastern Turkey and spread west and south via the silk route. Four centres of diversity have been identified in the Mediterranean, Central Asia, near East Asia and India, as well as a secondary centre of originated Ethiopia. It is the world third most important food legume and India is placed first in production. India is the largest producer of chickpea in the world covering 8.25 million hectare area and producing 7.33 million tonne of grain with an average productivity of 889 kg h^{-1} in year 2014-15 (Anonymous, 2016). In Uttar Pradesh, chickpea is cultivated on an area of 0.58 Million hectares in India 5.64% with an annual production of 0.48 Million tonne, in India 4.81% the average productivity of this crop in U.P is only 12.12q ha^{-1}. Yield 824 kg/hectare annual report (2014-15). Sowing date and temperature have been proved to be one of the most non-monetary inputs affecting the yield of chickpea. Sub optimal thermal regimes during crop growing season are known to have profound effect on crop productivity. The production potential of high productive varieties may be exploited by sowing them at their most optimum time. Chickpea cultivated with medium and long duration varieties is generally delayed. All the chickpea varieties are sensitive to photo and thermal-period. Delay in sowing causes early maturity of the cultivars resulting in drastic reduction of the yield. Optimum sowing time is considered for maximum advantages of environmental condition, especially in the terms of the thermal requirement by the crop canopy. The productivity of chickpea in eastern U.P. is quite below than the national average due to which suitable varieties will therefore, be quite helpful in increasing the yield (Shendge *et al.*, 2002) [4].

Materials and Methods
The present investigation entitled "Study the crop weather interaction on chickpea (*Cicer arietinum* L.)" was carried out during *Rabi* season of 2016-2017 at Student Instructional Farm

Phonological growth and development of chickpea (*Cicer arietinum* L.) cultivars at climatic condition

Ajeet Kumar, SR Mishra, AK Singh, RK Aryan and Anil Nishad

Abstract
A field experiment was conducted during *rabi season* of 2016 on the topic entitled "Study the crop-weather interaction on chickpea (*Cicer arietinum* L.) Cultivars" in sandy loam soil of N.D. University of Agriculture and Technology [illegible] Faizabad (U.P). The experimental consisted of nine treatment combinations comprised of three growing environment *viz.*, sowing on Oct.25th with temperature 24.2 ^{0}C, Nov.4th with temperature 22.5 ^{0}C and Nov.14th with temperature 22.2 ^{0}C and three varieties viz. Radhey, Pusa-372, and BG-256. Results revealed that Heat use efficiency (0.62 gm^{-2} ^{0}C day^{-1})and radiation use efficiency (1.6 g/MJ) was recorded when sowing was done sown Oct.25thwith temperature 24.2 ^{0}C followed by sowing done on Nov.4th while lowest heat use efficiency and radiation use efficiency was recorded when sowing was done on Nov.14th with sowing temperature 22.2 ^{0}C. Radhey cultivar was found more conducive and remunerative for growth development seed yield radiation use efficiency and heat use efficiency.

Introduction
Chickpea (*Cicer arietinum* L.) is one of most important pulse crop of India. Chickpea probably originated in south-eastern Turkey and spread west and south via the silk route. Four centres of diversity have been identified in the Mediterranean, Central Asia, near East Asia and India, as well as a secondary centre of originated Ethiopia. It is the world third most important food legume and India is placed first in production. Chickpea cultivated with medium and long duration varieties is generally delayed. All the chickpea varieties are sensitive to photo and thermal-period. Delay in sowing causes early maturity of the cultivars resulting in drastic reduction of the yield. Optimum sowing time is considered for maximum advantages of environmental condition, especially in the terms of the thermal requirement by the crop canopy. The productivity of chickpea in eastern U.P. is quite below than the national average due to which suitable varieties will therefore, be quite helpful in increasing the yield (Shendge *et al.*, 2002) [9]. The most important factors affecting chickpea development are generally temperature, photoperiod, and moisture. Temperature (Singh & Dhaliwal 1972; Siddique & Sedgley 1986) [11, 10], moisture (Saxena 1990) [8], and depth of sowing (Saxena 1987) [7] mainly control the duration from sowing to emergence. After emergence, temperature, and photoperiod (Sandhu & Hodges 1971) [6] coupled with the availability of soil moisture (Khanna-Chopra & Sinha 1987; Piara Singh 1991) [1, 3] control the rate of progress towards any phenological stage. In chickpeas, flowering is considered the critical stage, because environmental conditions that prevail at flowering and the duration of the reproductive phase determine, to a large extent, the percentage of fruit set and the final yield (Savithri *et al.* 1980) [5]. Therefore, being able to predict the time of flowering may be more important than any of the other phenological stages. Considerable work has been done on the photothermal responses of chickpeas to predict time to flowering (Summerfield & Roberts 1988) [12]. As in most grain legumes, increased temperatures speed up the rate of development of all developmental stages of chickpeas (Summerfield *et al.* 1984; Roberts *et al.* 1985) [12, 4].

Materials and Methods
The experiment comprised three different types of Cheakpea varieties Radhey (V_1), Pusa-372 (V_2), and BG-256 (V_3) at three growing environment *viz.*, October. 25th growing environment 24.2 °C (D_1), Nov.4th growing environment 22.5 °C (D_2), Nov.14th growing environment 22.2 °C (D_3) during 2016. The experiment was conducted in Randomized Block Design (RBD) and replicated the three times. The different growth parameters studied were measured as follows;

Soil moisture depletion as influenced by planting geometry and moisture regimes in *rabi* maize (*Zea mays* L.)

KKK Reddy, AK Singh and RS Singh

Abstract
A field experiment was conducted during *rabi* season 2016-2017 at Agronomy Research Farm, Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad (U.P.) to study soil moisture depletion as influenced by planting geometry and moisture regimes in *rabi* maize. The experiment was laid out in split plot design with three replications keeping combinations of planting geometry *viz.*, 60 × 10 cm, 60 × 15 cm, 60 × 20 cm, 60 × 25 cm and four moisture regimes *viz.*, 0.6 IW/CPE ratio, 0.9 IW/CPE ratio, 1.2 IW/CPE ratio, 0.9 IW/CPE ratio up to silking and 1.2 IW/CPE ratio for rest of the crop season. Among four planting geometries, highest soil moisture depletion (40.16 cm) was recorded in 60 × 10 cm. Among four moisture regimes, highest soil moisture depletion (45.91 cm) was recorded in 1.2 IW/CPE ratio. With respect to treatment combinations, higher soil moisture depletion (47.8 cm) was recorded in 60 × 10 cm and 1.2 IW/CPE ratio.

Keywords: Soil moisture depletion, *Rabi* maize, planting geometry, IW/CPE ratio, moisture regimes

Introduction
Maize (*Zea mays* L.) is the third most important grain crop in India after rice and wheat with respect to area and productivity. Globally maize is cultivated in an area of 177 million hectares with a production and productivity of 989 and 5.5 metric t ha^{-1}, respectively (Commodity profile-maize, 2015). In India it is grown in an area of 9.43 million hectares with production of 24.35 Mt and 2562 kg ha^{-1} productivity (CMIE, 2016). It has wide ecological adaptability and is grown in extreme semi-arid to sub-humid and humid regions as a staple crop for human beings, feed for animals and as a basic raw material for production of starch, oil, protein, alcoholic beverages, food sweeteners and more recently bio-fuel (Dass *et al.*, 2008) [3]. The average grain yield of maize is not only substantially lower compared with other important maize growing countries but also less than the production potential of existing genotypes. Traditionally maize is a rainy/*kharif* season crop in India and is extensively grown under rainfed conditions, but *kharif* crop suffers due to vagaries of monsoon, excessive rainfall leading to water stagnation, poor drainage, erratic and insufficient rainfall leading to moisture stress condition, severe infestation of pests and diseases, fertilizer losses, greater weed menace and high temperature throughout the growth period which tend to reduce grain yield. On the contrary, the risk of damage to the crop from excessive rainfall, water stagnation, inadequate soil moisture, pest and disease infestation during winter/*rabi* season is less. The average grain yield of maize is not only substantially lower compared with other important maize growing countries but also less than the production potential of existing genotypes. Low yield of maize is due to many constraints but among them, cultivation of local genotypes, imbalanced use of fertilizers, traditional sowing methods, improper water management, lack of optimal crop stand and optimum planting geometry are the factors of prime importance. Planting geometry and water management play an important role in enhancing the crop productivity. Planting geometry *i.e.* plant population per unit area have immense role since it is a non tillering crop. Sub optimal plant stand *i.e.* wider spacing leads to poor yield per unit area. While higher plant populations have greater competition for growth resources and leads to poor yield. In order to produce higher yields of maize, optimum soil moisture should be maintained as it is susceptible to both water logging and water deficit. Among the different approaches for scheduling, the climatological approach based on IW/CPE ratio (IW - irrigation water, CPE - cumulative pan evaporation) has been found most appropriate as it integrates all weather

Effect of different date of transplanting on growth and yield of rice (*Oryza sativa* L.) varieties under Indo-gangetic plains of Awadh area

Shashank Shekher Singh, Anil Kumar Singh and Permendra Singh

Abstract
The field experiment entitled "Effect of different date of transplanting on growth and yield of rice (*Oryza sativa* L.) varieties" was conducted at Agronomy Research Farm of Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj), Faizabad, Uttar Pradesh during *Kharif* season of 2015 with an objective to find out suitable date of transplanting of rice, the treatment consisted of three transplanting date (15 July, 25 July and 5 August) and three varieties (Sarju-52, NDR-359 and Swarna) there were 9 treatment combinations.

The values of growth contributing characters viz. plant height (cm), number of tillers, dry matter accumulation, leaf area index and yield attributes like number of panicles m^{-2}, length of panicle (cm), number of $panicle^{-1}$, grain weight $panicle^{-1}$, grain and straw yield (q ha^{-1}) were increasing significantly with 15 July date of transplanting followed by 25 July date of transplanting and significantly superior with 5 August date of transplanting. In case of variety the performance the growth characters like plant height (cm), number of $tillersm^{-2}$, dry matter accumulation (g m^2) leaf area index and yield attributes like number of panicles m^{-2}, length of panicle (cm), number of $panicle^{-1}$, grain weight $panicle^{-1}$, grain and straw yield (q ha^{-1}). Swarna recorded higher yield and yield attribute which was at par with NDR-359 and significant over Sarju-52.

Keywords: transplanting, *Oryza sativa*, indo-gangetic, awadh area

Introduction

Rice (*Oryza sativa* L.) is one of the most important cereal crops of *kharif* season. Rice is cultivated world-wide over an area of about 160.68 million ha^{-1} with an annual production of about 650.19 million tonnes. In India it is cultivated over an area of about 39.16 million hectares with an annual production of about 85.59 million tonnes and the productivity of 2.20 tonnes ha^{-1}. Uttar Pradesh is an important rice growing state in the country. The area and production of rice in U.P. is about 13.84 million hectare and 14.00 million tonnes respectively with an average production of 2.35 tonnes (Anonymous, 2013) [1-4]. Production of rice rank second among the food grain and half of the world population receiving the highest (26.2%) calories intake from it in the developing countries of their dietary protein (FAO, 2009) [6]. Rice is an excellent source of carbohydrate and to a certain extent it provides protein to regular human diet. So it is used as staple food crop by about half of the world population and eaten as cooked rice and also used for various preparations inhabiting in the humid tropics and subtropics. Further, rice has commercial and industrial importance also beside grains. Rice straw and rice hulls are used as fodder, mulching, packing and as insulation material etc.

Globally rice is grown on 153 mha (FAO, 2006) [5]. Though its production and consumption is concentrated in Asia, where more than 90% of rice is consumed. India produced 103.41 million tones during 2011-12 from 44.07 million hectares with average productivity of 2270.75 kg/ha. Dry matter accumulation in leaves decreased in test cultivars (PR-106, PR-109 and Basmati-370) with later transplanting dates. Delayed transplanting reduced seedling dry matter in PR-106 and PR-109, but an increase was observed in Basmati-370 with least accumulation of dry matter in leaves.

Different varieties respond variably under different date of transplanting. In view of above facts, the present investigation entitled, "Effect of different date of transplanting on growth and yield of rice (*Oryza sativa* L.) Varieties" was conducted during kharif 2015 with the

ABSTRACT

Wheat is important for food security of India and temperature is one of the most important abiotic factors affecting its productivity. A simulation study was conducted to analyze the effect of seasonal temperature change from normal on wheat productivity in different regions of India and secondly to determine the optimum sowing period for adapting the wheat to changed growing season temperature conditions. The CERES-Wheat simulation model available in DSSAT v4.5.0.0 was used to simulate wheat productivity at seven locations spread across wheat growing area of India. The results showed that the seasonal increase (normal + 3.0°C) in temperature may result in reduction in productivity of wheat sown at any time, except in case of late sown wheat at Palampur (northern hill zone) and Ludhiana (north western plain zone). The decrease in temperature may result in a reduction in productivity of early, timely and late sown wheat at Palampur and at Kanpur. While at Ludhiana productivity of timely and late sown wheat and at Udaipur that of late sown wheat was reduced. At rest of the location the decrease in temperature had favourable affect on wheat productivity. The productivity of early sown wheat at Ranchi and Raipur and that of late sown wheat at rest of the locations was less affected by seasonal increase in temperature as compared to other times of sowing. The wheat productivity at Raipur (Central zone) was most susceptible to change in temperature as compared to rest of the zones.

Introduction

Wheat (*Triticum aestivum* L.) is very important for food security of India and it is the second largest wheat producer in the world and produced 94.88 million tonnes of total wheat from 29.90 million hectares of area during 2011-2012 (Anonymous, 2013).

Many abiotic and biotic factors limit the production of wheat. Amongst the abiotic factors,

Effect of nitrogen levels on yield and yield attributes of rice (*Oryza sativa*) grown under different planting geometry

PRADEEP RAJPUT[1], A.K. SINGH[2], RAVINDRA KUMAR RAJPUT[3] AND ADESH SINGH[4]

Acharya Narendra deva University of Agriculture and Technology, Ayodhya, Uttar Pradesh 224 229

Received : March 2020; Revised accepted : June 2020

ABSTRACT

A field experiment was conducted during the rainy season (*kharif*) 2017 at Kumarganj Ayodhya, Uttar Pradesh, to study the effects of nitrogen on rice (*Oryza sativa* L.) grown under different planting geometry. Four planting geometry, viz. 15 cm × 10 cm, 15 cm × 15 cm, 20 cm × 10 cm and 20 cm × 15 cm and 4 nitrogen levels (0, 60, 120 and 180 kg/ha) were tested in a split-plot design, keeping as main and subplots, respectively, with 3 replications. The crop received a total rainfall of 804.9 mm, while the evaporation was 126.1 mm during the entire crop season. The experimental result revealed that different planting geometry and level of nitrogen had a remarkable influence on almost all the yield-attributing characters and yield of rice. Different yield-attributing characters, viz. panicle length, panicles/m², grains/panicle and test weight, were increased significantly with the increasing level of nitrogen from 0 to 180 kg/ha. On the other hand, plant spacing 20 cm × 10 cm resulted in significantly higher grain yield (5.40 t/ha). The highest grain and straw yields were recorded with the treatment of 20 cm × 10 cm plant spacing and 180 kg N/ha.

Key words: Nitrogen, Planting geometry, Rice, Yield and yield components

Rice is a most important cereal crop of rainy (*kharif*) season, grown under semi-aquatic condition and mostly under submergence or variable ponding conditions (alternate wetting and drying/ 2–4 days after disappearance of ponded water). It is a most important staple food of about more than 60% of total world population. Rice is a nutritious cereal crop, mainly used for human consumption. It is the main source of energy and is an important source of protein, providing substantial amount of the recommended nutrients intake of zinc and niacin. Agronomic management practices such as spacing and nitrogen application are 2 major factors influencing the growth and yield of rice. Optimum dose of nitrogen fertilization plays a vital role in growth and development and grain formation as a result of higher yield of rice plant. Excessive nitrogen fertilization encourages excessive vegetative growth which makes the plant susceptible to insect, pest and diseases, which ultimately reduces yield, whereas less than optimum rate affects both yield and quality of rice to remarkable extent. So, it is essential to find out the optimum rate of nitrogen application for its efficient utilization by the plants for better yield. Since optimum plant spacing ensures plants to grow properly both in their aerial and underground parts through utilization of solar radiation and nutrients, proper manipulation of planting density may lead to enhance the economic yield of transplanted rice (Sampath *et al.*, 2017). Planting geometry determines the planting density or plant population in unit area, thereby influencing the input-use efficiency and yield of the crop. Plant spacing is a major non-monetary input which plays a significant role in achieving greater nutrient-use efficiency with higher growth and yield of the crop. Salahuddin *et al.* (2009) reported that, the lowest number of grains/panicle was produced under control (0 kg N/ha) irrespective of the plant spacing. Though grain yield/ha increased with increasing level of nitrogen up to 180 kg/ha, irrespective of plant spacing. Keeping above points in view, the present investigation was carried out to assess the effect of nitrogen in transplanted rice under varying plant spacing in a sandy-loam soil.

The experiment was conducted during the rainy (*kharif*) season of 2017 at the Narendra Deva University of Agriculture and Technology, Kumarganj (26.47° N, 82.12° E and 113 meters above mean sea-level), Ayodhya, Uttar

Effect of El-Nino on rainfall and Production of major crops and strategies to enhance the productivity of Eastern Plain Zone of U.P.

Rakesh Kumar Kushwaha, AK Singh, AN Mishra, SR Mishra, Alok Kumar Pandey, Arun Kumar and Suraj Kumar

Abstract
District wise monthly rainfall data of Eastern Plain Zone of Uttar Pradesh recorded for the period of 1981 to 2017 were used under the present study. The total rainfall for the summer (March to May), South-West monsoon (June to September), Rabi (October - December) and winter (January - February) seasons were computed year wise for various districts of Eastern Plain Zone of U.P. The analysis was performed to assess the association between El-Nino episodes and rainfall and crop production & crop productivity of Eastern Plain Zone of UP. The average South-West monsoon rainfall, summer rainfall, winter rainfall, and total annual rainfall received during the years with El-Nino were found to be less as compared to normal years, In general, the South-West monsoon rainfall and the annual rainfall was found less during the El-Nino years. The average area, production, and productivity of crops were found to decrease during El-Nino years thereby indicating the risk associated with short duration crops grown under rainfed conditions during the Kharif season. The yield of long duration rabi crops like wheat, chickpea, pea, mustard, etc. grown either on residual soil moisture or irrigated were comparatively less affected during the El-Nino years. There is a need to enhance the agricultural production and productivity of crops during the El-Nino years. As the South-West monsoon rainfall and annual rainfall are likely to less than normal in the region. Short duration crops and varieties as main crops/intercropping system can be adopted in the zone. The productivity of Rabi crops can be improved by the judicious use of fertilizers and the adoption of insect pests & disease control during the early stages of its growth. Plantation crops like fruit and timber plants are likely to yield decline due to a decrease of pre-monsoon rainfall and therefore moisture conservation practices need to be adopted.

Keywords: Climatic variability, rainfall, El-Nino, production, productivity, major crops

Introduction
Rainfall is the direct source for both rainfed and irrigated agriculture. In general, it drives the agricultural productivity of India. The quantum and the distribution of rainfall determine agricultural productivity. In Eastern Plain Zone of Uttar Pradesh, it determines not only the crop selections during the Kharif season but also the crop sequences in double-cropping systems in rabi seasons. Thus the monsoon rainfall and its distribution are very crucial for crop success in Eastern Plain Zone of Uttar Pradesh. Some regions of India receive normal, some parts receive below normal, while some others receive above-normal rainfall. This type of spatial distribution of rainfall is important from the angle of agricultural planning. El-Nino is one of the most important factors that govern monsoonal rainfall over India. Assessment of the role of El-Nino on regional rainfall and agriculture has been attempted for the states of Andhra Pradesh (Rao. *et al.*, 2011) [7], Gujarat (Patel *et al.*, 2014) [5] and Karnataka (Venkatesh *et al* 2015) [8]. Among several factors that govern agricultural production, the weather appears to be the most critical factor as the farmers have no control over it, and its inter and intraseasonal variability' sare difficult to predict with greater reliability and confidence. So, the farmers generally believe that the weather in the coming year will be different from what they were aware of in the past. Prasanna (2014) [6] studied that the focuses on understanding the variations of precipitation during summer monsoon season and its impact on Kharif and rabi foodgrain yield over India. Total foodgrain yield over India during Kharif (summer) season is directly affected by variations in the summer monsoon precipitation (June-September). Hansen and Jones (2000) and Park (2001) [4] observed that recent advances in atmospheric and oceanic research, much of it focusing on El-Nino Southern oscillation and its teleconnections made it possible to forecast climate with useful skill with lead times of several months. Pandey *et al.* (2018) [3] analyzed the ENSO event has a profound impact on summer monsoonal rainfall across

An experiment was conducted at Agronomy research farm A.N.D.U.A.&T Kumarganj, Ayodhya during year 2017-18 on silty loam soil, having pH 8.6, EC 0.36 dSm-1, organic carbon 0.31%, available N, P and K 178.0, 14.5 and 231.5 kg ha^{-1} respectively. Experiment consisted of nine treatment combinations with three levels of nitrogen *viz.* 80, 120 and 160 kg N ha^{-1} and three herbicide treatments *viz.* pendimethalin *fb* 2, 4-D (1 + 0.5 kg a.i. ha^{-1}), clodinafop + metsulfuron(0.06 + 0.004 kg a.i. ha^{-1}) and sulfosulfuron (0.025 kg a.i. ha^{-1}). Results reveal that all the herbicides applied as post-emergence, except pendimethalin. Weed density and dry weight of weeds and nitrogen uptake by weeds increased consistently with increasing rate of nitrogen up to 160 kg N ha^{-1}. Post emergence application of clodinafop + metsulfuron (0.06 + 0.004 kg ha^{-1}) reduced the weed density and dry weight of weeds. Application of 160kg N $ha^{-1}$with clodinafop + metsulfuron (0.06 + 0.004 kg ha^{-1}) proved better to minimize the weed infestation and enhance the yield of wheat.

Keywords

Nitrogen level, Chemical herbicide, Weeds, Wheat

Introduction

Wheat is the fastest growing food grain in India and all set to overtake rice (113 million metric tonnes). The demand of wheat by 2020 has been projected to be between 105 to 109 million tonnes in the country. The increase in production has to be managed from integrated use of resources, as the land area under wheat is not expected to expand further. Weed alone causes average 30-33% reduction in wheat yield. Weeds are considered as one of the major constraints in wheat cultivation. In eastern U.P. wheat field was mainly infested with *Phalaris minor, Avenafatua, Chenopodium album, Cyperus rotundus, Convolvulus arvensis, Anagallis arvensis, Mililotus alba, Medicago denticulata* and *Cynodon dactylon* which compete for light, moisture, nutrients with crop(Singh *et al.,* 2013). The winter months are very cold whereas summers are hot and dry. Western hot winds start from the month of April and continue till the onset of monsoon. Weekly minimum and maximum temperatures during the crop season ranged from 5.50 to 17.20^{0}C and 18.34 to 37.60^{0}C and total rainfall received was 24.62 mm during the entire crop season.

Effect of sowing temperature on growth & yield of Indian Mustard (*Brassica juncea* L.)

Sumant Prasad, AN Mishra, AK Singh and Manoj Kumar

Abstract
A field experiment was conducted during the *Rabi* season of 2015-16 to access the "Effect of sowing temperature on growth and yield of Indian Mustard (*Brassica juncea* L.)" in silty loam soil at Agro-meteorological Research Farm, N.D. University of Agriculture & Technology, Kumarganj, Faizabad. The experiment was conducted with nine treatment combinations consisted of three dates of sowing *viz.* D_1 (7th November), D_2 (17th November) and D_3 (27th November) and three cultivars *viz.* V_1 (Varuna), V_2 (NDR-8501) and V_3 (NDR-4). Results revealed that 7th November sown mustard crop produced significantly higher growth and yield due to fulfilment of optimum thermal requirement and solar light requirement for various processes of plant. Among the different cultivars of mustard, NDR-8501 was found more conducive for growth, development and thermal use efficiency as compared to Varuna and NDR-4. Higher seed yield (19.14q/ha) was recorded under 7th November sowing date having average temperature 24.4 °C as compared to 17th November (21.5 °C) sown mustard crop and 27th November (18.7 °C). Thermal unit (1796 °C days) and Photo-thermal index (84.06) from sowing to maturity produced the high yield of Indian mustard.

Keywords: sowing temperature, Indian mustard, sown mustard crop

Introduction
Rapeseed-mustard is the third important oilseed crop in the world after soybean (*Glycine max* L.) and palm (*Elaeis guineensis* Jacq.) oil. It is grown in subtropical and tropical countries in the world comprise eight cultivated crops of tribe Brassiceae within the family Cruciferae (Brassicaceae). Cool temperature, dry weather with good amount of bright sunshine increases the oil yield. Mustard needs high temperature for vegetative growth (20 °C-32 °C) and cool temperature with clear sky during reproductive growth and maturity. Rapeseed - mustard follows C_3 pathway for carbon assimilation. Therefore, it has efficient photosynthetic response at 15 °C to 20 °C temperature. Rapeseed–mustard crops are grown in diverse agro-climatic conditions ranging from north-eastern/ north-western hills to down south under irrigated/rainfed, timely/ late-sown, saline soils and mixed cropping. Production potentiality of Indian mustard can be fully exploited under these conditions with suitable agronomic practices and varieties.

Among the different agronomic practices, optimum sowing time is very important for mustard production (Mondal and Islam, 1993; Mondal *et al.*, 1999) [2, 3]. Research findings have also shown that sowing date is one of the critical components affecting mustard crop productivity. It is one of the most important agronomic factor and non-monetary input which pave the way for better-use of time and play an important role to fully exploit the genetic potentiality of a variety as it provides optimum growth conditions such as temperature, light, humidity and rainfall. Sowing period information is needed for various other purposes like adjusting crop rotations; cropping patterns, crop growth simulations and climate change impact studies. The temperature and solar radiation play an important role in partitioning of biomass between various organs of plant which is related to, and often governed by phenological phase of the plant and the way in which a crop develops can affect the yield and yield attributes.

The growth phase of the crop should synchronize with optimum environmental conditions for better expression of growth and yield. It is a fact that specified genotypes does not exhibit the same phenotypic characteristics in all environmental conditions. Bora (1997) has reported that the yield potential of different mustard varieties may differ under different agro-climatic conditions because of their inherent capacity. The different genotype growth response varies to different environment and their relative ranking usually differ and ultimately decides the selection of genotypes for a particular or different sowing dates for stabilized higher yields (Eberhort and Russel, 1966 and Perkins and Jinks, 1968) [1, 4]. The mustard genotypes differ in their yielding ability, this calls for a need to generate more information on the response of

Climatic variability analysis of district Bahraich of Uttar Pradesh

Sumant Prasad, AN Mishra, AK Singh and Manoj Kumar

Abstract
The historical data of weather parameters especially rainfall and temperature (maximum and minimum) of district Bahraich of U.P were collected for study from the period of 1987-2016. Result reveals that in district Bahraich of U.P., the annual trend of rainfall have been studied using annual data series of 30 years (1987-2016) and divided into three decades which is 1987-1996, 1997-2006 and 2007-2016 respectively. Annual rainfall of Bahraich gradually declined over the normal 1036.2 (mm) in recent years. Annual average maximum temperature of district Bahraich of U.P. was found increasing trend over normal average maximum temperature (31.1 ^{0}C) during 30years (1987-2016) period. Rise in average maximum temperature by 2.2 ^{0}C was found in the year 2009 over the normal temperature of district Bahraich of U.P. A slight increasing trend of average minimum temperature of about 1.92^{0}C over the normal average minimum temperature (18.08 ^{0}C) was observed. Average temperature was increased by 1.7 ^{0}C over normal average temperature within this 30 years period. A decreasing trend of rainfall and increasing trend of both maximum and minimum temperature resulted into decreased agricultural production with respect to the present grain need scenario for the world population.

Keywords: Rainfall trend, annual rainfall variability, decadal, linear regression analysis

Introduction
Agriculture and related sectors, food security and energy security of India are crucially dependent on the timely availability of adequate amount of water and a conducive climate. The rainfall received in an area is an important factor in determining the amount of water available to meet various demands such as agricultural, industrial, domestic water supply and for hydroelectric power generation. Global climate changes may influence long-term rainfall patterns impacting the availability of water along with the danger of increasing occurrences of droughts and floods. Changes in climate over the Indian region, particularly the SW monsoon, would have a significant impact on agricultural production, water resources management and overall economy of the country. The heavy concentration of rainfall in the monsoon months (June-September) results in scarcity of water in many parts of the country during the non-monsoon periods.

Change in rainfall due to global warming or after 1990's (after industrialization) in the country, may influence the hydrological cycle and rainfall pattern. This compelled to review the demand of water hydrological design and agricultural practices. Therefore, long term trend analysis of rainfall and other weather parameters on different spatial scales will help in framing the future scenario for crop planning and management (Jain & Kumar, 2012) [2]. Keeping above facts in view the present investigation was under taken.

Materials and Methods
The rainfall data of last 30 years (1987-2016) of Bahraich (Uttar Pradesh) were collected. Data were analyzed for observing the past trend of rainfall and temperature. Bahraich is situated at 27°58' N Latitude, 81°55' E Longitude and altitude 126 m at mean sea level (MSL). Bahraich comes under North Eastern Plain Zone U.P. state in India. In North Eastern Plain Zone, consists of 11 districts, namely Bahraich, Shravasti, Gonda, Balrampur, Basti, Siddharthnagar, Sant Kabir Nagar, Gorakhpur, Maharajganj, Padrauna and Deoria. Eastern parts of U.P. has been divided into three agro-climatic zones, namely North eastern plain zone (NEPZ), Eastern plain zone (EPZ) and Vindhyan zone (VZ). As Eastern U.P. stretches from North India towards Eastern, the rainfall of NEPZ of U.P. is higher about 1270 mm as compared to other region of eastern U.P. and with drawl of monsoon is also in similar trend i.e. earlier in NEPZ. Trend analysis for different climatic parameters were done for the Bahraich district of NEPZ region.

ABSTRACT

Field experiment was conducted during *kharif*-2017 at Agronomy Research Farm, Narendra Deva University of Agriculture and Technology, Narendra Nagar, Kumarganj, Faizabad, Uttar Pradesh, to study the effect of planting geometry and nitrogen levels on growth of rice (*Oryza sativa* L.). In this experiment, 4 planting geometry (15x10cm, 15x15cm, 20x10cm and 20x15cm) and 4 Nitrogen levels (0, 60, 120 and 180 kg ha^{-1}) were tested in SPD with 3 replications. The crop received a total rainfall of 804.9mm while the evaporation was 126.1 mm during the entire crop season. The results showed that the plant height, number of tillers m^{-2}, leaf-area index and dry matter accumulation m^{-2}, being at par with 20x15 cm spacing were significantly higher under 20x10 cm than rest of the planting geometry. Nitrogen is also responsible for more leaf area and dry matter production due to higher rate of cell division and cell elongation. The application of nitrogen @ 120 kg N ha^{-1}, being at par with 180 kg N ha^{-1} significantly improved the plant height, number of tillers m^{-2}, leaf area index and dry matter accumulation m^{-2} than rest of the Nitrogen levels. The highest grain and biological yields were also noticed at 20x10 cm spacing and 180 kg N ha^{-1}.

Introduction

Rice (*Oryza sativa* L.) is a most important cereal crop, grown under semi-aquatic condition and mostly under submergence or variable ponding conditions. It is a most important staple food of about more than 60% of total world population. Rice is a nutritious cereal crop, mainly used for human consumption. It is the main source of energy and is an important source of protein providing substantial amounts of the recommended nutrients intake of zinc and niacin. Planting geometry of a crop affects the interception of solar radiation, crop canopy coverage, dry matter accumulation and crop

Effect of El-Nino on rainfall and temperature of Eastern Plain Zone of Uttar Pradesh

Rakesh Kumar Kushwaha, AK Singh, AN Mishra, SR Mishra, Alok Kumar Pandey, Arun Kumar and Suraj Kumar

Abstract
District wise monthly rainfall data of Eastern Plain Zone of Uttar Pradesh recorded during the years 1981 to 2017 were used in the present study. The rainfall totals for the summer (March to May), South-West monsoon (June to September), rabi (October to December) and winter (January to February) seasons were computed year wise for various districts of Eastern Plain Zone of U.P. The inter-seasonal and intra-seasonal variability in weather is believed in recent years to outsmart the abilities of climatologist and statisticians in defining the limits within which these variabilities can be observed. El-Nino is a pervasive climatic phenomenon that was found to be associated with regional climate variations throughout the world. Analysis of long term data suggests an inverse relationship between El-Nino and South-West monsoon rainfall. However, there is no one to one relationship as El-Nino years have not always produced severe drought. The analysis was performed to assess the association between El-Nino episodes on rainfall and temperature in the Eastern Plain Zone of U.P. The average South-West monsoon rainfall, summer rainfall, Winter rainfall, and total annual rainfall received during the years with El-Nino were found to be less compared to normal years, In general, it was observed that the South-West monsoon rainfall and the annual rainfall was found less during the El-Nino years. The mean annual temperature was found not to vary much during El-Nino years.

Introduction
Rainfall is the direct source for both rainfed and irrigated agriculture. In general, it drives the agricultural productivity of India. The quantum and the distribution of rainfall determine agricultural productivity. In Eastern Plain Zone of Uttar Pradesh, It determines not only the crop selections during the Kharif season but also the crop sequences in double-cropping systems during rabi seasons. Thus the monsoon rainfall and its distribution are very crucial for crop success in Eastern Plain Zone of Uttar Pradesh. It is known that whatever be the quantum of rainfall over India, some regions of India receive normal, some parts receive below normal, while some others receive above-normal rainfall. This type of spatial distribution of rainfall is important from the angle of agricultural planning. El-Nino is one of the most important factors that govern monsoonal rainfall over India. Assessment of the role of El-Nino on regional rainfall and agriculture has been attempted for the states of Andhra Pradesh (Rao *et al*., 2011) [5], Gujarat (Patel *et al*., 2014) [4] and Karnataka (Venkatesh *et al*., 2015) [7]. Among several factors that govern agricultural production, the weather appears to be the most critical factor as the farmers have no control over it and its inter and intraseasonal variability are difficult to predict with greater reliability and confidence. So, the farmers generally believe that the weather in the coming year will be different from what they were aware of in the past. In tropical countries like India, a region may experience a dry spell because no storms happen to pass that way for a time. Prediction of such stochastic events is not possible. Climatologists, now see, however, that many climatic variations are part of large scale, slowly evolving patterns. Many critical agricultural decisions from farm to policy level must be made several months before those weather conditions are experienced. Kothawale *et al.* (2010) observed that the during period 1901 to 2007 Indian annual mean, maximum and minimum temperature showed significant warming trends of 0.51 °C, 0.72 °C, and 0.27 °C 100 year^{-1}, respectively. However, severe warming in the recent decade 1998-2007 has accelerated the warming during 1971–2007. The mean, maximum, minimum temperatures have increased by about 0.2 °C per decade for the period 1971-2007. Asseng *et al.* (2010) [1] observed variations in average growing-season temperatures of ±2 °C in the main wheat growing regions of Australia can

To study the influence of planting geometry and nitrogen level on quality attributes nitrogen uptake and economics of rice (*Oryza sativa* L.) under upper gangetic plains region of India

Shashank Shekher Singh, Anil Kumar Singh and Permendra Singh

Abstract
A field experiment was conducted for two years during kharif season of 2017 and 2018 at Agronomy research Farm, N.D. University of Agriculture and Technology, Kumarganj, Ayodhya (U.P.) on sandy loam soil with a pH of 8.1 to study the Influence of planting geometry and nitrogen levels on rice (*Oryza sativa* L.)". The experiment was laid out in split plot design (SPD) with three replications Sixteen treatment combinations; comprised of four planting geometry, viz. (S_1) 15x10 cm, 15x15 (S_2),20x10 (S_3) and 20x15 (S_4) were kept in main plot and four nitrogen level, viz. 0kg/ha (N_0), 60kg/ha (N_1), 120kg/ha (N_2) and 180kg/ha (N_3) were kept in sub plot. Protein content of rice grain was not significantly affected due to planting geometry and N level during both the years of investigation, whereas plant spacing of 20×10cm recorded higher nitrogen uptake in grain which was at par with 15×15cm spacing while significant over rest both of the planting geometry. Cost of cultivation was recorded highest (Rs. 35435/ha) under S_1N_3 under planting geometry of 15×10cm spacing applied with 180kg N/ha followed by (Rs.35045/ha), while application of 120kg nitrogen/ha given in 20×10cm spacing recorded highest gross return Rs.102140/ha followed by Rs. 101845/ha in 15×15cm spacing applied with 180kg N/ha due to higher yield.

Keywords: Planting geometry, nitrogen level, *Oryza sativa* L.

Introduction
Rice (*Oryza sativa* L.) is the primary staple food of India as well as world. More than 60% of the world's population providing major source of the food energy. Globally, total rice consumption was recorded 491.5 million metric tonnes in 2014-15 (Anonymous, 2015-16) [1]. It is the important crop in the country's food security accounting about 44% of the total food grain production and holds about 20% share in national agricultural GDP and provides 43% calorie requirement for more than 70% of Indians.

It is grown in 114 countries across the world on an area about 160 million hectares with annual production of 494.3 million tonnes, and total supply of 711.5 million tonnes (Anonymous, 2015-16) [1]. Plant spacing is also an important factor that needs to be considered during transplanting of rice. Rice plants compete among themselves for space, nutrients, water, sunlight, air. Proper spacing may help to increase maximum leaf Area Index (LAI), light interceptions etc. which are required for better photosynthesis as well as yield of rice.

Nitrogen plays a key role in rice production and it is required in large amount. It is one of the most important limiting nutrient in rice production and has heavy system losses when applied as inorganic sources in puddled field. Nitrogen has a positive influence on the production of effective tillers per plant, yield and yield attributes. It is necessary to find out the suitable dose of nitrogen for efficient management and better yield of rice. A suitable planting geometry and dose of nitrogen is necessary for better yield.

Material and Methods
The field experiment was conducted during Kharif 2017 and Kharif 2018 at Agronomy Research Farm of Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Ayodhya (U.P.). Geographically the experimental site is situated at 26°.47' North latitude and 81°.12' East longitude with is an altitude of 113 m. from mean sea level in the Indo Gangatic Plain Zone of Eastern Uttar Pradesh. The climate in this region is sub humid. The soil is sandyloam with a pH of 8.1. Sixteen treatment combinations; comprised of four planting geometry, viz. (S_1) 15x10 cm, 15x15 (S_2),20x10 (S_3) and 20x15 (S_4) were kept

Response of irrigation scheduling on yield and economics of potato (*Solanum tuberosum* L.) varieties

Shubhranshu Singh, Anil Kumar Singh, Devesh Pathak and Rajkumar Pathak

Abstract
A field experiment was conducted on the topic entitled "Response of irrigation scheduling on yield and economics of potato (*Solanum tuberosum* L.) *varieties."* during the Rabi season of 2019-20 at Main Experiment Statin, Vegetable Research Farm, A. N D. University of Agriculture & Technology Kumarganj, Ayodhya. The treatment consisted of five potato varieties *viz.* K. Ashoka, K. Bahar, K. Neelkanth, K. Khyati, K. Sadabahar, and two irrigation scheduling *viz.* No Water Stress and Water Stress. The experiment was conducted in Factorial RBD and replicated three times. The soil of the experimental field was low in organic carbon (0.40%) and nitrogen (142.57 kg ha^{-1}), medium in available phosphorus (15.73 kg ha^{-1}), and high in potassium (242.23 kg ha^{-1}) with pH 8.3. The planting was done on 3rd November 2019. Among the various irrigation scheduling and potato varieties measure, Kufari Khyati irrigated with No Water Stress recorded higher yield and economics of potato.

Keywords: Potato varieties, irrigation scheduling, tuber & haulm yield, economics

Introduction
Potato is herbaceous annual plant and belongs to the family solanaceae. It has been brought to India from Europe. Ranked of potato by United Nation as the world's 4th most important food crop after rice, wheat and Maize (Anonymous 2006). It is among one of the most diverse and nutritious crop on the earth and content approximately 78% water 22% dry matter and less than 1% fat potato contains at least 12 essential amino acid, Minerals and is also source of vitamin C, thiamine, Iron and Folic acid. It is a good source of Carbohydrates with low fat contains which makes its balance food due to high protein calorie ratio (70 gm protein: 1000 kcal) and short vegetative cycle, potatoes yield substantially more edible energy, protein and dry matter per unit area per unit time. A field experiment on sandy loam soil during winter season of 2004-05 and 2005-06 at Indian Agricultural Research Institute, New Delhi. The treatments comprised of 5 irrigation levels (irrigation at critical stages of potato (Solanum tuberosum L.), irrigation at critical stages of French bean (Phaseolus vulgaris L.), and irrigation at 0.8, 1.2 and 1.6 IW/CPE ratio) as main plots and 3 cropping systems (sole potato, sole French bean and potato + French bean in 2:3 row ratio). Irrigation at IW/CPE ratio of 1.6 produced the highest tuber yield followed by irrigation at 1.2 IW/CPE ratios, while the lowest tuber yield was achieved with irrigation at 0.8 IW/CPE ratios (Tyagi *et al,* 2012) [7].

Materials and Methods
A field experiment was conducted on the topic entitled "Response of irrigation scheduling on yield and economics of potato (*Solanum tuberosum* L.) varieties." during the Rabi season of 2019-20 at Main Experiment Statin, Vegetable Research Farm, A. N D. University of Agriculture & Technology Kumarganj, Ayodhya. The treatment consisted of five potato varieties *viz.* K. Ashoka, K. Bahar, K. Neelkanth, K. Khyati, K. Sadabahar, and two irrigation scheduling *viz.* No Water Stress and Water Stress. The experiment was conducted in Factorial RBD and replicated three times. The soil of the experimental field was low in organic carbon (0.40%) and nitrogen (142.57 kg ha^{-1}), medium in available phosphorus (15.73 kg ha^{-1}), and high in potassium (242.23 kg ha^{-1}) with pH 8.3. The planting was done on 3rd November 2019.

Result and Discussion
Tuber and Haulm Yield (q/ha)
Tuber yield and haulm yield (q ha^{-1}) as influenced by various irrigation scheduling and potato

N D. University of Agriculture & Technology Kumarganj, Ayodhya. The treatment consisted of five potato varieties *viz*. K. Ashoka, K. Bahar, K. Neelkanth, K. Khyati, K. Sadabahar, and two irrigation scheduling *viz*. No Water Stress and Water Stress. The experiment was conducted in Factorial RBD and replicated three times. The soil of the experimental field was low in organic carbon (0.40%) and nitrogen (142.57 kg ha^{-1}), medium in available phosphorus (15.73 kg ha^{-1}), and high in potassium (242.23 kg ha^{-1}) with pH 8.3. The planting was done on 3rd November 2019. Among the various irrigation scheduling and potato varieties measure, Kufari Khyati irrigated with No Water Stress recorded higher in terms of growth and yields.

Keywords: Varieties of potato, irrigation scheduling, growth, plant height, number of haulm, tuber yield and yields

1. Introduction

The potato is a starchy tuber of the plant *Solanum tuberosum* and is a root vegetable native to the Americas, with the plant itself being a perennial in the nightshade family Solanaceae. Potatoes were introduced from the Americas to Europe in the second half of the 1+6th century by the Spanish. Now a dayds potatoes are a staple food in many parts of the world and an integral part of much of the world's food supply. As of 2014, potatoes were the world's 4th largest food crop after maize, wheat, and rice. A typical raw potato is 79% water, 17% carbohydrates (88% is starch), 2% protein, and contains negligible fat (see table) according to the United States Department of Agriculture. In a 100-gram (3½-ounce) portion, raw potato provides 322 kilojoules (77 kilocalories) of food energy and is a rich source of Vitamin B6 and Vitamin C (23% and 24% of the Daily Value, respectively), with no other vitamins or minerals in significant amount (see table). The potato is rarely eaten raw because raw potato starch is poorly digested by humans. When a potato is baked, its contents of vitamin B6 and vitamin C decline notably, while there is little significant change in the amount of other nutrients. The cultivated area is about 2.7 million hectares irrigated by surface irrigation from total cultivated area of 3.9 million hectares according to data issued by Ministry of Agriculture, Egypt in 2013. Despite this progressive water shortage farmer continue to use surface irrigation. Poor management, uniformity and distribution of water have been cited as the most frequent problems of surface irrigation, resulting in waterlogging, salinization and less water use efficiency (AbouKheira, 2009) [1]. Potato is considered one of the main important vegetable ranks as manufacture and export crop among the different vegetable crops in Egypt. About 178 thousand hectares are only cultivated in spring and winter seasons. Total production of potato in Egypt is about four million tons per year.

Irrigation scheduling is defined as deciding when to irrigate and how much water to apply. Several types of irrigation scheduling have been documented. Martin *et al*. (1990) classified methods of irrigation scheduling as belonging to one of two broad groups: soil water balance computations, and soil and/or crop monitoring techniques. Deficit irrigation lowers yield due to reduced leaf area and/or reduced photosynthesis per unit leaf area. (Van Loon, 1981) [9] Wateris the vital source for crop production and is the most limiting factor in Indian agriculture.

Effect of different planting density and nitrogen levels on growth characters and yield of rice (*Oryza sativa*) grown under eastern Uttar Pradesh

Shashank Shekher Singh, AK Singh, Pradeep Rajput and Permendra Singh

Abstract
The experimental result revealed that different planting geometry and level of nitrogen had a remarkable influence on almost all the growth characters and yield of rice. Growth characters, *viz.* plant height, number of tillers/m^2, Leaf area index, dry matter accumulation/m^2 were increased significantly with the increasing level of nitrogen from 0 to 180 kg/ha in both of year. On the other hand, plant spacing (20cm x 10cm) and produced significantly higher grain yield (3.95 t/ha in 2017 and 4.65 t/ha in 2018). The highest grain and straw yields were recorded with the treatment of 20 cm × 10 cm plant spacing and 180 kg N/ha in 2017 and 2018 respectively.

Keywords: Nitrogen, planting geometry, rice, growth and yield

Introduction
Rice (*Oryza sativa* L.) is the foremost staple food for more than 60% of the world's population providing major source of the food energy. It is grown in 114 countries across the world on an area about 160 million hectares with annual production of 494.3 million tones, and total supply of 711.5 million tones. Globally, total rice consumption was recorded 491.5 million metric tonnes in 2014-15 (Anonymous, 2015-16). More than 90% of the world's rice is produced and consumed in Asia. It is the important crop in the country's food security accounting about 44% of the total food grain production and holds about 20% share in national agricultural GDP and provides 43% calorie requirement for more than 70% of Indians. In India rice covers highest area by a single crop and it is also maximum area among all rice growing countries. It is an important crop in India which occupied 43.9 million hectares with the annual production of 103.6 million tonnes (Ministry of Agriculture, Directorate of Economics and Statistics, 2015). It is estimated that by the year 2025, the world's farmers should produce about 60% more rice than at present to meet the food demands of the expected world population at that time and by 2035, 114 million tones additional milled rice need to produce (Kumar and Ladha, 2011) [2]. Agronomic management practices such as spacing and nitrogen application are two major factors influencing the growth and yield of rice. Optimum dose of nitrogen fertilization plays a vital role in growth and development and grain formation as a result of higher yield of rice plant. Excessive nitrogen fertilization encourages excessive vegetative growth which makes the plant susceptible to insect, pest and diseases, which ultimately reduces yield whereas less than optimum rate affects both yield and quality of rice to remarkable extent. So, it is essential to find out the optimum rate of nitrogen application for its efficient utilization by the plants for better yield. Optimum plant spacing ensures plants to grow properly both in their aerial and underground parts through utilization of solar radiation and nutrients, therefore proper manipulation of planting density may lead to increase in the economic yield of transplanted rice (Sampath *et al.*, 2017) [7]. Planting geometry determines the planting density or plant population in unit area thereby influencing the input use efficiency and yield of the crop. Plant spacing is a major non monetary input which plays a significant role in achieving greater nutrient use efficiency with higher growth and yield of the crop. Salahuddin *et al.* (2009) [6] reported that the lowest number of grains/panicle was produced under control (0 kg N/ha) irrespective of the plant spacing. Though, grain yield /ha increased with increasing level of nitrogen up to 180 kg/ha, irrespective of plant spacing. Keeping above points in mind the present investigation was carried out to assess the effect of nitrogen in transplanted rice under varying plant spacing in a sandy loam soil.

Effect of different date of transplanting on growth and yield of rice (*Oryza sativa* L.) varieties under Indo-gangetic plains of Awadh area

Shashank Shekher Singh, Anil Kumar Singh and Permendra Singh

Abstract
The field experiment entitled "Effect of different date of transplanting on growth and yield of rice (*Oryza sativa* L.) varieties" was conducted at Agronomy Research Farm of Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj), Faizabad, Uttar Pradesh during *Kharif* season of 2015 with an objective to find out suitable date of transplanting of rice, the treatment consisted of three transplanting date (15 July, 25 July and 5 August) and three varieties (Sarju-52, NDR-359 and Swarna) there were 9 treatment combinations.

The values of growth contributing characters *viz.* plant height (cm), number of tillers, dry matter accumulation, leaf area index and yield attributes like number of panicles m^{-2}, length of panicle (cm), number of $panicle^{-1}$, grain weight $panicle^{-1}$, grain and straw yield (q ha^{-1}) were increasing significantly with 15 July date of transplanting followed by 25 July date of transplanting and significantly superior with 5 August date of transplanting. In case of variety the performance the growth characters like plant height (cm), number of $tillers m^{-2}$, dry matter accumulation (g m^2) leaf area index and yield attributes like number of panicles m^{-2}, length of panicle (cm), number of $panicle^{-1}$, grain weight $panicle^{-1}$, grain and straw yield (q ha^{-1}). Swarna recorded higher yield and yield attribute which was at par with NDR-359 and significant over Sarju-52.

Introduction

Rice (*Oryza sativa* L.) is one of the most important cereal crops of *kharif* season. Rice is cultivated world-wide over an area of about 160.68 million ha^{-1} with an annual production of about 650.19 million tonnes. In India it is cultivated over an area of about 39.16 million hectares with an annual production of about 85.59 million tonnes and the productivity of 2.20 tonnes ha^{-1}. Uttar Pradesh is an important rice growing state in the country. The area and production of rice in U.P. is about 13.84 million hectare and 14.00 million tonnes respectively with an average production of 2.35 tonnes (Anonymous, 2013) [1-4]. Production of rice rank second among the food grain and half of the world population receiving the highest (26.2%) calories intake from it in the developing countries of their dietary protein (FAO, 2009) [6]. Rice is an excellent source of carbohydrate and to a certain extent it provides protein to regular human diet. So it is used as staple food crop by about half of the world population and eaten as cooked rice and also used for various preparations inhabiting in the humid tropics and subtropics. Further, rice has commercial and industrial importance also beside grains. Rice straw and rice hulls are used as fodder, mulching, packing and as insulation material etc.

Globally rice is grown on 153 mha (FAO, 2006) [5]. Though its production and consumption is concentrated in Asia, where more than 90% of rice is consumed. India produced 103.41 million tones during 2011-12 from 44.07 million hectares with average productivity of 2270.75 kg/ha. Dry matter accumulation in leaves decreased in test cultivars (PR-106, PR-109 and Basmati-370) with later transplanting dates. Delayed transplanting reduced seedling dry matter in PR-106 and PR-109, but an increase was observed in Basmati-370 with least accumulation of dry matter in leaves.

Different varieties respond variably under different date of transplanting. In view of above facts, the present investigation entitled, "Effect of different date of transplanting on growth and yield of rice (*Oryza sativa* L.) Varieties" was conducted during kharif 2015 with the

Abstract
The present investigation entitled "To find out the suitable irrigation scheduling of transplanted rice, to assess the growth and yield of various treatments." A field experiment was conducted at Agronomy Research Farm of, Acharya Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya (U.P.) during *Kharif* season of 2020-21. The experiment was laid out in Randomized block design with four replications and eight treatments viz. One Irrigation at tillering, Two Irrigation at tillering + PI stage, Three Irrigation at tillering + PI + Flowering stage, Four Irrigation at tillering + PI + Flowering + milking stage, Two Irrigation at tillering + milking stage, Two Irrigation at PI + milking stage, Five Irrigation at tillering + PI + Flowering + milking + dough stage, No Irrigation. Results revealed that irrigation scheduling among treatments application Five Irrigation at tillering + PI + Flowering +milking +dough stage proved superior to other treatments with respect to higher crop growth, yield and yield attributes.

Keywords: Irrigation scheduling

Introduction
Rice (*Oryza sativa* L.) is one of the most important cereal crops belongs to Poaceae (Gramineae) family, diverse ecosystem of rice cultivated in India. It is most important staple food of about more than 65% of total world population. Rice occupies a pivotal role in Indian agriculture and it is staple food for more than 70% of population and a source of a livelihood for about 120-150 million rural households. It accounts for about 43% of total food grain production and 55% of total cereal production in the country. Rice is grown on over 158.7 million hectares around the world, with an annual production of about 700. Million tonnes and average productivity 4.19 tonnes per hectares. The Asian region produces and consumes about 90% of all rice formed worldwide. It is grown on 43.78 million hectare in India, producing 115.60 million tonnes with an average productivity of 25.78 q ha^{-1} (Anonymous, 2018).
Uttar Pradesh is the largest rice growing state after west Bengal where rice is grown in 5.81 million hectare with annual production of 13.27 million tonnes and average productivity of UP is 22.83 q ha^{-1} which is considered low as compared to productivity of Punjab 43.66 q ha^{-1}, Haryana 31.81 q ha^{-1} and West Bengal 29.26 q ha^{-1} (Anonymous, 2018). Transplanting at the right time may be one of the agronomic strategies maximizing a crops maximum potential and photoperiod sensitivity, resulting in higher yield and better grain quality. Delay in seeding causes poor emergence worse yield attributes, and ultimately lower yields. Manual transplanting require a lot of labors and also very expensive. Scarcity of labors in another major problem in some paddy growing areas of the countries. Rice has substantially lower water consumption efficiency than other crops. (Bouman 2009) [1]. actices such as improved irrigation management (Bouman and Tuong, 2001) [2] Earlier rice crop was transplanted in may under maximum temperature of 39-42 C, which increased the irrigation water requirement of crop to the tune of 180-240 cm per season (Brar, *et al*. 2012) [3]. Yield may decline under this practice, but water saving and water productivity increases. These previous studies focused on the applied amount of irrigation water without much attention in matching rain occurrence with the crop high needed water stage. Basically the main target was to keep daily soil moisture at saturation level and irrigation frequently stopped when rain occurred. However, high water productivity can not be achieved in irrigation regardless of rainfall occurrence opportunities at specific growth stage, specially for an area like Taiwan where

The economic feasibility of various treatment combinations of rice (*Oryza sativa* L.)

Shashank Shekher Singh, Permendra Singh, Ashutosh Pratap Singh and Anil Kumar Singh

Abstract
A field experiment was conducted on the topic entitled "The economic feasibility of various treatment combinations of rice (*Oryza sativa* L.)" during two consecutive *kharif* seasons of 2017 and 2018 at Agronomy Research Farm, Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Ayodhya (U.P.) Experiment was comprised with sixteen treatment combinations *viz.* four planting geometry and four nitrogen levels in split plot design. Four planting geometry i.e. 15x10 cm, 15x15 cm, 20x10 cm and 20x15 cm were kept in main plots and four nitrogen levels i.e. 0 kg N/ha, 60 kg/N ha, 120 kg N/ha and 180 kg/N ha were kept in sub plots. The experiment was replicated three times. Results reveal that application of 120 kg N/ha applied in 20cm×10cm planting geometry recorded highest gross nutrient Rs. 102140/ha; net return Rs. 68415/ha and highest net return per rupees invested 2.02.

Introduction

Rice (*Oryza sativa* L.) is the foremost staple food for more than 60% of the world's population providing major source of the food energy. It is grown in 114 countries across the world on an area about 160 million hectares with annual production of 494.3 million tonnes, and total supply of 711.5 million tonnes (Anonymous, 2015-16) [1]. Globally, total rice consumption was recorded 491.5 million metric tonnes in 2014-15 (Anonymous, 2015-16) [1]. More than 90% of the world's rice is produced and consumed in Asia. It is the important crop in the country's food security accounting about 44% of the total food grain production and holds about 20% share in national agricultural GDP and provides 43% calorie requirement for more than 70% of Indians. In India rice covers highest area by a single crop and it is also maximum area among all rice growing countries. It is an important crop in India which occupied 43.9 million hectares with the annual production of 103.6 million tonnes (Ministry of Agriculture, Directorate of Economics and Statistics, 2015). It is estimated that by the year 2025, the world's farmers should produce about 60% more rice than at present to meet the food demands of the expected world population at that time and by 2035, 114 million tones additional milled rice need to produce.

Rice farming in the state is most vulnerable and risk prone due to complex ecological situations marked by frequent flood or drought or both. It is clear that yield is stagnating around ≤ 2.0 t q/ha since 2001-2002 except in the year 2002-2003, 2004-2005 and 2009- 2010 due to erratic rainfall distribution causes excess water stagnation/ drought or both in different years. Rice is grown in all the districts of Uttar Pradesh with low to high acreage. It is part of the nearly every meal and it is grown on a majority of the rural farms. Uttar Pradesh is the leading producer of rice and rank 3rd in the country. Annual rice production is around 12 metric ton in state. It is cultivated mainly in Kharif season (wet season) in around 5.90 million hectares followed by Zaid (summer season) 35000-40000 hectare only. As regards the Boro rice, it is grown in only deeply flooded areas around 3000 ha or so mainly in the eastern districts of the Uttar Pradesh. The average productivity of the state is around 2 t/ha (Ministry of Agriculture, Directorate of Economics and Statistics, 2015). There are three rice growing seasons in the state. These are wet season (*Kharif*), winter season (Boro) and *Summer* season (Zaid). The growing period of rice in difference seasons are *Kharif* – June – July to October-November; Boro – October- November to April – May and *Zaid* – February to May- June. *Kharif* is the main rice growing season in the state and more than 98% rice (around 5.9 mha) is cultivated during kharif season covering early, medium and long duration varieties.

Effect of integrated nutrient management (INM) on growth parameters of timely sown wheat (*Triticum aestivum* L.)

Chandra Shekhar, Vishuddha Nand, Anil Kumar Singh, Navaneet Kumar, Deepak Kumar and Satyaveer Singh

Abstract
An experiment was conducted during *rabi* season of 2018-19 and 2019-20 at Agronomy Research Farm, ANDUA&T Kumarganj, Ayodhya (U.P.) India. The experiment consists of fourteen treatments were laid out in Randomized Block Design (RBD) with three replications. As per experiment the results revealed that the growth parameters were significantly influenced by different integrated nutrient management at successive growth stages of crop except 30 DAS. Crop growth rate increased progressively with increase in duration of wheat crop. Crop growth rate was maximum up to 90 DAS and thereafter, a slow increase in growth was obtained up to harvest. Among the integrated nutrient management, 75% RDN+25% N through (poultry manure) + ZnSO4 @ 25 kg ha^{-1} + Sulphur @ 40 kg ha^{-1} proved to found better as regarding of plant height (83.90, 95.90 cm), dry matter accumulation (1073.50, 1111.00 g m^{-2}) and number tillers per (334.66, 341.36 m^{-2}) at harvest stage in respective years. Whereas leaf area index was measured maximum at 60 DAS after than it declined. The minimum growth parameters were observed under control.

Keywords: Growth, wheat, plant height, dry matter, LAI and tillers

Introduction
Wheat (*Triticum aestivum* L.) being a major cereal crop cultivated in India and abroad. It belongs to Poaceae family. Wheat generally grown in *rabi* season and it can be successful grown in the tropical and sub-tropical climates and also in the temperate zone. Wheat can tolerate to severe cold and snow and resume growth with the setting in warm weather in spring. It can be cultivated from sea level to an altitude of 3300 meters. The most favorable climatic condition for wheat cultivation is cool and moist weather during the vegetative growth period followed by dry, warm weather for the grain to mature and ripening. The optimum temperature range for ideal germination of wheat seed is 20-25 ^{0}C. Warm and dry climatic conditions are not suited for wheat during the heading and flowering stage, excessively high or low temperatures and drought are harmful to wheat. Cloudy weather with high humidity and low temperatures is conducive for rust attack. It requires about 25-30^{0}C optimum average temperature at the time of ripening. The temperature at the time of grain filling and development are very crucial for yield. Temperatures above 25^{0}C tend to depress grain weight. Wheat contains more protein in the form of gluten than other cereals crop. Wheat occupied an acreages about 215.29 million ha with production of 730.84 million metric tonns with productivity of 3390 kg ha^{-1} (Anonymous, 2019) [2]. In India it is grown on 29.55 million ha^{-1} (13.43% global area) with the production of 101.20 million tonns (1.3% rises previous year) and productivity about 3424 kg ha^{-1} (Anonymous, 2019) [2]. In Uttar Pradesh wheat occupied about 9.78 million ha^{-1} achieved rank first in production (31.99 million tonns) with productivity (3269 kg ha^{-1}). But the productivity is comparatively lower than that the Punjab (5030 kg ha^{-1}) and Haryana (4410 kg ha^{-1}).

Present time adoption of intensive cropping system will meet the food as per the demands of increasing population, it requires high input energy, which are not only responsible for environment degradation but also increased the cost of cultivation. After the green revolution, production of crops has increased to a great extent due to the use of chemical fertilizers but their indiscriminate use has led to soil sickness, ecological hazards and depletion of other sources of energy. The recent energy crisis, high fertilizer cost and low purchasing power of the farming community have made it necessary to re-think alternatives.

Response of Indian mustard (*Brassica juncea* L.) to source and levels of sulphur on oil content and nutrient uptake

Shrimannarayan Dubey, AK Singh, Ravi Verma and Shivanand Maurya

Abstract
The present investigation entitled "Response of Indian mustard (*Brassica Juncea* L.) to sources and levels of sulphur on oil content and nutrient uptake." was carried out during *Rabi* season of 2018 and 2019 at Agronomy Research Farm of the A.N.D. University of Agriculture and Technology, Kumarganj, Ayodhya (U.P.). The 36 treatment combinations having three sulphur sources *viz.* Phosphogypsum, Elemental Sulphur and Single Super Phosphate were investigated with four levels of sulphur *viz.* 0.00 kg ha^{-1}, 20 kg ha^{-1}, 40 kg ha^{-1} and 60 kg ha^{-1} was kept in different plots. The experiment in F-RBD and replicated in three times. The total Nitrogen, Phosphorus, Potassium and Sulphur uptake by crop was highest recorded 106.55, 36.93, 150.63 and 20.93 kg ha^{-1} respectively with phosphogypsum source of sulphur significantly as compared to rest two sources of sulphur in seed, stover and crop during both the years of experimentation. As far as doses of sulphur was concerned, Nitrogen, Phosphorus, Potassium and Sulphur uptake increased with simultaneous increase in S doses resulting maximum value at 60 kg Sulphur ha^{-1}(108.17, 37.50, 152.73 and 21.93 kg ha^{-1} respectively) which exhibited significance over rest of sulphur doses. The trend of increase was similar in uptake by seed, stover and crop during both the years of study. The highest oil content 38.57% and 38.81% in seed was noted during first and second year respectively from phosphogypsum source of sulphur and level of sulphur is 60 kg Sulphur ha-1 which exhibited statistical similarity with rest sources of sulphur and level of sulphur.

Keywords: Indian mustard, oil content, nutrient uptake

Introduction
Indian mustard (*Brassica juncea* L.) is locally called Rai, Raya, Laha and Raiya, whereas, rapeseed is called Sarson, Toria, yellow Toria. Its green tender plants are used for preparing vegetable dish commonly called as "Sarson Ka Saag". The oil is utilized for human consumption throughout northern India for cooking and frying purposes. The whole seed is used as condiment in the preparation of pickles and for flavoring curries and vegetables. The mustard oil is also used in preparing vegetable ghee, hair oil, medicines, soaps, lubricating oil and in tanning industries. The oil content in mustard seeds varies from 37-49 per cent (Bhowmik *et al.,* 2014) [2]. The seeds are highly nutritive containing 38-57% erucic acid, 5-13% linolic acid and 27% oleic acid.

Oilseed crops occupy an important place in Indian agricultural economy as well as in human life. They are not only rich sources of energy and carriers of fat soluble vitamins A, D, E and K but they form the ingredients of foods and flavors; cosmetics and condiments; soap and detergents; lubricants and laxatives and also known for their medical and therapeutic use. Rapeseed-mustard is the third most important edible oilseed crop in India having 30 to 48 per cent oil content after soybean and groundnut.

Mustard seed has content 28 to 36% protein with a high nutritive value. Mustard is one of the major sources of oil in India. Indian mustard (*Brassica juncea* L.) is the most important *rabi* season oilseed crop, which thrives best in light to heavy loam soil in areas having 25 to 40 cm rainfall. Mustard oil is mainly used for cooking, frying and in pickles. The oil cake left after extraction is utilized as cattle feed and manure. Its oil cake contains 5.2, 1.8 and 1.2 per cent N, P and K, respectively.

Sulphur is the fourth major plant nutrient after nitrogen, phosphorus and potassium for Indian agriculture. It is essential for synthesis of amino acids, proteins, oils, and a component of vitamin A and activates enzyme system in plant. Three amino acids *viz.* methionine (21% S), cysteine (26% S) and cystine (27%S) contain S which are the building blocks of proteins about 90% of sulphur is present in these amino acids.

Abstract
The present investigation entitled "Response of Indian mustard (*Brassica Juncea* L.) to sources and levels of sulphur on oil content and nutrient uptake." was carried out during *Rabi* season of 2018 and 2019 at Agronomy Research Farm of the A.N.D. University of Agriculture and Technology, Kumarganj, Ayodhya (U.P.). The 36 treatment combinations having three sulphur sources *viz.* Phosphogypsum, Elemental Sulphur and Single Super Phosphate were investigated with four levels of sulphur *viz.* 0.00 kg ha^{-1}, 20 kg ha^{-1}, 40 kg ha^{-1} and 60 kg ha^{-1} was kept in different plots. The experiment in F-RBD and replicated in three times. The total Nitrogen, Phosphorus, Potassium and Sulphur uptake by crop was highest recorded 106.55, 36.93, 150.63 and 20.93 kg ha^{-1} respectively with phosphogypsum source of sulphur significantly as compared to rest two sources of sulphur in seed, stover and crop during both the years of experimentation. As far as doses of sulphur was concerned, Nitrogen, Phosphorus, Potassium and Sulphur uptake increased with simultaneous increase in S doses resulting maximum value at 60 kg Sulphur ha^{-1}(108.17, 37.50, 152.73 and 21.93 kg ha^{-1} respectively) which exhibited significance over rest of sulphur doses. The trend of increase was similar in uptake by seed, stover and crop during both the years of study. The highest oil content 38.57% and 38.81% in seed was noted during first and second year respectively from phosphogypsum source of sulphur and level of sulphur is 60 kg Sulphur ha-1 which exhibited statistical similarity with rest sources of sulphur and level of sulphur.

Keywords: Indian mustard, oil content, nutrient uptake

Introduction
Indian mustard (*Brassica juncea* L.) is locally called Rai, Raya, Laha and Raiya, whereas, rapeseed is called Sarson, Toria, yellow Toria. Its green tender plants are used for preparing vegetable dish commonly called as "Sarson Ka Saag". The oil is utilized for human consumption throughout northern India for cooking and frying purposes. The whole seed is used as condiment in the preparation of pickles and for flavoring curries and vegetables. The mustard oil is also used in preparing vegetable ghee, hair oil, medicines, soaps, lubricating oil and in tanning industries. The oil content in mustard seeds varies from 37-49 per cent (Bhowmik *et al.*, 2014) [2]. The seeds are highly nutritive containing 38-57% erucic acid, 5-13% linolic acid and 27% oleic acid.

Oilseed crops occupy an important place in Indian agricultural economy as well as in human life. They are not only rich sources of energy and carriers of fat soluble vitamins A, D, E and K but they form the ingredients of foods and flavors; cosmetics and condiments; soap and detergents; lubricants and laxatives and also known for their medical and therapeutic use. Rapeseed-mustard is the third most important edible oilseed crop in India having 30 to 48 per cent oil content after soybean and groundnut.

Mustard seed has content 28 to 36% protein with a high nutritive value. Mustard is one of the major sources of oil in India. Indian mustard (*Brassica juncea* L.) is the most important *rabi* season oilseed crop, which thrives best in light to heavy loam soil in areas having 25 to 40 cm rainfall. Mustard oil is mainly used for cooking, frying and in pickles. The oil cake left after extraction is utilized as cattle feed and manure. Its oil cake contains 5.2, 1.8 and 1.2 per cent N, P and K, respectively.

Sulphur is the fourth major plant nutrient after nitrogen, phosphorus and potassium for Indian agriculture. It is essential for synthesis of amino acids, proteins, oils, and a component of vitamin A and activates enzyme system in plant. Three amino acids *viz.* methionine (21% S), cysteine (26% S) and cystine (27%S) contain S which are the building blocks of proteins about 90% of sulphur is present in these amino acids.

Introduction
Indian mustard (*Brassica juncea* L.) is locally called Rai, Raya, Laha and Raiya, whereas, rapeseed is called Sarson, Toria, yellow Toria. Its green tender plants are used for preparing vegetable dish commonly called as "Sarson Ka Saag". The oil is utilized for human consumption throughout northern India for cooking and frying purposes. The whole seed is used as condiment in the preparation of pickles and for flavouring curries and vegetables. The mustard oil is also used in preparing vegetable ghee, hair oil, medicines, soaps, lubricating oil and in tanning industries. The oil content in mustard seeds varies from 37-49 per cent (Bhowmik *et al.*, 2014) [2]. The seeds are highly nutritive containing 38-57% erucic acid, 5-13% linolic acid and 27% oleic acid.

Rapeseed-mustard (*Brassica spp.*) is a major group of oilseed crops of the world with second largest acreage in India after China. Rapeseed-mustard contributed 24.5% in total oilseed production in the country. Indian mustard is preferred due to its high yield potential and oil content. Indian mustard has multiple uses as a spice or condiment in preparation, seasoning and stuffing of several foods and pickles in India. Yield potential of this crop can be explored by the use of agronomic-techniques. Among them, time of sowing is an important non monetary input. Variation in the sowing date, day length and temperature interact to influence growth, yield and quality of a crop. The optimum time of sowing can provide congenial conditions to have maximum light interception, best utilization of moisture and nutrients from early growth stage to seed filling stage. Sowing time is very important for mustard production. It is responsive to plant nutrient, especially nitrogen. Nitrogen is considered to be the most important nutrients for the crop to activate the metabolic activity and transformation of energy, chlorophyll and protein synthesis. Nitrogen also affects uptake of other essential nutrients and it helps in the better partitioning of photosynthetic to reproductive parts which increases the seed: stover ratio.

Sulphur occurs in soils mainly organic forms along with smaller amounts of inorganic forms (SO_4^{2-}) before it is used by the plant. Microbial mineralization of sulphur in soil is affected by various factors including moisture content, pH, temperature and soil aeration. Chemical fertilizers being used for supplementing the major nutrients are generally either deficient or low in sulphur content. Thus, the use of high analysis sulphur fertilizers can provide an impetus to oilseed production in the country. High analysis sulphur containing material may be gypsum, elemental sulphur and single super phosphate etc. which could be quite useful in augmenting the mustard production. Gypsum are generally used as soil amendments in salt

ABSTRACT

A field experiment was directed during the rabi period of 2020-21 in the sandy topsoil of A.N.D. University of Agriculture and Technology, Kumarganj, Ayodhya (U.P.). The investigation was directed in Split Plot Design (S.P.D.), comprising of three growing environments/ambient temperature *viz.* 31st October (22.6°C), 10th November(21.2°C), 20th November(19.4°C) and three cultivars *i.e.* NDR-8501 (V1), Kranti (V2) and Varuna (V3). The experiment was replicated four times. Results revealed that the highest thermal unit (1667.2 days) and thermal use efficiency (0.61 g/m²/°days) was recorded at developing climate/encompassing temperature of 31st October (T1) (22.6°C)while least gathered hotness units from planting to development (1468.9°C days) was seen under the developing climate/surrounding temperature of twentieth November. The late-planted mustard crop recorded the least GDD prerequisite at every one of the stages. The least Thermal use proficiency from planting to development 0.435g/m²/°days was seen under developing climate/encompassing temperature (tenth November)(21.2°C). Late planted cultivars recorded the least warm use effectiveness necessity at all stages.

ABSTRACT

This study evalutes 20 gentotypes of green gram *Vigna radiata* (L.) Wilczek for their susceptibility levels against the spotted pod borer *Maruca vitrata* (F.). The experiment was done during *kharif* 2014 and 2015 at the Agricultural Research Farm, Banaras Hindu University, Varanasi, Uttar Pradesh. The infestation was assessed at the flowering stage based on larval incidence/ plant. The results revealed that the incidence was observed in the 37th standard meteorological week (SMW) with a peak during the 40th SMW, and varied from 0.53 to 3.01 larva/ plant.Maximum larval population was observed in IPM 306-6 followed by IPM 05-3-22 and ML 1256 and the least with PM-5 followed by IPM 306-1 and ML 515. The genotype PM-5 (7.72 q/ ha) closely followed by IPM 306-1 (6.96 q/ ha) and HUM-16 (6.58 q/ ha) gave the maximum yield.

Key words: *Maruca vitrata,* green gram, genotypes, larvae/plant, yield, resistance, susceptible, yield, seasonal incidence

Green gram *Vigna radiata* (L.) Wilczek is one of the important legume crop with its origin in the India-Burma region, and secondary origin as Bihar, Munger district (Singh, 2001). Insect pests play an important role in the production (Swaminathan et al., 2012). Husain et al. (2002) reported more than 150 species of insect pests, out of which 25 species inflict heavy losses. Spotted or legume pod borer *Maruca vitrata* (F.) is the most serious pest, and the low yield is attributed to its regular outbreaks (Singh and Srivastava, 2017). It has extensive host range, is a persistent pest and cause heavy loss (Vishakanthaiah and Jagadeesh, 1980; Singh and Allen, 1980; Zahid et al., 2008). Host plant resistance (HPR) is an important IPM strategy against such pests and it is ecofriendly (Dhillon and Sharma, 2012). The present study evaluates the resistance to the *M. vitrata* in some promising green gram genotypes.

MATERIALS AND METHODS

The screening experiments were conducted during kharif 2014 and 2015 at the Agricultural Research Farm, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi. Twenty promising genotypes procured from ICAR- Indian Institute of Pulses Research, Kanpur were evaluated, with the recommended agronomic practices and without pesticides, in Randomized Block Design (RBD) with three replications. The row to row and plant to plant distance was maintained as 30 and 10 cm, respectively, in plot size of 4 x 0.60 m.The population density of *M. vitrata* was estimated by randomly selecting of 5 plants/ plot, at weekly intervals, and observations on pod damage made by counting a total number of pods harvested at the time of maturity. Observations were made on the characteristic *M. vitrata* entry/ exit holes on the pods. For recording grain damage, the pods were opened and the total number of the grain and number of damaged grain were recorded and % worked out. Based on the pod damage, the genotypes were categorized in based on the 1-9 scale (Rani et al., 2008) as follows: Scale/Score: incidence: category- 1: No damage: Resistant; 3:<10% damage: Moderately resistant; 5: 11-10% damage: Tolerant; 7: 21-40% damage: Moderately susceptible; and 9: >40% damage: Highly susceptible. The data on the grain yield were computed to plot yield and per ha yield. The larval population density and % pod and grain damage were subjected to ANOVA (p=0.05) and the treatment means compared using F-test. The data on population, % infestation, % pod and grain damage were subjected to square root and arcsine transformation, respectively before analysis.

(Received 26 March 2020, Accepted 5 May 2020)

ABSTRACT : A laboratory experiment was conducted on 15 genotypes of chickpea to investigate the role of some biochemical factors on quantitative losses caused by pulse beetle under storage conditions. The genotype HC-10 (47.92% and 64.00%, respectively) was recorded maximumseed damage and weight loss, while minimum seed damage and weight loss in genotype Digvijay (33.92% and37.99%, respectively). The maximum protein content was recorded in genotype Annegiri (23.67%) followed by HC-10 (23.51%) and PUSA-261 (22.17%). The minimum percentage of protein was recorded in Digvijay (14.20%). The maximum total soluble sugar content was observed in the genotype HC-10 (8.55 mg/g) and followed by PUSA-261 and minimum in genotype CSJD-884 (4.19 mg/g) followed by RSG-931 (4.21 mg/g). Maximum starch content was recorded in genotype HC-10 (50.82 mg/g) followed by PUSA-261 (50.23 mg/g) and minimum in the genotype Digvijay (41.36 mg/g) followed by CSJD-884 (41.98 mg/g). The highest activity of trypsin inhibitor was seen in Digvijay (34.80 TIU/mg protein) and lowest in the genotype HC-10 (7.20 TIU/mg protein). The maximum protease inhibitor activity was observed in Digvijay (31.50%) and followed by CSJD-884 (31.33%) and genotype in HC-10 (14.42%) followed by PUSA-261 (16.12%). A positive significant correlation was observed between per cent seed damage, per cent weight loss and biochemical parameters like protein content (r = 0.650*and r = 0.659, respectively), total soluble sugar (TSS) content (r = 0.961**and r = 0.958**, respectively) and starch content (r = 0.982**and r = 0.981**, respectively), whereas parameters like trypsin inhibitor activity (r = -0.972** and r = -0.970**) and protease inhibitor activity (r = -0.953** and r = -0.948**) were negatively correlated.**

Key words : Chickpea, biochemical factors, genotypes, pulse beetle, *Callosobruchus chinensis*, resistance.

INTRODUCTION

The pulse crops are attacked by more than 150 insect pests. Among these, the pulse beetles, *Callosobruchus* spp. are considered as the major storage pests of pulses. It has been reported that the genus *Callosobruchus* is a serious insect pest in the middle and Far East, Africa and India. Different pulse beetles attacking various pulses are *Callosobruchus chinensis*, *C. maculatus* and *C. analis*. The most destructive bruchid species to chickpea are *C. chinensis* and *C. maculatus* (Mishra *et al*, 2015). All most all pulse crops have been reported to be infested by this beetle all over the world (Singh *et al*, 1980). It is an oligophagous and cosmopolitan insect pest. Its infestation starts from the field and then carried to the storage. It refers to causes both pre and post-harvest losses in grain legumes. It is not only caused qualitative and quantitative losses but also impacts on germination ability of seeds. It is observed that up to 60 per cent of weight loss and 45.50 to 66.30 per cent loss in protein content of stored pulse seeds occur due to pulse beetle infestation (Golnaz *et al*, 2011; Faruk *et al*, 2011). Due to infestation, seeds undergo biochemical alterations which result in the loss of various constituents of the seeds. Grubs and adults both cause damage. Grubs eat up the endosperm of the grain kernel and make a cavity. Affected grains show emergence holes of beetles as well as minute white eggs adhering to the seed coat. This is the main evidence for pulse beetle damage. It makes the seeds unfit for consumption and useless as seed as well. The pulse beetles deteriorate the seed quality by denaturing and decreasing the soluble proteins (Mishra *et al*, 2015).

(Received 12 March 2020, Accepted 5 May 2020)

ABSTRACT : A laboratory experiment was conducted to determine the resistance of 15 chickpea genotypes against pulse beetle, *Callosobruchus chinensis* (L.). The minimum seed damage was recorded in JG 315 (27.75%) followed by genotype DCP 92-3 (28.00%). The genotype JG 11 recorded the highest per cent seed damage (50.50%) followed by Chaffa (48.75%). The maximum per cent loss in weight occurred in Chaffa (62.48%) followed by genotype H 82-2 (HC-1) (49.04%) and the minimum per cent weight loss was recorded on PBG 5 (33.92%) followed by GNG 469 (34.16%). The lowest protein content was recorded in genotype JG 315 (15.33%), Vikas (15.33%) and the highest protein content was recorded in genotype JG 11(22.70%) followed by Chaffa (22.67%). The lowest starch content was recorded in the genotype JG 315 (37.67 mg/g) followed by genotype Vikas (38 mg/g) and the highest starch content was noticed in genotype JG 11(48.67mg/g) and Chaffa (48.67mg/g). The minimum total soluble sugar content was found in genotype JG 315 (3.33 mg/g) followed by genotype Vikas (4.20 mg/g). The maximum total soluble sugar content was recorded in genotype JG 11 (9.63mg/g) followed by genotype Chaffa (9.58 mg/g). The highest trypsin inhibitor activity (TIU/mg protein) was seen in genotype JG 315 (39.67) followed by genotype Vikas (32.50) and the lowest trypsin inhibitor activity (TIU/mg of protein) was found in genotype JG 11(9.40) followed by genotype Chaffa (10.40 TIU/mg protein). The highest protease inhibitor activity was noticed in the genotype JG 315 (29.00%) followed by genotype Vikas (27.00%) and the lowest per cent protease inhibitor activity genotype was JG 11 (12.00%) followed by genotype Chaffa (13.00%). The negative and significant correlation between seed damage, weight loss and trypsin inhibitor activity, protease inhibitor activity was found. The significant positive correlation between seed damage and protein content, starch content and total soluble sugars was found, while a positive correlation between weight loss protein content, starch content and total soluble sugars was observed.

Key words : *Callosobruchus chinensis*, chickpea, biochemical, resistance, genotypes.

INTRODUCTION

Legumes are among the richest food sources of proteins and amino acids for human and animal nutrition. For the majority of the vegetarian population in India, pulses are the major source of protein. Pulses and pulse crop residues are also major sources of high-quality livestock feed. Chickpea is the premier pulse crop of the Indian subcontinent. It is considered as thebest alternative to animal protein for poor masses of the country. Seeds have about 20% protein, 5% fat and 55% carbohydrate. In addition to protein, chickpea is a good source of carbohydrates, dietary fibre, minerals (molybdenum, manganese, copper, phosphorus, iron and zinc) and vitamins (riboflavin, niacin, thiamin, folate and the vitamin 'A' precursor beta-carotene) (Jukanti *et al*, 2012). The *in vitro* protein digestibility of chickpea seeds was found to be higher compared with those for pigeon pea, green gram, black gram and soybean (Chitra *et al*, 1995).

Insects are not only causing damage to the crops growing in the field but also causing qualitative and quantitative damage under storage. Significant losses in grains occur during storage and the damage caused by insects may amount to 5-10 per cent in the temperate and 20 – 30 per cent in the tropical zone (Nakakita, 1998).

In India over 200 species of insects have been recorded infesting various pulses and out of five known species of *Callosobruchus*; the only three names, *Callosobruchus chinensis*, *C. maculatus* and *C. analis* are most common species of pulse beetle found in India to infest stored legumes (Raina, 1970). The pulse beetle,

The potential benefits of weeds: A comparative study: A review

Alka Sahrawat, Siddarth N Rahul, Sameer K Singh and Shweta Patel

DOI: https://doi.org/10.22271/chemi.2020.v8.i2b.10134

Abstract
A weed in a general sense is a plant, usually wild or feral, that is commonly considered to be a nuisance in a garden, lawn, or other agri-cultural development. More specifically the term is often used to describe plants that grow and reproduce aggressively. Weeds may be unwanted because they are unsightly, or because they limit the growth of other plants by blocking light or using up nutrients from the soil. The term weed in its general sense is a subjective one, without any classification value, since a plant or herb is not a weed when growing where it belongs or is wanted. Despite of being harmful some weeds are called, beneficial plants or herbs as they are edible, use for food or herbal medicine. Other advantage of such beneficial herbs may be the keeping away of some insect pests of crops. Many researchers have pointed out that there is scarce evidence to prove that pests move from the alternative host in sufficient numbers to cause significant crop damage, even in the case of pests such as some of the aphids which are obliged to alternate between hosts to complete their life cycle.

Keywords: Weed, harmful, beneficial effect, alternate host

Introduction
Weeds are defined as any plants that are growing in unwanted areas or plants growing in everlastingly human-disturbed environments but do not depend on human interference for reproduction and survival. These plants may be found growing on agricultural fields and gardens or as ruderal plants (Ngugi *et al.* 1978; Stephen 1982; Casas *et al.*1996) [1, 85, 3]. Weeds are usually seen to have adverse effects not only in agricultural lands but also in natural wild ecosystems. In terms of agriculture these plants compete against crop plants for available resources, lower the quality of agricultural produce, lower quality of pastures. Despite of these some are poisonous, increase costs of production, harbor pests, while some block irrigation after growing immeasurably (Ngugi *et al.* 1978; Klingman *et al.* 1982; Ivens 1989; Cousens & Mortimer1995) [1, 4, 5, 6]. In concern to biodiversity conservation considerations weed and other aggressive species are often supposed to act as "plant pests" (Miller 1999), one of the two major threats to biodiversity, second to habitat damage (Heywood 1995; Mungoro & Tezoo 1999) [8, 9]. This may be especially so when weed species are lack natural enemies, grow faster than native plant species and are able to produce plenty of seeds (Richardson *et al.* 1992) [10]. The species which grow on their own, without human efforts can be termed as weeds. They are in general harmful to the crops and can dominate the vegetation if not cared for. The weeds are of no use as they are harmful to crop. They are generally controlled from crop fields and destroyed. Many of the weeds are found to be medicinally important. Such weeds can be collected from crop fields and used for curing the diseases.

Losses caused by weed
The losses caused by weeds exceed the losses from any other category of agricultural pests, such as insects, nematodes and rodents. Among the total annual losses of agricultural product from various pest, weeds account for 45%, insects for 30%, diseases 20% and other pest 5% as shown in Figure 1 (Rao 2000) [81]

Evaluation of certain chickpea genotypes against pulse beetle, *Callosobruchus chinensis* (L.) under laboratory conditions

Lipika Pradhan*, P.S. Singh, S.K. Singh and R.P.N. Saxena**

Department of Entomology and Agricultural Zoology, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi - 221 005, Uttar Pradesh, India

ABSTRACT

Screening of fifteen chickpea genotypes namely GNG-146, HC-3, PUSA-209, Digvijay, Radhey-931, Annegiri, PBG-5, PUSA-261, HC-10, CSJD-884, GCP-101, RSG-10, RSG-931, L-550 and C-235 were conducted to quantify the losses caused by pulse beetle. The results revealed that the mean per cent of seed damage varied from 33.92 to 47.92% and mean per cent weight loss of chickpea seeds varied from 37.99 to 64.00%. The mean per cent seed damage was highest in the genotype HC-10 (47.92%) and lowest in Digvijay (33.92%). The genotype HC-10 (64.00%) recorded maximum per cent weight loss whereas; the genotype Digvijay recorded minimum per cent weight loss (37.99%). Among all the 15 genotypes; resistant genotype was Digvijay followed by CSJD-884, RSG-931, GNG-146, Radhey-931, L-550 and GCP-101. Most susceptible genotype was HC-10 followed by PUSA-261, RSG-10, HC-3, PBG-5, C-235, Annegiri and PUSA-209.

Key words : Chickpea, evaluation, genotypes, laboratory conditions, pulse beetle, pulse beetle.

INTRODUCTION

Pulses are an excellent source of dietary proteins (20-40%), carbohydrates (50-60%) and minerals like calcium and iron (Borget, 1992; Ofuya and Akhidue, 2005). India occupies the first position in pulse production in the world and contributes around 70 per cent (Anonymous, 2015). Although, being the largest pulse crops cultivating country in the world, in domestic food grains sector, pulses occupy only 7 per cent share in global production (Department of Agriculture and Cooperation, Ministry of Agriculture, New Delhi, 2015). Among all the grain legumes, Chickpea (*Cicer arietinum*) is considered to be the best food for the vegetarian population in South Asia, West Asia and Southern European countries. It acquires the fourth position based on both cultivated area and production in the world among all the pulses (FAOSTAT, 2014). It is commonly known as Bengal gram or White gram or Gram. The state contributing largest production in gram is Madhya Pradesh covering about 9.93 m ha area with the production of 7.17 mt (Anonymous, 2015). The average productivity of chickpea is about 800 kg/ha, which is much lower than their potential yields.

Several biotic and abiotic constraints are there which causes major yield loss. The biotic constraints include diseases and insect pests causing a yield loss of about 30% (Birthal and Sharma, 2004). The most destructive bruchid species to chickpea are *Callosobruchus chinensis* (L.) and *C. maculatus* (F.) (Mishra *et al*., 2015). It is observed that up to 60 per cent of weight loss of the stored seeds occurs due to pulse beetle (Golnaz *et al*., 2011). Pulse beetles are of the family Bruchidae and order Coleoptera. The life cycle of pulse beetle is studied by many workers. Egg, larval and pupal periods of pulse beetles are 3, 12 and 4 days respectively. White, elongate eggs are laid on the pulse. The grubs feed on the inner contents of pulses, pupate inside them and emerge out by cutting circular holes in the grains. It is reported that adults prefer to come on the surface of the layer of grains to get the free area for mating (Kunhikannan, 1919). Use of resistant or tolerant cultivars reduce the indiscriminate use of insecticides and involves no extra cost to the farmers and is an ideal way of effective, economical and safe management of insect pests. Resistance processes involve morphological,

Biochemical basis of resistance in green gram genotypes against pulse beetle, *Callosobruchus maculatus* (F.) under storage conditions

Usha R.*, P.S. Singh, S.K. Singh and R.P.N. Saxena**

Department of Entomology and Agricultural Zoology, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi - 221 005, Uttar Pradesh, India

ABSTRACT

Study on the biochemical basis of resistance in green gram genotypes against pulse beetle showed that highest seed damage was recorded in genotype Pant Mung-2 (69.25%) whereas, lowest seed damage was found in genotype ML-935 (46.50%). The maximum weight loss was recorded in genotype Pant Mung-2 (43.00%) and minimum weight loss was recorded on ML-935 (11.67%). The lowest protein content was recorded in genotype ML-935 (11.50 mg/g) while, highest protein content was reported in genotype Samrat (27.70 mg/g) followed by Pant Mung-2 (26.90 mg/g). The genotypes Samrat (40.36 mg/g) had the highest starch content followed by Pant Mung-2 (39.00 mg/g) and genotype ML-935 (26.53 mg/g) had the lowest starch content. The genotype Samrat (8.66 mg/g) received highest sugar content followed by Pant Mung-2 (7.90 mg/g) and genotype ML-935 (2.96 mg/g) received the lowest content of total soluble sugar. The genotype ML-935 (17.03 TIU/mg protein) showed highest trypsin inhibitor activity followed by ML1059 (14.50 TIU/ mg protein). The genotype Samrat (11.37 TIU/ mg protein) depicted lowest trypsin inhibitor activity followed by genotype Pant Mung-2 (11.90 TIU/ mg protein). The genotype ML-935 (29.06%) had the highest protease inhibitor activity followed by genotype ML1059 (26.50%). The genotype IPM-2-3 (17.16%) followed by genotype Ganga-8 (17.50%) showed protease inhibitor activity. A positive significant correlation was observed between per cent seed damage, per cent weight loss and biochemical parameters like protein content (r = 0.892 and r = 0.881**, respectively), starch content (r = 0.924** and r = 0.895**, respectively) and total soluble sugar (TSS) content (r = 0.886** and r = 0.855**, respectively), whereas parameters like trypsin inhibitor activity (r = -0.891** and r = -0.871****, respectively) and protease inhibitor activity (r = -0.937** and r = -0.921****, respectively) were negatively correlated.**

Key words : Biochemical, *Callosobruchus maculatus*, genotypes, green gram, pulse beetle, resistance.

INTRODUCTION

Pulses are an important source of protein, high in fibre content and provide ample quantity of vitamins and minerals. Keeping in view the large benefits of pulses for human health, the United Nations has proclaimed 2016 as the International Year of Pulses. Green gram is an important pulses crop in India and believed to be originated from India. It is a short-duration legume crop grown mostly as a fallow crop in rotation with rice. Similar to the leguminous pulses, green gram, enrich soil nitrogen content. It is grown mostly in the Asian region traditionally while its cultivation has spread to Africa and the Americas relatively in recent times. More than 70% of the world's green gram production comes from India.

In India among various pulses, green gram stands third and contributes 11% of the total pulse production with 1.61 mt from an area of about 3.42 m ha. The average yield of green gram is 512 kg/ha (INDIASTAT, 2015). Sprouted pulse seeds are rich in vitamin B, C and enzymes. Besides its nutritive value, it also plays an important role in improving soil physical properties and fixing atmospheric nitrogen (22 kg/ha) through a symbiotic relationship with rhizobium in the root nodule of the crop. Despite the economic and nutritional benefits, there are many constraints responsible for the low yield of mung bean. Among those, insect pests are considered to be most important (Chandrasekhar and Ghosh, 2002; Soumia *et al.,* 2015).

Abstract

A field investigation was conducted to evaluate the comparative efficacy of certain insecticides against Helicoverpa armigera *(Hübner) infesting chickpea at Agriculture Research Farm, Banaras Hindu University, Varanasi, U.P., during Rabi 2017-18. The results revealed that Chlorantiniprole 18.5 SC 92g a.i. ha^{-1} followed by Flubendamide 39.35 EC 49g a.i. ha^{-1} and Spinosad 45 SC 74g a.i. ha^{-1} were found most effective in reducing* H. armigera *population and pod damage. The highest yield was recorded in the treatment Chlorantiniprole 18.5 SC 92g a.i. ha^{-1} (17.33 q ha^{-1}) followed by Flubendamide 39.35 EC 49g a.i. ha^{-1} (16.44 q ha^{-1}) and Spinosad 45 SC 74g a.i. ha^{-1} (15.55 q ha^{-1}). The maximum yield increase over control was recorded in treatment Chlorantiniprole 18.5 SC 92g a.i. ha^{-1} (97.60%) and minimum in treatment Acephate 75 WP 750 g a.i. ha^{-1} (14.48%). The highest avoidable yield loss was recorded in Chlorantiniprole 18.5 SC 92g a.i. ha^{-1} (49.39%) and lowest avoidable yield losses were noticed in Acephate 75 WP 750 g a.i. ha^{-1} (12.64%). The highest benefit: cost ratio was observed in Indoxacarb 14.5 EC 36 g a.i. ha^{-1} (7.78:1) and lowest benefit: cost ratio was recorded from Chlorantiniprole 18.5 SC 92g a.i. ha^{-1} (1.19:1).*

Keywords: Comparative efficacy, insecticides, economics, gram pod borer, chickpea and *Helicoverpa armigera.*

Introduction

India is the largest in terms of area and production of chickpea in the world *i.e.* approximately 70 per cent of total chickpea production in the world (Wallace *et al*., 2016). History of chickpea can be traced since ancient times in India but it was reported first cultivated 7000 years ago in Middle East Asia from where it descended to Afghanistan and finally to India (Toker, 2009). Chickpea is the second most important food legume crop after common bean (FAOSTAT, 2015). Currently, chickpea is being cultivated in about 40 countries in the world and it is a very important part of pulse cultivation in the world , contributing about 58 million tonns produced which is approximately 15 per cent of the total pulse harvested all over the world. Nearly 90 per cent of the total global area and 88 per cent of total production is concentrated in Asia. India with the first rank in production is followed by Turkey (11%), Pakistan (8%), Iran and Syria (Kapoor *et al.,* 2010).

One of the main constrains in increasing the production of chickpea are insect pests. The number of insect pest species attacking the chickpea in Indian terrain is 57, and the economically important pests among them are nearly half a dozen. The most important insect species in terms of damage to the crop is the gram pod borer, *Helicoverpa armigera* Hübner (Lepidoptera: Noctuidae). The insect causes most damage in terms of attacking the economical part of the plant *i.e.* the pod and hence decreases the yield of the crop drastically. The pod borer has been a significant problem with a variety of crops for its polyphagous nature. The attack of pod borer is reported on nearly 182 economically important crop plant species ranging from food to fibre crops, horticulture crops and oil seeds etc. (Gowda, 2007).

The estimation of yield losses in case of *Helicoverpa* in case of chickpea are variable in case of variations of the weather conditions i.e. under normal weather conditions the losses by pod borer to chickpea crop may vary between 10-60 percent while in case of favourable weather conditions the loss can be in the range of 50-100 percent leading to total devastation of the crop (Khare and

(Received 27 February 2021, Accepted 24 April 2021)

ABSTRACT : The various genotypes of French bean obtained from Indian Institute of Pulses Research, Kanpur were sown at Agricultural Research Farm of Banaras Hindu University during the Rabi season of 2017-18 for assessing the resistance to leaf miner, aphid and pod borer. Genotype VL 63 showed resistant reaction to aphid (7.83 aphids/plant) compared to all other varieties, whereas, genotypes 405 (56.83 aphids/plant) and RE 15-1 (51.11 aphids/plant) showed susceptible reaction. Genotype RE 15-1 showed resistant reaction to leaf miner damage on leaves (13.27%), whereas, genotypes HUR 15 (27.04%) and 180 (24.87%) showed susceptible reaction with higher leaf damage. Pod damage due to pod borer (*Helicoverpa armigera*) was highest on genotype VL 63 (3.67%) and least incidence was recorded on genotype HUR 76 (0.33%). Genotype HUR 76 produced highest yield as compared to other genotypes (12.00 q ha^{-1}), while genotype 214 and 96 (6.67 q ha^{-1}) produced lowest yield.

Key words : *Phaseolus vulgaris*, *Chromatomyia horticola*, *Aphis craccivora*, *Helicoverpa armigera*.

INTRODUCTION

French bean, *Phaseolus vulgaris* L. that belongs to family Fabaceae also known as Rajmash, Snap bean, Kidney bean and Garden bean is an important source of protein for many developing countries (Markart, 1985). It approximately amounts to 90 per cent of total bean production (Dessert and Voysest, 1991). Its nutritional values indicates that it is rich in carbohydrates, sodium, protein, vitamin B_6, B_{12}, zinc, copper, manganese and essential amino acids like Thiamine, Lysine, Leucine, Proline, Glycine, Serine and Glutamic acid. It is highly nutritious, its dry seeds contain 22 per cent protein, 1.7 per cent fat, 78 per cent carbohydrate, 381 mg calcium, 425 mg phosphorus and 12.4 mg iron per 100 g of edible proteins (Joshi and Rana, 1995). The beans are used as a green vegetable, green shelled or dry as pulses according to the stage of harvest. In temperate regions, green mature pods are cooked and eaten as vegetable. Immature pods are marketed as fresh, frozen or canned, whole or fresh cut (Kaplan and Lynch, 1999). The immature pods of this crop are consumed as vegetable and dried seeds form an excellent pulse. It is said to be anti-diabetic and good for bladder burns, diarrhoea, dropsy, dysentery, eczema and hiccups. Use of improved quality seeds and unscrupulous application of chemical insecticide has led to adverse effects upon plant, animal, human and environmental health. Several workers *viz*., Rahman (1988), Sachan and Garg (1992), Sharma (1999), Singh (2013), Noor *et al* (2014) & Singh and Singh (2015) have reported insect pests of French bean from various regions of India. Development of cultivars with resistant traits against major insect pests would be an efficient, cost effective and sustainable mode for providing the best way to manage pest menace (Lateef, 1991). Taking into account the above facts, investigation was carried out to screen certain genotypes of French bean against major insect pests.

MATERIALS AND METHODS

The study was convened and investigation was carried out for evaluating resistance of 20 Rajmash genotypes against leaf miner (*Chromatomyia horticola*), aphid (*Aphis craccivora*) and pod borer (*Helicoverpa armigera*) at Agricultural Research Farm, Banaras Hindu University, Varanasi, Uttar Pradesh during *Rabi* 2017-18. All twenty genotypes were sown adopting Randomised

Population dynamics of fruit flies in bitter gourd (*Momordica charantia* L.) and its relationship with weather factors

Dharm Beer, Umesh Chandra, Jai Kumar Yadav and Sameer Kumar Singh

Abstract
Bitter gourd (*Momordica charantia* L.) is one of the important cucurbitaceous vegetable grown in India. Among the cucurbits, it is considered a high-quality vegetable because of its nutritive value especially ascorbic acid and iron. The study was undertaken to investigate the population dynamics of *Bactrocera* spp. (Diptera: Tephritidae) round the year. Significant variation in occurrence of the pest was recorded during the period of investigation. First incidence of *Bactrocera* spp. was observed from 31st SM and continued upto 52nd SM in parapheromone Methyl Eugenol and Cuelure) traps. Peak incidence of the pest was recorded during 39th SM and 42nd SM with 135 fruit flies/trap/week. *B. zonata* and *B. dorsalis* incidence had significant positive correlation (r) of with minimum and maximum temperature (r = 0.563 and r = 0.564 respectively) during *Kharif* 2018. The *B. cucurbitae* traped had positive correlation with minimum (r = 0.752), maximum temperature (r = 0.788) and relative humidity during *Kharif* 2018. Findings of this study helps in understanding the population dynamics of fruits flies in bitter gourd and developing forewarning strategies to combact the pest in advance.

Keywords: Bitter gourd, fruit fly, incidence, cuelure, methyl eugenol

Introduction
Bitter gourd is an important cucurbitaceous vegetable grown in India. Each part of this crop has been reported useful having some specific medicinal value (Allwood and Drew, 1996) [1]. Fruit flies are important insect pests of fruits, vegetables and other ornamental plants (Bharathi *et al.,* 2004) [5]. Melon fruit fly, *Bactrocera cucurbitae* (Coq.) (Diptera: Tephritidae) is one of the main tropical fruit fly causing considerable damage in cucurbits. *B. cucurbitae* has been observed to infest a wide range of crops in the Cucurbitaceous family. Infestation by melon fruit fly in bitter gourd was reported from 41 to 89 per cent (Rabindranath and Pillai, 1986). Melon fruit fly infests 95 percent of bitter gourd fruits in Papua New Guinea, 90 per cent snake gourd and 60 to 87 per cent pumpkin fruits in Solomon Island while 31.27 per cent in India, respectively (Hollingsworth *et. al*., 1997; Singh *et. al*., 2000) [9, 10]. Yield loss varies from 30–100% (Nath and Bhusan 2006) [2]. It is very much difficult to manage the pest through the application of chemical pesticides due to their peculiar biological features.
Among the various, alternate strategies available for the management of fruit flies, the use of male attractant traps stands as the most outstanding alternative. Various parapheromones are known which are used against fruit flies. Monitoring of pest population round the year is one of the most important basic information in formulating Integrated Pest Management concept for sustainable agriculture. The Cuelure traps have been reported to attract *Bactrocera cucurbitae* males and this sex attractant is more effective than food lure (Pawar *et. al*., 1991, Liu and Lin, 1993; Zaman, 1995) [3, 8, 4]. Keeping in view, present investigation was undertaken to study the population dynamics of fruit flies and its relation with weather factors.

Materials and Method
The study was conducted at the Agricultural Research Farm of Acharya Narendra Dev University of Agriculture and Technology, Kumarganj Ayodhya, India (26.54°N, 81.93°E). The seasonal incidence of fruit flies was monitored at weekly intervals in the cropping season 2018–2019. Cuelure and methyl eugenol baited bottle traps were used for the monitoring of population. The traps used for monitoring fruit flies consisted of a one-litre plastic mineral water bottle (10 cm base diameter and 25 cm in height) with a screw lid.

Biochemical Factors Associated with Resistance to Spotted Pod Borer, *Maruca vitrata* (Fabricius) in Green Gram

Sameer Kumar Singh[1], P.S. Singh

10.18805/LR-4302

ABSTRACT

Background: Legume pod borer or spotted pod borer, *Maruca vitrata* is one of the serious insect pest to the green gram, which causes damage mainly at the reproductive phase of the crop growth. The larvae of spotted pod borer are known to cause damage by webbing the leaves, bud, flower and pods together and feed from inside on them. Due to its webbing nature, it is very difficult to enter inside by natural enemies and chemicals cannot directly reach inside webbing. Host plant resistance to insect pests is an economically and ecologically preferred alternative as compared to other pest management tactics, particularly the synthetic pesticides. The present investigation was undertaken to examine the role of certain bio-chemical constituents of the immature pods of green gram in the expression of damage by the spotted pod borer.

Methods: The experiments on screening were conducted during the *kharif* 2014 and 2015 at the Agricultural Research Farm, Institute of Agricultural Sciences, Banaras Hindu University, Varanasi, (U.P.) to define the occurrence of *M. vitrata* on 20 promising varieties/ genotypes of green gram. Pods were collected at the immature stage from different varieties/genotypes and biochemical constituents such as total soluble sugar, total chlorophyll, protein were estimated.

Result: The maximum protein content was found in genotype IPM 306-6 (36.17 mg/g) and minimum in genotype PM-5 (20.53 mg/g). Highest total sugar content was reported from genotype ML 1256 (16.71 mg/g) and lowest total sugar content was recorded in PM-5 (10.94 mg/g).The phenol content in genotype PM-5 (9.00 mg/g) was significantly higher than others whereas, the minimum phenol content was reported in IPM 306-6 (5.14 mg/g). The higher amount of total chlorophyll content found in genotype IPM 306-6 (3.22 mg/g) and lowest in PM-5 (1.85 mg/g). The significant and positive correlation was observed between *M. vitrata* larval population, pod damage and protein (r=0.954** and r=0.952**, respectively) and total sugar content (r=0.986** and r=0.986**, respectively) and total chlorophyll content (r=0.994** and r=0.993**, respectively) in immature pods, while, the significant and negative correlation was found between phenol (r= -0.916** and r= -0.919**, respectively).

Key words: Biochemical factors, Green gram, Genotypes and resistance, *Maruca vitrata*.

INTRODUCTION

The insect pests such as jassids, whitefly, thrips, stem fly, Epilachna beetle, blister beetle, Galerucid beetle, pod sucking bug, spotted pod borer and tobacco caterpillar have more significance on mungbean throughout the year. Incidence of insect pests considerably reduces the yield and quality of mungbean (Elias ***et al***., 1986; Malik, 1994; Singh and Singh, 2014; Soundararajan ***et al***., 2013). Among the pod borers, legume pod borer or spotted pod borer, ***Maruca vitrata*** is one of the insect serious pest to the green gram, which causes damage mainly at the reproductive phase of the crop growth. Because of its extensive host range and destructiveness, it became a persistent pest in pulses particularly on the green gram, as it is available throughout the year in different seasons. The larvae of spotted pod borer are known to cause damage by webbing the leaves, bud, flower and pods together and feed from inside on them. Due to its webbing nature, it is very difficult to enter inside by natural enemies and chemicals cannot directly reach inside webbing. Host plant resistance to insect pests is an economically and ecologically preferred alternative as compared to other pest management tactics, particularly the synthetic pesticides (Barad ***et al***., 2016). Zahid ***et al***. (2008) had reported 20-30 per cent pod damage in mungbean. It is known to cause an economic loss of 20-25 per cent and yield loss of 2-84 per cent in green gram (Vishakanthaiah and Jagadeesh Babu, 1980; Umbarkar ***et al***., 2011a). Various biochemical compounds present in the plant parts play an important role in offering host plant resistance in suppressing the insect pests. The present investigation was undertaken to examine the role of certain bio-chemical

Biochemical traits associated with resistance to Whitefly, *Bemisia tabaci* (Gennadius) in green gram

Sameer Kumar Singh* and P.S. Singh**

Department of Entomology, College of Agriculture, Acharya Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya - 224 229, Uttar Pradesh, India

ABSTRACT

Results revealed that maximum population was reported in ML 5 (9.12 whitefly cage-1) followed by SM 48 (8.45 whitefly cage^{-1}) and the minimum population was recorded in PM-5 (3.02 whitefly cage^{-1}) closely followed by IPM 306-1 (3.51 whitefly cage^{-1}). However, the population local check cultivar, HUM-12 was 6.45 whitefly cage^{-1}. The biochemical factors like protein, total sugar, phenol and total chlorophyll were estimated in 20 promising varieties/ genotypes of green gram. The highest protein content was found in genotype ML 5 (12.77 mg g^{-1}) and minimum in genotype PM-5 (7.45 mg g^{-1}). Maximum total sugar content was reported from genotype ML 5 (07.86 mg g^{-1}) and minimum total sugar content recorded in PM-5 (03.34 mg g^{-1}). The phenol content in genotype PM-5 (4.23 mg g^{-1}) was significantly higher than others whereas, the minimum phenol content was reported in ML5 (2.43 mg g^{-1}). The higher amount of total chlorophyll content was found in genotype PM-5 (3.92 mg g^{-1}) and lower in genotype ML 5 (1.30 mg g^{-1}). The significant and positive correlation was witnessed between *B. tabaci* population and protein (r=0.976) and total sugar content (r=0.981**), while, the significant and negative correlation was found between phenol (r = -981**) and total chlorophyll content (r = -978**).**

Key words : *Bemisia tabaci*, biochemical traits, genotypes and resistance, green gram.

INTRODUCTION

The damage caused by insect pest is one of the major reason for the low productivity of mungbean in the country. In India, nearly 60 species of insect pests have been recorded from mungbean but only a few cause economic damage and are more common in large areas (Ooi, 1973; Soundararajan *et al*., 2013; Singh and Singh, 2014). Chhabra and Kooner (1985) noted 54.90% yield losses caused by pest complex in green gram. Whitefly, being one of the major pest of green gram, sucks the sap from under the surface of leaves resulting in chlorotic spot development, become reddish and crop premature growth. It also leads to the development of sooty mould on leaves, interfering with photosynthetic activity. It is a potential vector of mungbean yellow mosaic virus (MYMV), can cause losses ranging from 30 - 70% (Swaminathan *et al*., 2012). The whitefly, *Bemisia tabaci* is reported to infest the crop at different places on India (Naraiani, 1960; Srivatava and Singh, 1976; Chhabra *et al*., 1979; Lal *et al*., 1980; Chhabra and Kooner, 1981, Singh and Singh, 2014). These workers have also reported the indirect damage by whitefly to this by transmitting Yellow Mosaic Virus. Various biochemical compounds existing in the plants play vital role in offering host plant resistance in suppressing the insect pests. The present investigation was undertaken to study the role of certain bio-chemical components of the leaf of green gram in the expression of damage by whitefly.

(Received 10 September 2021, Accepted 18 November 2021)

ABSTRACT : A field investigation was conducted on the population dynamics of *Helicoverpa armigera* (Hübner) in chickpea during *Rabi* 2020-21. The results revealed that the infestation of gram pod borer started at 46th SMW with a mean population of 0.22 larvae/mrl and attained ETL at 48th SMW with 1.00 larvae/mrl. The peak appearance was recorded during 8th SMW with an average population of 8.80 larvae/mrl and it persisted up to 15th SMW with 0.40 larvae/mrl. The larvae population of H. armigera correlated with abiotic parameters and data revealed a negative non-significant correlation with maximum and minimum temperatures (r= -0.337 and r= -0.321, respectively), however, it showed a positive correlation with relative humidity in the morning which was non-significant and with evening relative humidity, it was significant (r= 0.296 and r = 0.496*, respectively) and there was no rainfall observed during the cropping season. Wind speed and sunshine hours also showed a positive non-significant correlation (r = 0.115 and r = 0.320) with the larval population.

Key words : Population dynamics, abiotic factors, gram pod borer, *Helicoverpa armigera*.

INTRODUCTION

The chickpea is the third most important crop after dry bean (*Phseolus vulgaris*) and pea (*Pisum sativum*). In India, chickpea is considered as King Pulses due to its high nutritional values and demand (Bhatt and Patel, 2001). It is a major supplement of protein (19g), calories 364 g), carbohydrate (61g), iron (34%), magnesium (28%) Vitamin B_6 (25%), vitamin C (6%) and contain various amino acids and medicinal properties (Anonymous, 2018) *i.e.* useful for stomach ailments, blood purifier and lowering of cholesterol (Bhargava, 2020). It has a high ability to fix more than 80 per cent atmospheric nitrogen in soil with help of symbiotic bacteria *Rhizobium* spp. (Baldev *et al*, 1998).

Globally, chickpea is grown about 10.70 million hectares with an average annual production of 9.00 metric tons. India leads the first rank in the area and production of chickpea. In India, chickpea occupies a 7.89-Million-hectare area and producing 7.06 Metric tons with 895 kg/ha productivity. Madhya Pradesh ranks highest in chickpea production (32.37%) followed by Rajasthan (19.46%), Maharashtra (15.82%), Andhra Pradesh (8.76%) and Uttar Pradesh (6.45%) these states contributing 82 per cent of the total production of the country. *Helicoverpa armigera* (Hübner) usually knows as gram pod borer, is one of the most important constraints of legume production. It has a wide host range due to its polyphagous nature and its feed on more than 250 crop species. The favourable weather conditions with frequent cloudy days during crop season that accounts for about 45 per cent to 95 per cent of damage caused by this pest (Sachan and Katti, 1994). Keeping these points in mind, above study was conducted to find the role of abiotic factors on the incidence of gram pod borer in chickpea.

MATERIALS AND METHODS

A field experiment was conducted at the Student's Instructional Farm (SIF), Acharya Narendra Deva University of Agriculture & Technology, Kumarganj, Ayodhya (U.P.) during *Rabi* 2020-21 on chickpea variety PUSA-262. The estimation of *H. armigera* larvae population was done under field condition in the plot size kept 10×10m with border 0.75m and row to row spacing kept 30cm and plant to plant spacing kept 10cm. An application of time series ARIMA forecasting model for predicting nutri cereals area in India

Rama Shankar Yadav, Vishal Mehta and Ashish Tiwari

Abstract
This study employed a time series modeling method (Box-Jenkins' ARIMA model) to anticipate nutri cereals area in India. The optimal ARIMA model arrangement was shown to be (0,1,1). Furthermore, by applying the ARIMA (0,1,1) model to our time series data, we attempted to anticipate the future nutri cereals Area as accurately as possible for a period up to ten years. The yearly nutri cereals Area, according to the anticipated results. It will continue to fall at a pace of about 1% each year on average.

Keywords: Forecasting, time series modeling, ARIMA, nutri cereals area

1. Introduction
India, known as the original home of nutri cereals, Minor millets (Nutri cereals) are the groups of small seeded cereals and belong to the family of *Poaceae*, which are highly drought tolerant and other extreme weather conditions and are grown with low inputs of chemical such as fertilizers and pesticides. In small millets there are up to Thirty five species of grasses from twenty genera. Millets are one of the oldest cultivated foods, grown and consumed from the past more than 5000 years. Which are highly nutritious? They are provided nearly all of the essential nutrients for normal functioning of human body. Millets are good for people who are gluten-intolerant because millets are Gluten free and non- allergenic.
Millets are a kind of cereal grain. Millets such as Sorghum (Jowar), Pearl Millet (Bajra), Finger Millet (Ragi/Mandua), Minor Millets such as Foxtail Millet (Kanngani/kakun), Kodo Millet (Kodo), Proso Millet (Cheena), Little Millet (Kutki), Barnyard Millet (Sawa/Sanwa/Jhangora), Brown top millet.
In this paper, an effort is made to forecast nutri cereals Area for the 10 leading years. The model developed for forecasting is an Autoregressive Integrated Moving Average (ARIMA) model. This model was introduced by Box and Jenkins in 1960 and hence this model is also known as Box-Jenkins Model which is used to forecast a single variable. The main reason of choosing ARIMA model in this study for the forecasting is because this model assumes and takes into account the non-zero autocorrelation between the successive values of the time series data.
For this investigation, the open source statistical programme 'R' (build 4.0.5) was utilised, as well as numerous statistical and time series packages such as 'tseries' version: 0.10-48, 'predict', and 'TTR', among others.

Table 1: Yearly data of nutri cereals area Area - Million Hectares

Use of double sampling to estimate the finite population mean

Manish Chouhan, Vishal Mehta, Rajesh Tailor, Ramkrishna S Solanki, Annu and Ajay Kumar Gautam

Abstract
We have discussed the topic of estimating the finite population mean in double sampling in this paper. In this article, Singh and Tailor (2005) propose a ratio-cum-product type estimator for double sampling. Up to the first degree of approximation, biases and mean squared errors (MSEs) were determined. Existing estimators have been compared to the recommended estimators. An empirical research was carried out to assess how well the recommended estimators performed.

Keywords: Population mean, ratio-cum-product type estimator, correlation coefficient, bias, mean squared error

Introduction

The finite population mean of the auxiliary variate is assumed by ratio, product, and regression type estimators, however in many actual circumstances, the population mean of the auxiliary variate is known in advance. As a result, double sampling is used. A large sample is chosen to estimate the population mean of the auxiliary variate, and then a subsample is drawn from the large sample or independently from the population in double sampling.

Singh (1967) [3] proposed a ratio-cum-product estimator for population mean using the population mean of two auxiliary variates. Singh and Tailor (2005) [6] proposed a ratio-cum-product estimator for the population mean in simple random sampling based on the correlation coefficient between two auxiliary variables. Tailor and Sharma (2013) [4] proposed a coefficient of kurtosis-based ratio-cum-product estimator of population mean. Sharma *et al.* (2014) [5] proposed a generalised product approach for population mean estimation in two-phase sampling. The ratio-cum-product estimator of Singh and Tailor (2005) [6] is examined in double sampling in this study.

Consider a population $U = \{U_1, U_2, U_3, \ldots, U_N\}$ with a finite size$N$. Let y be the study variable, and x and z be the auxiliary variables, so that x is positively associated with the study variate y and z is negatively correlated with it.

For estimating the population mean $\bar{Y}$ in simple random sampling, Cochran (1940) [1] defined the classical ratio estimator as

$$\hat{\bar{Y}}_R = \bar{y}\left(\frac{\bar{X}}{\bar{x}}\right). \quad (1.1)$$

Robson (1957) [2] proposed using a product estimator to estimate the population mean $\bar{Y}$ as

$$\hat{\bar{Y}}_P = \bar{y}\left(\frac{\bar{z}}{\bar{Z}}\right). \quad (1.2)$$

Singh and Tailor (2003) [7] used the correlation coefficient between the study variable and the auxiliary variate as well as recommended ratio and product type estimators for the population mean $\bar{Y}$ in their analysis as

$$\hat{\bar{Y}}_{STR} = \bar{y}\left(\frac{\bar{X}+\rho_{yx}}{\bar{x}+\rho_{yx}}\right), \quad (1.3)$$

And

$$\hat{\bar{Y}}_{STP} = \bar{y}\left(\frac{\bar{z}+\rho_{yz}}{\bar{Z}+\rho_{yz}}\right), \quad (1.4)$$

ABSTRACT

The research study based on time series secondary data (2001-02 to 2015-16) of 51 district which were related to net area sown, rainfall, total fallow land, area under non agricultural uses and net irrigated area. The whole Madhya Pradesh was subdivided into two head i.e. major (14) and other fallow land (37) districts for the study. The area under fallow land showed decreasing trend by -19.26 percent from 601.90 thousand ha (The base year) to 485.99 thousand ha (The current year) with fluctuation of 9.94 percent (56.80 thousand ha) and magnitude of -8.97 thousand ha per year this also showed a negative compound growth of 0.98 percent per year during the period under study. The 1.00 per cent increase in net area irrigated to net area sown resulting highly significant decrease in share of total fallow land to total net sown area by 0.27 per cent. The aim of study was find out the fallow land in various districts of Madhya Pradesh.

ABSTRACT

Attempts are made in this paper to investigate the trend of pulses in Eastern Uttar Pradesh, as well as their instability and non-linear model. This time series data on pulses pertains to the period 1980-1981 to 2014-15 and includes information on the area, production, and productivity of pulses. Pulses have had negative growth in terms of area, production, and productivity in all three zones of Eastern Uttar Pradesh, namely, the North Eastern plain zone, the Eastern plain zone, and the Vindhyan zone. Since 1980-81, there has been a rise in the area and output of pulses in the Vindhyan zone, as seen by the percentage change. The Eastern plain zone has the most stable pulse crop in terms of instability.

Highlights

- Zone wise study of growth rates of pulses crops helps in agricultural planning and determining agricultural operation at the state level to meet rising food and nutritional security.

Keywords: Growth, trend, linear growth rate (LGR), Instability index, non- linear regression

Pulses belong to the Fabaceae or Leguminos as family and are the third largest flowering clusters in the world. Since the dawn of the farming of the principal plants in the globe, people have grown pulses to be domesticated. Pulses are a vital constituent of the super molecule in the diet of an overwhelming majority of the poor and eating in Asia (Devi *et al*. 2021). In addition to grains, pulses offer a great blend of eater super high biological value molecules. Asian countries continue to be home to the precious gold of the world's ill-fed people. Asian countries are the largest producers, businessmen and buyers of pulses, representing twenty fifths of world production in thirty-fifths of the world's space Vishwajith *et al*. (2014). About 15.2 percent of people in Asian squares are poorly fed. This shows the importance of food and nutrition pulses for Indians (Vani and Mishra, 2019). Pulses are produced mostly in Asian countries, particularly in the Indian subcontinent. Various pulse crops are large measured in the Asiatic country in a wide variety of agro-climatic circumstances therefore it is a major global pulse participant. Pulses do not encompass crops which square measure

Effect of foliar application of nano-fertilizers on soil health and productivity in transplanted rice (*Oryza sativa* L.)

Dev Narayan Yadav, Robin Kumar, Amar Kant Verma and Pardeep Kumar

Abstract
A field experiment was conducted during *Kharif* season of 2019-20 at Main Experimental Station of Acharya Narendra Deva University of Agriculture & Technology, Kumarganj, Ayodhya (U.P.). The experiment consisted 6 treatment *viz.* T_1: Control, T_2: 100% NPK & 100% Zinc application (RDF),T_3: 50% N; 100% P & K + 2 spray of Nano Nitrogen, T_4: 0% Zn, 100% NPK + 2 spray of Nano Zinc, T_5: 50% N & 0% Zn; 100% P & K + 2 spray of Nano N mixed with Nano Zn and T_6: 50% N & 0% Zn; 100% P & K + 2 spray of Nano N mixed with Nano Zn & Nano Cu in Randomized Block Design with 4 replication. The results of experimental revealed that the highest grain yield was recorded with T_6: 50% N & 0% Zn; 100% P & K + 2 spray of Nano N mixed with Nano Zn & Nano Cu which was at par with T_5: 50% N & 0% Zn; 100% P & K + 2 spray of Nano N mixed with Nano Zn and T_4: 0% Zn, 100% NPK + 2 spray of Nano Zinc. The highest gross return (Rs 119841 ha-1), net return (Rs. 64711 ha-1) and benefit cost ratio (2.17) as well was obtained T_6: 50% N & 0% Zn; 100% P & K + 2 spray of Nano N mixed with Nano Zn & Nano Cu. The nitrogen(%), phosphorus(%), potassium(%), copper(%) and zinc(ppm) content in grain & straw are highest in grain & straw content was recorded under T_6: 50% N & 0% Zn; 100% P & K + 2 spray of Nano N mixed with Nano Zn & Nano Cu of central Uttar Pradesh.

Keywords: Seed yield, stover yield, harvest index, economics and uptake and content

Introduction

Rice (*Oryza sativa* L.) is one of the most important field crops after wheat in the world providing staple food to the millions. It is an indispensable source of calories for almost half of the population with in Asia. More than 90% of the world rice is produced and consumed in Asia, which is a native for 60% of the earth's population. Rice is the first most important crop in India where it is grown in an area of 43.79 million ha-1 with a total production of 112.91 million tones and an average productivity of 2578 kg ha-1 Singh *et al.,* (2020) [13]. The world Rice production was nearly 493.79 millions of tons in 2019-20. In May 2020 the United States Department of Agriculture (USDA) estimates that the World Rice Production 20-2021 will be 501.96 million metric tons. Rice Production last year was 493.79 million tons. This year's 501.96 estimated million tons could represent an increase of 8.17 million tons or 1.65% in Rice production around the Globe. Rice is one of the most important cereal crops consumed in Asian countries. 90% of world yields are grown and consumed in monsoonal Asia (East and South East Asia) where Rice is the staple because of its ability to tolerate excessive water conditions, both cold and warm climates. It has adjusted itself to cool, dry land conditions and Saline, Alkaline, and Acid sulphate Soils. India rank second among the top most Rice producers in the world after China. Global Rice production was only 495.9 million tons in (2018-19). In India total production of Rice during 2019-20 is estimated at record 117.47 million tones. It is higher by 9.67 million tones than the five years' average production of 107.80 million tons Anonymous, (2020) [1].

The nano-fertilizers or nano encapsulated nutrients might have the properties that are effective to crops, release the nutrients on demand, controlled release of chemical fertilizers that regulate the plant growth and enhanced target activity De Rosa *et al.* (2010) [2]. Effective application of nano-materials as fertilizer has been noticed. The most notable use of nano-fertilizers in crop production makes very innovative and effective initiation to boost the agricultural yields Raliya and Tarafdar (2013) [9]. As an alternative for conventional mode of fertilizer, nano-fertilizers provides a new way for the release of nutrients into the soil by the slow and controlled way, thus minimizing Eutrophication and water pollution Naderi and Abedi, (2012) [7].

Economic feasibility of organic manure-based treatments on crop performance in mustard, *Brassica juncea* (L.)

Pardeep Kumar, Robin Kumar and Dev Narayan Yadav

Abstract
Economics of Agriculture had direct impact on GDP of agri-based countries upto a large extent. The present study on field experiment was conducted during Rabi season on economic feasibility of mustard crop in 2020-2021. The experiment was laid with eight treatments and three replications in randomized block design. The result invoked that the cost of cultivation worth Rs. 49015 with gross income Rs. 131490 and net income costs Rs. 79640 per hectare in T5 (50% farm yard manure + 50% vermicompost + Natural liquid manure Jeevamrit). Which is at par with T6 (50% farm yard manure + 50% poultry manure + Natural liquid manure Jeevamrit) Whose cultivation cost Rs. 47980 with gross income Rs. 128655 and net income Rs. 61290 per hectare. Mathematically, the B: C Ratio of T5 (50% farm yard manure + 50% vermicompost + Natural liquid manure Jeevamrit) and T6 (50% farm yard manure + 50% poultry manure + Natural liquid manure Jeevamrit) treated plot was 1.62 and 1.59 respectively with with CD and SEM (+) revealed 0.15 and .05 respectively. Thus, application of T5 (50% farm yard manure + 50% vermicompost + Natural liquid manure Jeevamrit) was out yielded whereas T6 (50% farm yard manure + 50% poultry manure + Natural liquid manure Jeevamrit) was economically feasible for the mustard cultivation

Keywords: Mustard, FYM, vermicompost, poultry manure, Jeevamrit, gross & net income

Introduction
India is fourth largest producer of oilseeds accounting for about 20% of the global area and 10% of the globle production. In terms of acreage, production and economic value, oilseeds are second only to food grains. Oilseed cultivation is undertaken across the country in about 27.04 million ha, largely under rained areas covering 72% and producing around 33.42 million tonnes of oilseeds during 2019-2020. Nine oilseeds are the major source of vegetable oil in the country. Among nine major oilseed soybean (33.5%), groundnut (30%), and rapeseed & mustard (27%), contribute more than 90% of total oilseeds production in the country. However in terms of vegetable oil production of mustard, soybean and groundnut contribute 27%, 34%, 30% respectively. The area and production of oilseeds is concentrated in the central and south part of India mainly in the state of Madhya Pradesh (27.89%), Rajasthan (21.49%), Maharashtra (14.84%), Gujarat, Andhra Pradesh and Karnataka. Central organization for oil industry and trade (COOIT) has estimated 89.5 lakh tonnes of mustard seed to be produced in the country in the ongoing Rabi season of 2021-2022 against 75 lakh tonnes recorded last year, which brings a growth of about 19% over last year. Due to the gap between domestic availability and actual consumption of edible oils, India has to resort to import of edible oils. Organic manures are being widely used these days in the cultivation of mustard. Rapeseed-mustard is considered as major source of income especially even to the marginal and small farmers. Organic manures have a balanced role in production efficiency of mustard. Organic manures when combinely used with inorganic fertilizers produces a good yield compared to conventional nutrient application of farming (Srikanth *et al.* 2020).

Materials and Methods
The field experiment was conducted during Rabi season 2020-2021 at student instructional farm of A.N.D.U.A & T kumarganj, Ayodhya (U.P). It is situated on Ayodhya-Raibarelly road about 42 km. Away from Ayodhya head quarter at 26˚47′ N latitude and 82˚12′ E longitude and at an altitude of about 113 meter above the mean sea level. The field was well leveled having assured irrigation and drainage facilities. All the required materials and facilities necessary for the cultivation are readily available in the Department.

Plant Dis. 0:1, 2021; published online as https://doi.org/10.1094/PDIS-10-20-2188-PDN. Accepted for publication 14 December 2020.

Matthiola incana (L.) R. Br (family Brassicaceae) is an ornamental commonly known as hoary stock and has extremely fragrant flowers, which bloom in dense clusters in a large variety of colors. During a survey of flower nurseries in March 2019 at the Indian Institute of Sugarcane Research campus, Lucknow, flower virescence (MiV) symptoms were observed in *M. incana* pots with an incidence of over 40%. Leaf yellows symptoms were also observed on a weed, *Acalypha indica* (AiLY), in the *Matthiola* nursery. Nested PCR assays were carried out to detect and identify the possible association of phytoplasmas with MiV and AiLY symptoms. Symptomatic MiV and AiLY samples and nonsymptomatic samples were collected and processed for DNA extraction from the leaf midrib by the CTAB method. *Hishimonus phycitis* (HP) (Hemiptera: Cicadellidae) leafhoppers feeding on MiV symptomatic plants were also collected and DNA extracted. The DNA of eight symptomatic and four nonsymptomatic plants and from the 10 leafhoppers was used as a template for PCR assays. Phytoplasma specific primers for the 16S rRNA gene (P1/P7 and 3Fwd/3Rev; Schneider et al. 1995; Manimekalai et al. 2010) and multilocus gene specific primer pairs for *secA* (SecAfor1/SecArev3; SecAfo5r/SecARev2; Bekele et al. 2011), *secY* (SecYF1(VI)/SecYR1(VI); SecYF2(VI)/SecYR1(VI); Lee et al. 2010), and *rp* genes (rpFIC/rp(I)R1A; rp(VI)F2/rp(VI)R2; Martini et al. 2007) were employed as previously described. Amplified products of ~1.3 kb, ~600 bp, ~1.7 kb, and ~1.0 kb of 16S rRNA, *secA*, *secY*, and *rp* genes of phytoplasma were consistently amplified in all the MiV and AiLY samples and in the HP leafhopper. No amplifications were achieved in any of the asymptomatic plant samples. Amplified products of all the four genes of MiV, AiLY, and HP isolates were purified, sequenced, and submitted in GenBank. Sequence comparison and phylogeny analysis of the sequences of the four genes of MiV, AiLY, and HP isolates revealed 99 to 100% sequence identity and clustering with clover proliferation phytoplasma related strains (16SrVI group). The virtual restriction fragment length polymorphism analysis with 17 restriction endonucleases corresponding to the 16S rRNA gene sequences of MiV, AiLY, and HP phytoplasma strains by pDraw program assigned them into a novel phytoplasma subgroup strain under 16SrVI group. Because its *Hpa*II restriction profile was different from earlier classified 16SrVI subgroups but was very close to 16SrVI-E (GenBank accession no. AY270156). Earlier, peanut witches' broom (16SrII-A) phytoplasma was identified associated with *M. incana* from Italy (Davino et al. 2007). However, the association of clover proliferation phytoplasma (16SrVI) related strain associated with virescence symptom of *M. incana* is the first report in world. The weed (*A. indica*) and HP leafhopper were also reported as additional host and putative vector of the 16SrVI subgroup related new strain in India, which needs further investigation. The report of a new host and new subgroup of clover proliferation phytoplasma related strain in India has an epidemiological significance and warrants attention.

SHORT COMMUNICATION

Evaluation of *Aloe vera* genotypes against leaf rot disease under field condition

Susheel Kumar[1] · S. K. Pande[1] · S. K. Singh[1] · Jay Kumar Yadav[1] · Rajesh Saini[1]

© The Author(s) 2018

Abstract
Aloe vera (*Aloe barbadensis*) is a perennial, succulent plant belongs to the family Liliaceae. *Aloe vera* leaf rot is one of the major limiting factors in *Aloe vera* production, which decreases leaf, gel quantity and quality significantly. The experiment was conducted to evaluate the genotypes of *Aloe vera* against leaf rot disease Out of 26 genotypes, none of genotypes was found the free from disease, three genotypes viz, IC-111280, IC-112531 and IC-112513 were highly resistant, four genotypes viz., IC-111279,IC-112518, IC-285626 and IC-283655 were resistant, nine genotypes viz, IC-310618, IC-471886, IC-310904, IC-112569, IC-112519, IC-112532, IC-310611, IC-310617 and IC-310596 were moderately resistant and rest of the genotype were moderately susceptible to highly susceptible against the disease.

Keywords *Fusarium oxysporum* · Genotypes · Leaf rot · Screening

Aloe vera (*Aloe barbadensis* Miller) is a perennial, drought resisting succulent plant belong to the family Liliaceae which its believed to have originated in African continent specifically in Egypt (Daodu 2000). There are over 250 species of *A. vera* growing around the world however, only *A. barbadensis*, *A. ferox* and *A. arborescence* are used as herbal drugs. *Aloe vera* is grown largely in South America, Central America, Australia and Africa. *Aloe vera* is cultivated in fairly large area in many in parts of India. *A. barbadensis* which revealed three types of leaf spots and root rot disease (Sharma and Samota 2007). A stabilized product is incorporated in a wide variety of preparation, including juice, gel, ointments, cream, lotion and shampoos (Daodu 2000). The leaf yield varied from 0.599 to 2.922 kg per plant per year due to disease in different genotypes (Abhila and Jessyeutty 2010). The gel/juice is consumed directly and used in many preparations therefore it is necessary to raise plant without use of chemicals. Management of leaf rot disease of *Aloe vera* is mainly achieved through the use of chemicals. Use of fungicides has led to the emergence of several problems like enviremental pollution, residual effect, killing of benifecial organisms and devlopment of resistant in pathogen. Therefore, cultivation of resistant genotypes of *Aloe vera* is one of the desirable management options, but their long term stability virtue of true resistance are need for their confirmation under field condition because the role are mineral metabolism and total soluble phenol an imparting resistance/susceptibility against fungus diseases of plant has been also infested (Ashfaq et al. 2014a, b). The leaf rot resistant genotypes under open field condition have been reported by Kumar (2008). However, very limited information is available on the sources of resistance against leaf rot disease in *Aloe vera*. In view of the importance of *Aloe vera* in Indian agriculture, some *Aloe vera* genotypes were evaluated against leaf rot caused by *F. oxysporum*.

The experiment was conducted during *Kharif* season 2014 and 2015 at experimental farm of Medicinal and Aromatic Plant at N.D. University of Agriculture & Technology, Kumarganj, Faizabad. Twenty-six Aloe germplasm/cultivars were screened against *F. oxysporum*. The old suckers were transplanted in second week of July at a spacing of 50×40 cm in augmented design under field condition for evaluation of their resistance against leaf rot of *Aloe vera*. Three rows of Aloe leaf rot susceptible cultivar IC-471882 (Check) were planted. Recommended package of cultural practices was followed to raise the crop and to promote natural infection. Ten plants in each plot were randomly selected and tagged for visual observations on symptoms appearance

Date of Receipt: 26.08.2021; Accepted: 27.09.2021

ABSTRACT

The results revealed that egg hatching and larval mortality of *Meloidogyne incognita* in culture filtrate of *Trichoderma viride* and *Trichoderma harzianum* increased with the increase in the concentration of culture filtrate and time duration. The egg hatching in *Trichoderma viride* culture filtrate was highest (100.00) in the 5.0% concentration followed by 89.00, 81.50, 72.50, 66.25, 56.75, 53.50, 42.25 and 34.00 at 36 hours and 169.50, 154.25, 142.00, 128.25, 121.25, 95.50, 75.25, 65.50, 42.25 at 72 hrs time duration time in 5, 10, 15, 20, 30, 40, 50, 75, 100% filtrate concentration, respectively. The larval mortality was observed highest 72.25% in 100% concentration of the culture filtrate followed by 4.00, 17.00, 22.00, 42.25, 47.50, 54.50, 63.00, 67.50, and 72.25% at 36 hrs interval and 13.75, 26.00, 41.25, 56.75, 59.75, 66.50, 72.00, 77.75 and 81.00% mortality at 72 hrs in 5, 10, 15, 20, 30, 40, 50, 75 and 100% concentration treatment. In *Trichoderma harzianum* culture filtrate was recorded highest (82.25) in the 5.0% concentration followed by 72.00, 67.50, 60.25, 54.50, 49.25, 40.75, 31.50 and 24.75 at 36 hrs and 148.00, 136.75, 126.50, 118.00, 99.25, 79.75, 65.50, 52.50, 31.25 at 72 hrs time duration time in 5, 10, 15, 20, 30, 40, 50, 75, 100% filtrate concentration, respectively. The larval mortality was observed highest 86.00% in 100% concentration of the culture filtrate followed by 6.25, 16.75, 23.50, 29.50, 48.75, 58.25, 64.50, 74.00, and 86.00% at 36 hrs interval and 13.25, 32.00, 47.75, 53.50, 64.00, 69.50, 76.25, 84.75 and 93.50% mortality at 72 hrs in 5, 10, 15, 20, 30, 40, 50, 75 and 100% concentration treatment. The % reduction in egg hatching when eggs were exposed to the culture filtrate of *Trichoderma viride* and *Trichoderma harzianum* in comparison to the control was recorded 26.72, 35.85, 39.86, 46.32, 51.44, 56.12, 63.69, 71.93 and 77.95 at 36 hrs and 12.81, 19.44, 25.47, 30.48, 41.53, 53.01, 61.41, 69.07 and 81.59 at 72 hrs exposer time in *T. harzianum* culture filtrate on the other hand in *T. viride* recorded 10.35, 24.73, 31.07, 38.68, 43.97, 52.00, 54.75, 35.72, 71.25 and 71.25 at 36 hrs and 3.00, 11.73, 18.74, 26.60, 30.61, 45.35, 56.93, 62.51 and 75.82 % at 72 hrs exposer period.

Key words: Filtrate on egg hatching, *Meloidogyne incognita*, *Trichoderma* spp.

Nematode diseases are known to be one of the most widespread in the last two decades that attract the attention of researchers, especially those in the field of the plant protection, there are thousands of genus and species of plant parasitic nematodes, which cause damage in quality and quantity of the yield in varied crops; moreover, increasing the costs of production. The most famous and destructive genus around the world is the root-knot nematode, *Meloidogyne incognita*, because of its wide host range which includes more than 2000 hosts, such as vegetables, fruit trees, fiber, oil seeds, grain and

Abstract- Effect of chemical, bio-agents and *Rhizobium* was tested alone and in combination to see their individual as well as combined effect on wilt disease management in pot under net house conditions. Eighteen treatments were under taken in this study, among them highest per cent disease control (70.89%) was recorded with *Rhizobium* (ST)+ Carbendazim.(ST)+ *Pseudomonas sp.*(SoilT) followed by *Rhizobium*(ST)+Carbendazim.(ST)+ *Bacillus subtilis* (SoilT) (67.05), *Rhizobium* (ST)+Carbendazim. (ST)+T.h. (64.64%), *Rhizobium*(ST) + soilT *T.harzianum* (63.36%), *Rhizobium*(ST) + Carbendazim. (ST) (59.47%), *Rhizobium*(ST) + *Pseudomonas fluorescens* (SoilT) (58.94%), *Rhizobium*(ST)+*Bacillus subtilis* (SoilT) (57.12%), *Rhizobium(ST)* + *T.harzianum*(SoilT) (56.66%), *Rhizobium*(ST) + *T.harzianum*(ST) (56.41%), Carbendazim.(ST) (52.48%), *Pseudomonas fluorescens* (SoilT) (49.92%), *Bacillus subtilis* (SoilT)(46.24%), *T. harzianum* (SoilT) (43.52%), *Pseudomonas fluorescens* (ST) (42.08%), *Bacillus subtilis* (ST) (39.04%), *T. harzianum*(ST) (35.89%) and *Rhizobium*(ST) (17.58%) as compared to untreated pots during 2016-17.

Keywords -Biocontrol agent, Fusarium, Lentil, rhizobium sp. and fungicides.

I. INTRODUCTION

Lentil (*Lens culinaris* Medik.) is one of the major grain legume crops and play very important role in the supply of the protein to under nourished vegetarian population of the country. It is mainly grown in North-Eastern plain zone as sole and intercrop under rain-fed conditions. It suffers from a number of diseases. Wilt of lentil caused by *Fusarium oxysporum f. sp. lentis* is one of the most wide spread and destructive disease where ever crop is grown. Lentil is cultivated as a rain fed crop in all India about 1.34 million ha area with 1.02mt production and 759 kg/ha productivity (**Abraham, 2015**). In India lentil is predominantly grown in the North, particularly in Uttar Pradesh, Madhya Pradesh, Bihar and West Bengal. In Uttar Pradesh, it is grown in 620.000 lakh/ha area with 452.000lakh tones production and 732.0 kg/ha productivity (**Ahmad, *et al.*, 2018**).Many attempts have been made to control this disease using chemical, biological, varietal and cultural methods (**Ram and Pandey, 2011; Sinha and Sinha, 2004; Khan and Mehnaz, 2003; Srivastava *et al.*, 2000**). None of the control measures found to be effective individually at field level. Seed treatment with fungicide, *Rhizobium* and bio-agents are most commonly used methods are often used in integrated management. However, the present investigation deals with the integrated management of lentil wilt by integrating chemical, bioagents.

II. MATERIAL & METHODS

Experiment was conducted in pots under net house conditions with sterilized soil. Soil inoculated with *F. oxysporum* f.sp. *lentis* 5% inoculum Chemical, bio-agents and *Rhizobium* was tested alone and in combination to see their individual as well as combined effect on disease management. For seed treatment fungicide (carbendazim), bioagent (*T. harzianum*) and *Rhizobium,* integration of these treatments, the seed was first treated with carbendazim (0.2 per cent) followed by 24 hours later with *Trichoderma harzianum* (0.4 per cent) than *Rhizobium* (0.2 per cent) and soil treatment. The treated seeds was sown in the pots. The seed of lentil (susceptible variety- L 9-12) was sown in each pot (15 seed per pot) where finally 10 plants was maintained. The experiment was conducted in CRD with 18 treatments including control.

Treatment details:
Variety- L 9-12
Replication-3; Design-CRD; Treatments-18
T_1-Seed treatment with *Rhizobium leguminoserum*@0.2g/kg
T_2-Seed treatment with *Bacillus subtilis*. @10 g/kg
T_3- Seed treatment with *Trichoderma harzianum*@4g/kg

Diseases Caused by Bacteria and Phytoplasmas

First Report on Clover Proliferation Phytoplasma Related Strain Associated with *Matthiola incana* Floral Virescence in Uttar Pradesh, India

Pritam Panda,[1] Jay Kumar Yadav,[2] Sushil Kumar Singh,[2] Amrita Nigam,[3] and G. P. Rao[1]†

[1] Discipline of Life Sciences, Indira Gandhi National Open University, New Delhi 110068, India

Plant Dis. 0:1, 2021, published online as https://doi.org/10.1094/PDIS-10-20-2188-PDN. Accepted for publication 14 December 2020.

Matthiola incana (L.) R. Br. (family Brassicaceae) is an ornamental commonly known as hoary stock and has extremely fragrant flowers, which bloom in dense clusters in a large variety of colors. During a survey of flowers nurseries in March 2019 at the Indian Institute of Sugarcane Research campus, Lucknow, flower virescence (MiV) symptoms were observed in *M. incana* pots with an incidence of over 40%. Leaf yellows symptoms were also observed on a weed, *Acalypha indica* (AiLY), in the *Matthiola* nursery. Nested PCR assays were carried out to detect and identify the possible association of phytoplasmas with MiV and AiLY symptoms. Symptomatic MiV and AiLY samples and nonsymptomatic samples were collected and processed for DNA extraction from the leaf midrib by the CTAB method. *Hishimonus phycitis* (HP) (Hemiptera: Cicadellidae) leafhoppers feeding on MiV symptomatic plants were also collected and DNA extracted. The DNA of eight symptomatic and four nonsymptomatic plants and from the 10 leafhoppers was used as a template for PCR assays. Phytoplasma specific primers for the 16S rRNA gene (P1/P7 and 3Fwd/3Rev; Schneider et al. 1995; Manimekalai et al. 2010) and multilocus gene specific primer pairs for *secA* (SecAfor1/SecArev3, SecAfo5a/SecARev2; Bekele et al. 2011), *secY* (SecYFH(VI)/SecYRH(VI), SecYF2(VI)/SecYR1(VI); Lee et al. 2010), and *rp* genes (rpIF3C/rpCDR1A (rpVDF2/rpVDR2; Martini et al. 2002) were employed as previously described. Amplified products of ~1.8 kb, ~600 bp, ~1.7 kb, and ~1.0 kb of 16S rRNA, *secA*, *secY*, and *rp* genes of phytoplasma were consistently amplified in all the MiV and AiLY samples and in the HP leafhopper. No amplifications were achieved in any of the asymptomatic plant samples. Amplified products of all the four genes of MiV, AiLY, and HP isolates were purified, sequenced, and submitted to GenBank. Sequence comparison and phylogeny analyses of the sequences of the four genes of MiV, AiLY, and HP isolates revealed 99 to 100% sequence identity and clustering with clover proliferation phytoplasma related strains (16SrVI group). The virtual restriction fragment length polymorphism analysis with 17 restriction endonucleases corresponding to the 16S rRNA gene sequences of MiV, AiLY, and HP phytoplasma strains by pDraw program assigned them into a novel phytoplasma subgroup strain under 16SrVI group. Because its *Hpa*II restriction profile was different from earlier classified 16SrVI subgroups but was very close to 16SrVI-E (GenBank accession no. AY201566; Eastern peanut witches' broom (16SrII-A) phytoplasma was identified associated with *M. incana* from Italy (Davino et al. 2003). However, the association of clover proliferation phytoplasma (16SrVI) related strain associated with virescence symptoms of *M. incana* is the first report in world. The weed (*A. indica*) and HP leafhopper were also reported as additional host and putative vector of the 16SrVI subgroup related new strain in India, which needs further investigation. The report of a new host and new subgroup of clover proliferation phytoplasma related strain in India has an epidemiological significance and warrants attention.

ABSTRACT

Field experiments were conducted in Faizabad during 2014-15 and 2015-16 cropping season to evaluate the effect of different control options (seed treatment with Carbendazim, *Trichoderma harzianum* and intercropping with linseed, alone and in combination) on lentil wilt caused by *Fusarium oxysporum* f. sp. *lentis*. The results indicated that seed treatment with *Trichoderma harzianum* (4g/kg seed) + Carbendazim (1g/kg seed) + intercropping with linseed (2:1 ratio) found minimum wilt incidence (11.67%), maximum disease control (72.06%) and higher yield (1291 kg/h) as compared to check having maximum wilt incidence (41.78%) and lowest yield (597 kg/h).

Introduction

Lentil (*Lens culinaris* Medik.) is one of the major grain legume crops and play very important role in the supply of the protein to under nourished vegetarian population of the country. It is mainly grown in North-Eastern plain zone as sole and intercrop under rain-fed conditions. It suffers from a number of diseases. Studies on survey of dry root rot of chickpea incidence in chickpea growing districts of Uttar Pradesh

Jay Kumar Yadav and SK Singh

Abstract
Chickpea (*Cicer arietinum* L.) Is an important pulse crop of India popularly known as Gram. Dry root rot of chickpea is the most severe disease in the central and southern zone, where the crop is mostly grown under rainfed condition. *Rhizoctonia bataticola* (Taub.) Butler is one of the most distructive pathogen causing dry root rot disease in chickpea. The survey studies indicated that overall dry root rot incidence compratively higher in Ayodhya districts (27.39%) grown chickpea crop, compared to other four districts (Basti, Gonda, Sultanpur and Kanpur). In five districts of Uttar Pradesh survey, the disease was found to be widely distributed and regular occurance with moderate to severe incidence and its, average both years (2017-18 and 2018-19) incidence was found maximum in the districts of Ayodhya (27.39%) followed by Kanpur (25.29%), Sultanpur (23.89%), Gonda (11.41) and Basti district (10.30%).

Keywords: Chickpea, survey, dry root rot, disease incidence and *Rhizoctonia*

Introduction
Chickpea (*Cicer arietinum* L.) Known by different names i.e Gram, Spanish pea, Chestnut bean (English), Poischiche (French), Homos (Arabic), Garbanzo (Spanish) and Chana (Hindi). Mainly two types of chickpea are grown, brown seeded types (Desi) and white seeded called "Kabuli" (Haware *et al.* 1986). Chickpea belongs to Leguminaceae family usually grown after rainy season on conserved soil moisture during winter in the tropics; in spring in the temperate and Mediterranean regions. The total world acreage under pulses is about 85.40 (Mha) with production of 87.40 (Mt) and 1023 kg/ha productivity. India, with >29 Mha pulses cultivation area, is the largest pulse producing country in the world. It ranks first in area and production with 34 per cent and 26 per cent respectively. During 2017-18 the country's productivity at 835 kg/ha, is a significant increase over Eleventh (662 kg/ha) and Twelfth plans (745 kg/ha). The area of Uttar Pradesh is 562 Th area with a production of 626.00 Tt and productivity of 1114 kg/ha (Anonymous, 2018)[1]. Dry root rot is one of the major production constraints that cause 10-20 per cent annual loss (Vishwadhar and Chaudhary, 2001)[14]. Dry root rot of chickpea is the most severe disease in the central and southern zone, where the crop is mostly grown under rainfed condition. *Rhizoctonia bataticola* (Taub.) Butler is one of the most distructive pathogen causing dry root rot disease in chickpea. Among the diseases of chickpea, dry root rot is emerging as the most destructive constraint to chickpea production, as the disease is more prevalent during hot temperature of 30 to 35°C and low soil moisture conditions (Taya *et al.*, 1988; Pande and Sharma, 2010)[13, 8]. Dry root rot caused by *Rhizoctonia bataticola* (Taub.) Butler [Pycnidial stage: *Macrophomina phaseolina* (Tassi) Goid] is a soil and seed borne necrotrophic fungal pathogen that has a global distribution. It can infect more than 284 plant species throughout the world including monocot and dicots (Farr *et al.*, 1995)[2].

Method and Materials
The survey for the occurrences and incidence of chickpea dry root rot was conducted during crop *Rabi* season 2017-18 and 2018-2019. Observation was recorded on farmer's field under natural conditions. The survey were conducted to record the occurrence and distribution of dry root rot of chickpea in 25 blocks of the five chickpea growing districts in Uttar Pradesh, India *viz.* Basti, Gonda, Faizabad, Sultanpur and Kanpur during Rabi 2017-18 and 2018-2019. The blocks and farmers field in each districts were selected randomly. The five blocks visited per district and a distance of 15 - 20 km. To assess the disease incidence, five to seven fields were observed in each blocks and average incidence of the disease in each blocks was calculated. During the survey disease incidence was recorded. Four 1m2 quadrants were randomly selected in each field and infected plants were counted in each quadrant. Based on infected and

Efficacy of different soil amendment on disease incidence of dry root rot of chickpea during year 2017-2018

Jay Kumar Yadav and SK Singh

Abstract
Chickpea (*Cicer arietinum* L.) is an important pulse crop of India popularly known as Gram. Dry root rot of chickpea is the most severe disease in the central and southern zone, where the crop is mostly grown under rainfed condition. *Rhizoctonia bataticola* (Taub.) Butler is one of the most distructive pathogen causing dry root rot disease in chickpea. The efficacy of different soil amendment *viz.*, Neem oil cake, Mustard oil cake, Linseed oil cake, Saw dust and Parthinium were evaluated for the management of dry root rot disease of chickpea in pot condition during 2017-18. Among the amendment, Neem oil cake was found effective in reducing the disease incidence, delay the appearance of disease and increase in germination, fresh and dry plant weight, number of branches/plant, number of pods/plant, plant height(cm), test weight (100 seed) and yield (gm)/plant. Among the amendment Neem oil cake was found most effective which delayed appereance of symptoms till 110 days after sowing (DAS) and maximum seed germination (92.67%) as compared to control 85 DAS and seed germination (80.0%) during 2017-2018.

Keywords: Chickpea, soil amendment, dry root rot, disease incidence and *Rhizoctonia*

Introduction
Chickpea (*Cicer arietinum* L.) known by different names *i.e* Gram, Spanish pea, Chestnut bean (English), Poischiche (French), Homos (Arabic), Garbanzo (Spanish) and Chana (Hindi). Chickpea belongs to Leguminaceae family usually grown after rainy season on conserved soil moisture during winter in the tropics; in spring in the temperate and Mediterranean regions. Application of botanicals for effective management of *Alternaria* blight of Pigeon pea

Utkarsh Singh Rathore, SK Singh, Sandeep Kumar and Saloni Rishi

Abstract
Pigeon pea (*Cajanus Cajan* L. Millsp.) is an important pulse crop of India and grown in *Kharif* seasons. *Alternaria* blight caused by *Alternaria tenuissima* is one of the most important disease of pre-rabi Pigeon pea. An inexpensive and environment friendly management regimen is required to minimize loss due to *A. temuissima*. The inhibitory effect of 17 botanicals were evaluated both *in vitro* and *in vivo* at 10 and 15 per cent concentration of plant extracts against *A. tenuissima*. The results showed that the effectiveness of extracts was directly proportional to their concentration. Among all plant extracts were neem showed maximum inhibition against *A. tenuissima* at 15% concentration after 7 days of incubation *in vitro* followed by Eucalyptus and Garlic. However, percent disease control in between Neem and Eucalyptus; Garlic and Mehandi; Ginger and Tulsi; Kaner and Onion; Lantana and Sadabahar; Bael and Bhang; Parthenium and Marigold were at par to each other.

Keywords: Pigeon pea, botanicals, percent disease control, *Alternaria tenuissima*

Introduction
The yield of Pigeon pea (699kg/ha) is much lower than potential yield of 2000 to 2500 kg/ha with improved varieties. The poor yield of Pigeon pea is mainly due to biotic stress like diseases and insect pests.

The crop is infected by 210 pathogens (83 fungi, 4 bacteria, 19 viruses and mycoplasma and 104 nematodes) reported from 58 countries. The maximum number has been reported from India with 98 pathogens (Nene *et al.*, 1996) but only few of them like wilt, sterility mosaic, phytophthora blight and *Alternaria* blight are major and destructive diseases.

Alternaria blight caused by *Alternaria tenuissima* is one of the most widespread and destructive foliar diseases of Rabi Pigeon pea. The disease was first described by Pavgi and Singh in 1971 followed by Kannaiyan and Nene in 1977-1980 crop season on September planted Pigeon pea cultivar (Bahar and Basant) in northern Indian staes of Uttar Pradesh and Bihar (Mehta and Sinha, 1982; Narula, 1983 and Venkateswarlu et al., 1981). The fungus causing leaf spot of Pigeon pea observed by Kannaiyan and Nene in year 1997 at ICRISAT, Hyderabad. The disease appeared in epiphyotic form on September planted Pigeon pea during February, 1980 in Muzzaffarpur district of Bihar and also in 1981 in Varanasi and other areas of eastern Uttar Pradesh. (Kannaiyan and Nene, 1977).

The incidence varied from 18.0% to 37.5% in different locations of Central Uttar Pradesh. (Kushwaha *et al.*, 2010). Hence, for minimizing the losses caused by *Alternaria* blight need inexpensive and environmentally safe management practices.

It was, therefore considered desirable to disease management through botanicals with the following objectives:

1. Efficacy of botanical against *A.tenuissima in vitro* and
2. Efficacy of botanical against *A.tenuissima in vivo*.

2. Materials and Methods
The present studies were carried out in the laboratory and glass house of the Department of Plant Pathology, Narendra Deva University of Agriculture and Technology, Narendra Nagar (Kumarganj), Faizabad (U.P.). The details of materials used, experimental procedures followed and techniques adopted are given as under:

Lentil (*Lens culinaris* Medik.), one of the major pulses cultivated and consumed in India, is also known as Masur It has a high nutritive value and major source of dietary proteins (25%) after soybeans in human and animal diet. *Fusarium* wilt of lentil caused by *Fusarium oxysporum* f.sp. *lentis* is the most serious disease of lentil. Ten isolates of *F. oxysporum* f.sp. *lentis* were studied for its cultural, morphological and pathogenic variability. Pigmentation is varied among the isolates. Out of 10 isolates, 4 isolates FOL-R3, FOL-V8, FOL-M6 and FOL-R9 were Purple, were dull yellowish, isolates FOL- B7, and FOL-S10, four isolates like FOL-A2, FOL-L4, FOL-S5 and FOL-S10 were white FOL-F1was light puff in coloure. The size of microconidia varied between7.30×3.43 (FOL-L4) to 13.25 x 2.68µm (FOL-S10) and macroconidia varied from 24.11×4.67 (FOL-A2) to 40.05 x 4.71µm (FOL-V8). The number of septa in macro-conidia was mostly 3-6 and micro-conidia are mostly no septum and some are 0-1. Chlamydospore are terminal and intercalary. Pathogenic variability revealed that most of the isolates were highly pathogenic.

Introduction

Lentil (*Lens culinaris* Medik.), is a member of Leguminaceae family and it is commonly known as masoor or poor man's meat. It has a high nutritive value and major source of dietary proteins (25%) after soybeans in human and animal diet (Rahman *et al.,* 2010). It is cultivated as a rain fed crop in all India about 1.34 million ha area with 1.02mt production and 759 kg/ha productivity (Abraham, 2015). In India lentil is predominantly grown in the North, particularly in Uttar Pradesh, Madhya Pradesh, Bihar and West Bengal. In Uttar Pradesh, it is grown in 620.000 lakh/ha area with 452.000 lakh tones production and 732.0 kg/ha productivity (Ahmad, 2017). It suffers from a number of diseases. Wilt of lentil caused by *Fusarium oxysporum f. sp. lentis* is one of the most wide spread and destructive disease where ever crop is grown. The yield losses due to this disease as much as 50 percent have been reported in India (Anonymous, 1999). The disease manifests as mortality of young seedlings (within 25 to30 days after sowing) to wilting or death of adult plants. Early wilting causes more loss than late

Abstract Phytoplasma suspected symptoms of little leaf, flat stem, witches' broom and leaf yellowing were recorded on the four legume species, cowpea (*Vigna unguiculata* (L.) Walp.), pigeon pea (*Cajanus cajan* (L.) Millsp.), lentil (*Lens culinaris* Medikus) and mung bean (*Vigna radiata* (L.) Wilczek) in the states of Delhi, Uttar Pradesh (UP) and Kerala from 2014 to 2016. DNA specific fragments of approximately 1.3 kb were amplified from symptomatic samples of cowpea, pigeon pea, lentil and mung bean in nested PCR assays by using two sets of universal phytoplasma nested specific primers P1/P7 followed by 3Far/3Rev. No DNA amplifications were observed in any of the non-symptomatic legume samples with same primer pairs. Pair wise sequence comparison, phylogeny and virtual RFLP analysis of 16S rDNA sequences of the four legume species confirmed the association of four different groups and subgroups of phytoplasmas in the present study. The mung bean witches' broom at Delhi was identified to be associated with strain related to '*Ca.* P. aurantifolia' (16SrII-D), pigeon pea little leaf at Faizabad, UP with strain related to '*Ca.* P. phoenicium' (16SrIX-C), lentil witches' broom at Faizabad, UP with '*Ca. P. trifolii*' (16SrVI-D) and cow pea flat stem disease at Kerala with '*Ca.* P. cynodontis' (16SrXIV-A). Association of '*Ca.* P. cynodontis' (16SrXIV-A) infecting cowpea, '*Ca. P. trifolii*' (16SrVI-D) in lentil and phytoplasmas strain related to '*Ca.* P. phoenicium' (16SrIX-C) infecting pigeon pea are the new reports to the world.

Keywords Phytoplasma · Identification · Cowpea · Pigeon pea · Lentil · Mung bean

Legumes are a significant source of protein dietary fiber, carbohydrates and dietary mineral, grown agriculturally, primarily for their seed, for livestock and silage, and as soil-enhancing green manure. Cowpea is one of the most important legumes across the semiarid tropics valued for its pods and dried seeds (Kumar et al. 2012). In India, cowpea is grown in an area of 3.9 million hectares with a production of 2.21 million tonnes with the national productivity of 683 kg per ha (Singh et al. 2012). Mung bean is an important edible legume grown in Asia, particularly in the Indian subcontinent, where it is used for human and animal consumption. India is the world's largest producer as well as consumer of green gram (*Vigna radiata*). It produces about 1.5 to 2.0 million tons of mung bean annually from about 3 to 4 million hectares of area, with an average productivity of 500 kg per hectare. Lentil (*Lens culinaris*) is one of the oldest known protein-

Abstract

The main objective of the present study was to analysis the economics and benefit cost ratio of Brinjal in two villages of Ghazipur district of Uttar Pradesh, India. It was found that the farmers of all selected randomly groups has been taken the crop on their field through a good advance package of practices, therefore their yield and net return in all size groups increased respectively in time. The study concludes yield and net return should be increased in future if they go through a good farm plans along with better crop management systems.

Key Words: Village, Farmers, Yield, Income, Farm plans.

Introduction

Brinjal (*Solanum melongena* L.) is warm season crop its plant not with stand frost the main sowing season being during July-August for a good yield 20-25 tons of FYM per hectare incorporated into the soil at the time of field preparation. It is necessary to maintain an even moisture supply in the soil; over watering is as harmful as insufficient irrigation. In this crop, phomopsis wilt is the most important fungal disease and is seed borne. Hot water treatment of the Seed helps to reduce the incidence of the disease. Little leaf is caused by mycoplasma and can be partially controlled with antibiotics. Brinjal is prone to attack by many damages caused by insects, pests, fungus, bacteria and viruses Purohit ML and Khatri AK (1973). Brinjal productions area consistently and extensively damaged by brinjal fruit and shoot borer and other fruit borer insects reported by Kuppu Swamy and Balasubramanian (1980). To reduce pest linked damage in brinjal as well as to protect the environment from adverse effect of pesticides, as an insect resistance management strategy Ghosh *et al.,* (2003). In India brinjal is the major source of profitable income for farmers because of local demand and it is a perennial crop so that fruit can be harvested throughout the year. A large number of brinjal varieties and hybrids are grown by small medium, large size of farmers throughout the year.

Materials and Methods

The present study was conducted in two randoml selected villages namely Jaitpur (Block-Sador) an secondly Gaura (Block-Sadat) in Ghazipur district of Utta Pradesh, India with farmers Scientist Collaborations i demonstrated groups small, medium and large size whil selected randomly seven farmers from each group Narendra hybrid Baigan-1 has been suggested seed rat 500-600 gram per hectare during field preparations 2 tons of FYM allowed to the soil planting distance line t line 60-75 cm and plant to plant are 45-60 cm. wa proposed. Crop was taken on the field during July-Augus Season N:P:K:@ 100:50:25 Kg/hectare for better qualit and better yield advised. All the advance package c practices has been specify for timely whenever neede Survey method has been used to collect the data an tabular analysis was being used. Family schedule ha been used to collect the data from the selected farme according to their size of holdings, family size, area the productionand income of the crop etc.The economi has been calculated at their current price rates.

[5]Department of Horticulture, Krishi Gyan Kendra, Baribag, Ghazipur (U.P.), India.

Abstract

The main aim of present study was to find out the productivity and income levels of Potato (Kufri Sinduri) on randomly selected in different farm size groups in randomly selected village Govindpur and Kusmahi Khurd of Ghazipur district of U.P., India. It was found that yield and net income was increased in all size groups in both villages, but village Kusmahi Khurd farmers perform well. The result shows that all the package of practices was properly used. For the better yield and good quality of crop in future farmers of the both villages have aware about their application of all the Agro-Economical package of practices and crop management.

Key words: Yield, Income, Package of practices, Specific trends.

Introduction

Potato is one of the most valuable and cash crop in the world as well as in our country Indian. It is capable of producing more weight and calories for human beings in comparison to other crops. For this crop some time manual weeding is tedious which causes root injury resulting yield and qualities are affected under such circumstances chemical weeding is economical and preferable. Gran manuring, recycling crop residues and animal manures, and the inclusion of legumes in rotation, is important. Integrated nutrient supply is essential for production and qualities. Nitrogen plays an important role in improving the growth and its yield. Evidence is growing of favorable effect of phosphate solubilizing bacteria in providing plant nutrients to several crops and in supplements the expensive inorganic fertilizers. Sing and Sharma (1994) and Daka and Dutta (1997) reported significant response of potato to Nitrogen level in acidic soils. Combine inoculation of Azotobacter and Phospho-inoculant culture is good for tuber yield and qualities. Use of Azotobactor and phospho-inoculant indicates that the bio-fertilizer increased the efficiency of applied nitrogen. Use of organic sources of nutrients, good quality of compost is better for tuber yield with better qualities Potato tubers are planted either whole or cut into pieces. This crop needs irrigation of frequent intervals depend upon the soil and climatic conditions. Usually, six irrigation are sufficient.

Materials and Methods

The present study was conducted in the selected randomly Village Govindpur of (Block-Mardah) and Kusmahi Khurd (Block-Devakali) in Ghazipur district of Uttar Pradesh, India through collaborations of farmers-scientist on the basis of small, medium and large size of farms. Randomly selected seven farmers from each groups Kufri-Sinduri Variety of potato suggested for the above demonstrated groups. For better yield suggested 25 tons of FYM along with 120:80:100 Kg/heet of NPK. The crop has been taken on the field during second fort night of November on ridges. All advance packages of practices has been specify for timed application or whenever it needed. Survey method has been used to collect the data and tabular analysis was being made. family schedule has been used to collect the data from the selected farmers according to their size of holdings family size, area of the production and income of the

[4]Department of Agricultural Economics, College of Agriculture, Kotwa, Azamgarh (U.P.), India.
[5]Department of Home Science, Krishi Gyan Kendra, Deoria (U.P.), India.

Abstract

The main objective of the present study was to study the Economics of Chilli in the randomly selected farmers of villages in Ghazipur district of Uttar Pradesh, India. It was found that farmers has adopted all the advance package of practices and applied time to time during the cropping time resulted good yield and high net incomes. In future it will also be improved whenever they use better crop management practices with high profile business thinking.

Key Words: Village, Yield, Farmers, Specific, Trends, Exhibits.

Introduction

Chilli also called 'red paper' is an important cash crop in India and is grown for its pungent fruits, which are used both green and ripe (the letter in the dried form) to import pungency to the food. As a condiment, it has becomes indispensable in every Indian home. It is also used medicinally, and in chantries and pickles. Capsicum plants are herbaceous or semi woody annuals or perennials very high rainfall during its growth is harmful. Under irrigation and good manuring, excellent crops can be raised in sandy and light alluvial loans as well as in red loamy soils. As a garden crop, it is sometimes allowed to grow as a stand-over crop for one or two seasons. The land is ploughed and harrowed 3 or 4 times to obtain a fine fifth. Recommended dose of FYM is better for good yield and better qualities. The Chilli is generally transplanted, through direct sowing. Foliar spray of Zinc and Iron not increase the yield and quality of the crop Pillai and Vadivelu (1967). The combined spray of Zinc, boron and iron through soil or its foliar Spray is better for good yielding. Saryandrayra and Hariprasad (1985) reported that these micronutrients increased the green yield of Chillies. Hosmani and Hosmani (1993) give details about Chillies inthier second edition. Seeds taken from healthy, well matured fruits selected for the purpose are mixed with ashes and shown evenly in well-manured nursery beads. The nursery treatment and other recommended practices had been taken at the time of their requirements.

Materials and Methods

The present study was conducted on the field in Ghazipur district of Uttar Pradesh, India in randomly selected two villages namely Bishunpura (Block-Karanda) and Secondly Gajpatpur (Block-Berno) through farmers-scientist collaborations ranging small, medium and large size farmers groups. Seven farmers from each groups has been selected randomly. Pusa Sadabahar Chilli Variety has been offered for the demonstrations. Allowed 1 Kg. seed for a hectare to maintain line to line distance about 50 Cm and plant to plant distance 45 Cm. The crop has been taken on the field on the field during August-September. All the package of practices has been introduced to the farmers for their better yield and qualities regarding time to time applications. All the information has been collected through survey method and tabular analysis was being used. Family schedule has been used to collect the data regarding family size, area of the crop, expenditure and net income. Emphasis has been given on cultural operation irrigation and other recommended practices for the upliftment of the crop.

Abstract: Integrated Weed Management (IWM) means integrating multiple weed control tactics into a single weed management program, optimizing control of a particular weed problem. The past several decades have seen simplified weed control practices that rely heavily on a few popular herbicides. However, the rapid spread of herbicide-resistant weeds has required farmers to incorporate alternative weed management approaches. While many farmers are incorporating different herbicides, this is likely to have only short-term success. Using non-herbicide approaches in combination with multiple, effective sites of action is needed for long-term success. It might be better to first discuss why weed control is necessary. Weeds negatively impact crop yields, interfere with many crop production practices, and weed seeds can contaminate grain. Based on national research, corn and soybean yield can be reduced by approximately 50% without effective weed control.

Herbicide application is the main weed control strategy used. Reliance on this one method has led to the development of herbicide-resistant weeds. There are a limited number of herbicides available to use and cases of herbicide resistance are rapidly increasing in the US. As a result, herbicides are in need of extra help to continue to ensure adequate weed control.

IWM tactics span a wide range of options and complexity. Many IWM tactics can be integrated without substantial change to current management programs, while others require more extensive planning and implementation. Some options that are easier to implement include: equipment cleaning, timely scouting, altering herbicide tank mixes; while more extensive options include: changing crop rotation, cover cropping, changing tillage practices, and harvest time weed seed control.

The goal of IWM is to incorporate different methods of weed management into a combined effort to control weeds. Just as using the same herbicide again and again can lead to resistance, reliance on any one of the methods below over time can reduce its efficacy against weeds. Two major factors to consider when developing an IWM plan are (1) target weed species and (2) time, resources, and capabilities necessary to implement these tactics.

ABSTRACT

Basmati, pronounced is a variety of long, slender-grained aromatic rice which is traditionally grown in India, Pakistan, Bangladesh and Nepal. As of 2019, India accounted for 65% of the international trade in basmati rice, while Pakistan accounted for the remaining 35%.Many countries use domestically grown basmati rice crops; however, basmati is geographically exclusive to certain districts of India and Pakistan.According to the Indian Government agency APEDA, a rice variety is eligible to be called basmati if it has a minimum average precooked milled rice length of 6.61 mm (0.260 in) and average precooked milled rice breadth of up to 2 mm (0.079 in), among other parameters. The areas which have GI tag for basmati rice production in India are in the states of Punjab, Haryana, Himachal Pradesh, Delhi, Uttarakhand, Western Uttar Pradesh and Jammu and Kashmir. India's total basmati production for the July 2011–June 2012 crop year was five million tonnes.From April 2018 to March 2019, India exported 4.4 million metric tons of basmati rice.In 2015–16, Saudi Arabia, Iran and UAE were the three biggest destinations for India's basmati rice exports and exports to these three countries accounted for more than half of India's total basmati exports.In 2015–16, basmati rice worth US$3.4 billion was exported from India.

There are several varieties of basmati rice. Traditional Indian types include basmati 370, basmati 385, and basmati Ranbirsinghpura (R.S.Pura) and Gujjar Chack area in Jammu province situated at the India-Pakistani border in Jammu and Kashmir state of India. 1121 and Muradabadi 6465 Extra Long Grain Rice. Pakistani varieties of basmati rice are PK 385, Super Kernel Basmati Rice and D-98.Scientists at Indian Agricultural Research Institute, Delhi, used conventional plant breeding to produce a hybrid semi-dwarf plant which had most of the good features of traditional basmati (grain elongation, fragrance, alkali content). This hybrid was called Pusa Basmati-1 (PB1; also called "Todal", because the flower has awns); crop yield is up to twice as high as traditional varieties. Fragrant rices that are derived from basmati stock but are not true basmati varieties include PB (also called sugandh-2), PB3, and RS-10.

Key words: Yield, Income, Package of practices, Specific trends.

Introduction

Potato is one of the most valuable and cash crop in the world as well as in our country Indian. It is capable of producing more weight and calories for human beings in comparison to other crops. For this crop some time manual weeding is tedious which causes root injury resulting yield and qualities are affected under such circumstances chemical weeding is economical and preferable. Gran manuring, recycling crop residues and animal manures, and the inclusion of legumes in rotation, is important. Integrated nutrient supply is essential for production and qualities. Nitrogen plays an important role in improving the growth and its yield. Evidence is growing of favorable effect of phosphate solubilizing bacteria in providing plant nutrients to several crops and in supplements the expensive inorganic fertilizers. Sing and Sharma (1994) and Daka and Dutta (1997) reported significant response of potato to Nitrogen level in acidic soils. Combine inoculation of Azotobacter and Phospho-inoculant culture is good for tuber yield and qualities. Use of Azotobactor and phospho-inoculant indicates that the bio-fertilizer increased the efficiency of applied nitrogen. Use of organic sources of nutrients, good quality of compost is better for tuber yield with better qualities Potato tubers are planted either whole or cut into pieces. This crop needs irrigation of frequent intervals depend upon the soil and climatic conditions. Usually, six irrigation are sufficient.

Materials and Methods

The present study was conducted in the selected randomly Village Govindpur of (Block-Mardah) and Kusmahi Khurd (Block-Devakali) in Ghazipur district of Uttar Pradesh, India through collaborations of farmers-scientist on the basis of small, medium and large size of farms. Randomly selected seven farmers from each groups Kufri-Sinduri Variety of potato suggested for the above demonstrated groups. For better yield suggested 25 tons of FYM along with 120:80:100 Kg/heet of NPK. The crop has been taken on the field during second fort night of November on ridges. All advance packages of practices has been specify for timed application or whenever it needed. Survey method has been used to collect the data and tabular analysis was being made, family schedule has been used to collect the data from the selected farmers according to their size of holdings family size, area of the production and income of the

Abstract

The main aim of present study was to find out the productivity and income levels of Potato (Kufri Sinduri) on randomly selected in different farm size groups in randomly selected village Govindpur and Kusmahi Khurd of Ghazipur district of U.P., India. It was found that yield and net income was increased in all size groups in both villages, but village Kusmahi Khurd farmers perform well. The result shows that all the package of practices was properly used. For the better yield and good quality of crop in future farmers of the both villages have aware about their application of all the Agro-Economical package of practices and crop management.

Abstract: Integrated Weed Management (IWM) means integrating multiple weed control tactics into a single weed management program, optimizing control of a particular weed problem. The past several decades have seen simplified weed control practices that rely heavily on a few popular herbicides. However, the rapid spread of herbicide-resistant weeds has required farmers to incorporate alternative weed management approaches. While many farmers are incorporating different herbicides, this is likely to have only short-term success. Using non-herbicide approaches in combination with multiple, effective sites of action is needed for long-term success. It might be better to first discuss why weed control is necessary. Weeds negatively impact crop yields, interfere with many crop production practices, and weed seeds can contaminate grain. Based on national research, corn and soybean yield can be reduced by approximately 50% without effective weed control.

Herbicide application is the main weed control strategy used. Reliance on this one method has led to the development of herbicide-resistant weeds. There are a limited number of herbicides available to use and cases of herbicide resistance are rapidly increasing in the US. As a result, herbicides are in need of extra help to continue to ensure adequate weed control.

IWM tactics span a wide range of options and complexity. Many IWM tactics can be integrated without substantial change to current management programs, while others require more extensive planning and implementation. Some options that are easier to implement include: equipment cleaning, timely scouting, altering herbicide tank mixes; while more extensive options include: changing crop rotation, cover cropping, changing tillage practices, and harvest time weed seed control.

The goal of IWM is to incorporate different methods of weed management into a combined effort to control weeds. Just as using the same herbicide again and again can lead to resistance, reliance on any one of the methods below over time can reduce its efficacy against weeds. Two major factors to consider when developing an IWM plan are (1) target weed species and (2) time, resources, and capabilities necessary to implement these tactics.

Assessment of variability of rice (*Oryza sativa* L.) germplasm using agro-morphological characterization

SP Giri, DK Diwedi, Saurabh Dixit, Aman Singh, V Prasad, N Prakash, SKS Rajpoot and RA Singh

Abstract
Investigation was undertaken at Crop Research Station, (ANDUAT) Masodha during 2019 to study the performance of various rice genotypes. The present study was carried out to characterize nine hundred seventy five rice germplasm accessions on the basis of twenty-nine morphological and eight agronomical traits. Most of the morphological characters showed variation in different accessions except leaf collar leaf ligule and leaf shape of ligule. A significant amount of variation was displayed for most of the agronomical traits examined. After evaluation of 975 accessions for eight quantitative characters, on the basis of mean values, top ten accessions were identified for the yield and ancillary traits. These can be used to identify phenotypically divergent sources for traits of interest in breeding programmes.

Keywords: agro-morphological characters, germplasm, variability, rice, phenotypically

Introduction
Rice (*Oryza sativa* L.) is the world's most important food crop belongs to Poaceae. It serves as the staple food for more than half of the globe's population (khan *et al*., 2013). Rice is the second most important crop which brings economic prosperity of the growers as well as earns billions of rupees through its export for country. Rice is the third highest produced cereal after wheat and maize (FAOSTAT, 2012) [9]. It is the main staple food for about 50% of the world's population, especially in developing countries (FAO, 2017) [9]. By the year 2025, global demand for rice will be 880 million tonnes compared to the current world production of 470 million tonnes of milled rice (IRRI, 2010). The average growth rate of rice yield was 3.68% annually in the 1980s, but it decreased to 0.75% per year in the late1990s and rice productions are still low in the world (FAO, 2017) [9]. In years to come, expanding the areas of rice cultivation will be limited because of land and water resource scarcity due to climate changes, urbanization and population growth. Pressure from biotic and abiotic factors, declining productivity in intensive rice production systems, increasing the cost of production and low yielding varieties are some of the factors responsible for the low yield of rice obtained by farmers. The large scale spread of modern, high yielding varieties has replaced the traditional varieties especially in the irrigated rice ecosystem leading to reduced genetic base and thus increased genetic variability. In past few decades, increase in share of high yielding varieties and shrinkage in the area of local varieties have been reported in India (Hore 2005; Rana *et al*., 2009) [17] as well as in several other countries (Chaudhary *et al*., 2006; Itani 1993) [5, 12]. There is an urgent need to broaden the genetic base of the important crop by introgressing genes from diverse sources. Breeding for rice varieties that produces higher yields of grain per unit land area is crucial to achieving increased rice production especially because of reduction in the land available for rice cultivation (Paterson *et al*., 2005) [6]. The effectiveness of any rice improvement programme depends on the utilization of different germplasm around the world (Susan *et al*., 2012) [18]. These germplasm can only be utilized optimally by breeders if it is well characterized. Therefore, the objective of this study was to characterize a set of rice germplasm collected from eastern Uttar Pradesh analyzed the agro-morphological traits.

Material and Methods
The experiment was conducted during WS 2017, 2018 and 2019 at Crop Research Station, Masodha, which is situated at 26.47°N (latitude), 82.12 °E (longitude) and at 113 m (altitude). Soil of the experimental field is sandy loam with pH 7.2, organic carbon 0.40%. Crop nursery was grown in raised beds and twenty three days old seedlings were transplanted in the first

Genetic variability studies for qualitative and quantitative traits in rice (*Oryza sativa* L.)

Rahul Kumar Maurya, DK Dwivedi, NA Khan, SP Giri and Saurabh Dixit

Abstract
The experiment was consisted of nineteen rice germplasm *viz*; IET26383, DRR Dhan-49, R-RHZ-1B-80, R-RH-2-M1-93, CGZR-1/IET 23824, Samba mahsuri, DRR Dhan 48, CR Dhan 311, R-RHZ-SM-14, MI 127, R-RHZ-111-82, IR 64, CGZR-2(IET23824), Zinco rice(IET25477), CR Dhan-310(IET 24780), R-RHP-MI-30(IET 25461), MI156, CR2818-1-11-1-B-1-1-2-B-1 and DRR Dhan 45. The analyses of variance revealed that mean sum of squares were highly significant for all the traits for rice genotypes. Genetic variability, phenotypic coefficient of variability (PCV), genotypic coefficient of variability (GCV), heritability in broad sense and genetic advance in percent of mean were analyzed. High variability was observed in case of plant height cm, grain width and total spikelets. High estimates of heritability were observed for biological yield/plant. The magnitude of phenotypic correlation was higher than the genotypic correlation. Grain yield/plant showed highly significant and positive correlation with panicle length and grain width.

Keywords: Genetic advance, Genetic variability, Heritability and Rice

Introduction
Rice is an ancient staple food cereal crop of the world's and feeding the variety of dishes and dietary needs of people living in the tropics and subtropics. The introduction of high yielding heterotic hybrids under commercial agriculture has resulted in a quantum leap in rice yield enhancement. However, because rice is the country's basic food, increasing its productivity has become critical (Subbaiah *et al*., 2011) [17]. For genetic inhencement, understanding the nature and extent of genetic variation influencing the inheritance of quantitative traits like yield and its components is critical. A thorough examination of genetic diversity is required before beginning any crop improvement effort or using appropriate selection procedures. India is not self-sufficient in food grain production, but also the world's second largest producer and exporter of high-quality rice (Sreedhar *et al*., 2005) [16]. Rice is a vital crop that feeds nearly half of the world's population, accounting for more than half of their daily calorie intake (Maclean *et al*., 2002) [9]. Magnesium, thiamin, niacin, phosphorus, vitamin B6, zinc, and copper are all found in it. Iron, potassium, and folic acid are all present in some kinds. White rice is one of the least protein-dense grains; yet, some enhanced types may deliver 14 gm of protein per 100 gm. Rice contains a variety of energy-dense substances such as carbohydrates, lipids, protein, and a moderate quantity of calcium and riboflavin (Juliano *et al*., 1993) [7]. Humans consume the majority of rice. *Oryza sativa* is a cattle feed with a variety of industrial and non-industrial uses, in addition to providing a major share of the daily calorie and protein intake for half of the world's population. Correlation is a great tool for studying character associations, and it was thus highly beneficial in determining a selection strategy for improving a character without compromising gains in other qualities. Correlation and route analysis reveal the magnitude of the relationship between grain yield and its components, as well as the relative importance of their direct and indirect impacts, providing a clear picture of their relationship with grain yield (Babu *et al*. 2012) [3]. Rice possesses the world's biggest collection of genetic diversity, and India is home to a wide range of rice cultivars, landraces, and many lesser-known types that have been cultivated by farmers for centuries. The evaluation of genetic diversity is a fundamental principle in crop improvement breeding, which involves the transfer of beneficial features to other genotypes Sasaki (2005) [12] and Varshney *et al*. (2008) [19]. Evaluation of locally adapted germplasm is the first stage in breeding for a specific characteristic, and land races are an excellent starting point for breeders looking to develop crop varieties with desirable traits (Shimelis and Laing 2012).

ABSTRACT

The breeding value is an important genetic parameter determines utility of lines genotypes to be used as parent in breeding program. This study was aimed at dissecting the breeding values (combining abilities) in 8 short duration rice lines for yield and 15 attributing traits. Altogether, 28 F1s developed under half-diallel fashion along with eight parents were evaluated. The study revealed importance of both additive and non-additive gene effects in governing yield and yield components with preponderance of non-additive gene action for most of the yield components. Additive gene action was found important for 1000-grain weight. The parental genotype (NUD3) and (NDR 359) were found to be good general combiners. The hybrids namely NDR359 Sarjoo-52, NDR359 NUD2, NDR359 NDRK5088, NDR359 NDR1, NDR359 Nagina22, NDR359 NUD3, NDR359 CSR10, Sarjoo52 NDRK5088, Sarjoo52 X NDR 1, NUD 2 NDR1, NUD 2 NUD3, NDRK5088 Nagina22, NDRK5088 NUD3, NDRK5088 CSR10, NUD 3 Nagina 22, Nagina 22 NUD3, NUD3 CSR 10 have shown significant favourable sca effect for yield and different yield components.

Key words: *Diallel analysis, breeding value, combining ability, gca effect, sca effect, additive gene action*

INTRODUCTION

Rice, a staple food crop which nourish over half of the global population is seems to be threatened adversely under shattering climatic scenario (Khus et al., 2005; Kumar et al., 2018; Rout et al. 2020). Rice researchers are increasingly challenged in the new century to meet the rapidly growing food demands of an ever-growing population. Its production is affected by many biotic and abiotic stresses across the ecologies throughout the world. Poor water management, increased competition for limited water resources, and the uncertain threats associated with global warming all highlight the looming water crisis that threatens agricultural productivity worldwide. The cultivation of short duration rice is very economical for farmers, but owing to very poor in yield potential and sustainability under extreme condition needs further research attention. In order to formulate efficient breeding strategies for improvement of yield, it is essential to characterise the nature and mode of gene action that determines the yield and its components. A sound breeding methodology rests on a proper understanding of the gene effects involved (Kumar et al., 2012).

The breeding value and combining ability studies of the parents and their crosses provide insights for the selection of compatible parents which prerequisite for any breeding program. Assessment of breeding values/ combining ability of the parents helps in its judicious utilization with precision and accuracy.

Collection and evaluation of Kalanamak rice germplasm from traditional Kalanamak Agromorphological characters of eastern Uttar Pradesh

SP Giri, Saurabh Dixit, V Prasad, DK Diwedi, N Prakash, SKS Rajpoot and RA Singh

DOI: https://doi.org/10.22271/chemi.2021.v9.i1b.11436

Abstract
A field experiment was conducted at Crop Research Station, Masodha, Faizabad to agro morphologically characterize the ninety five aromatic short grain rices Kalanamak of diverse origin, collected from different districts of eastern Uttar Pradesh *viz*: Maharajganj, Sidharth Nager, during kharif 2017 and 2018. The 40 DUS characters are, (1) Basal leaf sheath colour (2) Leaf pubescence of Blade surface (3) Leaf auricles (4) Leaf anthocyanin colouration of auricles (5) Ligule shape (6) Ligule colour (7) Days to 50% flowering (8) Flag leaf attitude of blade early obs (9) Spikelet density of pubescence of lemma (10) Lemma anthocyanin colouration of area below apex (11) Spikelet color of stigma (12) Stem length (13) Stem anthocyanin colouration of nodes (14) Panicle Length (15) Flag leaf attitude of blade late obs (16) Panicle curvature of main axis (17) Spikelet colour of tip of lemma (18) Panicle awns (19) Panicle color of awns late obs (20) Panicle distribution of awns (21) Panicle attitude of branches (22) Panicle exertion (23) Sterile lemma colour (24) Decorticated grain length (25) Decorticated grain width (26) Decorticated grain shape (27) Decorticated grain color (28) Endosperm presence of amylose (29) Decorticated grain aroma (30) Vegetaive vigour (31) Tillering ability (32) Productive tillers/Plant (33) Plant Height (34) Panicle threshability (35) Phenotypic acceptability (36) Spikelet number plant (37) Fertile Grains Plant (38) Sterile grains /Plant (39) Plot Yield in gms (40) 100 Grain weight. Yield kg/ha ranged from 1110 to 3250 kg/ha. The promising germplasm grain yield kg/ha was Kalanamak Nichlol (A) is 3250 kg/ha followed by Kalanamak Birdpur (C) 3160 kg/ha, Kalanamak Aligarh 3110 kg/ha, Kalanamak Kapilvastu 3090 kg/ha. Specialty rice, in general, and aromatic rice in particular, possess enormous market potential for enhancing farm profits. However, systematic characterization of the diversity present in this natural wealth is a major pre requisite for using it in the breeding programs. This study reports qualitative phenotypic trait based characterization of 95 short grain aromatic Kalanamak rice genotypes, collected from different areas of the state of U.P., India.

Keywords: Genetic diversity, germplasm collection, UP, landraces, rice

Introduction

Rice is an important cereal crop, grown under diverse agro-ecological conditions. It is one of the very few crop species endowed with rich genetic diversity which account over one lakh landraces and improved cultivars (Samal, 2014) [17]. The success of any breeding programmes depends upon the genetic variability present among populations. Genetic uniformity is an alarming situation among new rice varities (Morishima and Oka 1995) [12] as it increases the chance of disease epidemics and insect infestation. Genetic divergence among the genotypes plays an important role in the selection of parents having wider variability for different yield and quality characters (Sarawgi and Binse, 2007) [5] which may be useful for breeding programmes. Rice is a traditional staple food in many countries of the world, importantly in Asian countries, therefore rice consumption is determined by the population needs in food. Rice (*Oryza sativa* L.) is a monocot grass species and belongs to Gramene family and Oryza genus which originated at least 130 million years ago (Khush, 1997) [10, 20]. Domestication of rice simultaneously (probably) observed in north east part of India and southern region of china about 800 years ago (Sang and Ge, 2007) [10].

The promising germplasm grain yield kg/ha was Kalanamak Nichlol (A) is 3250 kg/ha followed by Kalanamak Birdpur (C) 3160 kg/ha, Kalanamak Aligarh 3110 kg/ha, Kalanamak Kapilvastu 3090 kg/ha. Specialty rice, in general, and aromatic rice in particular, possess enormous market potential for enhancing farm profits. However, systematic characterization of the diversity present in this natural wealth is a major pre requisite for using it in the breeding programs. This study reports qualitative phenotypic trait based characterization of 95 short grain aromatic Kalanamak rice genotypes, collected from different areas of the state of U.P., India.

Keywords: Genetic diversity, germplasm collection, UP, landraces, rice

Introduction
Rice is an important cereal crop, grown under diverse agro-ecological conditions. It is one of the very few crop species endowed with rich genetic diversity which account over one lakh landraces and improved cultivars (Samal, 2014) [17]. The success of any breeding programmes depends upon the genetic variability present among populations. Genetic uniformity is an alarming situation among new rice varities (Morishima and Oka 1995) [12] as it increases the chance of disease epidemics and insect infestation. Genetic divergence among the genotypes plays an important role in the selection of parents having wider variability for different yield and quality characters (Sarawgi and Binse, 2007) [8] which may be useful for breeding programmes. Rice is a traditional staple food in many countries of the world, importantly in Asian countries, therefore rice consumption is determined by the population needs in food. Rice (*Oryza sativa* L.) is a monocot grass species and belongs to Gramene family and Oryza genus which originated at least 130 million years ago (Khush, 1997) [10, 20]. Domestication of rice simultaneously (probably) observed in north east part of India and southern region of china about 800 years ago (Sang and Ge, 2007) [10].

ABSTRACT

In the present investigation 234 Indian mustard germplasm were screened in infested field against major disease of Indian mustard. Out of 234 Brassica germplasm, these screening was not found immune or highly resistant and resistance against Alternaria blight. Seven genotypes viz., PRG-909, CN-107719, CM-8, PRG-2001-62, LM-114-6, Bio-179, Bio-169-95 were found moderately resistant with disease severity of 5-10 percent were rated as moderately susceptible were found 114 genotypes with disease severity 11-25 percent. 131 genotypes were marked as susceptible in which disease severity was found to be 26 to 50 percent. The highly susceptible only two genotypes was found to be >50 present with disease severity respectively.

Introduction

Indian mustard (*Brassica juncia* (L.) Czern and Coss) is the third important oil seed crop in the world after soybean (*Glycine max* L.) and palm (*Elaeis guineensis* Jacq.) oil. It is grown in subtropical and tropical countries in theworld comprise eight cultivated crops of tribe *Brassiceae* within the family Cruciferae (*Brassicaceae*). In India, it is the second most important edible oil seed after groundnut and sharing 27.8% in the India's oilseed production. The oil of the Rapeseed mustard is mainly used in human diet. The crop also has important place in industrial uses such as for manufacturing soap, paints, varnishes, hair oil, lubricants, textile auxiliaries and various other products. Indian mustard [*Brassica juncea* (L.) Czern and Coss.] is predominantly cultivated in Rajasthan, Uttar Pradesh, Haryana, Madhya Pradesh and Gujarat. Among these states, Rajasthan, Uttar Pradesh and Madhya Pradesh hare the major Rapeseed-mustard growing state to the national acreage during The corresponding contribution to production was 48.6%, 13.4%

DOI: https://doi.org/10.22271/chemi.2020.v8.i4m.9793

Abstract
The study was conducted with the objective to assess the resistance source against blight in rapeseed-mustard at Student's Instruction Farm, Acharya Narender Deva University of Agriculture and Technology Kumarganj Ayodhya (U.P.) during *Rabi* 2018-19. Screening of Indian mustard 47 genotypes, these screening was not found highly resistant, resistant and moderately resistance against Alternaria blight of rapeseed mustard six genotypes *viz*., Kiran, TMR-14-6, TMR-14-1, TMR-14-5, TMR-14-3, TMR-14-4 with disease severity of 5-10 per cent respectively were rated as moderately susceptible were found nine genotypes with disease severity 11-25 percent. 31genotypes were marked as susceptible in which disease severity was found to be 26 to 50%. The highly susceptible only one genotypes was found to be >50 present with disease severity respectively. It could be noticed that the vulnerability level was relatively quite high as compared to resistance status.

Keywords: Rapeseed- mustard, Alternaria blight, disease reaction, screening

Introduction

Brassica species are the largest oilseed crop in the world oilseed production followed by peanut (*Arachis hypogaea* L.) and sunflower (*Helianthus annus* L.). In India, rapeseed-mustard is grown over in diverse agroclimatic conditions ranging from north-eastern/north-western hills to down south. These crops require cool growing season and moderate temperature throughout, hence are sown in the month of 1 November to 15 November in northern India (Das *et al.*, 2009) [4].

Brassica juncea (L.) Czern & Coss., also known by the name of Indian mustard, belongs to the plant family *Brassiceae* (*Cruciferae*) or the mustard family. It is commonly referred to as Rapeseed-mustard along with four other closely related cultivated oilseed species *viz*. *B. rapa*, *B. napus*, *B. carinata* and *Eruca sativa*. Indian mustard is largely self pollinated. Indian mustered (*B. juncea* L. czern and coss). popularly known as rai, raya or laha is one of the most important oil seed crop of the country. *Brassica juncea* (n = 18) is an amphidiploid species dérived from interspecific crosses between *B. nigra* (n = 9) and *B. rapa* (n = 10).

Rapeseed mustard are the world's third most important sources of vegetable edible oil. It also contains adequate amounts of the two essential fatty acids, linoleic and linolenic, which are not present in many of the other edible oils. The oil is also used as hair oil and as lubricant. A peculiar use of mustard oil is to retard the fermentation process when making cider from apples. Vegetable oils and fats are valuable food ingredients in human diet. They contain saturated and unsaturated fatty acids. The Indian mustard have nutritional value *viz*., carbohydrates 4.51g, sugar 1.41g, dietary fiber 2g, fat 0.47g and protein 2.56g per 100 g (3.5 oz). It is a good source of protein (28-36%).

The tender leaves of these cultivars serve as vegetable, while the seeds as a source of lubricating and cooking oil. The residue left after oil extraction being rich in protein (Durrani and Khalil, 1990; Chattopadhyay *et al.*, 2005) [6, 3] can be used as livestock feed. It produces 9 k cal energy from 1gm of oil per unit in comparison with other diets (carbohydrate and Protein). Mustard seeds have relatively high protein content (28-36%). Until now mustard seeds have been used mainly for condiment production. (Gadei *et al.*, 2012) Mustard oil contains a high amount of selenium and magnesium, which gives it anti-inflammatory properties.

Screening of rice (*Oryza sativa* L.) for salinity tolerance at seedling stage under hydroponic condition

Anuj Kumar, DK Dwivedi, Pratibha Yadav, Rahul Kumar, Preeti Kumari, Archana Devi and NA Khan

DOI: https://doi.org/10.22271/chemi.2020.v8.i4e.9875

Abstract
Rice is one among the foremost suitable crop for saline soils although it's usually considered moderately sensitive to salinity. The phenotypic response of twenty rice genotypes with salt stress at EC=12 dsm^{-1} was assessed under hydroponic condition at seedling stage. The rice genotypes FL-478, IR68144-2B-2-2-3-1-120, IR-68144-2B-2-2-3-1-127 were found tolerant, while IR-91167-99-1-1- 1-3, NUD-3, NUD-2, CSR-13, IR-92953-49-1-3 and NDRK-2008 showed moderately tolerant to salinity and genotypes NDR-359, MTU-1010, TARAMON, SAMBHA MANSURI, SWARNA IR-28 and AYYAR showed vulnerable to salinity. Tolerant varieties are suggested to use as donor parents for salinity tolerance in back cross breeding and for allele mining for salinity tolerance gene/QTLs.

Keywords: QTL: qualitative trait loci, Allele: contrasting pair of gene, EC: electrical conductivity, Hydroponic condition: soil-less culture

Introduction
The plant response to salinity consists of various processes that must function in coordination to enhance both cellular hyperosmolarity and ion disequilibrium. Salt stress adversely affects agricultural yield throughout the world affecting production. Many species of higher plants, including most crops, are subjected to growth inhibition under high-NaCl condition. Rice is one among the foremost suitable crop moderately sensitive to salinity (Akbar *et al.*, 1972)[3]. It is relatively tolerant to salinity at the germination stage but its panicle initiation and pollination stage are two most salinity-sensitive growth stages which is directly related to crop yield (Heenan *et al.*, 1988, Khatun and Flower, 1995, Zeng *et al.*, 2001)[4, 5, 10]. Screening of rice genotypes at seedling stage is comparatively easier than reproductive stage and also rapid. It is very difficult at the reproductive stage (Gregario *et al.*, 1997)[2]. The typical mechanism of salinity tolerance in rice is that the exclusion or reduction of Na uptake and increased absorption of K to take care of an honest Na^+-K^- balance within the shoot. Salt injury starts with reduction in effective leaf area. The oldest leaves start to roll then die, followed by the next older, and so on. Rice is extremely sensitive to salinity at seedling stage. Its height, root length, emergence of latest roots and dry matter decreases significantly at EC 5-6 dSm^{-1} (Pearson *et al.*, 1966, Akbar and Yabuno., 1974)[7, 1]. Salinity suppresses leaf elongation and formation of latest leaves. The screening technique is based on the ability of seedling to flourish in salinized nutrient solution.

Materials and Methods
Plant materials
Total twenty rice genotypes were used in this study, which were IR68144-2B-2-2-3-1-120, IR-68144-2B-2-2-3-1-127, IR-91167-99-1-1-1-3, IR-91167-133-1-1-2-3, NUD-3, NDR-359, IR-28, FL-478, NUD-2, CSR-13, AYYAR, NDRK-2008, IR-64, SWARNA, IR-92953-49-1-3, IR-91171-66-3-2-1-3, IR-83668-35-2-2-2, SAMBHA MANSURI, TARAMON and MTU-1010.

In the present study, the fungus was isolated from infected leaf of potato and identified as *Alternaria solani*. Twenty four bacterial strains isolated from potato rhizosphere on PDA media. The screening of all 24 potato rhizosphere isolates for IAA, phosphate solubilization, Insecticide tolerance, salt tolerance, antibiotic sensitivity and ammonia production was performed. Out of these isolates, only four isolates (5, 15, 16 and 23) showed high inhibitory effect on the pathogenic fungus in dual culture. PGPR isolate no 5 showed highest 95% inhibition against *Alternaria solani*.

Introduction

Potato (*Solanum tuberosum* L.) is one of the world's most important food crops, and is grown in more than 100 countries with different climate conditions including temperate, subtropical and tropical zones. There are several diseases in potato caused by fungi, bacteria, viruses, nematodes and abiotic factors. Among which an early blight caused by *Alternaria solani* has been known to cause yield losses up to 80% (Martin, 1986). The disease manifests as leaf spots with dark brown to black concentric ring which later enlarge and result in blighting of leaves and fruits. The dark spot and sunken lesions also

ABSTRACT

The present investigation was carried out with the objectives to estimate genetic variability for yield and yield contributing components. The investigation consisted of twenty rice genotypes and the experiment was conducted during Kharif-2018-19 in Randomized Block Design with three replications. The data were recorded for fourteen quantitative characters to study genetic variability, heritability and genetic advance. Analysis of variance among twenty genotypes showed significant difference for all characters under studied. Highest genotypic coefficient of variation (GCV) and phenotypic coefficient variation (PCV) was observed for grains per panicle followed by panicle bearing tillers per plant and spikelets per panicle in controlled condition, whereas, in saline condition highest genotypic coefficient of variation (GCV) and phenotypic coefficient variation (PCV) was observed for panicle bearing tillers per plant followed by grains per panicle and spikelets per panicle. These characters could be used as selection parameters for crop improvement. High estimates of heritability were observed for K^+ followed by plant height, days to 50% flowering, harvest index% and grains per panicle in normal soil condition, whereas, in saline condition highest broad sense heritability was recorded in the case of plant height, spikelets per panicle followed by days to 50% flowering, grains per panicle, K^+ and harvest index %. In controlled condition high genetic advance were observed for grains per panicle followed by spikelets per panicle, whereas, in saline condition maximum genetic advances was recorded in grains per panicle followed by panicle bearing tillers per plant. It indicated that the presence of additive gene action. Hence, emphasis should be given to select these quantitative traits to enhance the yield potential of rice (*Oryza sativa* L.) under both conditions.

Introduction

Rice (*Oryza sativa* L.) is a diploid (2n = 24) and self-fertilized monocot. There are two species of cultivated rice - *Oryza sativa* and *Oryza glaberrima*. *Oryza sativa* is the rice cultivated in majority of rice growing countries. As a food crop, it forms the staple food of more than three billion people accounting for about 50-80% of their daily

A B S T R A C T

Pigeonpea is the major source of dietary protein for vegetarian population in India and other developing countries. The following study was taken to understand the genetic relationship between genotypes on the basis of protein profiling of leaves and seed protein. Ten genotypes of Pigeon pea [*Cajanus cajan* (L.) Millspaugh] including one wild species was sown in the field at Student Instructional Farm, ANDUA & T Kumarganj Ayodhya. Total protein was extracted using 0.1 M Sodium phosphate buffer (pH 7.2) containing NaH_2PO_4 and Na_2HPO_4. Protein was electrophoresed on 12% SDS- PAGE along with standard protein marker and detected by commassive brilliant blue staining. Pigeonpea leaves and seeds protein showed variability in banding pattern of polypeptide on gel. RM values of different pigeonpea genotype were measured. The results showed that both leaves and seeds protein migrated between a range of < 10 to 250 kDa. NDA-3, MAL-6 and MAL-13 had minimum protein bands (8 bands) while maximum protein bands was observed in NDA-14-6 (12 bands) in leaves. In protein profile of seeds it has been seen that *Cajanus scarabaeoides* showed maximum bands (20 bands) while NDA-2 showed minimum protein band (11). All the accessions commonly showed at least six major bands in leaves while 11 major bands in seeds. In this context we can say that seeds of wild genotype contain more protein than cultivated pigeonpea genotype. The main objective of this study is to reveal intra-specific similarities and genetic diversity in protein content amongst ten genotypes of pigeon pea.

Introduction

The pigeon pea [*Cajanus cajan* (L.) Millspaugh] is an often cross-pollinated diploid (2n = 2x = 22) crop with genome size 833.07 Mb belongs to the family Fabaceae. It is an important grain legume crop of rain fed agriculture in the tropical and sub-tropical regions of the world. It is the first seed legume which has been complete genome sequenced (Singh *et al*., 2012; Varshney *et al*., 2012). Pigeon peas production is estimated at 4.49 million tons in world (FAOSTAT 2018). In India Pigeonpea production is 4.25 Million tons in a total area of 4.43 Mha at productivity level of 960 kg ha (ever highest yield) during 2017-18 (DES 2018).

Pigeon pea seeds are a rich source of protein and are widely consumed by people in developing countries to meet their caloric and protein needs (Salunkhe *et al*., 1986; Singh *et al*., 1990). Due to high protein content (18–

ABSTRACT

Rice is a staple food crop and forms the energy for more than half of the world population. Salinity may be a serious environmental constraint to rice production. Salinity affects rice genotypes were performed at the reproductive stages in the net house of the department of PBMB&GE. Phenotyping of the genotypes was done at EC 12dSm at reproductive stage in net house. Most desirable genotypes days to 50% flowering were IR 68144-2B-2-3-1-120, CSR-13, FL-478, NDR-359, AYYAR and NUD-2, SAMBHA MANSURI and MTU-1010 for plant height IR-68144-2B-2-3-1-127, NUD-3, NUD-2, NDRK-2, IR-9113-1-99-3-2-1-3, SAMBHA MANSURI, CSR-13, MTU-1010, for panicle beard to transplant FL-478, NDR-359 and SWARNA for panicle length IR-68144-2B-2-3-1-127, IR-9113-1-99-3-1-1-3, IR-29, FL-478, NDRK-2-03 and IR-92952-49-1-3, for spikelets/panicle IR-91167-99-1-1-1-3, NDRK-2004, SWARNA, IR-92952-49-1-3, IR-31171-65-2-2-1-3, IR-67663-35-2-2-2 and MTU-1010 for grains/panicle SWARNA, IR-92952-49-1-3, IR-31171-63-

ABSTRACT

The present investigations were conducted in randomized block design with three replications within the net house of the department of PMB&GE, A. N.D.U.A.T, Kumar Ganj, Ayodhya to estimate the genetic divergence under normal and salt stress conditions involving 20 rice genotypes during Kharif 2018-19, on the basis of relative parameters of D^2 values, the clustering pattern of 20 rice genotypes under normal and salt stress conditions were grouped into five non-overlapped clusters. Under normal condition, Cluster III having highest 7 rice genotypes, Cluster II having 5 genotypes, cluster V having 4 genotypes and IV having highest 3 rice genotype. Cluster I having only one genotype. Under saline condition, Cluster I having highest rice 6 genotypes, cluster III having 5 genotypes and cluster II & IV having 4 genotypes respectively. Cluster V having only one genotype. It means the genetic similarity was found in the genotypes were expressed within the cluster and the pattern of distribution of genotypes in various clusters exhibited that topographical diversity wasn't

Altogether 334 rice lines alongwith8 global check varieties were tested for submergence survival and yield performance at Crop Research Station, Masodha, Ayodhya. These lines and check varieties, namely IR 64-Sub 1, Swarna-sub 1, Sambha Mahsuri-Sub 1, Ciherang-Sub1, TDK1, Ciherang, RC18, SambhaMahsuri and 3 local check viz. Swarna, MTU 1010 and Sahabagidhan were laid out in augmented design with 10 blocks. For survival testing in submergence, the experiment was conducted in the submergence pool and for yield performance (optimal condition), the experiments was conducted in the irrigation field. Each entry was direct sown in two rows of 3 meter length and after 25 days of sowing complete submergence of one meter water depth was imposed for 20 days. Data recorded for submergence survival as no. of plant counted before and after submergence. In yield performance experiments observation recorded on days to 50% flowering, plant height, Ebt/m2, total biomass, harvest index and yield kg/ha. Among 334 lines none of the lines have recorded 100% survival however, eight lines viz., TTB 944-31-10-1-2 (95.2%), CR-2859-1-S-B-2-1-B-B-5-1 (94.7%), IR103410-B-B-2-3 (87.5%), CR 2851-S-1-B-4-1-4-1-1 (IET27051) (84.2%), IR 97034-21-2-1-3 (69.6%), IR09A130 (66.7), CR 2859-S-B-2-1-B-7-1 (60%) and NSIC 2016 RC 468 (57.9%) survived and 42 lines falls under 20-56 % survival, were recorded. The entries were selected on the basis of (i) selection based on survival % and vigor, (ii) selection based on productivity under submergence, (iii) selection based on the variables of morphological and agronomic characters. The entry IR103410-B-B-2-3 (87.5%) (4667 kg/ha),IR 97034-21-2-1-3 (69.6%)(4667 kg/ha),TTB 944-31-10-1-2(95.2%) (4000 kg/ha) and NSIC 2016 RC 468 (57.9%) (3333 kg/ha) also good for survival and yield. These lines are considered promising for tolerant to submergence as well as yield.

Introduction

Rice (*Oryza sativa* L.) is one of the most important crops of the world and provides food to more than 50% global population. More than 90% of the world's rice is grown and consumed in Asia, where 60% of the earth's people live. It was estimated that 35-60% of the calories consumed by 3 billion Asians comes from rice. Rice demand in

Technological and extension gap of yield and profitability can be bridges by adopting package of practices with emphasis of improved variety, use of proper seed rate, balance nutrient application and proper use of plant protection measures. The study was carried out through front line demonstrations during Kharif season of 2017 and 2018 in three adopted district and sixteen village of Ayodhya, Gonda and Azamgarh on farmers field with the active participation of farmers with an objective to evaluate the performances of improved technology of high yielding rice variety Sambha Mahsuri-Sub 1 and compared to the local check (Sambha Mahsuri). The Sambha Mahsuri-Sub 1 recorded grain yield 50.20 q/ha which was 20.92 per cent higher yield than local check (Sambha Mahsuri 41.53 q/ha.) In spite of increase in yield of improved technology the technological gap, extension gap and technology index existed which was 4.80 q/ha, 8.67 q/ha and 8.73 per cent, respectively. The improved technology of HYV Sambha Mahsuri-Sub 1 gave higher gross return of Rs. 79818/ha with a benefit cost ratio of 1.69 and additional net return of Rs.13780/ha as compared to local check variety. Hence, the existing high yielding rice variety Sambha Mahsuri can be replaced by HYV Sambha Mahsuri-Sub 1.

Introduction

Rice is the staple food crop of India and occupies highest area among all the crops grown in the country (Shobha Rani *et al.*, 2010). Currently India produces rice that is sufficient not only to meet the domestic demands, but also was the largest exporter during 2012 (Mahender Kumar *et al.*, 2013), imparted to the selected farmers regarding different aspect of cultivation (Venkattakumar *et al.*, 2010). Rice is the only crop grown in the wet season from lowland ecosystem. Poor sunshine, inclement weather, disease pest incidence and the associated adversities affect crop growth. The scenario needs cutting edge technologies for increasing rice production in India. Although productivity of rice has increased from 2372 kg per hectare in 2011-2012 to 2390 kg/ha in 2016-2017, due to development of high yielding varieties with site specific

Genetic divergence was assessed among 21 rice variety including Basmati(3), Aromatic Short Grain (5), Medium Slender (3) and HYV(10).The experimental materials were evaluated during kharif- 2017 and 2018 at Crop Research Station, Masodha, Ayodhya. Physicochemical, cooking, pasting and textural properties of some rice varieties of Basmati, Aromatic short grain, Medium Slender grain and HYV were studied, of all the studied varieties was more than 3.0 and the L/B ratio of basmati varieties grains was significantly higher than non-basmati grains.Present study was carried out having high mean values for the economically important characters viz., number of total grains per panicle, number of productive tillers per plant and grain yield kg/ha etc.Hulling, mulling, head rice recovery, kernel length. Kernel bright, L/B ratio, ASV,AC, GC and aroma for the grains. Grain yield of Pusa Basmati 1 significantly higher (3672 kg/ha) followed by Pusa 1121(3488 kg/ha.), Ketki Joha (ASG)grain yield recorded was 3683 kg/ha followed by Shobini 3620,Swarna-Sub 1 (MS) grain yield was recorded in 6063 kg/ha. followed by Swarna 5750 and HYV grainyield of NDR 359(5475kg/ha.) followed by PA 6444 (5325 kg/ha.). The head rice recovery significantly higher 68.3% (MTU 1010) followed by Swarna-Sub 1 (67.20%), the mulling % higher Ketki Joha 72.20% followed by MTU 1153 71.60%. Basmati and aromatic cultivars had intermediate amylose content and MTU 1153 and Sahbhagi Dhan were grouped as low amylose containing cultivars. The GC was observed significantly lower of Gontra Bidhan 3, Swarna Chittimuthyalu, Tarori Basmati,Pusa 1121 and Shobini (GC 22) followed by Pusa Basmati 1 and BPT 5204 (GC 24) showing the lowest hardness among all the selected rice varieties.

Introduction

The slogan 'Rice is life' aptly describes the importance of rice in food and nutritional security. Rice (*Oryza sativa L.*) is the world's second most important cereal crop and staple food for more than 60% of the global population providing about 75% of the

Genetic divergence of 41 indigenous and exotic rice varieties of which five procured from India, one from Sri Lanka and 35 from IRRI, Philippines was investigated using Mahalanobis, D^2 statistic. Based on thirteen agromorphological characters, the forty one germplasm both indigenous and exotic were grouped into seven clusters based on the relative magnitudes of D^2 values following Tocher's method of cluster formation. Cluster II is the largest cluster consisting of 12 genotypes while Cluster I was the smallest with only a single genotype. The maximum intra cluster distance (D = 133.58) was found in cluster III consisting of 5 varieties. In the present study, maximum inter cluster distance was estimated between cluster III and VII ($\sqrt{D^2}$ = 913.36) which was followed by clusters II and VI ($\sqrt{D^2}$ = 755.83). Based on the rank totals, the characters which contributed maximum towards genetic divergence in the present studies were spikelets per panicle (30.24%) followed by days to 50% flowering (16.59%), flag leaf area (16.34%), plant height (14.39%), biological yield per plant (9.15%), spikelet fertility (5.12%), length/breadth ratio (3.41%), 1000 grain weight (3.17%), harvest index (1.46%) and panicle length (0.12%). Hence these traits could be focused for selection while improving quantitative traits. On the basis of their greater inter cluster distance, high value of cluster mean and performance of the individual germplasms for the character, the germplasm could be used in hybridization programme for improvement of different plant characters of the rice.

Exotic Rice (*Oryza sativa* L.) under Saline-Alkali Condition

Introduction

Rice, being the staple food for more than 70 per cent of our national population and source of livelihood for 120 to 150 million rural households, is backbone of the Indian Agriculture. Salt affected areas have increased day by day because of excessive use of irrigation water with improper drainage coupled with the poor quality irrigation water. Development of varieties for underutilized soil is the only option to increase the production. Thus, adoption of high yielding rice varieties to various stress environment and underutilized land such as saline-alkalinity affected soil would be an important strategy to meet this challenge. The scarcity of productive agricultural land

Abstract
The present study was carried out to evaluate the influence of Moringa oleifera leaf extracts on carcass traits and mortality of broiler chickens. A total of 250-day-old broiler chicks (Vencobb-430) were randomly distributed into five groups with 5 replicates of 10 birds in each. Different dietary treatments were; basal diet with no supplement (NC- negative control) and basal diet supplemented with antibiotics (PC-positive control), aqueous extract of 1.5% Moringa powder (MOAQE), ether extract of 1.5% Moringa powder (MOEE) and alcoholic extract of 1.5% Moringa powder (MOALE). Percent weight of various cut parts, eviscerated weight and drawn yield were evaluated after 35 days of experiment. The results showed significantly higher eviscerated weight and drawn yield percentage in Moringa extracts supplemented groups compared to PC group. PC and MOAQE group recorded significantly (P<0.05) higher drumstick % compared to NC, MOEE and MOALE group. Moringa extracts group recorded significantly (P<0.05) lower mortality than PCand NC group birds. From above results it was concluded that supplementation of Moringa extract of 1.5% Moringa oleifera leaf powder improved the carcass traits and reduced the mortality of birds.

Key words: *Broiler, Extract, Carcass, Mortality and Moringa (words in alphabetical order)*

Introduction

Major cost involved for poultry enterprise is in the form of feed. Various approaches such as feed supplements and additives are being used to obtain more net return and to minimize expenditure on feed (Agasheet *al.*, 2017). *Moringa oleifera* leaf (MOL) has fascinated great attention as a non-traditional feed component because of its unique qualities. Moringa oleiferagrows fast, drought-tolerant tree native belonging to sub-Himalayan tracts of northern India, Pakistan, Bangladesh and Afghanistan. Moringa is currently cultivatedglobally in the tropics and subtropics (Faheyet *al.*, 2001). Crude protein content in Moringa varies from 25% to more than 30% on a dry matter basis (Melesse et al., 2013), with a high proportion of essential amino acids (Lu *et al.*, 2016). Moringa leaves, flowers and Pods are used as good sources of vitamins A, B and C, riboflavin, nicotinic acid, folic acid, pyridoxine, ascorbic acid, beta-carotene, calcium, iron and alpha-tocopherol (Dahot M.U., 1988). Moringa leaves are the preferred part of tree for use in animal diets as leaf meal due to high nutritional and medicinal properties (Abbas, 2013). The meat obtained from broiler chickens is an excellent source of protein, vitamins, mineralsand lower in fat content, so having a great demand among non-vegetarians(Naji *et al.*, 2013).Addition of*Moringa oleifera* leaf meal in broilers diet resulted significant increase in dressed weight, eviscerated weight and dressing percentage (Ayo-Ajasa *et al.* 2016). Dietary supplementation of Moringa leaves would be a potential strategy to improve the meat quality in broilers due to its antioxidant potential. It was further reported that phytosterols could lower malondialdehyde content and increase glutathione concentration in the breast muscle of broiler chickens (Naji *et al.*, 2013).

This study was carried out to evaluate the effect of different extracts (1 5%) of *Moringa oleifera* leaves powder as feed supplement in broiler diets on carcass characteristicsand mortality of broiler birds.

(Please correct red marks)

Materials and Methods

The present experiment was conducted after an approval from "Institutional animal ethical committee (IAEC)" was obtained vide reference number IAEC/CVSc/P-36/2019. A total of 250 one-day old Vencobb-430 strain chicks were randomly allocated into five dietary treatment groups with 5 replicates of 10 chicks in each. The chicks were kept on five dietary treatments which includes a basal diet without any additive in negative control (NC) or that supplemented with antibiotics (Positive control-PC), aqueous extract of 1.5% Moringa powder (MOAQE), ether extract of 1.5% Moringa powder (MOEE) and alcoholic extract of 1.5% Moringa powder (MOALE) in basal diet. Birds were fed *ad libitum* in different phases of experimental trial. The composition of formulated experimental diets as per BIS (2007) has been given in Table 1.

The chicks were kept on deep litter system under uniform standard management conditions with availability of clean, fresh and wholesome drinking water. Mortality was recorded during the entire research period. At the end of trial one bird per replicate (5 birds/treatment) were selected randomly for the carcass evaluation and sacrificed after 12 hours pre-slaughter fast though drinking of water was allowed. After complete bleeding carcass were dipped in hot water (58°C) for 1-2 minutes and feather were removed. Evisceration was done by making a slit from tip of breast bone up to the area around the cloaca. Thorough washing and cleaning were done after evisceration. After that the carcass were kept hanging on the special racks for 5-10 minutes. The visceral organs were removed by supporting the bird with one hand via the incised abdomen. Eviscerated carcasses were weighed and cut parts like thigh, drumstick, breast, wings, back, head, neck and shank were also weighed.The relative weight of dressed, drawn yield and different edible cuts were calculated as percentage of live weight.

The data were analysed under completely randomized (CRD) by employing one way analysis of variance (Snedecor and Cocran, 1994) and means of different dietary treatments were compared with Duncan multiple range test. The P value lower than 0.05 was thought-out significant.

(Please correct red marks)

Results and Discussion

Carcass characteristics:

The data pertaining to the carcass traits of broilers presented in Table 2. The results showed that the dressed weight and thigh weight of different groups was similar and showed no significant (P>0.05) effect of various Moringa extracts. The eviscerated weightof aqueous extract (72.24), ether extract (73.10) and alcoholic extract (73.09) supplemented group broilers were similar to NC (72.05) group, however significantly (P<0.05) higher than PC (70.39). The drawn yield of MOAQE, MOEE, MOALE and NC also significantly (P<0.05) higher than PC group. Leg and drumstick weight % of PC group was significantly (P<0.05) higher than MOEE and MOALE group. However, leg weight was

Abstracts

The present study was conducted to investigate the effect of different litter materials on growth performance of Kadaknath chicks. 300 Kadaknath chicks were raised on three litter treatments viz. Sand, rice hulls and rice hulls plus chopped paddy straw (1:1) co of two replicates in each treatment. The result showed that chicks reared on paddy straw + rice hulls litter had significantly hig weight, lower feed intake and better FCR($P<0.05$). The body weight of chicks raised under sand and rice hull litter did n significantly, however the average daily feed intake of chicks under rice hulls was significantly higher than that of under sand li performance index of the earlier study period was significantly higher in paddy straw+ rice hulls followed by sand and ri respectively.

***Key words:** Kadaknath, feed, body weight, sand, rice hulls, litter materials*

Introduction

Desi fowls are cheaply reared as scavenging flocks by feeding household left over and their meat and egg taste are preferred over those of exotic chickens (Dessie and Ogle, 2001).Wood shaving has been standard choice for poultry litter for many years. Rice hulls appear to be a favourable alternative to wood shavings (Grimes *et al.*, 2007).Various types of litter materials like sand (shields *et al.*, 2005), gypsum (Grimes *et al.*, 2007), rice and wheat straw (Srechari Sharma 2010), ground corn cob and soyabean straw(De Avila *et al.*, 2008) have been utilised as bedding materials for rearing of poultry birds. Sand has shown good potential as an alternate litter for more reuse quality and very less caking.

Pine shavings and saw dust are the most desirable and most widely used litter materials for broiler production in the United States. About 60% of farmers used saw dust as litter materials, 16.7% used wood shaving, 20% used both wood shaving and saw dust while 3.3% of farmers do not use bedding materials. The types of litter used by farmer depend on locality and availability (Kalu E. 2015) . Paddy husk is most commonly used litter material in northern India.Sigroha et al., (2017) used saw dust, wheat straw, rice husk, river bed sand and sandy soil as litter materials and found higher weight of birds at 42 days of age in wheat straw followed by sandy soil, saw dust, river bed sand and rice husk. As far as seen in literature there is no concert conclusion for litter type and thickness for various regions and climates. In view of above a study was undertaken with following objectives-

To investigate the effect of litter material on the growth perf of kadaknath fowls

To study the feed conversion efficiency of kadaknath fow various bedding materials

Materials and Methods:

The present investigation was carried out to study the different litter materials on growth performance, feed gain Kadaknath fowl. The study was carried out at the poultry Teaching Livestock and Poultry farm of the College of V science and Animal Husbandry, N.D.U.A.T. Kumarganj, U.P., situated at a distance of 42 km away from Faizabad cit km away from Jagdishpur Industrial area at an altitude o above sea level and latitude of 26° 47' North and longitude East and it falls in Eastern plain Zone of Middle Gange region of India.

Experimental period and climatic conditions

The experiment was conducted in the months of Nove February which comprised winter season of this region. Du period, the climatic parameters have been shown in table average minimum temperature recorded during study pe 12.54°C, while the average maximum temperature was There were a few showers of rain, ranging from 62 to 123 average was 92.5 cm during this period. The topography o almost even and most of the farm area remains dry round Parasitic infestation was moderate.

Climatological parameters recorded during experiment period

S.No	Climatological Parameters	Average Value	Average Max	Average Min
1.	Environmental temperature(°C)	18.7	24.86	12.54
2.	Relative humidity (%)	70.35	77.68	57.86

Experimental animals

To carry out present investigation, 300 straight run day old Kadaknath Chicks, from college hatchery were got issued. These 300 kadaknath chicks were divided into two batches; each batch consisted of 150 Kadaknath Chicks. Each batch was subdivided in three equal groups of 50 chicks viz. Group1 (sand), Group2(rice hulls), Group3(paddy straw + rice hulls) randomly distributed among three pens. Each pen was equipped with fresh litter, feeder and waterer. All the birds were raised on pukka floor with sand, rice hulls and paddy straw + rice hulls (50:50) as litter materials. Chicks were reared under standard uniform managemental practices up to the age of 42 days and observations for different parameters were recorded simultaneously. Thereafter, a replication was made with the next batch of chicks.

Brooding and rearing of chick

Brooder house

The cold room brooding method was applied for brooding an of Kadaknath Chicks in the brooder house. Brooding was pukka floor using deep litter system. Each group of Kadakna placed in separate pens which were visually isolated from e along with provision of adequate ventilation and artificial li brooder house.

Preparation of brooder house to receive Kadaknath chic

Brooder house was properly scrubbed and cleaned at leas before the trail began. After the house, equipments were cleaned. The house was allowed to dry out thoroughly. The h equipments were fumigated using 1% formalin. Three inches litter were made on the floor. Few days before the chick equipments were arranged in brooder house and the elect were started to adjust temperature and light. The temperatu the brooder house was slightly above 35°C. The corners of space were made rounded off with cardboard and metal chi to prevent chicks from piling up in the corner. All these pre

STUDY THE PHYSIO-HEMATOLOGICAL RESPONSE BEFORE AND AFTER DISBUDDING IN CALVES

Shiv Swaroop[1], P.S. Pramanik[1], K.D. Singh[2*], A.K. Verma[1], Vishuddha Nand[1] and A.K. Srivastav[1]

[1]Department of Livestock Production Management, College of Veterinary Science and Animal Husbandry NDUAT, Kumarganj, Faizabad- 224229, Uttar Pradesh, India [2]Department of Livestock Farm Complex, College of Veterinary Science and Animal Husbandry NDUAT, Kumarganj, Faizabad- 224229, Uttar Pradesh, India

Abstract

The aim of the present investigation was to examine the effect on Physio-haematological profile before and after disbudding in calves. The study was carried out at Livestock Farm Complex, College of Veterinary Science and Animal Husbandry, NDUAT, Kumarganj, Faizabad and nearby villages. Twenty four cattle calves were utilized to study Physio-haematological parameters that are Respiration Rate (RR), Pulse Rate (PR), Rectal Temperature (RT), Haemoglobin (Hb (gm/dl), Neutrophil (%), Basophil (%), PCV (%), Lymphocyte (%), Monocyte (%), TLC (10^3/ µl), Eosinophil (%) and N:L ratio) before and after disbudding in to four groups viz. control (T_0), lignocaine (T_L), tramadol (T_T) and lignocaine + tramadol (T_{L+T}). After medication calves were disbudded by hot iron method. The physiological parameters recorded just before (0h) and after disbudding on 1h, 6h and 24h. The blood samples were collected for haematological parameters just before (0h) and after disbudding on 6h, 24h and 72h. The results showed that, at 0h, 1h, 6h and 24h RR were significantly different among treatment groups. Only at 0h PR was significantly different among different treatment groups and during rest of the period up to 24h there is no significant different among groups. There was significant difference for RT only at 24h among different treatment groups. At 24h, T_0 group showed significantly lowest Hb (10.66±0.49%) which was statistically similar to T_T and T_{L+T} groups. At 0h, 6h and 72h means of PCV% were significantly different among treatment groups. There was no significant different in eosinophil, neutrophil and TLC among different treatment groups during the whole period of study. The lowest lymphocytes (64.00±1.00) was observed in T_T group at 6h. The T_0 group showed significantly lowest basophil (0.00±0.00) which was statistically similar to T_T and T_{L+T} groups but significantly different from T_L group at 6h. At the same interval, T_0 group showed significantly lowest monocytes (4.66±0.61) which was significantly different with T_L, T_T and T_{L+T} groups. At 6h, T_0 group showed significantly lowest N/ L ratio (0.15±0.01) which was statistically similar to T_T and T_{L+T} groups but significantly different from T_L group. It may be concluded that generally physiological responses like RR, PR and RT were higher in control groups than treatment groups before and after disbudding. No significant difference was observed in eosinophil%, TLC, neutrophil% and monocyte% counts between control and treatment groups. However Hb%, basophil%, PCV% and lymphocyte% were significantly different between control and treatment groups. N/L ratio was significant only at 6h. Most of the cases T_{L+T} group showed comparatively better performance.

Introduction

Disbudding is painful yet common husbandry practice in the cattle industry, especially on dairy farms, because hornless cattle are safer (ALCASDE, 2009) and injuries to cattle and other animals are reduced (Prayaga, 2007). Dehorned cattle are safer to handle and cause fewer injuries to workers, other cattle, and farm animals (Stafford and Mellor, 2005). Cattle are also dehorned to reduce bruising and hide damage and to meet transport requirements (Goonewardene and Hand, 1991; Faulkner and Weary, 2000; Prayaga, 2007). Several disbudding methods exist, including cautery, the use of caustic paste, and hot iron. All of these methods involve tissue damage and have been described as painful (Stafford and Mellor, 2005; 2011). The *Model Code of Practice for the Welfare of Animals: Cattle*, however, strongly advises against caustic disbudding (PISC, 2004).

Despite this knowledge, dehorning is commonly performed without pain relief because of the costs and impracticalities associated with recognized methods (Petherick, 2005). The breeding of polled cattle eliminates the need for dehorning and because horns are inherited as an autosomal recessive with polledness being dominant (Long and Gregory, 1978). The legislation pertaining to dehorning and disbudding differ between countries like in Sweden, disbudding without local anaesthesia and sedation was banned in the 1992 Animal Rights Act (Bengtsson *et al* 1996), but calves may be dehorned in Denmark without local anaesthesia until they are 4 weeks of age (Grondahl-Nielsen *et al* 1999). The Council of Europe recommends the use of anaesthesia for the dehorning of calves over 4 wk of age (Oliver, 2009). Pain control is also required for all calves under the *Canadian Code of Practice for the Care and Handling of Dairy* Cattle (NFACC, 2009). Furthermore, the Australian *Model Code of Practice for the Welfare of Animals: Cattle* recommends the use of local analgesics for dehorning calves over 6 month of age (PISC, 2004). Thus, the need to meet industry standards and the availability of suitable dehorning pain relief regimens for commercial production remain a challenge. Very little work has been done on the disbudding distress in Indian dairy animals particularly in indigenous animals.

Materials and Methods

The aim of the present investigation was to examine the Physio-hematological response before and after disbudding in calves. Study was carried out at the Instructional Livestock Farm Complex of the college of Veterinary Science and Animal Husbandry, NDUAT, Kumarganj, Faizabad and around the campus. Twenty four (24) farm born cattle calves of 2 to 3 weeks were randomly divided into four groups within each comprising of 3 males and 3 females, Control (T_0), Lignocaine hydrochloride (2%) @ 1 ml/ bud (T_L) (Tramadol @ 0.25 mg/ kg body weight I/M) (T_T) and Lignocaine + Tramadol at above dose rate (T_{L+T}). Medication was done 5-10 minutes before disbudding. Two doses of lignocaine per bud were injected for corneal nerve block in calves.

(a) Physiological responses

Physiological responses recorded before and after disbudding were as follows-

Respiration rate (no./ minutes)	Pulse rate (no./ minutes)	Body temperature (°F)

(b) Haematological parameters

Haematological responses recorded before and after disbudding were as follows

a) Hb (gm/dl)	d) Neutrophil (%)	g) Basophil (%)
b) PCV (%)	e) Lymphocyte (%)	h) Monocyte (%)

Impact of integrated nutrient management (INM) on growth of Berseem (*Trifoliumalexandrinum* L.) at various cutting stages

Vishuddha Nand, RK Gupta, RS Yadav, KD Singh, RK Yadav and AK Srivastav

Abstract
An experiment was conducted during winter season of 2016-17 on Berseem (cv. Mescavi). The experiment comprised of twelve treatments *viz.* T_1 (control), T_2 (100% RDF, 20 kg N + 80 kg P_2O_5 ha^{-1}), T_3 (100% N through Farm Yard Manure (FYM), T_4 (100% N through Poultry Manure), T_5 (50% RDF +50% N through FYM), T_6 (50% RDF +50% N through Poultry Manure), T_7 (50% N through FYM+50% N through Poultry Manure), T_8 (50% RDF +25%N through FYM +25% N through Poultry Manure), T_9 (75% RDF +25% N through FYM), T_{10} (75% RDF +25% N through Poultry Manure), T_{11} (25% RDF +75% N through FYM) and T_{12} (25% RDF +75% N through Poultry Manure) were tested in Randomized Block Design with three replications. the results revealed that the maximum plant height, fresh weight of leaf and stem, dry weight of leaf and stem, shoot : root ratio $plant^{-1}$ and number of nodules $plant^{-1}$ were observed with the application of 100% RDF (20 kg N + 80 kg P_2O_5 ha^{-1}) fallowed by 75% RDF +25% N through poultry manure and 75% RDF +25% N through FYM.

Keywords: FYM, Poultry manure, INM, growth, RDF, plant height, and leaf

Introduction
Berseem (*Trifoliumalexandrinum* L.) is one of the most important winter forage crop of India, due to high forage yield, palatability and nutritive value. It has become a very popular as *rabi* forage in irrigated areas or all most all over the country. Berseem belongs to one of the largest and most useful plant family leguminaceae and sub family faboideae. Berseem is known as king of fodder crops and it is popular among the world. It is one of the oldest cultivated crops, domesticated in Egypt and later introduced into many other parts of the world. Berseem was introduced in India in 1903 (Roy *et al.*, 2009) [5]. It is now widespread in the irrigated regions of west and south Asia. Most of the farmers conserved the berseem as hay to get cheap, palatable and nutritive forage during scarcity periods or early winter and summer. Berseem is a cheapest source of increasing milk production as well as improving soil fertility. Berseem can be sown in early autumn and can thus provide feed before and during the colder months but the optimum conditions are 18-25 °C. If the winter temperature falls to 6-8° C the crop growth is severely affected. This is nutritious, succulent and palatable fodder available for fairly long period during winter, spring and early summer (Chaterjee and Das, 1989) [2]. Grazing is possible though less common than cutting. The most important cultural practices that need to be carefully adjusted to achieve maximum benefit from the forage grass-legume mixtures. The ability to fix atmospheric nitrogen and convert it to a useable form for plant growth is the main trait to these legumes (Allen and Allen, 1981) [1].
Poultry manure is an excellent soil amendment that provides nutrients for growing crops and also improves soil quality when applied widely, because it has high organic matter content combined with available nutrients for plant growth (Ryssen *et al.*, 1993) [7]. The application of FYM with chemical fertilizers and composted with rock phosphate to improve crops yield is very well established (Shafi *et al.*, 2012) [8]. Fertilizers play an important role in enhancing forage productivity. Chemical fertilizers are soluble and immediately available to the plants; therefore, the effect is usually direct and fast, the price is lower and they are quite high in

GENETIC STUDIES ON REPRODUCTIVE TRAITS OF HARIANA COWS

Abstract

The performance records of 211 Hariana cows, progeny of 27 sires, born during the year 1966 to 1985 having at least records up to second calving were utilized in this study. These cows were maintained at D.D.D. farm, Mathura and livestock farm, Madhurikund (Mathura). The average post partum oestrus interval was estimated to be 185.43± 11.18, the heritability estimate of post partum oestrus interval was estimated to be 0.021±0.175. The magnitude of the effect of sires was non significant and the variation in post partum oestrus accounted due to sires was very small (8.7%) in total variation. The least squares means and their standard errors of number of service per conception were estimated to be 2.19±0.26. The heritability estimate of the number of service per conception was estimated to be 0.294±0.210. The contribution of sires was 21.8% in the total variation of the trait.

Introduction

The cow is an efficient machine for converting farm crops into useful human food like milk and milk products, which are the main source of animal protein in the diet of a large vegetarian population of the country. Hariana breed of zebu cattle has been well established dual-purpose breed known for its milk yield as well as for draught ability. The breed has reduced significantly and is continuing to decline at an alarming rate. Apart from the declining population, Hariana cattle have also deteriorated in their productivity (Joshi et al., 1995).

Materials and Methods

The present study was undertaken on Hariana cows. All the animals taken into consideration were farm bred. The data used in this investigation were collected from the pedigree sheets, milking register and breeding record of Hariana cows maintained at DDD Farm, Mathura. The performance record of 211 cows, having at least record up to second calving were collected for genetic studies. The statistical analysis of the data was carried out by using the LSMLMW (Least Squares and Maximum Likelihood Method)- Harvey (1990) PC-2 version computer programme and Henderson (1953) model were used.

Results and Discussion

The least squares mean of the post-partum oestrus interval along with their standard errors have been presented in table 1. The average post-partum interval was estimated to be 185.43±11.18 days. The frequency of animal in various PPO groups (class interval of 40 days) is about 23.69% animals had post-partum oestrus interval below 90 days. The maximum frequency of animals was in 90 to 130 days group (26.54%). Present observation is comparatively higher than the average of post-partum interval reported by Luktuke and Subramanium (1961), Singh et al., (1964), Arora et al., (1971), Acharya et al. (1971) and Khanna (1998) for Hariana cows. Whereas, Kohli and Suri, 1957, Kohli and Suri, 1960 and Tomar and Arneja, 1972 have reported comparatively higher post-partum oestrus in Hariana cattle.

Least squares analysis of variance was performed to study the effect of farm, period and session of calving are present in table 2. The perusal of the table revealed that the effect of farm was found to be non-significant on post-partum oestrus interval in Hariana cows, although the contribution of farm was highest (83.5%) in total variation. However, Ashraf et al., (2000) observed highly significant farm effect on post-partum oestrus interval. The effect of period and season of calving were found non-significant. However, Mahmoud et al., (1991) observed a significant effect of month of calving.

Heritability estimate of post-partum oestrus interval was estimated to be 0.021±0.175. The magnitude of the effect of sires was non-significant and the variation in PPO accounted for due to sires was very small (8.7%) in total variation. The findings were indicative of zero heritability for this trait in these animals. Similar observations were reported by Prasad (1958) for Tharparkar cattle and Singh et al., (1964) for Hariana cattle.

Conclusion

Any selection programme based on post-partum oestrus interval will not prove beneficial in these cattle because the genetic variability for this character in these animals does not seem to exist. In view of the above observations, improvement in managemental practices may lead improvement in this trait.

Abstract
To assess the associations among body condition score at calving (BCSC), BCS during lactation (BCSL), production performance and udder health status of dairy cows, 50 cows (HF cross) at 2nd parity were selected randomly. The animals after random distribution into 3 groups i.e. group I (BCS<3.0, thin), group II (3.0<BCS>3.5, moderate), group III (BCS>3.5, fat) kept in observation for 120 days. The BCS of group-III cows were significantly (P<0.05) higher than group I. The FCM, fat and SNF was positively correlated with BCSC and negative with BCSL. The somatic cell score (SCS) was correlated negatively with BCSC and positively with BCSL.

Key words- BCS, Milk, Milk composition, Udder health, SCS

Introduction

Milk quality is as significant as the milk quantity in dairy animals. High yielding dairy cows had higher incidence of mastitis that can be assessed by somatic cell count (SCC) of milk (Kadarmideen and Bryce, 2001). Optimal body condition of dairy cow is important for obtaining elite herd and quality milk. Low or higher body reserves may pose a risk of lower milk yield and higher SCC in milk respectively (Berry et al., 2007). High yielding dairy cows exhibit negative energy balance after calving which may influence both immune and metabolic system of the individual that predispose the animals to mastitis. Body condition score had a favourable correlation with SCC, but it was not strong (Berry *et al* Loc. cit.). Dang et al., (2010) reported non-significant relationship between BCS and SCC. Hence, it is postulated that there are no consistent results regarding the relationship between body condition score and somatic cell counts of the dairy animals. Therefore, the present study was carried out to investigate the association among body condition score, production performance and udder health status of dairy cows.

Materials and Methods

This study was carried out in the area under subtropical zone of Indo-Gangetic plane. Fifty lactating dairy cows (HF cross) of second parity available at the Teaching Livestock Farm in the College of Veterinary Science and Animal Husbandry, N.D.U.A.T., Kumarganj, Faizabad (U. P.) and in the small dairy farms of the surrounding villages were selected. Observations were recorded for 4 months. The animals in farm and field conditions were maintained under loose housing system and the stanchion system, respectively. The data collected at fortnightly intervals were, the Body Condition Score (BCS), Production performances and Somatic cell count (SCC). Milk yield of selected animals in the farm and the field were recorded on the observation days both morning and evening. Milk samples were collected directly from the animal during milking to assess the milk composition such as fat, SNF (solid not fat), CLR (corrected lactometer reading) by EKO milk ultra, milk analyser (Milkana KAM98-2A). The milk yield was further corrected on 4% fat basis (Fat corrected milk, FCM) according to the formula given by Gaines (1928) as under-

FCM = 0.4 × milk yield (l) + 15 × milk fat (kg).

Body condition score of animals after calving were assessed in the morning milking by the chart formulated by Prasad (1994) having 1-6 scale with 1 indicating under body condition and 6 representing over body condition of the dairy cows. 1 to 6 scales were further splitted in to half or quarter point increment (e.g., 2.5 or 3.25). For the better interpretation of BCS effect on the milk yield, milk composition and udder health status, the animals were divided in to three groups on the basis of BCS at calving i.e. group-I (BCS <3.0, thin), group-II (3.0≤BCS≥3.5, moderate) and group-III (BCS > 3.5, fat). The udder health status was determined by somatic cell count (SCC) of milk immediately after collection as per methodology of IDF (1984). The SCC was log-transformed into the fortnightly test day observation SCS (Somatic cell score) as SCS=$\log_{10}$SCC (Mrode and Swonson, 1996).

The collected data were analyzed by SPSS (version 11.5). The means of various measurements were compared by Duncan's Multiple Range test (Duncan, 1955). The Pearson's correlation coefficient was estimated to find relationships among observations.

Results and Discussion

Out of 50 animals, 13 cows were classified as thin (group–I), 20 as moderate (group–II) and 17 as fat (group–III) at parturition. BCS of cows at calving was 2.83±0.06, 3.38±0.03 and 4.22±0.11, in group I, II and III, respectively (Table-1). BCSC differ significantly (P<0.05) among the three groups of cows. The BCS during calving to 15 days were significantly (P<0.05) higher than rest period of lactation. The declining BCS might be due to mobilization of body fat reserves to cover milk production during early lactation (Buckley *et al.*, 2000, Friggens *et al.*,

Abstract

The genetic worth of a sire can be measured directly but it has to be estimated either on the basis of phenotypic performance or observed value of a trait in the sire itself, or information from relatives in sex-limited traits such as milk yield.

The present investigation was undertaken on 1367 first lactation records of Sahiwal cattle maintained at GLF, Chak Ganjaria, Lucknow (U.P.) over a period of 71 years (1944-2014). The study was conducted on breeding value estimation of sires, relationship between Estimated Breeding Values (EBV's) for first lactation and life time traits using daughter's average, least-squares and best linear unbiased prediction methods of sire evaluation and effectiveness of these methods. The rank correlations among the breeding value of sires estimated from first lactation milk yield and life time milk were medium to high and highly significant (P<0.01). Therefore, the daughters of the sires selected on the basis of high first lactation milk yield would tend to produce higher life time milk yield. The product moment correlations among the estimated breeding value of the sires for first lactation traits by all the three methods ranged from medium to very high and highly significant (P<0.01) in all the three methods of sire evaluation.

Introduction

Cattle rearing has been an important source of livelihood in India and is closely associated with agricultural economy. The agriculture and allied sectors contribute nearly 14 per cent of the Gross Domestic Production. The agriculture and livestock are the main source of employment in rural areas and about 52 per cent of the population is engaged in agriculture and rearing of livestock in our country.

The effectiveness of sire evaluation is the backbone of any breed improvement programme. This investigation was planned to evaluate Sahiwal sires as its performance is remarkable in hot climate and has been recognized worldwide as one of the best milch breed (Ilatsia et al., 2011). Various sire evaluation methods viz. daughter's average, least-squares analysis and best linear unbiased prediction (B.L.U.P.) were used to evaluate the sires and their effectiveness were compared for Sahiwal cattle. The information on the production of first lactation is mainly required for getting genetic improvement through selection, since it serves as an index of life time production in dairy cows. Therefore, it is very much essential for the sire evaluation to correlate the first lactation milk yield with life time milk production.

Materials and Methods

The data for the present investigation were collected over a period of 71 years (1944-2014) from pedigree sheet of 1367 Sahiwal cows born to 112 sires maintained at Government Livestock Farm, Chakganjaria, Lucknow (U.P.). Only the sires having the records on at least three or more daughters were included in the present study. The total duration of the present study was divided into 8 periods.

Out of 8 periods 7 are of 9 years each and 8th period of 8 years only. Each year was divided into three seasons namely winter (November-February), Summer (March- June) and Rainy (July- October). In order to classify the data for different periods and seasons year and season of calving was considered for all the traits.

Statistical Analysis

Rank correlation

After estimation of breeding value of sires, the sires were given rank as per their genetic merit. The Spearman's rank correlation between breeding values of sires derived by various methods was used to judge the effectiveness of different methods. The rank correlation was estimated as per methods developed by Steel and Torrie (1960).

$$r_s = 1 - \frac{6\sum d_i^2}{n(n^2-1)}$$

Where,

r = Rank correlation coefficient

n = Number of sires under evaluation

d_i = Difference of rank between paired items under two methods

The significance of rank correlation was tested by t-test as given below

$$t = r\frac{\sum(n-2)}{(1-r^2)}$$

It was compared with t-table value with (n-2) degree of freedom.

Simple product moment correlations

The simple correlations (r) between the estimated breeding values of bulls by different sire evaluation methods were also calculated by the following formula:

$$r_{(XY)} = \frac{Cov(XY)}{\sqrt{[Var\ (x)\ \ Var\ (Y)]}}$$

Where,

$$Cov\ (XY) = \sum XY - \frac{(\sum X)\ (\sum Y)}{n}$$

$$Var\ (X) = \sum X^2 - \frac{(\sum X)^2}{n}$$

$$Cov\ (Y) = \sum Y^2 - \frac{(\sum Y)^2}{n}$$

Where,

X, Y= The breeding value of sires estimated by two different methods

n= Number of pairs of breeding value

Rank correlation

The rank correlations of most efficient method (LSM) of sire evaluation for LTMY was statistically highly significant (P<0.01) with their values 1.00 ($\overline{D}$ and LSM), 0.71 ($\overline{D}$ and BLUP) and 0.71 (LSM and BLUP). For LTLL, the rank correlation between the different methods were 1.00 ($\overline{D}$ and LSM), 0.79 ($\overline{D}$ and BLUP) and 0.79 (LSM and BLUP). The rank correlation of estimated breeding values of LTMY between daughter's average and least squares method was very high (100%) (Table-1).

It revealed that ranking of sires for the estimated breeding value by daughter's average and least-squares method was similar while ranking of sires from BLUP was different. Similarly, for the LTLL, the rank correlation of estimated breeding values between ($\overline{D}$) and LSM was very high (100%). It revealed that ranking of sires for the estimated breeding value by $\overline{D}$ and LSM was similar while ranking of sires by BLUP was different.

Product moment correlation

The product moment correlations of most efficient method (LSM) of sire evaluation for LTMY with other two methods of sire evaluation (

EFFECT OF DIFFERENT LITTER MATERIALS ON BEHAVIOR OF KADAKNATH FOWLS

College of Veterinary Science and Animal Husbandry, N.D.U.A.T., Kumarganj, Faizabad, Uttar Pradesh- 224229 (India)

Abstract
The present study was conducted to investigate the effect of different litter materials on behavior of Kadaknath chicks. A total 300 Kadaknath chicks were raised on three litter treatments viz. Sand, rice hulls and rice hulls plus chopped paddy straw (1:1) comprising of two replicates in each treatment. The results indicate that Kadaknath chicks reared on sand and rice hull litter had significantly higher proportion of time in activities like drinking, dust-bathing and perching than paddy straw+rice hulls. The behavioral activities like drinking, dust bathing, stretching, standing and perching in sand litter, dust-bathing, peaking, stretching, walking, lying and perching in rice hulls and peaking, stretching and standing in straw+rice hulls were seemed to be significantly differed in morning, noon and evening hour interval.

Keywords: Kadaknath, feed, behavior, sand, rice hulls, litter materials

Introduction

Desi fowls are cheaply reared as scavenging flocks by feeding household left over and their meat and egg taste are preferred over that of exotic chickens (Dessie and Ogle, 2001). Wood shaving has been standard choice for poultry litter for many years. Rice hulls appear to be a favourable alternative to wood shavings (Grimes *et al.*, 2007). Various types of litter materials like sand (shields *et al.*, 2005), saw dust (Grimes *et al.*, 2007), rice and wheat straw (Sreehari Sharma 2010), ground corn cob and soyabean straw (De Avila *et al.*, 2008) have been utilised as bedding materials for rearing of poultry birds. Sand has shown good potential as an alternate litter for more reuse quality and very less caking.

Pine shavings and saw dust are the most desirable and most widely used litter materials for broiler production in the United States. About 60% of farmers used saw dust as litter materials, 16.7% used wood shaving, 20% used both wood shaving and saw dust while 3.3% of farmers do not use bedding materials. The types of litter used by farmer depend on locality and availability (Kalu E. 2015) . Paddy husk is most commonly used litter material in northern India.Sigroha et al., (2017) used saw dust, wheat straw, rice husk, river bed sand and sandy soil as litter materials and found higher weight of birds at 42 days of age in wheat straw followed by sandy soil, saw dust, river bed sand and rice husk. As far as seen in literature there is no concert conclusion for litter type and thickness for various regions and climates. In view of above a study was undertaken with following objectives-

- To investigate the effect of litter material on the behavior of Kadaknath fowls

Materials and Methods

The present investigation was carried out to study the effect of different litter materials on growth performance, feed gain ratio of Kadaknath fowl. The study was carried out at the poultry unit of Teaching Livestock and Poultry farm of the College of Veterinary science and Animal Husbandry, N.D.U.A.T. Kumarganj, Faizabad U.P., situated at a distance of 42 km away from Faizabad city and 38 km away from Jagdishpur Industrial area at an altitude of 113 m above sea level and latitude of 26^0 47' North and longitude of 82^0 12' East and it falls in Eastern plain Zone of Middle Gangetic Plain region of India.

Experimental period and climatic conditions

The experiment was conducted in the months of November to February which comprised winter season of this region. The average minimum temperature recorded during study period was 12.54^{0}C, while the average maximum temperature was 24.86^{0}C. There were a few showers of rain, ranging from 62 to 123 cm and average was 92.5 during this period. The topography of land is almost even and most of the farm area remains dry round the year. Parasitic infestation was moderate.

Experimental animals

To carry out present investigation, 300 straight run day old Kadaknath chicks, from college hatchery were got issued. These 300 kadaknath chicks were divided into two batches; each batch consisted of 150 Kadaknath Chicks. Each batch was subdivided in three equal groups of 50 chicks viz. Group1 (sand), Group 2(rice hulls), Group3 (paddy straw + rice hulls) randomly distributed among three pens. Each pen was equipped with fresh litter, feeder and waterer. All the birds were raised on pukka floor with sand, rice hulls and paddy straw + rice hulls (50:50) as litter materials. Chicks were reared under standard uniform managemental practices up to the age of 42 days and observations for different parameters were recorded simultaneously. Thereafter, a replication was made with the next batch of chicks.

Brooding and rearing of chick

Brooder house

The cold room brooding method was applied for brooding and rearing of Kadaknath Chicks in the brooder house. Brooding was done on pukka floor using deep litter system. Each group of Kadaknath chicks placed in separate pens which were visually isolated from each other along with provision of adequate ventilation and artificial light in the brooder house.

Preparation of brooder house to receive Kadaknath chicks

Brooder house was properly scrubbed and cleaned at least a week before the trail began. After the house, equipments were properly cleaned. The house was allowed to dry out thoroughly. The house and equipments were fumigated using 1% formalin. Three inches depth of litter were made on the floor. Few days before the chicks arrived, equipments were arranged in brooder house and the electric bulbs were started to adjust temperature and light. The temperature under the brooder house was slightly above 35^{0}C. The corners of brooding space were made rounded off with cardboard and metal chick guards to prevent chicks from piling up in the corner. All these preparations were completed for Kadaknath chicks before they were procured to brooder house. A chick guard of about 15 cm height was used at a distance of 30 to 40 cm away from the brooder and was moved away for the every day. It was completely removed after two weeks.

Litter materials

For the present experiment three litter materials namely sand, rice hulls and paddy straw + rice hulls (50:50) were used for rearing the Kadaknath chicks. Rice hulls were procured from the nearby rice mill, paddy straw taken from village shivnathpur and sand was taken from kumarganj market. These litters were clean, dry and free from fungal growth. The thickness of litter was 3.0 cm. After spreading this litter on the floor with proper thickness was covered with newspaper up to 4 days of brooding.

Parameters recorded

Behaviour

The behaviours in the Kadaknath recorded in this study were chosen from preliminary observations and defined as a list of 12 states which have given here.

1. Eating
2. Drinking

ABSTRACT

An experiment was conducted on "Effect of land configuration and moisture regimes on productivity of hybrid maize (*Zea mays* L.) in summer season." during 2018-19 at Agronomy Research Farm, ANDUA and T, Kumarganj, Ayodhya (U.P.). The experiment accomplished of 12 treatment combinations and laid out in split plot design, replicated three times. The Experiment consisted of three land configuration *viz.* flat bed planting (P_1), ridge planting (P_2) and paired row planting on raised bed (P_3) were kept in main plots and four moisture regimes *viz.*0.5 IW/CPE ratio, 0.7 IW/CPE ratios, 0.9 IW/CPE ratios and 1.1 IW/CPE ratios were allotted in sub plots. The experimental results revealed that growth parameters, such as plant height, leaf area index, dry matter accumulation, days to 50 percent ear emergence and days to50 percent maturity and yield were obtained maximum with the paired row planting methods followed by ridge planting and flat bed planting and yield attributes such as number of cobs plant^{-1} , number grains row^{-1}, number of grains cob^{-1}, cob length (cm), cob girth (cm), grains weight cob^{-1}(g), cob weight (g), shelling percentage (%), grain yield (q ha^{-1}), stover yield (q ha^{-1}), and biological yield (q ha^{-1}) were also increased similarity in same treatment. In case of moisture regimes, the same trends were observed maximum when applied irrigation at 1.1 IW/CPE ratios as compared to other moisture regimes.

Determinants of behavioural indicators of potato (*Solanum tuberosum*) growers in Kannauj district of Uttar Pradesh

ASHWANI KUMAR VERMA[1], R K DOHAREY[2], S K DUBEY[3]*, O P SINGH[4] and S N SINGH[2]

ICAR-Agricultural Technology Application Research Institute, Kanpur, Uttar Pradesh 208 002, India

Received: 07 July 2020; Accepted: 31 August 2021

ABSTRACT

The present study was carried out to find out the factors that may affect the behavioural dimensions of potato farmers, viz. their knowledge and adoption level as well as their knowledge-adoption gap about scientific potato cultivation practices in Kannauj district of Uttar Pradesh during 2016–17. Multiple regression and stepwise regression analysis was done with selected independent variables to see the effect of independent variables on the selected indicators. The analysed data showed that at knowledge level out of 18 variables taken for analysis of regression, four variables, viz. housing pattern, occupation, material possession and formal extension contact were highly significant (P<0.01); five variables, viz. education, housing pattern, informal extension contact, scientific orientation and risk orientation were highly significant (P<0.01) for their adoption level; and at knowledge-adoption gap one variable i.e. education was highly significant (P<0.01). The R^2 value and F value of knowledge, adoption and knowledge adoption level were 0.59, 0.29, 0.33 and 8.63, 2.52 and 2.95 (P<0.01), respectively. The R^2 value of stepwise regression in knowledge, adoption and knowledge-adoption gap level was 0.54, 0.24 and 0.24.

Keywords: Adoption, Knowledge, Multiple regression, Potato

Potato (*Solanum tuberosum* L.) belongs to family Solanaceae, is well known as the king of vegetables and has emerged as the most important food crop of India. Despite higher retail price of potato, the sowing of tuber is set to shrink in Northern states as farmers prefer alternate crops including onion, garlic, sugarcane and other perishables during *rabi*. Introduction of potato crop is not only important for ensuring socio-economic upliftment of the local farmers but for warranting financial sustainability of crop husbandry also (Rana *et al.* 2017). In last few years, the gap between wholesale and retail price of potato has widened by two-three times. It has disappointed potato growers and many are shifting to other crops. Mostly big farmers who store their produce have incurred losses in potato business and many such farmers are shifting from cultivation of tuber. In the last three years, glut in potato production has caused unrest among farmers in North. The annual output has grown to 53 million tonnes (MT) in 2018–19 compared to 51 million tonnes in 2017–18 (Krar 2019). The increase in area of potato cultivation has squeezed margins for growers as well as traders in the region.

Uttar Pradesh is a major potato growing state in India followed by West Bengal and Bihar with the production of 10455.30, 7482.30 and 1720.20 thousand tonnes, respectively. It produced almost 13.1 MT of potato, thus contributing nearly 28.6% of total potato production in the country (Directorate of Economics and Statistics 2016). Kannauj district is the highest producer of potato followed by Farrukhabad and Agra with production of 9.43, 8.33 and 6.47 lakh metric tonnes with area being 34.6, 29.8 and 18.20 thousand hectares, respectively (Anonymous 2001–02). Therefore, considering the significance of potato in Kannauj district, the study was carried out to analyse the profile of potato farmers of the district and to identify the determinants which may affect their behavioural dimensions in terms of their level of knowledge, adoption and knowledge-adoption gap.

MATERIALS AND METHODS

The present study was carried out in Kannauj district of Uttar Pradesh during 2016–17, which was selected purposively due to its high grown area under potato crop. It is considered to be the most climatically suitable area for potato cultivation. Jalalabad block of Kannauj district with maximum area under potato cultivation was further selected purposively. Five villages, viz. Paraspur, Gadnapur, Mirpur, Purva, and Bisundhua were selected randomly and from each village, 25 farmers actively involved in cultivating potato were further selected randomly.

Factors influencing adoption level of farmers regarding organic farming in eastern UP

Arvind Pratap Singh, Prakash Singh, RK Doharey, RK Singh, Rishi Kumar Singh, Abhay Kumar Singh and Vikash Pandey

Abstract
This study was undertaken in three districts selected randomly from each Zone namely (1) North Eastern Plains Zone (2) Eastern Plains Zone (3) Vindhyan Zone in Eastern Uttar Pradesh. From each selected district, two blocks were selected randomly. Thereafter two villages from each block was selected randomly, thus make a total 12 villages. The majority of respondents were of middle aged and literate including formal and informal education. Highest number of the respondents (55.83%) was observed in the medium category (33 to 44) of materials possession. Majority of farmers (60.41%) had medium level of overall extent of awareness about organic farming practices. The variables like age, family size, material possession and economic motivation, were found positively correlated but not significant with adoption level regarding organic farming practices. The variables like education, caste, family type, housing pattern, land holding, occupation, income, social participation, extension contact, value orientation, risk orientation and attitude were found negatively correlated but not significant with adoption level regarding organic farming practices.

Keywords: block, proportionate, age, education, overall materials possession, organic farming practices, adoption, correlations etc

Introduction
The organic movement in India has its origin in the work of Howard who formulated and conceptualized most of the views which were later accepted by those people who became active in this movement. Organic farming is a production system which avoids, or largely excludes, the use of synthetic fertilizers, pesticides, growth regulators, and livestock feed additives.

The Indian government has initiated various promotional activities, such as setting up a National Institute of Organic Farming in Ghaziabad, Uttar Pradesh, in 2003, appointment of accreditation and certifying agencies for organic farm products, developing norms for certifying organic products and providing financial support to implement promotional activities for organic farming. The task force constituted by the Government of India has also recommended the initiation of post-graduate level courses in organic farming. One of steering committee constituted by Central Government under the chairmanship of Mr. M.S. Swaminathan, Chairman, farmer's commission, has suggested taking up organic farming as a challenging national task and to take up this as a trust area of the 10th Five Year Plan. The Ministry of Commerce launched the National Organic Program in April, 2002 and processed food products export.

"Organic farming is a production system that avoids or largely excludes the use of synthetically compounded fertilizer, pesticides, growth regulators and livestock feed additives. Organic farming systems rely to the maximum extent on crop rotations, crop residues, animal manures, legumes, green manures, off-farm organic wastes, and aspects of biological pest control to maintain soil productivity and tilt, to support plant nutrients and control insects, weeds and other pests". (Kanel, 2005) [2].

Methodology
The present study was conducted in six blocks of three districts namely Barabanki Basti, and Prayagraj of Uttar Pradesh. Each district selected two block and find out the different independent variables and their level of adoption of organic farming practices in organic farming. Those blocks namely Masauli, bani kodar, Haraiya, Vikram jot, Phulpur and Dhanupur was selected randomly having production area of agriculture.

Hence, the present study has been designed to explore the level of adoption of organic farming practices in Barabanki, Basti, and Prayagraj districts of Uttar Pradesh with specific objective.

ABSTRACT

Agriculture is the most important sector of the Indian economy and is more or less a compulsion for the livelihood of millions of farmers. Many initiatives have been taken in this regard to utilize mobile phones by private sector (Indian Farmers Fertilizer Cooperative Limited, Nokia, Airtel, Tata Consultancy Services, etc.), public sector (Ministry of Agriculture and Farmers Welfare, Agricultural Universities, Research Institutions like Indian Council of Agricultural Research, State Governments). The Indian government and other development agencies promote farmers and their income generating projects as a way of encouraging growth through increased agricultural production. The impact of new technology to economic growth can only be realized when the use of these new technologies is widely diffused. Introduction of mobile phones and services in agriculture can be advantageous to farmers, traders and producers for improving their decision making.

Keywords : Agriculture, mobile phone, farmers, e-Mandi, Mandi Trades

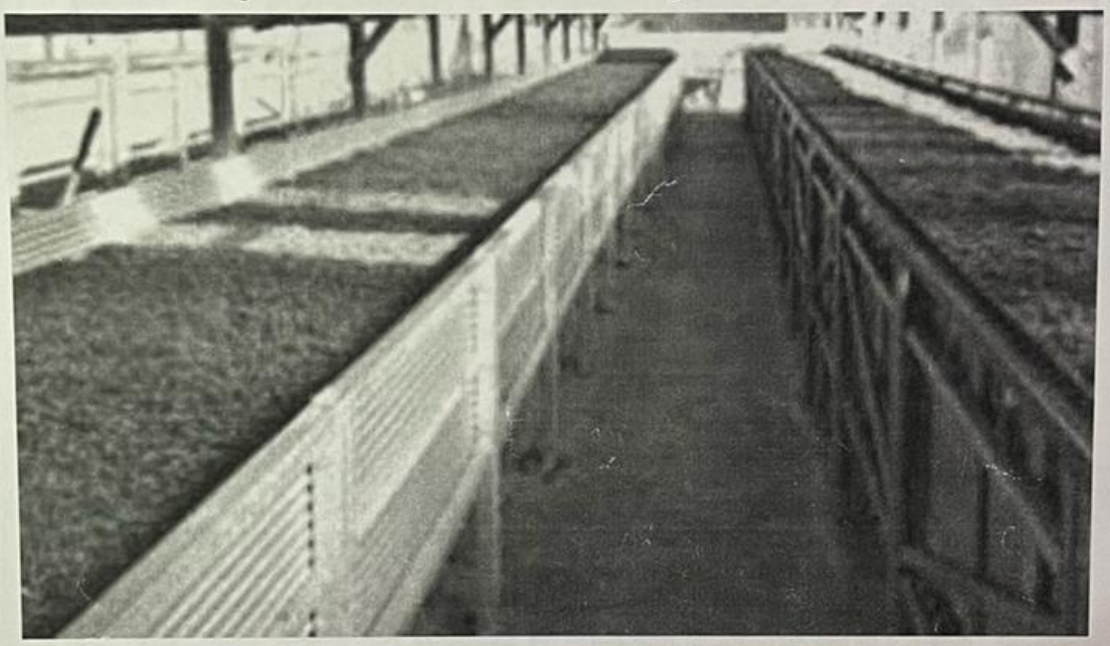
INTRODUCTION

Indian economy is the most important aspect of the agricultural sector. Research, extension and farmer's efforts have all contributed significantly in increasing food production from 50 million tonnes in 1950-51 to a landmark achievement of an estimated 259.32 million tonnes in 2011-12 (MOA, GOI, 2013). Estimates indicated that 60 per cent of farmers do not access any source of information for advanced agricultural technologies resulting in a huge adoption gap (NSSO, 2005). Government, private, and general public agencies are often interested in the decisions made by the Indian farmers as they have large influences beyond the farm. Agriculture clearly remains one of the most important portfolios in

वर्मीकम्पोस्ट या केंचुआ खाद क्या है केंचुआ खाद तैयार करने की विधि

आर0के0 दोहरे एवं आर0के0यादव

नरेन्द्र देव कृषि एवं प्रौद्योगिक विश्वविद्यालय, कुमारगंज, फैजाबाद (उ०प्र०)



परिचयः– केंचुआ खाद या वर्मीकम्पोस्ट पोषण पदार्थों से भरपूर एक जैव उर्वरक है। यह केंचुआ आदि कीडों के द्वारा वनस्पतियों एवं भोजन के कचरे आदि को मिलाकर बनाई जाती है। केंचुओं के आंतों के अन्दर जो पोषक तत्व होते हैं उसके द्वारा ग्रहण कर लिये जाते हैं और बाकी का जो मल निकलता है वह उत्तम गुणवत्ता वाला जैविक खाद होता है। वर्मी कम्पोस्ट में बदबू नहीं होती है और मक्खी एवं मच्छर नहीं बढ़ते हैं तथा वातावरण भी प्रदूषित नहीं होता है। अवघटनशील व्यर्थ कार्बनिक पदार्थों जैसे–भूसा, पुआल, घास–पत्ते, गोबर आदि कचरे को मिलाकर केचुओं को आहार के रूप में भोजन मिलता है उसे वर्मीकम्पोस्ट कहते हैं।

एक अनुमान के अनुसार केंचुआ 1000 टन कार्बनिक पदार्थ को 300 टन जैविक खाद में बदल देते हैं। गंदगी नियंत्रण में केंचुए की अहम भूमिका है। यह रबर, प्लास्टिक व धातु को छोडकर लगभग सभी कुछ खा जाते हैं। वर्मीकम्पोस्ट बनाने के लिए इस विधि में क्षेत्र का आकार अवश्यकतानुसार रखा जाता है। मध्यम वर्ग के किसानों के लिए 100 वर्ग मीटर क्षेत्र पर्याप्त है। अच्छी गुणवत्ता के केंचुआ खाद बनाने के लिए सीमेन्ट तथा ईंटों से पक्की क्यारियां बनाई जाती हैं। प्रत्येक क्यारी की लम्बाई 3 मीटर, चौडाई 1 मीटर एवं ऊँचाई 35–50 सेमी0 रखते हैं।

वर्मीकम्पोस्ट या केंचुआ खाद तैयार करने की विधि :–

1. **केंचुओं का चुनाव**– वर्मीकम्पोस्ट में केंचुओं की उन प्रजातियों का चुनाव किया जाता है जिनमें प्रजनन वृद्धि दर तीव्र हो, प्राकृतिक तापमान में उतार–चढाव सहने की क्षमता हो। उदाहरण– आइसीनियाँ फीटिडा, यूडिलस, यूजेनी तथा पेरियोनिकस एकस्केवेटस। कानपुर या उन्नाव जनपद के लिए आस–पास के सभी क्षेत्रों में आइसीनियाँ फीटिडा वर्मी कम्पोस्ट के लिए उपयोगी है।
2. **वर्मीकम्पोस्टिंग योग्य पदार्थ**– इस प्रक्रिया के लिए सभी प्रकार के जैव कार्बनिक पदार्थ जैसे– गाय, भैंस, भेड, सुअर, तथा मुर्गियों आदि का मल बायोगैस स्लरी, शहरी कूडा, प्रौद्योगिक खाद्यान्न का बचा हुआ पदार्थ

ABSTRACT: Field demonstration is the elderly concept of Front-Line Demonstration. FL developed by the Indian Council of Agriculture Research with the beginning of the Technology operation on Oilseed Crops during mid-eighties. Field demonstrations carry out close regulation of scientists of National Agriculture Research System recognized as frontline demonstrations because technologies are demonstrated in front of farmer by the scientists before being fed into the major extension method of the State Department of Agriculture. Adoption level of the beneficiaries were medium to high even as non-beneficiaries were found small level of adoption are enhanced production practice of mustard crop, proper training and extension strategies to be followed maximum adoption of mustard crop in the research area.

Keyword: Frontline Demonstration, KVK, Yield, economics, growth, management practices and India.

INTRODUCTION

The Krishi Vigyan Kendras were assigned different actions pertaining to evaluation, modification and expression of different novel technologies. This includes conduction of association of Frontline demonstration, estimation, training programmes and sophistication of different agriculture and related technologies during OFT. Extension activities and movement of Krishi Vigyan Kendras do significant movement for the farmers and useful in hole crop period. Krishi Vigyan Kendras are the base of all organizations who work for purpose of technology through refinement, evaluation and demonstration of confirmed technology under diverse "micro farming" situation in a region (Das, 2007). In the year 1991-92 Indian Government established a "Technology Mission on Pulses" to improve the pulse production and productivity through frontline demonstration. The mandate of the Krishi Vigyan Kendra (KVKs) are application of technology through refinement, demonstration and assessment of verified technologies under different "micro farming" situations in a region (Das, 2007).

Frontline demonstrations is show recently released crop protection and production technology and its running practice on the farmers field under diverse farming situation and agro-climatic regions. While demonstrating the technologies on farmer's field, the scientist are compulsory to study situation, factors and elements involving in higher crop production, Limitation of production and thereby create production data and feedback information. Frontline demonstrations were conduct in two adopted villages at pasture of 20 farmers within area of 0.4 hectare each. Moong crop was grown according to the package and practices of moong crop according field demonstration (Anonymous, 2017).

Effect of plant growth-promoting rhizobacterium (PGPR) on chlorophyll content of chickpea plant (*Cicer arietinum* L.)

KM Komal, Adesh Kumar, Muzaffar Ali Khan, Akrati Dev, Ashish Kumar, Shambhoo Prasad and Niyaj Ahamad

Abstract
Green plants produce a varied arrangement of primary and secondary metabolites. Chlorophylls are the principal metabolites that give leaves and fruits their colour. Chlorophylls spectrum characteristics are critical for capturing light energy and transducing absorbed light energy for photosynthesis. Like other plants, Chlorophyll content affects leaf colour and photosynthetic activity. The amount of Chlorophyll in a plant's leaves impacts its photosynthetic capability per unit area of its leaf and stress and nutritional inadequacies. The Arnon method was used to analyze the concentrations of Chlorophyll a and b. This work investigates the PGPR element regulating Chlorophyll content and supply defence in chickpea plants. After that, the chickpea plant was examined for a Chlorophyll estimation test for 30, 60, and 90 days. We noticed treated crops having CHL content, which was found to have different values after thirty, sixty, and ninety days.

Keywords: PGPR, *Cicer arietinum* L., chickpea, *Fusarium oxysporum*, *Bacillus*, *Pseudomonas*

Introduction
The commercial worth of plant organs is determined by colour, while the freshness of most vegetables is determined by texture. Pigments are responsible for the perception of colour. Pigments are abundant in fruits and vegetables, which appeal to customers. Plant pigments are classified into different groups based on their chemical makeup. Chlorophyll, carotenoids, anthocyanins, and flavonoids can be identified (Manolopoulou *et al*., 2016) [18].
The amount of Chlorophyll in leaves is a crucial feature studied to measure Chloroplast concentration, photosynthetic activity, and plant metabolism. Chlorophyll is an antioxidant found in green leaf plants' Chloroplasts, primarily in the roots, branches, florae, andleaves (Mirza *et al*., 2013; Srichaikul *et al*., 2011) [19, 25]. Instead, CHL product primarily depends on sunlight piercing and is the plant's primary energy source (Srichaikul *et al*., 2011)[25]. Extract the pigments; it's commonly done in the lab with a pestle and mortar and acarbon-based solvent like acetone (Arnon 1949; Porra *et al*., 1989) [1]. Plant photosystems require the pigments Chlorophyll A and Chlorophyll B. (Richardson *et al*., 2002) [21]. Furthermore, CHL a is the most abundant colourant for photosynthesis in plants, supporting producing energy (Srichaikul *et al*., 2011) [25]. Ontheotherhand, CHLaconc in plantsis 2-3 times larger than subordinate CHL b conc (Srichaikul *et al*., 2011) [25]. Chlorophyll absorbs light of various wavelengths, especially in the visible spectrum's red (650–700 nm) and Amethyst colour (400–500 nm) areas. The green colour comes from the fact that green light (550 nm) is reflected rather than absorbed. Chlorophyll A is an Aquamarine colour pigment, whereas CHL B is a Chartreuse colour. The volume of solar energy consumed by a leaf is primarily determined by the conc of photosynthetic pigments on its foliar surface. As a result of low CHL levels, photosynthetic capacity and primary production may be limited (Da Matta *et al*., 2008; Kumari *et al*., 2018) [14, 16].
Compared to Chlorophyll, non-Chlorophyll accessory pigments such as carotenoids are found in a and b. It absorbs light and sends it to a different photosystem. By absorbing and dispersing excess light energy, carotenoids also serve as antioxidants. The spectra of CHL and non-CHL pigments differ for 1-2 reasons.
Chickpea is a frequently consumed member of the pulse plant family. It is the most commonly submitted Pod in South Asia and its third most popular edible bean. It is a vital basis of protein for many persons in evolving nations, notably in Asia's south region, where most people are vegetarians, either voluntarily or because of economic constraints (Gaur *et al*., 2010) [8].

ABSTRACT

Drought stress is a critical limiting factor in plant growth. Substances such as salicylic acid (SA) may enhance drought tolerance in plants. The present investigation focused on biochemical changes in JG14 and Dahod yellow seed by salicylic acid (SA) and Hydro-Priming with foliar application of SA and water in the drought and excessive moisture stress (EMS). The impacts on yields of chickpea bean were assessed for normal (3Novemaber 2014) and late (1 January 2015) sowing environments and foliar spray of salicylic acid (5 nano mole). Significantly higher yield parameters, yield, were recorded with foliar spray of salicylic acid. The experiment was Randomized Block Design (RBD) with six treatment viz, T_1-No treatments (control), T_2-Seed priming with salicylic acid (5 nano mole) till initiation of radicle (root), T_3- Foliar spray of water at 1st flower and one week after 1st flower T_4-Foliar spray of water at 50% podding one week after 50% podding, and two week after 50% podding, T_5-Foliar spray of salicylic acid (5 nano mole) at 1st flower and one week after 1st flower and T_6- Foliar spray of salicylic acid (5 nano mole) at 50% podding, one week after 50% podding, and two week after 50% podding. The highest seed yield (37.15 g in V1 and 46.49 g in V_2 plant^{-1}) was obtained by the treatment T_5-Foliar spray of salicylic acid (5 nano mole) at 1st flower and one week after 1st flower in the timely sown and 17.08 g in V_1 and 7.00 g in V_2 was found in late sowing treatment followed by treatment T_6- Foliar spray of salicylic acid (5 nano mole) at 50% podding, one week after 50% podding, and two week after 50% podding, grain yield plant^{-1} was recorded 27.70 (V_1) and 31.70 (V_2) g plant^{-1} and 8.27 (V_1) & 7.03 g (V_2) plant^{-1} in timely sown and late sown respectively presented in Table 2. Grain yield significantly increase over control 216.01% (V_1) & 206.46% (V_2) under normal sowing and 106.24% (V_1) and 59.62% (V_2)grain yield plant^{-1} under late sown condition, followed by T_6- Foliar spray of salicylic acid (5 nano mole) at 50% podding, one week after 50% podding, and two week after 50% podding normal sowing grain yield plant^{-1}, respectively.

ABSTRACT

Soil quality deterioration, especially in intensive cropping system has become a serious problem for crop productivity. Consequently, strategies for sustainable crop production and soil health are urgently required. Therefore, a field experiment was conducted to study the impact of organic and inorganic nutrient sources on yield attributes and yield of maize-mustard cropping system during two consecutive *kharif* and *rabi* seasons of 2019-20 and 2020-21, respectively. The experiment was laid out in randomized block design assigning eight treatments of organic and inorganic nutrient sources comprising of (T_1) RDF (120:60:40 kg $N:P_2O_5:K_2O$ ha^{-1}), (T_2) RDF + Zn, (T_3) RDF + S, (T_4) RDF + Zn + S, (T_5) RDF + VC (5 t ha^{-1}), (T_6) RDF + VC (10 t ha^{-1}), (T_7) RDF + FYM (5 t ha^{-1}) and (T_8) RDF + FYM (10 t ha^{-1}) and were replicated thrice. The results reported that the higher yield attributes and yield of maize *viz.*, number of cobs $plant^{-1}$, number of seeds cob^{-1}, cob length, seed yield, stover yield and biological yield and for mustard *viz.*, siliquae $plant^{-1}$, number of seeds $siliquae^{-1}$, length of siliquae, seed yield, stover yield and biological yield were recorded with application of RDF + VC (10 t ha^{-1}) which was statistically at par with RDF + FYM (10 t ha^{-1}). However, seed index/test weight and harvest index of maize-mustard cropping was failed to show any significant effect due to above treatments.

Abstract

Four rice genotypes Nagina 22, Swarna sub1, NDR 9830102 and NDR 97 were for characterization of submergence related traits by physio-biochemical indices. Thirty five days old seedling of rice genotypes were exposed to 11 days complete submergence. The shoot elongation, catalase activity, total chlorophyll content and total soluble sugar were recorded just after desubmergence of rice genotypes. Swarna sub1 and NDR9830102 showed less shoot elongation, high catalase activity and less reduction in total soluble sugar and high survival percentage over Nagina 22 and NDR 97. Less shoot elongation preserve inherent energy and utilize it for survival. High catalase activity of Swarna sub1 and NDR9830102 prevent from oxidative damage just after desubmergence and and increased survival percentage of the plan. Nagina failed to survive due to high shoot elongation and oxidative damage.

Key word: Submergence, Survival, Stress, genotypes and shoot elongation.

Introduction

Rice (*Oryza sativa* L.) is the important primary cereal crop that has been extensively cultivated in most diverse ecosystem of the world, which accounts for more than 21% of the calorific needs of the world's population and up to 76% of the calorific intake of the population of South East Asia. It is widely grown in tropical and sub-tropical regions. It is primary source of the food for 57% of the world population and played a major role as a staple food for over 2.7 billion peoples worldwide (Khush and Virk, 2000).

Rice crops are prone to various types of stresses, both biotic and abiotic. Biotic stresses include insect pests, fungus, bacteria, viruses, and herbicide toxicity. Among abiotic stresses, drought, cold, submergence and salinity are also well studied in rice (Ansari *et al.*,2015). Rice production in these ecosystems depends mainly on monsoon rainfall and run-off water from the catchment areas (Zeigler and Puckridge, 1995).

Abiotic stress limits crop productivity (Araus *et al.*, 2002; Boyer, 1982), and plays a major role in determining the distribution of plant species across different types of environments. Abiotic stress and its effects on plants in both natural and agricultural settings is a topic that is receiving increasing attention because of the potential impacts of climate change on rainfall patterns and temperature extremes, salinization of agricultural lands by irrigation, and the overall need to maintain or increase agricultural productivity on marginal lands. In the field, a plant may experience several distinct abiotic stresses either concurrently or at different times through the growing season (Tester and Bacic, 2005).

Under rainfed lowland condition, among number of abiotic stress, submergence and drought are major ones and it affects rice production a lot. Drought and submergence are the two major limiting factors that reduce rice production. These two abiotic stresses can completely destroy crop production in extreme conditions, and consequently both of stresses are considered as key determinants of global food security. Rice is grown in a wide range of ecologies ranging from irrigated to uplands, rainfed lowland, deep water and tidal wetlands. About 29% of India's total rice area, i.e. 13 m ha is rainfed lowland, which contributes only 19% to national rice production. Rainfed lowlands constitute highly fragile ecosystems, always prone to flash-floods (submergence) with an average productivity of only 1.2 tonnes ha–1 in normal years and hardly 0.5 tonnes ha–1 in case of submergence (Sarkar *et al.*, 2009).

Submergence generally occurs at vegetative stage while drought at reproductive stage in frequent manners in life span of the crop. During submergence, tolerant rice plants exhibit inhibition of shoot elongation, retain chlorophyll in leaf tissues and maintain viability. If rice is submerged under water more than a few days, gradual loss of oxygen leads to withering and death due to the effect on respiration and photosynthesis. Water stress may affect on the plants anatomy, morphology, physiology and biochemistry and influence on almost all of their growth and development aspects (Ram et al., 2002; Reddy and Mitra, 2013).

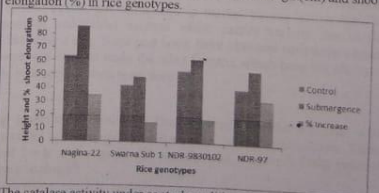
Materials and Methods

Four rice genotypes Nagina 22, Swarna sub1, NDR 9830102 and NDR 97 were selected to exposed complete submergence for characterization of submergence related traits by physio-biochemical indices. Seeds of rice genotypes were direct sown in pot condition in two sets with five replications as per CRD design. Finally, three seedlings were maintained in each pot for recording physio-biochemical parameters. All the standard cultural practices were followed as per norms during the crop growth. Submergence treatment was given to 35 days old seedling for 11 days complete submergence in submergence tank. Shoot elongation rate, catalase activity (Sinha, 1972), total chlorophyll content (SPAD 502 Plus Chlorophyll Meter) and total soluble sugar (Yemm and Willis, 1954) were recorded at the end submergence treatment against the control. Plant survival percentage was recorded after 20 days of desubmergence against control.

Results and Discussion

Under the eleven days complete submergence treatment, shoot elongated rate increases in all rice genotypes over control (Fig.1). High shoot elongation percent was recorded in Nagina 22 (34.5%) followed by NDR 97 (33.4) and NDR 9830102 (17.71). Least percent elongation was recorded at the end of submergence treatment in Swarna sub1 (10.6). The shoot elongation due to submergence was found to be high in susceptible varieties than the tolerant varieties (Singh *et al.*, 2001; Das et al., 2005). The level of shoot elongation during submergence depends upon the genetic characters of the cultivar and is affected by the submergence environment (Kawano *et al.*, 2009)

Fig.1: Effect of submergence treatment on plant height(cm) and shoot elongation (%) in rice genotypes.



The catalase activity under control condition was nearly same in rice genotypes but it abruptly increased just after desubmergence (Fig.2). High catalase activity was recorded in Swarna sub1 and NDR9830102 while less in Nagina 22 and NDR 97. observed a

ABSTRACT

A pot experiment was conducted with five rice genotypes to evaluate rice genotype at reproductive stage drought stress. Rice genotypes were exposed to 15 days drought at reproductive stage by receding the water. The leaf rolling, relative water content (RWC) leaf, total chlorophyll content (SPAD) and leaf proline content were recorded at the end of drought. Less leaf rolling and less reduction in RWC and SPAD value and high proline content were recorded in Nagina 22 over other genotypes. Swarna sub1 was the most susceptible rice genotype as it showed high leaf rolling and more reduction in RWC and SPAD value and less accumulation in proline content.

INTRODUCTION

Drought is one of the important abiotic stresses that severely effects on growth, development, and metabolism renfed areas [7]. Drought is an abiotic stress which affects plants at various levels and stages of their life period. But drought stress at reproductive stage is more serious than any other stage. The drought stress not only affects plant–water relations through the reduction of water content, turgor, and total water, but it also affects stomatal closure, limits gas exchange, reduces transpiration, and disturbs photosynthesis and ultimately yield of the plant [17]. A low water potential effect of on mineral nutrition and plant metabolism which decrease the leaf area and alter assimilates partitioning among the plant organs [15, 19].

Rice varieties have differential responses to abiotic stresses because of the complexity of interactions between stress factors and various molecular, biochemical, and physiological processes that affect plant growth and development [20, 21]. Drought stress affects the growth behavior and yield and yield components irrespective rice genotypes [20]. Drought stress due to water deficit is a common constraint in upland cultivation systems of plants [9, 10]. Drought stress reduces the rice growth and severely affects different traits, such as seedling biomass, stomatal conductance, photosynthesis, starch metabolism, and plant–water relations [12, 14, 16, 18]. Rice genotypes have differential response to water deficit 6]. Grain yield of some rice varieties was reduced by up to 81 % under drought condition and this reduction depended on timing, duration, and severity of the plant water stress [14, 18]. When rice genotyped exposed to water deficit; panicle length and fertile grains in two tolerant varieties were not significantly decreased, leading to greater productivity than in two sensitive cultivars.

MATERIALS AND METHODS

Five rice genotypes Nagina 22, Swarna sub1, NDR 97, Sushk Samrat and NDR 9830102 were selected to give heat treatment at reproductive stage. Rice genotypes were sown in pot condition two sets with five replication as per CRD design. All the standard cultural practices were followed as per norms during the crop growth. Drought treatment was given for 15 days at reproductive stage by receding the water. Leaf rolling (IIRI Scale), RWC (Slatyer, 1967), total chlorophyll content (chlorophyll meter) and proline

Effect of processing on phytic acid content and iron availability in selected rice variety

Arun Kumar, Deepak Kuma, SKZ Rizvi, Ajit Tiwari, Akanksha Singh, Adesh Kumar, Shambhoo Prasad and KN Singh

Abstract
Rice (*Oryza sativa* L.) which belongs to the family of grasses, Poaceae, is the main food source for more than two-third of the world's population especially in Southeast Asia. Nutrient paucity due to unavailability of quality food sources is a major impediment to the progress in improvement in the field of human nutrition. Phytic acid is a major anti nutritional factor that binds with cationic nutrients like zinc and iron, and makes them unavailable for human intestinal absorption. Iron is the important nutrients required for human growth and development. This study was aimed to know the effect of soaking on phytic acid contents. Minimum phytic acid measured in the Sarjoo-52 was 5.61 g/kg and maximum phytic acid measured in the Swarna was 9.12 g/kg followed by NDR-359 was 8.05 g/kg. After processing in case of after soaking minimum phytic acid content measured in the Sarjoo-52 was 3.63 g/kg and maximum phytic acid content in parents after soaking measured in Swarna was 6.76 g/kg. Minimum phytic acid content after germination measured in the Sarjoo-52 was 3.08 g/kg and maximum phytic acid content in parents after germination measured in Swarna was 6.05 g/kg. The soaking treatment reduced the inherent phytic acid content in seeds of rice. The highest iron was obtained in sarjoo-52 (24.15 ppm) and lowest obtained in swarna (12.48 ppm).

Keywords: processing, rice, nutrients, phytic acid, iron

Introduction
Rice grain is the staple food for more than half of the world's population and grows in more than 100 countries. The top 10 rice producing countries in the world today are India, China, Indonesia, Bangladesh, Thailand, Vietnam, Burma, Philippines, Cambodia, and Pakistan. China, India, Indonesia, Bangladesh, Thailand, and Vietnam produce about 80 percent of the world rice production. Among the rice producing countries, India ranks second in total production (90.00 million tonnes) next to China (184.25 million tonnes) with an average productivity of 3.09 t/ ha-1 (FAO, 2013) [2]. Nutrient deficiencies have plagued the world's population from ancient days. The number and proportion of undernourished people in the world is estimated to be 870 million and 13% of the population respectively (WHO report, 2014) [47].

In the last few years, food scientists have laid an emphasis on the effects of mineral nutrient deficiencies and it has become increasingly evident that the lack of minerals may have similarly severe negative consequences on human health (Bouis 2000) [3]. These deficiencies have major negative effects on human health, and development; working ability and quality of life (Welch and Graham 2004; Shailen *et al*., 2005; Anne and Paula 2006; White and Brown, 2010) [43, 38, 1, 46]. Although micronutrient requirement is very small, every one in three humans worldwide is not getting enough quantity, especially the poor, women and children (Gibson 1994; Ramakrishna *et al*., 2006) [32].

Phytic acid (PA) or myo-inositol hexaphosphate is a strong chelator of multivalent metal ions, especially iron, zinc and calcium (Hurrel, 2004) [15]. For many years, phytic acid was considered an antinutritional compound because it reduces the bioavailability of several minerals important for human nutrition (Bohn *et al*., 2007; Li *et al*., 2008; Schelemmer *et al*., 2009) [4, 37]. However, since the 1990s, phytic acid has been scientifically emphasized for its beneficial effects on human health, particularly in the prevention of diabetes (Lee *et al*., 2006) [21], Renal calculi (Saw *et al*., 2007) [35], Parkinson's disease (Xu *et al*., 2008) [48] and cancer (Vucenik and Shamsuddin, 2006). The application of 0.50% PA acid rice bran added to the drinking water after tumor induction, reduced the risk of colon cancer in rats (Norazalina *et al*., 2009). Its antioxidant effect, described by several researchers (Lee and Hendricks, 1995; Soares *et al*., 2004; Stodolak *et al*., 2007; Harbach *et al*., 2007) [22, 39, 40, 12], is due to its ability to inhibit the formation of hydroxyl radicals and to form chelates with Fe2+ ions, causing them

Phenotypic and biochemical characterization of microorganisms associated with the entomopathogenicity against *Helicoverpa armigera* and selection of best potent bacteria having insecticidal activity

Divya Srivastava, Adesh Kumar, Ashutosh Tiwari, Praveen Tiwari, Nandan Singh, Jaswant Singh and Bhawana Mathur

Abstract
There was a sum of four strains which were found to be entomopathogenic against *Helicoverpa armigera*. All of these bacterial strains were gram positive endospore forming strains. In the present study, the phenotypic and biochemical nature of all larvicidal strains was studied followed by a leaf based bioassay to obtain the best potent strain. As a result of this study, 4c culture was found to be best potent as 100% mortality was observed.

Keywords: *Helicoverpa armigera*, gram pod borer, bio-insecticide, bio-control of insect, microbes based insecticide

Introduction
Helicoverpa armigera is n economic important insect pest which is also known as gram pod borer. It plays a detrimental role and damage the complete chickpea crop. Chickpea is the world's third most important pulse crop. This pod borer, *Helicoverpa armigera* is highly poly phagous in nature and attacks over 182 plants species as cotton, maize, tobacco, pigeon pea, chickpea and tomato etc. [1]. So it is a harmful pest for both, widely grown and economically important crops. The yield loss in chickpea due to pod borer was reported as 10-60 per cent in normal weather conditions [2]. It attacks on the pod of the chickpea which is consumed by a huge number of public and agriculturalist face this problem as it is one of the main food crop of developing nation including India. As this damage is caused during flowering and pod formation stages so it results in substantial yield loss [3]. There are a number of chemical pesticides available to control this insect pest but chemicals are harmful for complete eco-system so there biological control agents got introduced in market among which *Bacillus thuringiensis* is the most popular insecticidal bacteria which causes toxicity due to the presence of crystal proteins. But now a day, these pod borer have obtained resistance against *Bt.* based bio-control. This work was done to study the other bacteria which have the ability to act as a bio-control and all the biochemical tests were done.

Materials and Methods
Bacterial culture showing insecticidal activity: The entomopathogenic bacteria were isolated and analysed using a castor leaves based test coated with the bacterial cultures. These leaves were fed by larvae of borer and insecticidal activity was observed. Only positive cultures were selected for future studies [4].

Media to study colony morphology and phenotypic characteristic: Nutrient agar media was used. The selected strains were subcultured on Nutrient agar plated and their morphology was observed as shown in Table 1 and fig 1.

Biochemical Analysis
Motility test, Methyl red and Voges-proskaeur tests were performed following Olutiola *et al.*, 2000 [5] and Catalase test, Indole test and Oxidase tests were performed following Cheesbrough, M, 2006 [6].

Abstract
In the present study biocontrol agents *Bacillus safensis* and *Bacillus licheniformis* has been isolated from wilt affected lentil crop of agro-climatic zone of eastern UP like Faizabad, Mau, Varanasi, Gazipur.Lentil seed treatment has been given by these isolated strains as bioagents against wilt pathogen in pot experiment in lentil crop Rabi-season 2019-2020.Result of conducted pot experiment showed the maximum chlorophyll content was found in T3 (*Bacillus safensis* +*Bacillus licheniformis* +*Fusarium oxyporum f.sp lentis*+Lentil Rasistant variety IPL-316 + Susceptible variety K-75) followed by treatments T2 (*Bacillus licheniformis* +Resistant Variety IPL-316+Susceptible variety K-75) and T1 (*Bacillus safensis* +Lentil Resistant variety IPL-316 + Susceptible Variety K-75)' as compare to negative control T5 (Lentil Resistant variety IPL-316 + Susceptible Variety K-75+No bacterium inoculum) and pathogen T4(*Fusarium oxysporum f.spp.lentis* + Resistant variety IPL-316 + Susceptible Variety K-75. The aim of this paper is to study the bio-agent's factor affecting the chlorophyll content and provide protection against pathogen in lentil plant. After that chlorophyll estimation test was performed on treated lentil crop on 30, 60 and 90 days. We observed chlorophyll content in treated crops and maximum chlorophyll content was found at 30 and 60 *days which minimize at 90 days*.

Keywords: *Bacillus safensis, Bacillus licheniformis, Fusarium oxysporum f.spp. lentis*, Lentil seed resistant variety (IPL-316), Lentil seed susceptible variety (K-75)

Introduction
Lentil (*Lens culinaris Medik.*) is a member of Leguminaceae family and commonly known as legume, masoor or poor man's meat. The global production of lentil has reached nearly 5.0 million tonnes in 2014 (Ahmad Nasim 2018) [4]. It is the second largest growing rabi pulse after chickpea in India. Lentils *(Lens culinaris Medikus*) produces commonly in cold weather which is an important pulse crop grown widely throughout the Indian subcontinent, Canada, Turkey, Australia, USA, Nepal, China and Ethiopia. About 80 percent of the lentil production in India during 2015-16 has been reported from Madhya Pradesh (30.94%), Uttar Pradesh (28.72%), Bihar (15.24%) and West Bengal (5.81%) (Ahmad *et al*., 2018). Lentil has a high nutritional value and major source of dietary proteins (25%) after soyabeans in humans and animal diet (Rahman *et.al*., 2010) [3] and also plays a significant role in the improvement of soil fertility (Frederick *et al*., 2006) [1].
Fusarium wilt disease caused by pathogen *Fusarium oxysporum f.sp. lentis* is the most important biological constraints to productivity of lentil worldwide (Bhalla *et al*., 1992) [2] and is considered as to be the most important biotic stress affecting the crop's productivlty (Khare, 1981) [7]. It is a soil borne root pathogen, colonizing the xylem vessels and blocking them completely and in this way it prevents water to reach towards the other parts of the crop. Wilt symptoms appear from flowering to late pod-filling stage and are characterized by sudden drooping of top leaflets of the affected plant, leaflet closure without premature shedding, dull green foliage followed by wilting of the whole plant or individual branches. This pathogen can cause infection at all the stages of plant growth with more incidences at flowering and podding stages than early vegetative stage (Chavdarov, 2006) [8]. As the pathogen *F. oxysporum* can survive for longer period in soil and difficult to eliminate, it may cause severe obstructs to the plant's xylem hence deficit the water in leaves and also lowers the gas exchange properties

An experiment was conducted with four rice genotypes Swarna Sub1, Nagina-22, NDR-102 and NDR-97 submergence related traits at the student's instructional farm of Narendra Deva University of agriculture and technology, Kumarganj Ayodhya (U.P). Thirty five days old direct seeded rice seedlings was exposed to 11 days complete submergence treatment. Shoot elongation rate, catalase and peroxidase activity was recorded at the end of submergence treatment. Less shoot elongation and high catalase activity were recorded in Swarna Sub1 and NDR-102 while Nagina-22 and NDR-97 showes high reduction and less increase respectively. Swarna Sub1and NDR-102 showed fast recovery after desubmergence. NDR-97 poorly survived and Nagina-22 fail to survive during submergence period. Days to 50% flowering was less affected in Swarna Sub1 and NDR-102 it delayed in case of NDR-97.Grain yield per plant was highly affected in NDR-97 while less in Swarna Sub1 and NDR-102.

Introduction

Rice is the world's single most important food crops and primary food source for one third of the world population. Within the country, rice occupies 1/3 of the total cropped area, contributes about 40 to 43% of total food grain production and continues to play a key role in the national food and livelihood security system. India rank second among the top most rice producers in the world after China. Rice crops are prone to various types of stresses, both biotic and abiotic. Biotic stresses include insect pests, fungus, bacteria, viruses, and herbicide toxicity Among abiotic stresses, drought, cold, submergence and salinity are also well studied in rice (Ansari *et al*., 2015).

Submergence and drought are the two most

Abstract

Twenty six isolates of wheat rhizosphere were characterized on the basis of biochemical features like IAA production, ammonia production and P Solubilization. The quantitative IAA production was recorded in all test isolates. Production of IAA from the isolates ranged between 54.00 µg/ml to141.60 µg/ml. Wheat PGPR isolates were also evaluated for their efficiency to promote plant growth under pot condition. The maximum increase in seed germination (300%) was recorded over control. Seed inoculation by wheat PGPR isolates led to maximum increase in root length (47.59%), shoot length (131.89%), root fresh weight (51.74%), shoot fresh weight (68.97%), root dry weight (31.89%) and shoot dry weight (60.58%).The protein profiling of isolates by SDS-PAGE was done to differentiate the proteomic variability based on polymorphism.

Key words: Wheat rhizobacteria, IAA, Plant growth promoting traits, Seed germination, Pot experiment.

IntroductionWheat (*Triticum aestivum*) belongs to order Poales (*Glumiflorae*), family *Poaceae* (Graminae), tribe *Triticaceae* and it is considered as one of the most important staple crops across the globe. It is widely cultivated and domesticated cereal. However, it needs a substantial increase in its productivity to meet the demands of increasing population. Next to rice, wheat provides more calories than any other crop and a good source of high quality protein and dietary fibre. Increasing wheat production in the past has been dependent in part on the availability of nitrogenous fertilizers, however, systems that do not rely heavily on substantial fertilization (Armstrong *et al.* 1997). The rhizosphere bacteria provide many services to increase plant productivity. PGPR have the ability to promote the growth directly by producing different substances such as phytohormones, ammonia production, HCN, phosphate solubilization and fixing N_2 (Van Rhijn and Vanderleyden 1995, Ferdaous *et al.*, 2017) or indirectly by producing antibiotics to control pathogens (Milner *et al.* 1996). Many rhizobacteria secrete a variety of antifungal molecules under in vitro and in situ conditions. There are several reports of in vitro antagonism of pathogenic fungi and field performance by bacteria recovered from the rhizosphere of plants in India. The quantitative estimation of IAA production ability of selected soil isolates on nutrient agar broth was carried out by Vishwakarma *et al.*, 2017. Growth promoting rhizobacteria can modify the root architecture (Remans *et al.* 2008) that may function in increasing plant productivity and nutrient acquisition efficiency (Shahzeona *et al.* 2008). Hence, PGPR applications have been extensively studied and used to enhance the plant growth. They are able to produce the important bacterial enzyme ACC deaminase under different conditions including stress, which can effectively control the stresses. Rhizobacteria releases the enzyme ACC deaminase whose activity is responsible for the stimulation of plant growth. ACC is the immediate precursor of ethylene in plants and therefore lowering of the level of ethylene resulting in root elongation. Various species of bacteria like *Pseudomonas, Azospirillum, Azotobacter, Klebsiella, Enterobacter, Alcaligenes, Arthrobacter, Burkholderia, Bacillus* and *Serratia* have been reported to actively colonize wheat plant roots region and increase plant growth and yield (Cheoug *et al.*, 2017). The PGPR strains show useful traits which can enhance the plant growth without any undesirable effect on the environment. So, the use of PGPRs as plant growth enhancer may indirectly reduce the use of chemical fertilizers. Therefore, the study has become essential to investigate PGPRs associated with wheat in order to enhance the wheat production with the aim to limit the use of chemical fertilizers.

Materials and Methods

Soil sample collection and isolation of rhizobacteria from wheat The root adhering soil (RAS) samples were collected from wheat crop. The soils were sampled from different locations in the districts viz., Faizabad (FZD), Mucunfiw sugar (MUS), Barabanki (BBK), Lucknow (LKO), Kanpur Dehat (KNP) and Jhanpur (JAN) of Uttar Pradesh, India. Serial dilutions were made up to 10^{-4} of each samples. 10^{-3} and 10^{-4} dilution were plated on to three media, Jensen's medium, King's B (KB) medium and Nutrient agar (NA) medium. Plates were incubated at 28°C for 72 hours. A total of 26 rhizobacterial isolates selected on the basis of morphological traits like form, elevation, margin, color, appearance, texture and surface.

Screening of wheat rhizospheric bacteria for plant growth promoting attributes

Quantitative estimation of IAA

Culture isolates were incubated at 28°C for 24 hrs in Luria Bertani (LB) broth. Cells were removed from the media by centrifugation at 10,000 rpm for 15 minutes. The Ortho-phosphoric acid (2-3 drops) was added to 2ml of supernatant and was mixed vigorously with 4ml of Salkowski's reagent (0.5M solution prepared in 50ml of 35% $HClO_4$) and incubated at room temperature for 25 minutes at 37°C temperature in water bath and observed for the color formation (Fischer, *et al.*, 2007). The optical density was taken at 530 nm and concentration of IAA in supernatant was calculated.

Ammonia production

Isolates were incubated for 4 days in peptone water (Peptone 10 g, NaCl 5g in litre, pH 7.0). Nessler's reagent (1ml) was added in each tube and observed for color formation (Shuferaw *et al.*, 2004).

Phosphate Solubilization

The plates were prepared with Pikovskaya's medium. All the bacterial isolates spot inoculated on the surface of Pikovskaya's agar plate and phosphate solubilizing activity was estimated after 4 days of incubation at 28°C. Phosphate solubilization activity was determined by the development of the clear zone around the bacterial colonies (Tsiore, 1996).

Seed germination test:

The seeds were surface sterilized with 0.1% $HgCl_2$ for 3 minute followed by successive washing was done with sterile distilled water. The seeds were treated with rhizobacterial cultures (Grown in their respective medium for 48 hours containing atleast 10^8 cells/ml) for 10 minutes. The plates were prepared with 0.8% sterile agar medium. The seeds were placed on soft agar plates and incubated at 30° C for 2-3 days. In control plates, seeds were treated with sterilized medium alone. After 3 days, the data was recorded on seed germination.

Pot experiment

Soil was collected, air dried, sieved (2mm) (6-mesh) and sterilized by repeated autoclaving before filling into pots. Wheat seeds were surface sterilized by exposing to 95% ethanol and immersing in 0.2% $HgCl_2$ solution for 3 minute. The seeds were then subjected to 5 washing with sterile distilled water. The seeds were dipped for 10 minutes in overnight grown bacterial suspension then seeds were transferred to pots containing sterile soil to a depth of 5 mm. Six seeds were sown in each pot and the experiment was performed in duplicate for each isolate. Sterile seeds treated with non-inoculated media were used as control. The pots were kept in sunlight and were

Evaluation of integrated nutrient management in respect to yield, microbial population, nutrient content and uptake by wheat (*Triticum aestivum* L.) under eastern Uttar Pradesh

Abhimanyu Yadav, Adesh Kumar, Lalit Krishna Yadav, Pramod Kumar, Ashok Kumar, Awadhesh Kumar Singh and NK Arora

Abstract
Field experiment was carried out in randomized block design with three replications and the treatment consisted of T_1- control, T_2- 100% RDF (120:60:40 kg ha^{-1} N: P_2O_5: K_2O); T_3- 75% RDF, T_4- 75 % RDF + 25 % N-FYM, T_5- 75% RDF+ Bio-fertilizer (*Azotobactor*), T_6- 50% RDF + 50 % N-FYM, T_7- (50 % RDF + 50 %N-FYM + PSB) and T_8- 50 % RDF + *Azotobacter* + PSB. The treatment effect was compared based on yield, soil microbial population, nutrient content, protein content and nutrient uptake by wheat crop. The grain and straw yield (q ha^{-1}), soil microbial population, nutrient content, protein content and uptake of nitrogen, phosphorus and potassium were maximum under T_7, which was at par with T_2 T_4 and T_6 and significantly superior over T_1, T_3, T_5 and T_8.
The maximum grain and straw yield of wheat (41.90 & 60.65 q ha^{-1}) was recorded with T_7 which was significantly higher over than T_1 (17.90 & 26.5 q ha^{-1}), T_3 (32.84 & 49.09 q ha^{-1}), T_5 (35.64 & 53.0 q ha^{-1}) and T_8 (34.80 & 51.75 q ha^{-1}) while at par with T_2 (41.60 & 60.33 q ha^{-1}) T_4 (39.55 & 57.0 q ha^{-1}) and T_6 (39.88 & 57.15 q ha^{-1}). Maximum number of bacteria (39.38 X 10^7 g^{-1} soil) was recorded in T_7 (50 % RDF + 50 % N-FYM + PSB) which was statistically at par with value recorded in T_6 (50 % RDF + 50 % N-FYM). Treatment T_7 and T_6 were found significantly higher over rest of treatments while the minimum number (6.21 X 10^7 g^{-1} soil) of bacteria was recorded under treatment T_1 (control). Similar trend also reported in the population of fungi and Actinomycetes in the soil after harvest of wheat crop. The maximum NPK content in grain (1.82, 0.50and 0.54 %) and in straw (0.55, 0.13 and 1.52 %) was observed under treatment T_7 (50 % RDF + 50 % N- FYM + PSB) and minimum NPK content in straw (1.53, 0.43 and 0.50 %) and in straw (0.49, 0.10 and 1.43 %) was observed under treatment T_1 (control). The maximum protein content (11.38 %) was observed in treatment T_7 (50% RDF + 50% N-FYM + PSB) which was statistically at par with treatments T_2, T_4, T_5 and T_6 and significantly superior over treatments T_1 (control), T_3 and T_8 while the minimum protein content (9.56 %) was recorded under treatment T_1 (control). The maximum uptake of N (110.12 kg ha^{-1}), P (28.83 kg ha^{-1}) and K (114.81 kg ha^{-1}) were observed under treatment T_7 (50 % RDF + 50 % N-FYM + PSB). While minimum uptake of N (40.37 kg ha^{-1}), P (10.35 kg ha^{-1}) and K (46.85 kg ha^{-1}) were observed under T_1 (Control).

Keywords: wheat, yield, FYM, PSB, azotobactor and RDF etc

Introduction
Wheat (*Triticum aestivum* L.) is the first important strategic cereal crop for the majority of world's populations. It is the most important staple food of the world. It exceeds in acreage and production every other grain crop (including rice and maize) and is therefore, the most important cereal grain of the world, which is cultivated over a wide range of climatic conditions. India has achieved self-sufficiency in food production at present, but the realistic demand for food has been estimated at 301.08 million tons for 2020, which will reach 330.18 million tons by the year 2030 (Goyal and Singh 2002). About 91% of the total wheat production is contributed by northern states. India is one of the principal wheat producing and consuming country in the world.
Adoption of intensive cropping system will meet the food demands of increasing population, requires high input energy, which are not only responsible for environment degradation but also increased the cost of cultivation. The manufacture of chemical fertilizer is highly cost effective and depends on non-renewable fossil fuel that is in acute shortage. To compensate the supply and recent price hike in inorganic fertilizers,

Kumarganj, Ayodhya 224229, U.P., India

Received-08.02.2022, Revised-22.02.2022, Accepted-14.03.2022

Abstract: Sixteen lentil rhizobacteria were isolated at nutrient agar medium. Out of which, twelve isolates showed antagonistic activity against *Fusarium oxysporum* f.sp. *lentis*. All the antagonistic isolates produced diffusible and volatile antifungal metabolites. The isolates 10 and 14 showed a maximum antagonism 72% and 68.6% respectively. All the antagonistic isolates showed PGPR activity such as phosphate solubilization, IAA production and ammonia production. Isolates produced IAA ranging from 1.25 to 3.61 ug/ml. The highest amount of IAA was produced by isolate 14.

Keywords: Antagonistic activity, PGPR, *Fusarium oxysporum* f. sp. *lentis*, PGP traits

INTRODUCTION

Lentil (*Lens culinaris* Medik.) is the second most important grain legume widely cultivated in semi-arid regions of the world (Malik 2005). Cultivation of lentil attributes the soil by enriching the soil nutrients by the help of nitrogen fixation, carbon and organic matter accumulation which promotes proceeding crop production and productivity. The crop production reduces due to suffering from various plant diseases caused by fungi, viruses, nematodes, insect pests and parasitic weeds ultimately resulted in huge economic losses. Lentil *Fusarium* wilt caused by *Fusarium oxysporum* f.sp. *lentis* plays a major role in limiting the yield potential and causes severe damage of leaves, pods, stems and roots (Pouralibaba *et al.* 2015; Singh, 2015). Lentil legume has ability to fix atmospheric nitrogen into a biologically useful form by the symbiotic association of rhizobacteria. Several environmental conditions limits the symbiotic relations resulting reduced nitrogen fixing system, application of plant protective chemicals, fertilizers are harmful for plant and bacteria both (Andres, 2012). The rhizosphere is the narrow zone of soil influenced by the root system of plant and populated with variety of microorganisms and the bacteria colonizing this zone is known as rhizobacteria (Beneduzi*et al.* 2012).The plant growth promoting rhizobacteria have the capability to stimulate the plant growth by the root colonization and exert beneficial effects on the plant (Sulsowe*t al.* 1979) by increasing plant-microbe symbiosis, competition for nutrients, root colonization space and limit the activities of plant pathogens (Glick 1995; Lugtenberg 2002). PGPRs have both the mechanisms of direct and indirect. Direct mechanism of PGPR consists of phosphate solubilization, nitrogen fixation, Ammonia production, Siderophore production and procurement of plant hormones like auxins, cytokinins and gibberellins and limiting the ethylene by ACC deaminase activity. In order to indirect mechanism of PGPRs consists of pathogen suppression by means of production of enzymes and compounds like chitinase, protease, cellulose, antibiotics, HCN, ammonia and volatile organic compound *etc*.Plant growth promoting rhizobacteria can biologically fix nitrogen, solubilize phosphate and maintains the proper level of phytohormones such as Idole acetic acid that help in the improvement of lentil (Rani *et al.* 2012).Rhizospheric bacteria can promote root growth and yield and play an alternative role to increase abiotic stress tolerance in legumes (Rashid *et al.*, 2012, Sarma and Saikia 2014). Plant growth promoting rhizobacteria can increase growth by variety of mechanisms, such as nitrogen fixation, phosphate solubilization, and phytohormone production (Rashid *et al.*, 2012). Some bacteria synthesizes indole acetic acid (IAA) hormone which regulates the growth and development of the plant, act as signal molecule that control the expression of several genes (Ducae*t al.*, 2014). Plant growth promoting bacteria colonize the roots of plant rhizosphere that enhances the plant growth. Rhizospheric microbial population is different from its surroundings due to root exudates that function as a source of nutrients for microbial growth (Burdmane*t al.*, 2000). PGPR enhance the plant growth by the control of phytopahtogenic agents, primarily by the production of metabolites that contribute to the antibiosis and antifungal properties that acts as defence systems. The mechanism would involve the production of hydrolytic enzymes, such as chitinase and glucanase producing bacteria could inhibit fungal growth (Kumar *et al.*, 2010).
Thus, the identification and characterization of PGPR populations indigenous to leguminous rhizosphere are therefore, to characterize these isolates on the basis of morphology and determination of PGPR properties along with antifungal activity.

Phenotypic and biochemical characterization of microorganisms associated with the entomopathogenicity against *Helicoverpa armigera* and selection of best potent bacteria having insecticidal activity

Divya Srivastava, Adesh Kumar, Ashutosh Tiwari, Praveen Tiwari, Nandan Singh, Jaswant Singh and Bhawana Mathur

Abstract
There was a sum of four strains which were found to be entomopathogenic against *Helicoverpa armigera*. All of these bacterial strains were gram positive endospore forming strains. In the present study, the phenotypic and biochemical nature of all larvicidal strains was studied followed by a leaf based bioassay to obtain the best potent strain. As a result of this study, 4c culture was found to be best potent as 100% mortality was observed.

Keywords: *Helicoverpa armigera*, gram pod borer, bio-insecticide, bio-control of insect, microbes based insecticide

Introduction
Helicoverpa armigera is n economic important insect pest which is also known as gram pod borer. It plays a detrimental role and damage the complete chickpea crop. Chickpea is the world's third most important pulse crop. This pod borer, *Helicoverpa armigera* is highly poly phagous in nature and attacks over 182 plants species as cotton, maize, tobacco, pigeon pea, chickpea and tomato etc. [1]. So it is a harmful pest for both, widely grown and economically important crops. The yield loss in chickpea due to pod borer was reported as 10-60 per cent in normal weather conditions [2]. It attacks on the pod of the chickpea which is consumed by a huge number of public and agriculturalist face this problem as it is one of the main food crop of developing nation including India. As this damage is caused during flowering and pod formation stages so it results in substantial yield loss [3]. There are a number of chemical pesticides available to control this insect pest but chemicals are harmful for complete eco-system so there biological control agents got introduced in market among which *Bacillus thuringiensis* is the most popular insecticidal bacteria which causes toxicity due to the presence of crystal proteins. But now a day, these pod borer have obtained resistance against *Bt.* based bio-control. This work was done to study the other bacteria which have the ability to act as a bio-control and all the biochemical tests were done.

Materials and Methods
Bacterial culture showing insecticidal activity: The entomopathogenic bacteria were isolated and analysed using a castor leaves based test coated with the bacterial cultures. These leaves were fed by larvae of borer and insecticidal activity was observed. Only positive cultures were selected for future studies [4].

Media to study colony morphology and phenotypic characteristic: Nutrient agar media was used. The selected strains were subcultured on Nutrient agar plated and their morphology was observed as shown in Table 1 and fig 1.

Biochemical Analysis
Motility test, Methyl red and Voges-proskaeur tests were performed following Olutiola *et al.*, 2000 [5] and Catalase test, Indole test and Oxidase tests were performed following Cheesbrough, M., 2006 [6].

A field experiment was conducted during winter season of 2014-15 on wheat at Instructional Farm of Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (UP). The soil of the experimental field was silt loam having pH 8.25, EC 0.35 dSm^{-1}, organic carbon 4.4 g Kg^{-1} available nitrogen 195 Kg ha^{-1}, available P 12 Kg ha^{-1} and available K 240 Kg^{-1} he experiment was consisted of 8 treatments *viz.* T_1 (control), T_2 (100 % RDF), T_3 (75 % RDF), T_4 (75 % RDF + 25 % N-FYM), T_5 (75% RDF + *Azotobacter*), T_6 (50 % RDF + 50 % N-FYM) T_7 (50 % RDF + 50 %N-FYM + PSB) and T_8 (50 % RDF + *Azotobacter* + PSB) were laid in the randomized block design with three replication. The highest values of yield and yield attributes were recorded with treatment T_7 (50% RDF + 50% N- FYM + PSB) which was significantly superior over control as well as T_3 (75% RDF), T_5 (75% RDF + *Azotobacter*) and T_8 (50% RDF + *Azotobacter* + PSB) and statistically at par with rest of the treatments.

Introduction

Wheat (*Triticum aestivum* L.) is one of the most important cereal crops of the world. Among the world's most important food grains, it ranks next to rice. It is eaten in various forms by more than one billion in the world. Millions of farmer in developing countries need adequate resource for augmenting crop productivity and sustainability of soil. Therefore to maintain fertility and productivity of soil at sustainable level for long duration, there is need to adopt the concept of integrated nutrient management. Organic manure such as farm yard manure, vermin-compost, crop residues, biofertilizer, green manure and chemical fertilizer are considered to be an integral component of integrated nutrient management and may help to recover soil health in cropping system. As they improve soil fertility and physical properties such as soil structure, aeration, porosity, infiltration rate and water holding capacity and decrease soil crusting, organic matter in soil improve physical condition of the soil for better performance of micro-organism and physical status of soil. Organic matter affects crop

ABSTRACT

A pot experiment was conducted with five rice genotypes to evaluate rice genotype at reproductive stage drought stress. Rice genotypes were exposed to 15 days drought at reproductive stage by receding the water. The leaf rolling, relative water content (RWC) leaf, total chlorophyll content (SPAD) and leaf proline content were recorded at the end of drought. Less leaf rolling and less reduction in RWC and SPAD value and high proline content were recorded in Nagina 22 over other genotypes. Swarna sub1 was the most susceptible rice genotype as it showed high leaf rolling and more reduction in RWC and SPAD value and less accumulation in proline content.

INTRODUCTION

Drought is one of the important abiotic stresses that severely effects on growth, development, and metabolism renfed areas [7]. Drought is an abiotic stress which affects plants at various levels and stages of their life period. But drought stress at reproductive stage is more serious than any other stage. The drought stress not only affects plant–water relations through the reduction of water content, turgor, and total water, but it also affects stomatal closure, limits gas exchange, reduces transpiration, and disturbs photosynthesis and ultimately yield of the plant [17]. A low water potential effect of on mineral nutrition and plant metabolism which decrease the leaf area and alter assimilates partitioning among the plant organs [15, 19].

Rice varieties have differential responses to abiotic stresses because of the complexity of interactions between stress factors and various molecular, biochemical, and physiological processes that affect plant growth and development [20, 21]. Drought stress affects the growth behavior and yield and yield components irrespective rice genotypes [20]. Drought stress due to water deficit is a common-constraint in upland cultivation systems of plants [9, 10]. Drought stress reduces the rice growth and severely affects different traits, such as seedling biomass, stomatal conductance, photosynthesis, starch metabolism, and plant–water relations [12, 14, 16, 18]. Rice genotypes have differential response to water deficit 6]. Grain yield of some rice varieties was reduced by up to 81 % under drought condition and this reduction depended on timing, duration, and severity of the plant water stress [14, 18]. When rice genotyped exposed to water deficit; panicle length and fertile grains in two tolerant varieties were not significantly decreased, leading to greater productivity than in two sensitive cultivars.

MATERIALS AND METHODS

Five rice genotypes Nagina 22, Swarna sub1, NDR 97, Sushk Samrat and NDR 9830102 were selected to give heat treatment at reproductive stage. Rice genotypes were sown in pot condition two sets with five replication as per CRD design. All the standard cultural practices were followed as per norms during the crop growth. Drought treatment was given for 15 days at reproductive stage by receding the water. Leaf rolling (IIRI Scale), RWC (Slatyer, 1967), total chlorophyll content (chlorophyll meter) and proline

In the present study, the fungus was isolated from infected leaf of potato and identified as *Alternaria solani*. Twenty four bacterial strains isolated from potato rhizosphere on PDA media. The screening of all 24 potato rhizosphere isolates for IAA, phosphate solubilization, Insecticide tolerance, salt tolerance, antibiotic sensitivity and ammonia production was performed. Out of these isolates, only four isolates (5, 15, 16 and 23) showed high inhibitory effect on the pathogenic fungus in dual culture. PGPR isolate no 5 showed highest 95% inhibition against *Alternaria solani*.

Introduction

Potato (*Solanum tuberosum* L.) is one of the world's most important food crops, and is grown in more than 100 countries with different climate conditions including temperate, subtropical and tropical zones. There are several diseases in potato caused by fungi, bacteria, viruses, nematodes and abiotic factors. Among which an early blight caused by *Alternaria solani* has been known to cause yield losses up to 80% (Martin, 1986). The disease manifests as leaf spots with dark brown to black concentric ring which later enlarge and result in blighting of leaves and fruits. The dark spot and sunken lesions also

ABSTRACT

Field experiments were conducted in Faizabad during 2014-15 and 2015-16 cropping season to evaluate the effect of different control options (seed treatment with Carbendazim, *Trichoderma harzianum* and intercropping with linseed, alone and in combination) on lentil wilt caused by *Fusarium oxysporum* f. sp. *lentis*. The results indicated that seed treatment with *Trichoderma harzianum* (4g/kg seed) + Carbendazim (1g/kg seed) + intercropping with linseed (2:1 ratio) found minimum wilt incidence (11.67%), maximum disease control (72.06%) and higher yield (1291 kg/h) as compared to check having maximum wilt incidence (41.78%) and lowest yield (597 kg/h).

Introduction

Lentil (*Lens culinaris* Medik.) is one of the major grain legume crops and play very important role in the supply of the protein to under nourished vegetarian population of the country. It is mainly grown in North-Eastern plain zone as sole and intercrop under rain-fed conditions. It suffers from a number of diseases. Wilt of lentil caused by *Fusarium oxysporum f. sp. lentis* is one of the most wide spread and destructive disease where ever crop is grown. The yield losses due to this disease as much as 50 percent have been reported in India (Anonymous, 1999).

Many attempts have been made to control this disease using chemical, biological, varietal and cultural methods (Ram and Pandey, 2011; Sinha and Sinha, 2004; Khan and Mehnaz, 2003; Srivastava *et al*., 2000).

None of the control measures found to be effective individually at field level. Seed treatment with fungicide and bioagents is most commonly used methods and intercrop is often used in integrated management. However, the present investigation deals with the integrated management of lentil wilt by

An experiment was carried out during rabi season (2016-17) at the Student Instructional Farm of Narendra Deva University of Agriculture and Technology, Kumarganj Faizabad-224229 (U.P.), India. Five wheat lines NWL-10-14, NWL-12-13, KO-307, NWL-12-2, and NWL-12-4 were exposed to heat stress by delay sowing of forty days from normal date 15 November so that wheat lines could experienced severe heat stress at grain filling stage. The screening of wheat genotypes was done on the basis of plant height, tiller number per plant, stay green duration, number of grain per spike, test weight and yield plant^{-1}. The heat stress at time of grain filling reduced grain yield and its components irrespective of wheat lines. Among the five wheat genotypes KO-307(12.72%), NWL-12-13(14.92%) showed tolerant on the basis of stability in chlorophyll content and stay green duration.

Introduction

Wheat (*Triticum aestivum* L.), a member of family Poaceae is one of the leading cereals of many countries of the world including India. Being most important food crop of India, it is a main source of protein and energy. In India, wheat is the second most important food crop after rice both in terms of area and production. The northern and western part of India has maximum area and production under wheat cultivation.In India, Uttar Pradesh, Punjab and Haryana are the three major wheat producing states. As a C3 plant wheat is capable of growing in cool environments. Optimal growth of wheat occurs at an average temperature of 25°C, with minimums at times as low as 3°C to 4°C and maximums of 30°C to 32°C.(Curtis *et al.*, 2002).

Abiotic stress factors such as heat, cold, drought, salinity, and nutrient stress have a huge impact on world agriculture, and it has been suggested that they reduce average yields by >50% for most major crop plants (Wang *et al.*, 2003). Heat stress is an important constraint to wheat productivity affecting different growth stages specially anthesis and grain filling. Heat stress may be defined as "the rise in temperature beyond a threshold level for a period of time sufficient to cause irreversible damage to plant growth and development. It has already been

A B S T R A C T

Today crop pests have become a major concern for the farmers across the world. *Helicoverpa armigera* commonly known as Gram Pod-Borer is an economic important insect pest of gram crop, which was used to be treated with chemical insecticides. Due to misuse and overuse of these chemical insecticides, resistance is being developed in many insects resulting in increased survival rate of the insect pests. There is an urgent need for alternatives of these chemical insecticides. Bio-insecticides are eco-friendly insect/pest control which is obtained from naturally occurring substances (biochemicals), microbes and plants. Before developing a new insecticide, the scenario of *H. armigera* and its bio-control should be presented with the help of some prior studies. This paper describes the national and international research work based on the microbial pesticide/ insecticides against *H. armigera*.

Introduction

Agriculture is the backbone of Indian economy which has gone through immense changes in the second half of the twentieth century. Adoption of technologies, high yielding varieties, and agrochemicals between 1960 to 2000 lead to 'The Green Revolution' increasing the crop yield per hectare. Today crop pests have become a major concern for the farmers across the world. *Helicoverpa armigera* is commonly known as Gram Pod-Borer.

Productivity of Gram crop is strongly affected by *H. armigera*, which damages 90-95% crop during favorable weather conditions, due to its high fecundity, migratory and polyphagus nature, and its resistance to insecticides. Yield losses of 400 kg/ha caused by the Pod-borer have been reported, with damage to pods ranging from 30-40% to 90-95% (Dhaliwal *et al.*, 2010). Economic damage is the greatest in cotton and vegetables.

Comparative study on the Effect of Different Lead Concentrations on Two varieties of *Triticum aestivum* L. (Wheat)

Divya Srivastava, Mamta Baunthiyal, Adesh Kumar, Kavita Yadav, Dheeraj Yadav and Sharvan Kumar

Abstract
Lead (Pb) is the most common heavy metal contaminant in the terrestrial and aquatic ecosystems. It enters the ecosystem through various natural and anthropogenic sources. Plants absorb Pb from their environment; but it is not an essential element. Wheat (*Triticum aestivum* L.) is a main link in tropic chain; and it is one of the economically important food crops. Wheat is also the main pathway for ingestion of the pollutant by humans and animals through food and feed. The present work discusses how Pb affects nutrient uptake and metabolism in wheat, Pb gets accumulated in a dose-dependent manner in wheat plant, and causes toxicity in the plant. A pot-culture experiment was conducted to study the effects of Pb (applied as lead acetate) on two wheat varieties: PBW-373and PBW-343. Lead was applied to wheat seedlings at 0, 2, 4 and 8 g/kg quantity of lead acetate mixed with soil. The shoot length was observed to be decreased slowly with increasing concentration and at the highest concentration of Pb, the root length was decreased by four times of control in both variety. It decreased the growth and yield of plant as well as different parameters of growth measurements. Both varieties PBW 373 and PBW 343 has a great capacity to accumulate lead which shows their tolerance against lead but PBW 373 has a higher capacity of accumulation as compared to PBW 343.

Keywords: Lead, Wheat, Source of lead, Mechanism of toxicity, pot experiment, lead accumulation

Introduction
Wheat (*Triticum aestivum* L.) is a staple food of overgrowing world population. Millions of tons of wheat are grown each year throughout the globe. Yield of wheat is low, due to different reasons such as drought, salinity, water logging, lack of balanced nutrition of the crop, infertile soils and contaminated soils with various contaminants including chemicals and heavy metals. The over use of natural resources and rapid industrialization in developing countries have further increased the contamination of agricultural soils with metals. Heavy metal contamination is harmful to wild life, humans and agricultural products produced. Selected heavy metals are essential micronutrients, for example, as they act as cofactors of key metabolic enzymes, but when their concentration becomes high in soil, they become more toxic to the plants. The sources of lead (Pb) indeed are from numerous daily used common products in diverse locations, some of them quite unexpected (Srivastava *et al*., 2015) [7]. Lead adsorption onto roots has been documented to occur in several plant species. Once adsorbed onto the rhizoderm roots surface, lead may enter the roots passively and follow translocating water streams. High level of lead is inhibitor for seed germination and different growth parameters of plants; it reduces germination by lowering the enzymatic activity and growth by slow the rate of cellular division and expansion. Various physiological processes such as water transport, photosynthesis, respiration, metabolism of carbohydrates are inhibited by lead.
This paper represents how the increasing concentration of lead alters the photosynthetic pigments of two different wheat varieties viz. PBW 373 and PBW 343 as a comparative study.

Material and Method
For the experiment seeds of two different varieties of *T. aestivum* viz. PBW 343 and PBW 373 were obtained from Krishi Vigyan Kendra, Dariyapur, Rae Bareli, Uttar Pradesh. The germinated seeds of these two varieties were grown in soilrite medium and their leaves were harvested after 45 days of germination. The various chemicals used in this study were of analytical grade and procured from HI-media. Lead acetate was used for lead source to the plants.

Microbial analysis of selected fast foods popular among college students of rural and urban areas

Sadhna Singh, Jyoti Tiwari, Deepti Giri, Ravindra Singh and Adesh Kumar

Abstract
The present study was undertaken to assess the microbial quality of fast foods popular among college students. Faizabad district was purposively selected for the study. Two colleges namely Chandrabali Singh Urmila Mahavidyalaya, Shivnagar, Kumarganj, Faizabad from rural area and Saket P.G. College, from urban area Faizabad were selected for the study. A sample of 260 college students 130 each, were selected from two colleges. Information regarding age, sex, caste, family composition, education and economic status of the family and specific information regarding fast food choice, type of fast food liked, reason for consuming fast food, opinion of respondents about fast food etc. were gathered through self structured questionnaire. In this study the majority of respondents were belong to general category (33.84%). In case of their preference of fast foods majority of respondents in rural area like chaat (30.76%), samosa (29.23%), chole-bhature (18.46%), burger (30.0%) etc. On the other hand, in urban area the majority of respondents liked kachorie (23.84%) and samosa (22.30%) followed by chole-bhature (13.84) and burger (28.46%).The microbial analysis of fast foods explored showed that maximum colonies were found in chaat (6.01×10^5/gm) and burger (3.45×10^5/gm), whereas, in pastry (1.2×10^5/gm) and samosa (2.25×10^5/gm) lowest colony were observed. The reason behind this could be that in chat boiled chole is added which is boiled in the morning and is used as such tillate night which favours the growth of microbes, while in burger raw cut vegetable like tomato, cabbage, onion are added. These vegetables are cut in the bulk in the morning and used throughout the day and have greater chance for microbial growth. Whereas samosa are deep fried and pastry are kept in air conditionered show cases.

Keywords: Fast food, Self-structured questionnaire, fast food preferences, Microbial composition

Introduction
Fast foods are foods or beverages that are low in nutrient density and they provide calories primarily through fats or added sugars and have minimal amount of vitamins and minerals. In short they are energy dense foods poor in micronutrients. Regular and consistent consumption of such food over a long period of time may therefore, be deleterious to health. Foods like burger and cola are nutritionally only refined carbohydrate containing empty calorie and hardly any vitamins, minerals and proteins. But their sodium content is very high. Some may contain chemical, artificial colour, flavours and preservatives which are not good for health. (Vani, 2016) [8] There are many options for microorganisms to contaminate fast foods ie. If the food is prepared, processed, handled, and stored under unhygienic conditions. The microbiological quality of different fast foods of Jessore city was determined whether the samples are contaminated with coliforms or not. Among the fast food *Enterobacteriaceae*, *Klebsiella spp.* was the most prevalent bacteria found (Ahmed *et al.* 2014) [4]. Fast food is especially popular among adolescents, who visit fast food outlet twice per week. Several factors have contributed to this phenomenal increase in the intake of fast foods including – a greater number of working women, dual career families, more diverse schedule of family members, an aging population and an increasing number of one and two persons households. Fast food meet the needs of many people because they are quick,

Abstract

The investigation entitled "Effect of salicylic acid and cycocel on biochemical and phenology change of mustard(*Brassica juncea* L. Czern & Coss)"was conducted during *rabi* season, 2016-17 at the Instructional Farm of Narendra Deva University of Agriculture & Technology, Kumarganj, Ayodhya (U.P.) in randomized block design with 7th treatments, three replications and variety Narendra rai (NDR-8501). Various concentrations of (T_1) Control, (T_2) Salicylic acid (50ppm), (T_3) Salicylic acid (100ppm), (T_4) Salicylic acid (200ppm) and (T_5) Cycocel (100ppm) , (T_6) Cycocel (150ppm), (T_7) Cycocel (200ppm). Observations were recorded at 30, 60, 90 DAS and at maturity. The observations were taken on biochemical and phenology parameters like Chlorophyll content, Oil content (%), Days to 50 % flowering. The maximum chlorophyll 'a' and 'b' content was observed in salicylic acid 200ppm followed salicylic acid 100ppm at 60 DAS and 80 DAS over the control and maximum oil content was recorded in salicylic acid 200ppm followed by salicylic acid 100ppm and lowest increase was recorded in cycocel 200ppm among all treatments & Maximum increase in number of flowers plant $^{-1}$ was observed with the treatment of salicylic acid 200ppm followed by salicylic acid 100ppm and lowest increase was recorded in control among ten treatments.

Keyword: Biochemical, phenology, salicylic acid, cycocel

Introduction

Oilseed crops play an important role in agricultural economy of India. Rapeseed-mustard is the third important oilseed crop in the world after soybean (*Glycine max*) and palm oil (*Elaeisguineensis*Jacq.). Mustard is an important *rabi*crop of Rajasthan, Gujarat, Madhya Pradesh, Uttarakhand, Uttar Pradesh, Bihar, West Bengal and Assam. India is one of the largest rapeseed-mustard growing countryin the World, occupying the first position in area and third position in production after China and Canada. India occupies the second position in area after China and third position in production of rapeseed-mustard in the world after China and Canada. In India, it is the second most important edible oilseed crop after groundnut sharing 25-30 percent Indian oilseed economy. The share of oilseeds is 14.1 % out of the total cropped area, in India, rapeseed-mustard accounts for 3% of it. Mustard seed is the second largest produced oilseed in the world with an area of 37.0 m ha, with the production of 63.09 m tones and productivity of 11.90 q ha^{-1}. India contributes 28.3 % and 19.8 % in world acreage and production. India produced around 7.4 mt of rapeseed-mustard next to China (11-12 mt) and EU (10-13 mt) with significant contribution in world rapeseed industry. Among the entire oilseed crops producing states in India, in U.P. the area under cultivation was 6.39 lakh ha with production of 7.9 lakh metric tonnes and productivity of 12.36 q ha^{-1} (Anonymous,2015).In India, mustard is mostly cultivated for use as edible oil. It is used as condiments and spices to improve the flavour of pickles and also as fodder for livestock. There is an increasing interest in crop as source of erucic acid for chemical industry. Rapeseed and mustard cake is used as a protein supplement in livestock and poultry feed. The cake has minerals like, S, P, Co, K, Mg, Zn and vitamins like niacin, thiamine, riboflavin, and vitamin E. The Indian mustard possesses oil content ranging from 31-48 per cent in air dried seeds. PGRs are extremely important agent and play an important role from germination up to senescence of the plant. Plant growth regulators (PGRs) can play an important role in increasing its yield by making the plants photosynthetically more effective. Use of growth regulators increased. Salicylic acid is ortho-hydroxyl benzoic acid and is a secondary metabolite acting as analogous of growth regulating substances. It helps in protection of nucleic acids and prevention of protein degradation. The salicylic acid is also known to induce many genes coding for parthenogenesis and proteins in response to biotic and abiotic stresses (Enyedi *et al*., 1992). Foliar application of salicylic acid increased the IAA content in broad bean leaves. Foliar application of salicylic acid exerted a significant effect on plant growth metabolism when applied at physiological concentrations, and thus acted as one of the plant growth regulating substances (Kalarani *et al*., 2001). Cycocel (2-Chloro ethyl three methyl ammonium chloride) is the most usual anionic plant growth, regulator. There are reports that anionic compounds treated plants were tolerant to drought conditions compared to untreated plants. Moreover, they had higher net photosynthesis potential. From a biochemical point of view, CCC prevents ent-kaurene synthesis in GA3 biosynthetic cycle leading to GA3 deficiency and the subsequent reduced vegetative growth reported that any yield increase by CCC was related to the enhanced dry matter accumulation. Cycocel foliar application increased cytokinin translocation from roots to shoots, leading to prolonged aboveground parts life-span and hence increased yield

Materials and Methods

The experimental site is situated at the student Instructional Farm of the university on the Ayodhya, Raibareli road, at a distance of 42 km from Faizabad city and 23 km away from Jagdishpur. In the present study, Variety Narendra rai (NDR-8501) Various concentrations of (T_1) Control, (T_2) Salicylic acid (50ppm), (T_3) Salicylic acid (100ppm), (T_4) Salicylic acid (200ppm) and (T_5) Cycocel (100ppm) , (T_6) Cycocel (150ppm), (T_7) Cycocel (200ppm). Observations were recorded at 30, 60, 90 DAS and at maturity. The observations were taken on growth parameters like Chlorophyll content, Oil content (%), Days to 50 % flowering.

Results and Discussion

Biochemical:

Chlorophyll content

The data presented in Table 1. clearly indicate that the foliar application of plant growth regulators improved the chlorophyll contents in leaf up to 60 DAS and after 60 DAS the decline trend was recorded in chlorophyll content. The maximum increase in chlorophyll content was registered in T_4 (salicylic acid @ 200ppm) at 40 DAS (2.31), 60 DAS (2.97), 80 DAS (1.98) followed by T_3(salicylic acid @ 100ppm) at 40 DAS (2.24), 60 DAS (2.88),80 DAS (1.92) and minimum increase in T_7 (cycocel @200ppm) at 40 DAS (1.95), 60 DAS (2.51), 80 DAS (1.67) and over control at 40 DAS (1.89), 60 DAS (2.43),and 80 DAS (1.62). Bekheta 2004 and Bekheta *et al*., 2006.

Table-1: Effect of salicylic acid and cycocel on chlorophyll of mustard at different growth stages

ABSTRACT
The lack of micronutrients such as Fe and Zn in staple food crops is a widespread nutrition and health problem in developing countries. Mineral bioavailability in rice could be improved by the selection of varieties with high Fe and Zn, as well as low phyticacid (PA) content. Therefore, present study was undertaken to investigate the variations of Fe, Zn and PA content in some popular high yielding local varieties. The study also investigated the effect of morphology of rice kernels on these parameters. For this purpose, we selected six varieties (Sarjoo-52, Madhukar, NDR-359, CSR-13, Swarna Sub-1 and Swarna varieties) The highest amount of phytic acid content was found in Swarna (9.12 g/kg) and lowest in Sarjoo-52 (5.61g/k). The highest iron content was found in Sarjoo-52 (24.15 ppm) and lowest in Swarna (12.48 ppm). The zinc content varied greatly from rice to rice. The highest zinc content was found in Sarjoo-52 (35.50 ppm) and lowest in CSR-13 (25.86 ppm). The highest protein was found in Swarna (8.78 %) and lowest in Madhukar (7.47 %). Highest carbohydrate content was found in Madhukar (74.43 g/100g) and lowest in Swarna (70.07 g/100g).
Keywords: Phytic acid, Iron, Zinc, Protein, Carbohydrates.

INTRODUCTION

Rice (*Oryza sativa L.*) which belongs to the family of grasses, Poaceae, is the main food source for more than two-third of the world's population (Sasaki and Burr, 2000), especially in Southeast Asia (Nwugo and Huerta, 2011; Wang *et al.*, 2011). It contains approximately 6-12% protein, 70-80% carbohydrate, 1.2-2.0% mineral matter and significant content of fats and vitamins (Khush*et al.*, 1997). It supplies 23% of global human/ capita energy and it fulfils 16% of per capita protein requirements. Rice has a relatively low protein contents but could be raised. Rice seed storage proteins are generally divided into water-soluble albumins, salt-soluble globulins, alcohol-soluble prolamines, and alkali or acid soluble glutelins. In rice grains glutelin is the major protein of the starchy endosperm and accounting for 60% to 80% of total seed protein (Kawakatsu *et al.* 2008). It is essential that these values must increase to up lift nutritional quality.

Rice is also the major source of intake of micro-nutrients such as zinc, iron, calcium, selenium and vitamins for Indian people specially those who live in the urban countryside (Doesthale*et al.*, 1979). Iron (Fe) is necessary for oxygen transport in the blood that iron is the central atom of the heme group, a metal complex that binds molecular oxygen (O_2) in the lungs and carries it to all of the other cells in the body (*e.g.*, the muscles) that need oxygen to perform their activities (Casiday and Frey, 2000). Like Iron, the micronutrient zinc is essential for all organisms (Andreini*et al.* 2006; Broadley*et al.*2007). Zn deficiency in humans is widespread and is estimated to affect more than 25 % of the world's population (Maret and Sandstead 2006). For Increasing these content including protein in local high yielding variety for this it is important that know their basic content.

Carbohydrates are the most prevalent source of food energy in the world. They play a major role in human diet, comprising about 40-75% of energy intake. In rice carbohydrate content have been reported approximately 87 % in grain (Devindra and Longvah2011). Our aim is to see its status in local varieties and how it is comparable in terms of other nutrients.

ISOLATION AND EVALUATION OF ANTAGONISTIC PLANT GROWTH PROMOTING RHIZOSPHERIC BACTERIA FROM CHICKPEA

Km. Komal, Adesh Kumar, Niyaj Ahamad* and Shambhoo Prasad

Department of Plant Molecular Biology & Genetic Engineering, ANDUAT, Kumarganj Ayodhya (U.P), 224229, India
Email: komalkataria36595@gmail.com

Received-08.02.2022, Revised-19.02.2022, Accepted-07.03.2022

Abstract: Chickpea is an economically most important significant crop. Plant growth-promoting bacteria have been proved as potential tools not only for improving plant growth and development but also to protect host plants from stress conditions and pathogens. The present research is aimed to isolate bacteria from the rhizosphere of chickpea and to evaluate their antagonistic activity against *Fusarium oxysporum* and Plant growth promoting properties. A total of twenty one bacteria were isolated from four sampling sites. Out of which seventeen have displayed antagonistic activity against the pathogen of chickpea wilt. Among these seventeen isolates, elevenwere able to produce ammonia production, nine were able to produce Indole-3- acetic acid in tryptophan-supplemented medium, fourteen were able to solubilize inorganic phosphate in vitro and seven were able tosolubilize zinc.

Keywords: PGPR, Chickpea, PGP traits, *Fusarium oxysporum*

INTRODUCTION

Chickpea (*Cicer arietinum* L.) is the world's fourth most significant legume crop, accounting for 3.1 percent of global grain legume production. Gram, is a nutritious addition to a cereal diet in developing nations, and it is primarily planted for its highly proteinated edible seeds, which can be processed for seed and fodder production (Yadav *et al.*, 2011).

The continuously increasing population of the globe escalating the demand for pulses while decreasing the agricultural area at the same time. To meet the global demand, the application of chemical fertilizers in the agro-lands has become a common practice. On the other hand, the development of fungal diseases in leguminous crops substantially contributes to decreasing the pulses yield. Though the use of fungicides can manage the disease, their application is harmful to the ecosystem and the viability and survival of beneficial microbes (Heckel, 2012). Furthermore, the rising expense of pesticides and chemical fertilizers, as well as customer demand for pesticide free food, has prompted a search for cost effective and environmentally friendly alternatives.

Soil microbes are critical factors of soil fertility and health and play an important role in nutrient recycling. There is a group of special soil micro organisms which develop a close interaction with plant roots, colonize in the rhizosphere, and assist the plants by stimulating growth and suppressing diseases, which are known as plant growth-promoting rhizobacteria (PGPR) (Kloepper, 1978). PGPRs could establish a symbiotic, associative, or neutral association with plants and substantially affect crop growth and development. Currently, the PGPRs is considered as a unique and promising technique Currently, the PGPRs is considered as a unique and promising technique for delivering significant agricultural advantages (Niranjan *et al.*, 2005) as these microbes can promote plant growth either directly or indirectly at different stages of plant life (Gamalero and Glick, 2012). Direct growth promotion includes mobilization of nutrients like nitrogen fixation (Malik *et al.*, 1997), phosphate solubilization (Alori *et al.*, 2017), or enhancement of minerals availability (Korir *et al.*, 2017). Furthermore, other beneficial effects could also be posed by PGPRs like phytohormone production (Egamberdieva *et al.*, 2017), osmotic adjustment, stomatal regulation, modification of root morphology, *etc.* under abiotic stress conditions (El-Esawi*et al.*, 2018). On the other hand, the indirect growth promotion of PGPR is linked to their biocontrol ability. They can produce antagonistic chemicals such as phenazine, diacetylphloroglucinol (DAPG), hydrogen cyanide (HCN), 2–3 butanediol, acetoin, which help to protect plants from phytopathogens (Compant*et al.*, 2005). Several previous studies have employed PGPR as a biocontrol tool for suppression of plant diseases and also as inducers of disease resistance in plants (Bais *et al.*, 2004). Bacterial strains belonging to genus *Pseudomonas*, *Azotobacter* and *Bacillus* have been successfully used as PGPR to suppress plant diseases and improve plant growth (El-Sayed *et al.*, 2014).

Thus, the identification and characterization of PGPR populations indigenous to leguminous rhizospheres are therefore critical to the discovery of strains that can be utilized to improve growth and have the potential to suppress fungal diseases of legumes. The objectives of the present study were to isolate bacterial strains from the chickpea rhizosphere, to characterize these isolates on the basis of morphology and determination of PGPR properties along with antifungal activity.

Keywords

Lead stress, Biochemical analysis, wheat, lead effect on wheat, abiotic stress, and lead stress tolerance

A B S T R A C T

A pot-culture experiment was conducted to study the effects of lead (Pb) (applied as lead acetate) on two varieties of *Triticum aestivum* L. (Wheat): PBW-373 and PBW-343. Lead was applied to wheat seedlings at 0, 2, 4 and 8 g/kg quantity of lead acetate mixed with soil. Lead also showed deleterious effects on the production of photosynthetic pigments, carbohydrates; soluble protein in all variants but Pb toxicity increased the Proline accumulation in leaves of plants as the result of lead toxicity to plants. This work represents the effect of variable lead concentrations on biochemical properties of two wheat varieties and we could conclude that PBW 343 got more toxicity as compared to PBW 373 hence it has the tolerance capacity.

Introduction

Biotic stress includes the damage caused by different life forms e.g. pathogens like virus, bacteria, fungi etc., and insects and pests. Abiotic stress refers to the impact of environmental factors like climatic factors, edaphic factors, environmental pollution etc. Heavy metals and salinity in the environment are on the increase, affecting crop productivity. Lead is known to cause a broad range of toxic effects in living organism, including those that are morphological, physiological, and biochemical in origin (Srivastava, *et al.*, 2015). Ratlam (Madhya Pradesh), Bandalamottu Mines (Andhra Pradesh), Vadodara (Gujarat) and Kobra (Chhattisgarh) these are four site of lead in India. These places are highly contaminated with lead so cannot be used for farming as lead is highly toxic heavy metal; only lead tolerant crops can be grown at these places.

With this work we tried to find out if wheat can tolerate the lead concentration and can be grown in lead contaminated soil. To study this, we performed a pot experiment and give different lead concentration to two randomly selected wheat varieties PBW 343 and PBW 373 followed by different biochemical analysis.

Determinants of behavioural indicators of potato (*Solanum tuberosum*) growers in Kannauj district of Uttar Pradesh

ASHWANI KUMAR VERMA[1], R K DOHAREY[2], S K DUBEY[3]*, O P SINGH[4] and S N SINGH[2]

ICAR-Agricultural Technology Application Research Institute, Kanpur, Uttar Pradesh 208 002, India

Received: 07 July 2020; Accepted: 31 August 2021

ABSTRACT

The present study was carried out to find out the factors that may affect the behavioural dimensions of potato farmers, viz. their knowledge and adoption level as well as their knowledge-adoption gap about scientific potato cultivation practices in Kannauj district of Uttar Pradesh during 2016–17. Multiple regression and stepwise regression analysis was done with selected independent variables to see the effect of independent variables on the selected indicators. The analysed data showed that at knowledge level out of 18 variables taken for analysis of regression, four variables, viz. housing pattern, occupation, material possession and formal extension contact were highly significant (P<0.01); five variables, viz. education, housing pattern, informal extension contact, scientific orientation and risk orientation were highly significant (P<0.01) for their adoption level; and at knowledge-adoption gap one variable i.e. education was highly significant (P<0.01). The R^2 value and F value of knowledge, adoption and knowledge adoption level were 0.59, 0.29, 0.33 and 8.63, 2.52 and 2.95 (P<0.01), respectively. The R^2 value of stepwise regression in knowledge, adoption and knowledge-adoption gap level was 0.54, 0.24 and 0.24.

Keywords: Adoption, Knowledge, Multiple regression, Potato

Potato (*Solanum tuberosum* L.) belongs to family Solanaceae, is well known as the king of vegetables and has emerged as the most important food crop of India. Despite higher retail price of potato, the sowing of tuber is set to shrink in Northern states as farmers prefer alternate crops including onion, garlic, sugarcane and other perishables during *rabi*. Introduction of potato crop is not only important for ensuring socio-economic upliftment of the local farmers but for warranting financial sustainability of crop husbandry also (Rana *et al.* 2017). In last few years, the gap between wholesale and retail price of potato has widened by two-three times. It has disappointed potato growers and many are shifting to other crops. Mostly big farmers who store their produce have incurred losses in potato business and many such farmers are shifting from cultivation of tuber. In the last three years, glut in potato production has caused unrest among farmers in North. The annual output has grown to 53 million tonnes (MT) in 2018–19 compared to 51 million tonnes in 2017–18 (Krar 2019). The increase in area of potato cultivation has squeezed margins for growers as well as traders in the region.

Uttar Pradesh is a major potato growing state in India followed by West Bengal and Bihar with the production of 10455.30, 7482.30 and 1720.20 thousand tonnes, respectively. It produced almost 13.1 MT of potato, thus contributing nearly 28.6% of total potato production in the country (Directorate of Economics and Statistics 2016). Kannauj district is the highest producer of potato followed by Farrukhabad and Agra with production of 9.43, 8.33 and 6.47 lakh metric tonnes with area being 34.6, 29.8 and 18.20 thousand hectares, respectively (Anonymous 2001–02). Therefore, considering the significance of potato in Kannauj district, the study was carried out to analyse the profile of potato farmers of the district and to identify the determinants which may affect their behavioural dimensions in terms of their level of knowledge, adoption and knowledge-adoption gap.

MATERIALS AND METHODS

The present study was carried out in Kannauj district of Uttar Pradesh during 2016–17, which was selected purposively due to its high grown area under potato crop. It is considered to be the most climatically suitable area for potato cultivation. Jalalabad block of Kannauj district with maximum area under potato cultivation was further selected purposively. Five villages, viz. Paraspur, Gadnapur, Mirpur, Purva, and Bisundhua were selected randomly and from each village, 25 farmers actively involved in cultivating potato were further selected randomly.

Factors influencing adoption level of farmers regarding organic farming in eastern UP

Arvind Pratap Singh, Prakash Singh, RK Doharey, RK Singh, Rishi Kumar Singh, Abhay Kumar Singh and Vikash Pandey

Abstract
This study was undertaken in three districts selected randomly from each Zone namely (1) North Eastern Plains Zone (2) Eastern Plains Zone (3) Vindhyan Zone in Eastern Uttar Pradesh. From each selected district, two blocks were selected randomly. Thereafter two villages from each block was selected randomly, thus make a total 12 villages. The majority of respondents were of middle aged and literate including formal and informal education. Highest number of the respondents (55.83%) was observed in the medium category (33 to 44) of materials possession. Majority of farmers (60.41%) had medium level of overall extent of awareness about organic farming practices. The variables like age, family size, material possession and economic motivation, were found positively correlated but not significant with adoption level regarding organic farming practices. The variables like education, caste, family type, housing pattern, land holding, occupation, income, social participation, extension contact, value orientation, risk orientation and attitude were found negatively correlated but not significant with adoption level regarding organic farming practices.

Keywords: block, proportionate, age, education, overall materials possession, organic farming practices, adoption, correlations etc

Introduction
The organic movement in India has its origin in the work of Howard who formulated and conceptualized most of the views which were later accepted by those people who became active in this movement. Organic farming is a production system which avoids, or largely excludes, the use of synthetic fertilizers, pesticides, growth regulators, and livestock feed additives.

The Indian government has initiated various promotional activities, such as setting up a National Institute of Organic Farming in Ghaziabad, Uttar Pradesh, in 2003, appointment of accreditation and certifying agencies for organic farm products, developing norms for certifying organic products and providing financial support to implement promotional activities for organic farming. The task force constituted by the Government of India has also recommended the initiation of post-graduate level courses in organic farming. One of steering committee constituted by Central Government under the chairmanship of Mr. M.S. Swaminathan, Chairman, farmer's commission, has suggested taking up organic farming as a challenging national task and to take up this as a trust area of the 10th Five Year Plan. The Ministry of Commerce launched the National Organic Program in April, 2002 and processed food products export.

"Organic farming is a production system that avoids or largely excludes the use of synthetically compounded fertilizer, pesticides, growth regulators and livestock feed additives. Organic farming systems rely to the maximum extent on crop rotations, crop residues, animal manures, legumes, green manures, off-farm organic wastes, and aspects of biological pest control to maintain soil productivity and tilt, to support plant nutrients and control insects, weeds and other pests". (Kanel, 2005) [2].

Methodology
The present study was conducted in six blocks of three districts namely Barabanki Basti, and Prayagraj of Uttar Pradesh. Each district selected two block and find out the different independent variables and their level of adoption of organic farming practices in organic farming. Those blocks namely Masauli, bani kodar, Haraiya, Vikram jot, Phulpur and Dhanupur was selected randomly having production area of agriculture.

Hence, the present study has been designed to explore the level of adoption of organic farming practices in Barabanki, Basti, and Prayagraj districts of Uttar Pradesh with specific objective.

ABSTRACT

Agriculture is the most important sector of the Indian economy and is more or less a compulsion for the livelihood of millions of farmers. Many initiatives have been taken in this regard to utilize mobile phones by private sector (Indian Farmers Fertilizer Cooperative Limited, Nokia, Airtel, Tata Consultancy Services, etc.), public sector (Ministry of Agriculture and Farmers Welfare, Agricultural Universities, Research Institutions like Indian Council of Agricultural Research, State Governments). The Indian government and other development agencies promote farmers and their income generating projects as a way of encouraging growth through increased agricultural production. The impact of new technology to economic growth can only be realized when the use of these new technologies is widely diffused. Introduction of mobile phones and services in agriculture can be advantageous to farmers, traders and producers for improving their decision making.

Keywords : Agriculture, mobile phone, farmers, e-Mandi, Mandi Trades

INTRODUCTION

Indian economy is the most important aspect of the agricultural sector. Research, extension and farmer's efforts have all contributed significantly in increasing food production from 50 million tonnes in 1950-51 to a landmark achievement of an estimated 259.32 million tonnes in 2011-12 (MOA, GOI, 2013). Estimates indicated that 60 per cent of farmers do not access any source of information for advanced agricultural technologies resulting in a huge adoption gap (NSSO, 2005). Government, private, and general public agencies are often interested in the decisions made by the Indian farmers as they have large influences beyond the farm. Agriculture clearly remains one of the most important portfolios in

ABSTRACT: Field demonstration is the elderly concept of Front-Line Demonstration. FL developed by the Indian Council of Agriculture Research with the beginning of the Technology operation on Oilseed Crops during mid-eighties. Field demonstrations carry out close regulation of scientists of National Agriculture Research System recognized as frontline demonstrations because technologies are demonstrated in front of farmer by the scientists before being fed into the major extension method of the State Department of Agriculture. Adoption level of the beneficiaries were medium to high even as non-beneficiaries were found small level of adoption are enhanced production practice of mustard crop, proper training and extension strategies to be followed maximum adoption of mustard crop in the research area.

Keyword: Frontline Demonstration, KVK, Yield, economics, growth, management practices and India.

INTRODUCTION

The Krishi Vigyan Kendras were assigned different actions pertaining to evaluation, modification and expression of different novel technologies. This includes conduction of association of Frontline demonstration, estimation, training programmes and sophistication of different agriculture and related technologies during OFT. Extension activities and movement of Krishi Vigyan Kendras do significant movement for the farmers and useful in hole crop period. Krishi Vigyan Kendras are the base of all organizations who work for purpose of technology through refinement, evaluation and demonstration of confirmed technology under diverse "micro farming" situation in a region (Das, 2007). In the year 1991-92 Indian Government established a "Technology Mission on Pulses" to improve the pulse production and productivity through frontline demonstration. The mandate of the Krishi Vigyan Kendra (KVKs) are application of technology through refinement, demonstration and assessment of verified technologies under different "micro farming" situations in a region (Das, 2007).

Frontline demonstrations is show recently released crop protection and production technology and its running practice on the farmers field under diverse farming situation and agro-climatic regions. While demonstrating the technologies on farmer's field, the scientist are compulsory to study situation, factors and elements involving in higher crop production, Limitation of production and thereby create production data and feedback information. Frontline demonstrations were conduct in two adopted villages at pasture of 20 farmers within area of 0.4 hectare each. Moong crop was grown according to the package and practices of moong crop according field demonstration (Anonymous, 2017).

Genetics and epigenetics-role in development of climate resilient crops

Piyusha Singh, Akanksha Tiwari, Vimlesh Kumar and Alok Kumar Singh

Abstract
Today's era, Recent advancements in the area of -omics of crops have facilitated effect on plant response to environmental stresses and identification of epigenetic marks. As climate change effects the crop growth, so there is need to develop climate resilient crop variety. As germplasm plateu occur in many crops so there is need to examine genes from wild variety, which are high yielding and resistant to climate change. As global warming occur temperature fluctuation rate is very high. To better adapt genetics and epigenetics transiently or lastingly to stimuli from the surrounding environment, the chromatin states in plant cells vary to allow the cells to fine tune their transcriptional profiles. Conceptually genetics deals with gene function and genes whereas epigenetics deals with gene regulations. Modifications in chromatin states include a wide range of histone post-transcriptional modifications, histone variants, DNA methylation and non-coding RNAs, which can arrange various chromatin states that epigenetically determine specific transcriptional outputs. Specifically genetics focuses on how DNA sequences changes in the cell while epigenetics focuses on how DNA is regulated to achieve those changes. This has paved the way to exploitation of epigenetic variation in crop breeding. That helps to develop climate resilient crop varieties.

Keywords: Omics, genetics and epigenetics

Introduction
Epigenetic has emerged as an valuable research field for crop improvement under the present climatic changes. Epigenetic phenomenon Plant response to abiotic stresses is complex and involves multiple mechanisms, activated and controlled by massive changes in gene expression and nuclear organization (Budak *et al.*, 2015) [4]. Epigenetic diversity provide additional sources of variation within a species that could be captured and created improvement in crops. Evidence found from model plants indicates that epigenetic modifications, some of them inherited to the next generation, play an important role in this response. However, the role of epigenetic variation in adaptation of crops to abiotic stress is still not well understood (Niederhuth and Schmitz, 2014) [16]. It is important to keen understand the sources of epigenetic variation and the stability of newly formed epigenetic variants from one generation to another to use potential of epigenetic variation for improvement of crops. Epigenetics is new and fascinating field of genetics, completely meddling with classical knowledge of interaction between the hereditary material and the phenotype. Plant breeding has relied on combining the genetic diversity and variation present within species to develop various combinations of alleles which provide desired traits. If we talk about the epigenetics, It is "the study of mitotically and/or meiotically heritable changes in gene function that cannot be explained by changes in DNA sequence" (Russo *et al.*, 1996) [22]. Epigenetic changes, which include histone modifications, DNA methylation, chromatin remodelling and small RNAs, are thus heritable, but do not follow the known patterns of inheritance (Bräutigam *et al.*, 2013) [2].

Genetics and Epigenetics
In plants, active maintenance mechanisms are enable to transfer of epigenetic information throughout gametogenesis, then fertilization and early embryogenesis (Rival and Jaligot, 2012) [21]. However, epigenetic states may often be unstable. Therefore, to achieve plant improvement that may persist over generations to generations, there is need to learn more which epigenetic state can be stably transmitted (Kinoshita and Seki, 2014) [10]. The application and development of methods for widespread epigenome profiling and engineering may generate new avenues for using the potential of epigenetics in crop improvement.

ABSTRACT

The present investigation entitled "Biochemical changes of mango varieties associated with post harvest salicylic acid treatment and cardboard carton storage" had seven treatment combination replicated three times in Completely Randomized Design. At maturity condition mango fruits were harvested and stored in cardboard carton by post harvest application of salicylic acid at 0.1, 0.5 and 1.0 g/l doses. On the basis of two years data analysis it was recorded that maximum pectin content (1.90 and 1.97 %) was recorded in Langra variety at 15 days storage period by 0.5 g/l salicylic acid application. Maximum polyphenol oxidase enzyme activity (50.14 and 50.60 units/g) was reported in variety Dashehari at 7 days ambient storage period by 0.1 g/l salicylic acid treatment. Maximum peroxidase enzyme activity and beta carotene content (862.09 and 866.70 units/g, 3493.91 and 3496.73 µg/100g) was found in variety Dashehari at 20 days ambient storage period by 0.5 g/l salicylic acid application. Highest ascorbic acid content (39.37 and 39.42 mg/100g) was recorded in variety Dashehari at 5 days ambient storage period by 0.5 g/l salicylic acid application. Maximum TSS content (24.80 and 27.80 Brix°) was reported in the variety Dasheri at 20 days ambient storage period by 0.5 g/l salicylic acid application. Thus the present investigation indicated that post harvest application of enhanced the quality characteristics of mango fruits during storage in cardboard carton.

Impact of various establishment methods on yield of rice under rainfed condition

AK Singh, Anand Kumar Pandey, Ankit Singh, Alok Kumar Singh, RK Yadav, Ashish Kumar Srivastava and Sudhanshu Singh

Abstract
The water crisis is threatening the sustainability of the irrigated rice system and food security in Asia. Our challenge is to develop novel technologies and production systems that allow rice production to be maintained or increased in the face of declining water availability. Water shortage is becoming severe in many rice-growing areas in the world, prompting the introduction of water-saving aerobic rice, which is direct-seeded in non-puddled, nonflooded aerobic soil, aerobic rice systems can reduce water use in rice production by as much as 50% 'Aerobic rice' and 'upland rice' are both grown under aerobic conditions. This paper introduces principles that govern technologies and systems for reducing water inputs and increasing productivity. We concluded that, Sanda technology mainly knows as double transplanting increases yield up to 8-10%.

Keywords: Rice, puddled, un-puddled, Sanda technology

Introduction
Food security depends on the ability to increase production with decreasing availability of water to grow crops. Rice, as a submerged crop, is a prime target for water conservation because it is the most widely grown of all crops under irrigation. To produce 1 kg of grain, farmers have to supply 2–3 times more water in rice fields than other cereals. In Asia, more than 80% of the developed freshwater resources are used for irrigation purposes; about half of which is used for rice production. Rapidly depleting water resources threaten the sustainability of the irrigated rice and hence the food security and livelihood of rice producers and consumers. In Asia, 17 million hectare (Mha) of irrigated rice areas may experience physical water scarcity and 22 Mha may have economic water scarcity by 2025. There is also much evidence that water scarcity already prevails in rice-growing areas, where rice farmers need technologies to cope with water shortage and ways must be sought to grow rice with lesser amount of available water. Traditional farming consists of technologies developed by farmers over decades of adjusting farming systems to local agro climatic and social conditions (Venkata Ramaiah and Rama Raju, 2004) [8]. Double step transplanting referred as kaiam is followed in Siddharth Nagar for establishment of crop of the traditional tall scented rice cultivar Kalanamak in rainfed lowland areas. Singh *et al.*, (2005) [6] enumerated potential benefits of the practice over normal transplanting as saving of seeds, staggered use of labor, protection from lodging, increased number of grains per panicle, larger panicles and about ten days of advanced maturity. Farmers practice a system of double transplanting of rice, locally known as Sanda to avoid crop failure from submergence. One-month old seedlings are transferred to another field with dense transplanting, and then re-transplanted to the main after the risk of flash flood is over. Scientists argue that the system would have lower yield and higher costs; This practice helps in producing healthy and taller seedlings that can easily overcome the adverse situation like high water depth at the time of transplanting (Rautaray, 2007; Ashim *et al.*, 2010) [4, 1]. In some flood-prone areas, farmers practice double transplanting (even triple transplanting) to produce taller seedlings for transplanting in standing water at the beginning of the season (India and Bangladesh) or to rejuvenate seedlings while waiting for the floodwater to recede to levels that can allow transplanting in the main field, proper management of seedlings in nurseries or after transplanting in the field (Ram *et al.*, 2010) [3]. It is also said that double transplanted rice produce more yield than normal transplanting with same aged seedlings (Ziagua, 2000; Satapathy, 2015) [9, 5].

Effect of NPK and chemical application on nitrogen uptake and yield of rice under rainfed condition

AK Singh, Anand Kumar Pandey, Ankit Singh, Alok Kumar Singh, RK Yadav, Ashish Kumar Srivastava and Sudhanshu Singh

Abstract
Crop productivity and quality are dependent on better availability of essential crop nutrients. However, application of nutrients at best optimum is essential depending on genotype for improved yield and quality. Field experiment was carried out to assess the influence of various levels of chemical and NPK fertilizers (F1: RDF-NPK Zn @ 80-60-40-5 kg N-P_2O_5-$K_2$0-Zn kg/ha), F2: F_1 + 70 kg $CaSO_4$ ha^{-1}, F3: F_2 + 1% KCl foliar spray at panicle initiation and F4: F_3 + Brown manuring with sesbania) on nitrogen uptake and yield components of drought tolerant rice variety under rainfed condition (Sahbhagi Dhan) at Instructional Farm, Acharya Narendra Deva University of Agriculture & Technology. Results revealed that application of (F4: F_3 + Brown manuring with sesbania) improved the nitrogen uptake, nitrogen use effciency and yield related traits *viz.* productive tillers $^{m-2}$, panicle length, 1000 grain weight, grain yield, as compared to other NPK levels. Among treatments F4 performed better than treatments. Results conclude that drought tolerant variety can yield better, by applying NPK combination with 70 kg $CaSO_4$ ha^{-1}, 1% KCl and sesbania with acceptable characteristics as compared to other treatments.

Keywords: Chemicals, NPK fertilization, $CaSO_4$ and KCl

Introduction
Rice is one of the most important cereal crops in the world. Rice ranks second among food grains, and half of the world's population depends on rice by getting the highest (26.2%) calories intake from it. Out of this almost 90% rice production and consumption takes place in Asian countries (Islam *et al.*, 2010) [7]. In Asia, the largest rice producing countries include China, India, Indonesia, Bangladesh and Pakistan (FAO, 2011) [6]. India is the second largest producer in the world. India has the largest area of rice cultivation at global level (44 m ha). Determination of optimum levels of NPK fertilizers is essential for obtaining maximum economic returns. According to Ananthi *et al.* (2010) [2] best rate of fertilizer application is that which gives maximum economic returns at least cost. Among various essential plant nutrients, the macro nutrients NPK are crucial for determining the yield and quality. It has been noticed that farmers utilize imbalanced dose of N fertilizer which leads to higher insects/disease attack ultimately producing lower yield (Mannan *et al.*, 2009; Alam *et al.*, 2011) [8, 1]. Therefore, there is dire need to determine the best level of NPK fertilizers which may give maximum crop productivity with minimum losses.
Itrogen is required by plants in the processes of photosynthesis and photosynthesis, and is involved in the energy reactions in the form of ATP; a key component of chlorophyll, proteins and enzymes; and assists the plants in the synthesis and use of carbohydrates (Mengel and Kirkby, 2001; Sara *et al.*, 2013) [9, 12]. Phosphorus plays a crucial role in the root proliferation, consistent grain filling, and higher grain yield and quality as well being a constituent of nucleotides such as in ADP and ATP energy bonds and also being involved in many processes such as photosynthesis, mitotic activities, tissue growth and development (Bhattacharyya and Jain, 2000) [3]. Plants cannot reach their maximum yield without adequate supply of phosphorus (Alam *et al.*, 2009; Murtaza *et al.*, 2014) [10]. Potassium is essential for the maintenance of electrical potential across cellular membranes and cellular turgor enhancing the cell expansion and enlargement, opening and closing of stomata, and pollen tube development. It is also involved in activation of many enzymes, translocation of nitrate and sucrose (Britto and Kronzucker, 2008) [4]. It is an important plant nutrient and is required in higher amount especially for rice. About 100 kg K is removed by rice plants for a yield of about 5 t ha-1. Intensive cropping systems and the use of modern rice varieties to obtain high yield causes a heavy decline of K in soil, especially in absence of K fertilization (Saha *et al.*, 2009) [11].

Effect of foliar application of plant growth regulators on growth and development, biochemical changes and yield of mung bean (*Vigna radiata* L.)

Bhupender Mishra, RK Yadav, Sumant Pratap Singh, Alok Kumar Singh and AK Singh

Abstract
A experiment was conducted under field condition at Students Instructional Farm of Acharya Narendra Deva University of Agriculture & Technology, Narendra Nagar (Kumarganj), Ayodhya, U.P. during *Kharif* season 2019 based on a Randomized Block Design with three replications, variety Narendra Mung-1 (v-00), seven treatments were taken. The foliar sprayed of GA3 75 ppm was found most effective for increasing the plant height, number of branches per plant, dry total dry biomass per plant (29.75 g) and chlorophyll content SPAD value (40.38), protein content in seed (24.62%), number of pod per clusters (2.30), number of pods per plant (18.92), pod length (8.92 cm), number of seeds per pod (9.21), number of seeds per plant (155.33), 100 seed weight (3.67 g), seed yield per plant (15.07g), followed by foliar sprayed of NAA 150 ppm over rest of the treatments. Generally, the use of growth regulators in foliar application increased the yield and yield components.

Keywords: Mungbean, GA3, chlorophyll content, physiological, NAA, salicylic acid

Introduction
Mung bean is botanically recognized as *Vigna radiata* Linn. Wilczek and belongs to the family *Fabaceae* (*Leguminaceae*). The genus *Vigna* has been broadened to include about 155 species but only twenty-two species are native to India. Where they are grown in large numbers and are often grouped under distinct varieties and sub species. One of the most important among these species is *Vigna radiata* with dark-green foliage, spreading pods and green seeds. Green gram is the third most important pulse crop in India (Anonymous, 2004) [1]. It has high nutritive value and due to this, has advantage over the other pulses. The seed contains 24.20% protein content, 1.30% fat, and 60.4% carbohydrates, calcium (Ca) 138 and phosphorus (P) is 340 mg per 100 g of seed, respectively (Imran *et al*., 2016).

In India, pulses are grown over an area of 29.28 mha with a production and productivity of about 22.40 m tonnes and 765 kg/ha respectively. This covers about 20% of total area and 8% of total grain production in India. India has largest area and production of pulses in the world. All over India, total pulse production was recorded about 23.95 million tonnes in (2017-18).

Naphthalene acetic acid is a synthetic plant hormone in the auxin family and is an ingredient in many commercial plant rooting horticultural product, it is a rooting agent and used for the vegetative propagation of plants from stem and leaf cutting. Naphthalene acetic acid has been shown to greatly increase cellulose fiber formation in plants when paired with another phytohormone called gibberellic acid. Because it is in the auxin family it has also been understood to prevent premature dropping and thinning of fruits from stems.

Gibberellic acid may play an important role as this is known to affect many facets of plant life, including: seed germination, leaf expansion, N-fixation, phloem loading, water and mineral uptake, assimilate translocation, harvest index. Gibberellic acid occupies a prominent position in mediating a variety of plant physiological processes including seed germination, leaf expansion, flower and fruit set, dry matter production, photosynthesis, translocation of food material and synthesis of mRNA coding for hydrolytic enzymes (Mollat Mazid 2014) [12].

Materials and Methods
The field experiments were carried out during *kharif* seasons of 2019 in Students instructional Farm of Acharya Narendra Deva University of Agriculture & Technology, Narendra Nagar, (Kumarganj), Ayodhya. Solution of GA3 25 ppm, GA3 50 ppm, GA3 75 ppm, NAA 50 ppm, NAA (100 ppm) and NAA (150 ppm) were prepared.

Effect of seed priming with plant growth regulators on growth, biochemical changes and yield of Mung bean (*Vigna radiata* L.)

Rohit Nandan, RK Yadav, Sumant Pratap Singh, Alok Kumar Singh and AK Singh

DOI: https://doi.org/10.22271/chemi.2021.v9.i4ao.11673

Abstract
Seed priming is employed for better crop stand and higher yield in a range of crops. In order to evaluate the effect of seed treatments with growth regulators on the yield and yield components of mung bean (*Vigna radiata* L.) variety, a experiment was carried out under field condition at students instructional farm of Acharaya Narendra Deva University of Agriculture & Technology, Narendra Nagar, (Kumarganj), Ayodhya U.P. during *kharif* season 2019 based on a Randomized Blok Design with three replications variety of Narendra Mung-1 with seven treatments were taken. The maximum germination percentage (90.25%) was recorded with seed priming of GA_3- 100ppm over other treatments including control. Growth characters as plant height, total dry biomass, and chlorophyll content and nitrogen content in green leaves and protein content in mature seeds were found significantly superior with seed priming of GA_3-100ppm followed by NAA-100ppm over control. Yield and yield contributing traits *viz*: number of pod clusters per plant (8.33), number of pods per plant (48.26), pod length (7.66cm), number of seeds per plant (416.66), number of seeds per pod (10.33), 100 seed weight (3.92g), seed yield per plant (11.36g), seed yield (11.66 q h^{-1}) and harvest index (36.06%) were also found statistically superior with seed priming of GA_3-100ppm followed by priming in NAA-100ppm over control. Generally, the use of growth regulators as a pre-treatment of seed increased the yield and yield components.

Keywords: Mung bean, GA_3, biochemical, physiological, NAA, salicylic acid

Introduction
Mungbean is the third most important pulse crop of India after chickpea and pigeonpea (Singh and Singh, 2014) [22]. Mung bean (*Vigna radiata* (L.) Wilczek) is native to India and central Asia especially in tropical and subtropical Asia and belong to family Fabaceae and sub- family Papilionaceae (Singh and Singh, 2014) [22]. The nutritive value of mungbean is high and easily digestible protein with approximately 25-28%, oil 1.0-1.5%, fiber 3.5-4.5%, ash 4.5-5.5%, carbohydrate 62-65%, water 9.1%, and vitamins on dry weight basis (Singh *et al*., 2014) [22]. In India, pulses are grown over an area of 29.28 m ha with a production and productivity of about 22.40 m tonnes and 765 kg/ ha, respectively (Anonymous, 2017) [3]. This covers about 20% of total area and 8% of total grain production. These are the cheapest and best sources of vegetable proteins consisting of about 27 per cent of total dietary protein in our country and India has largest area and production of pulses in the world.
Plant growth regulators (PGRs) are known to influence plant growth and development at very low concentrations. They are non-toxic to plants over a wide range of concentration and effective in promoting the root system of a large number of plant species (Taiz and Zeiger 2006) [23]. Gibberellins (GAs) are the most important natural growth regulators and generally involved in the growth and development of different plant. They control seed germination, leaf expansion, stem elongation, and flowering (Magome *et al*., 2004 and Kumar *et al*., 2018) [15, 11, 12]. Gibberellic acid (GA) is used to induce great changes in the growth characters, chemical composition, and yield criteria of the plant (Choudhury *et al*., 2013) [8].
Salicylic acid (SA) is a phytohormone of phenolic nature. It is ubiquitous in plants generating a considerable impact on plant growth, development, mineral uptake and transport, photosynthesis, and transpiration. Salicylic acid and other salicylates are known to affect

Effect of foliar application of different nutrients on growth and yield of wheat (*Triticum aestivum* L.) under sodic soil

RK Yadav, Manendra Kumar, Pradip Kumar Saini, Alok Kumar Singh, AK Singh, Brijesh Kumar, AK Pandey and Ankit Singh

DOI: https://doi.org/10.22271/tpi.2021.v10.i1h.5594

Abstract
The present investigation entitled "Effect of foliar application of different nutrients on growth and yield of wheat (*Triticum aestivum* L.) under sodic soil" was carried out at main experiment station (MES) of Acharaya Narendra Dev University of Agriculture & Technology, Kumarganj, Ayodhya (U.P.). During *rabi* season - 2017-18. The experiment was laid in field condition with randomized block design and three replications. Seven treatments comprised of five different nutrients as zinc sulphate (0.5%) and (0.7%), boric acid (0.2%) and (0.4%) and potassium nitrate (0.1%) and (0.3%) applied as foliar application at 35 DAS of crop growth. A controlled set was also maintained. The observations were recorded as growth parameters at, 40, 60 and 90 DAS, yield and yield attributing traits were recorded at harvest. All the foliar application of nutrients increased the growth characters viz., plant height (cm), number of tillers per m^2, dry weight plant was found significantly superior with foliar application of 0.7% zinc sulphate at all the stages of crop over control. Yield characters viz., length of spike (10.5cm), No. of grains per spike (45.10), no. of grains per plant (40.20), Grain yield/m^2 (285), grain yield /ha^1 (38.59), test weight (38.26g) and harvest index (29.80%) were recorded significantly higher with foliar application of 0.7% zinc sulphate followed by foliar application of 0.3% of potassium nitrate over control.

Keywords: wheat, zinc sulphate, sodicity, boric acid, potassium nitrate

Introduction
Wheat (*Triticum aestivum* L.) is a staple food of the world and belongs to family Poaceae (Gramineae). It is most important staple food of about two billion people (36% of the World population). About 55% of the world population depends on wheat for intake of about 20% of food calories. Wheat is self-pollinated crop and it has been described as the 'King of cereals'. It is the world's most widely cultivated food crop and is primarily grown in temperate regions and also at higher altitude under tropical climatic areas in winter season. Wheat is the single most important cereal crop that has been considered as integral component of the food security system of the several nations. It is grown in the world with an area of 221.60 million hectare, production of 728.3 million tonnes with productivity of 3.3 tonnes per hectare (Anonymous 2015) [1]. In India, it is grown in an area of 30.47 million hectare, production 95.85 million tone's with a productivity of 3.15 tonnes per hectare. Uttar Pradesh having first rank in respect of both area (9.95 million hectare) and production (30.24 million tone's) with a productivity of 3.10 tone's per hectare in 2015 (Anonymous 2015) [1]. Plants need large quantities of potassium, the uptake of which frequently exceeds the uptake of nitrogen. Not only the plant tissues had higher K^+ content than the other cations but K^+ regulates effectively many physiological and biochemical processes (Bajwa, 1994) [2]. Potassium utilization by plants through foliar application is well recognised and is being practiced in agricultural advanced countries (Fernandez and Eichert, 2009) [3]. Foliar applied fertilizers often show a better efficacy which may help to reduce the required dose. Therefore, this study was planned to compare different concentrations of K_2SO_4 and KNO_3 for foliar application to obtain optimum wheat yield under different wheat planting techniques. Sodic soils are characterized by a disproportionately high concentration of sodium (Na) in their cation exchange complex. They are usually defined as containing an exchangeable sodium percentage greater than 15%. These soils tend to occur within arid to semiarid regions and are innately unstable, exhibiting poor physical and chemical properties, which impede water infiltration, water availability and

Introduction
Wheat (*Triticum aestivum* L.) is a staple food of the world and belongs to family Poaceae (Gramineae). It is most important staple food of about two billion people (36% of the World population). About 55% of the world population depends on wheat for intake of about 20% of food calories. Wheat is self-pollinated crop and it has been described as the 'King of cereals'. It is the world's most widely cultivated food crop and is primarily grown in temperate regions and also at higher altitude under tropical climatic areas in winter season. Wheat is the single most important cereal crop that has been considered as integral component of the food security system of the several nations. It is grown in the world with an area of 221.60 million hectare, production of 728.3 million tonnes with productivity of 3.3 tonnes per hectare (Anonymous 2015) [1]. In India, it is grown in an area of 30.47 million hectare, production 95.85 million tone's with a productivity of 3.15 tonnes per hectare. Uttar Pradesh having first rank in respect of both area (9.95 million hectare) and production (30.24 million tone's) with a productivity of 3.10 tone's per hectare in 2015 (Anonymous 2015) [1]. The fast growing population of our country makes it imperative to enhance wheat production accordingly. Wheat is cultivated on an area of 8693 thousand hectares with a total production of 25,286 thousand tonnes during year 2012-13 (GOP, 2012-13). The major fraction of potash fertilizer directly applied to soil gets fixed by the clay fraction and becomes unavailable to crop plants (Ali *et al.*, 2010) [2]. The available zinc in Indian soil ranges between 0.08-20.5 ppm. Application of zinc has been found to boost the growth and yield of crops to a great extent. Zinc deficiency includes rosetting and poor tillering leading to decreased productivity in crop plants. Since zinc is co-factor of carbonic anhydrase and aldolase, therefore, it may adversely affect enzyme activities and carries corresponding metabolic reactions when zinc is deficient in soil. Zinc is also involved in synthesis of protein, tryptophan (amino acid). Superoxide dismutase (SOD) activity is much lower but can be restored *in vitro* by resupplying zinc to the assay medium, indicating that the zinc is an essential structural components for normal functioning of superoxide dismutase enzyme. In zinc stressed plants, protein synthesis is inhibited and amino

Abstract
The present study involved evaluation of 12 genotypes of rice under control salt and field conditions. The characters studied were days to 50% flowering, plant height (cm), panicles bearing tillers/plant, spikelets/panicle, grains/panicle, panicle length, spikelet fertility (%), test weight (g), biological yield/plant (g), harvest index (%), and grain yield plant (g) After 7 days of salinisation, all the genotypes viz. IR68144-2B-2-2-3-1-120, IR-68144-2B-2-2-3-1-127, IR-91167-99-1-1-1-3, IR-91167-133-1-1-2-3, NUD-3, NDR-359, IR-28, HL-478, NUD-2, CSR-13, Ayyar and NDRK-2008 were salinity tolerance. After 14 days of salinisation, HL-478 were tolerant, while IR68144-2B-2-2-3-1-120, IR-68144-2B-2-2-3-1-127, IR-91167-133-1-1-2-3, NUD-3, NUD-2 and CSR-13 were moderately tolerant genotypes and NDR-359 were susceptible genotype. After 21 days of salinisation, HL-478 were tolerant genotype, while IR-91167-99-1-1-1-3, NUD-3, NUD-2, CSR-13 and NDRK-2008 were moderately tolerant genotypes and genotypes IR68144-2B-2-2-3-1-120, IR-68144-2B-2-2-3-1-127, IR-91167-133-1-1-2-3, NDR-359, IR-28 and Ayyar were susceptible genotype. Under salinity condition at reproductive stages of rice genotypes Ayyar followed by showed highly tolerant to salinity at reproductive stage. The genotype NUD-3, NDRK-2008 and IR-91167-99-1-1-1-3 exhibited highly susceptible to salinity at reproductive stage. The higher magnitude of positive direct effect on grain yield/plant exerted by biological yield/plant and harvest index under control condition, under saline condition biological yield/plant followed by harvest index and spikelets/panicle showed positive and direct effect on grain yield/plant. Under field condition positive and direct effect on grain yield exerted by biological yield/plant followed by harvest index, spikelets/panicle and spikelet fertility. In the present study, the 12 genotypes of rice were grouped into four different non-overlapping clusters under saline, field and control conditions. The highest intra cluster distance was recorded for cluster IV under controlled condition, cluster II under saline condition and cluster III under field condition. Under controlled condition highest inter cluster distance recorded in cluster II and cluster IV. Under saline condition, cluster II and cluster III had highest inter cluster distance. Under field condition, the highest inter cluster distance recorded in cluster I and cluster IV. RM 10772 exhibited polymorphism in 12 rice genotypes, while RM10745 exhibited Monomorphism in 12 rice genotypes.

Keywords: Cluster analysis, genetic diversity, rice genotypes, SSR marker, salt tolerance

Introduction
Rice is one of the most important cereal crops in the world. One in every three persons depends on rice for more than half of their daily food requirement (Khush and Virk, 2000). Rice (*Oryza sativa* L.) is the world's most important crop and more than half of the world's population depends on it for food (calories and protein especially in developing countries) grain. Asia is the largest producer of rice (97%) with an average productivity 3.9 tonnes per hectare. China and India account for about 50% of the world's rice area and 56% of production (Hossain and Pingali, 1998). Rice is a most important cereal crop in India and it contributes about 45% to the cereal production, 41% of the total food grain production and accounts for 20-25 per cent of the agricultural GDP.
Salinity is one of the major abiotic stresses that substantially limiting crop production and reduces the average yield of major crops by more than 50% (Abdallah *et al.*, 2016) [1]. The deleterious effects of salt stress on agricultural yield are significant, mainly because crops exhibit slower growth rates, reduced tillering and, over months, reproductive development is

Role of boron
Soil and foliar application

ABSTRACT

The deficiency of boron is spreading rapidly in Indian soils. Boron deficiency in crops is more widespread than deficiency of any other essential micronutrient. However, imbalanced or excess use of boron fertilizers found to impose negative impact on crops due to very narrow range of boron deficiency and toxicity in soil and plants which increases production cost also. Therefore, optimized boron fertilizer supply in boron deficient soils is important in order to attain normal crop growth, yield and high-quality produce. It this review the role of boron in crop production, its deficiency in crop plants has been discussed.

INTRODUCTION

The essentiality of boron (B) for the growth and development of higher plants was demonstrated by Warington in the year (1923) and considered as an essential element for plant growth and development (Pollard *et al.*, 1977; Marschner, 1995). B plays an important role in both structural and functional integrity of plasma membrane (Pollard *et al.*, 1977). B has been reported to affect the plant growth due to its role in cell division, expansion, cell wall formation and stabilization, lignification and xylem differentiation (Marschner, 1995). B has been implicated in counteracting toxic effects of aluminum on root growth of dicotyledonous plants (Dale *et al.*, 1998). It imparts drought tolerance to the plant (Rattan and Goswami, 2002). In muskmelon, application of B improved plant growth and fruit quality, and in addition the incidence of chilling injury decreased in harvested fruit during cold storage at 5°C (Combrink *et al.*, 1995). B is continuously required for the normal growth of most plants, otherwise, plants grown in low B containing media exhibit B deficiency symptoms of various forms (Gupta, 1993). The deficiency of B spreading rapidly in Indian soil from 2% in 1980 (Katyal and Vlek, 1985) which reached to 52% soils (Singh, 2012). B deficiency has mostly been reported in the soils of Assam, Bihar, Meghalaya, West Bengal, Jharkhand and Odisha mainly in acid red and lateritic soils including high pH calcareous soils (Behera *et al.*, 2009). Now next to zinc, B has become an important micronutrient in Indian Agrarian (Sathya *et al.*, 2009) required for normal plant growth and obtaining high quality crop yields (Murmu *et al.*, 2014). The important facts pertaining to this important micronutrient is furnished in Table 1.

BORON IN SOIL SYSTEM

Among the essential micronutrients B is the only non-metal and present in non-ionic form. Total B contents in Indian soils ranged between 7 to 630 mg B kg^{-1} soils (Prasad *et al.*, 2014). Singh *et al.* (2015) observed that soils were highly deficient in available B with mean contents of 0.55, 0.49, 0.66 and 0.62 mg kg^{-1} in Chandauli, Mirzapur, Sant Ravidas Nagar and Varanasi district, respectively. Availability of B in soil is influenced by several factors including soil reaction, soil moisture, active calcium and organic matter content (Dregne and Power, 1942). Light textured soils (sandy loam and loamy sands) found to be deficient in B content because they were well drained and had good leaching (Abid *et al.*, 2002). Most of the tea soils of Darjeeling hills are sandy loam and loamy sand soil (light textured) except

Effect of salinity on biochemical and enzymatic activities of rice (*Oryza sativa* L.)

Ankit Singh, Reeshu Singh, Anubhuti Singh, Alok Kumar Singh and Al Singh

Abstract
In the present study deals with the *Oryza sativa* L. was selected for the physiological and biochemic studies in laboratory condition for 10 days (2nd, 4th, 6th, 8th and 10th day) that were carried unde different salinity levels. Six genotypes of rice crop i.e. tolerant- CSR-36, CSR-43, Usar Dhan-3 ar Susceptible- Swarna Sub-1, IR-28, Pusa-44, were used to germinate under varying concentrations NaCl i.e.0 to 100 mM. The salt stress significantly reduced the germination percentage with increasin salt stress from 0 to 100 mM NaCl. A continuous decrease in carbohydrate content with increase in sa stress was observed in all the varieties. The rate of proline accumulation was observed maximum in Usa dhan-3 at 100 mM NaCl stress. The enzymetic activity of catalase and α-amylase was higher in contr than sample induced with salinity stress. This study overall showed better tolerance to salt stress with lesser extent of antagonistic effect of NaCl on Usar dhan -3 than any other variety.

Keywords: Salt stress, germination, *Oryza sativa*. L., proline

Introduction
Rice (*Oryza sativa* L.) is among the most consumed cereals in the world. Production of ric (*O. sativa* L.) ranks second among food grains, and half of the world's population subsists o rice by receiving the highest (26.2%) calories intake from it (FAO, 2009) [5]. In Asia where i covers half of the arable land used for agriculture in many countries. More than 90% of rice i produced and consumed in Asia and it is the only major cereal crop that is consumed almos exclusively by human. India is the largest rice growing country accounting for about one-thir of the world acreage under the crop. About 84% of rice production growth has been attributec to the use of modern technologies. However, salinization of paddy land in the coastal regio may develop by advancement of sea or rising of the saline ground water to the upper surface o the soil. This problem is due to high levels of evaporation and salt accumulation in the roo zone in arid and semi arid areas (FAO, 1997) [4].

Salinity is one of the major abiotic factors that limits plant growth and productivity in many regions of the world due to increasing use of poor quality of water for irrigation and soi salinization (Munns and Tester 2008, Rozema and Flowers 2008, Kronzucker and Britto 2011 Zhang and Shi 2013) [12, 7, 8, 19]. One of the most detrimental effects of salinity is the accumulation of Na^+ and Cl^- ions in tissues of plants subjected to soils with high con centrations of NaCl (Maathuis *et al.* 2014) [10]. High concentration of Na^+ inhibits uptake of K^+ which is an essential macronutrient for plants growth and development that results in low productivity and may even cause death (Kronzucker *et al.* 2013, Gupta and Huang 2014) [9, 6]. Plants have developed various physiological and biochemical mechanisms to maintain a relatively stable intracellular environment via accumulating various solutes under saline condition (Gupta and Huang 2014, Roy *et al.* 2014) [6, 16]. The osmotic adjustment in plants can maintain the uptake of water and the turgor of cell, allowing regular physiological metabolisms (Radić *et al.* 2013) [14]. Proline, as an important osmoprotectant, contributes to osmotic adjustment, protecting enzymes from oxidative damage under saline condition (Ashraf and Harris 2004, Gupta and Huang 2014) [6]. In addition, under saline condition, the accumulation of other compounds such as soluble sugar, which at higher temperatures are non-toxic to cytoplasmic functions, allowing turgor maintenance and/or protection of macromolecular structure against the destabilizing effects of the decrease in water activity, has also been reported in many plants species (Juan *et al.* 2005) [17].

A major challenge towards world agriculture involves production of 70% more food crop for an additional 2.3 billion people by 2050 worldwide. Salinity is a major stress limiting the increase in the demand for food crops. More than 20% of cultivated land worldwide (~ about 45 hectares) is affected by salt stress and the amount is increasing day by day.

A B S T R A C T

Altogether 334 rice lines alongwith8 global check varieties were tested for submergence survival and yield performance at Crop Research Station, Masodha, Ayodhya. These lines and check varieties, namely IR 64-Sub 1, Swarna-sub 1, Sambha Mahsuri-Sub 1.. Ciherang-Sub1, TDK1, Ciherang, RC18, SambhaMahsuri and 3 local check viz. Swarna, MTU 1010 and Sahabagidhan were laid out in augmented design with 10 blocks. For survival testing in submergence, the experiment was conducted in the submergence pool and for yield performance (optimal condition), the experiments was conducted in the irrigation field. Each entry was direct sown in two rows of 3 meter length and after 25 days of sowing complete submergence of one meter water depth was imposed for 20 days. Data recorded for submergence survival as no. of plant counted before and after submergence. In yield performance experiments observation recorded on days to 50% flowering, plant height, Ebt/m2, total biomass, harvest index and yield kg/ha. Among 334 lines none of the lines have recorded 100% survival however, eight lines viz., TTB 944-31-10-1-2 (95.2%), CR-2859-1-S-B-2-1-B-B-5-1 (94.7%), IR103410-B-B-2-3 (87.5%), CR 2851-S-1-B-4-1-4-1-1 (IET27051) (84.2%), IR 97034-21-2-1-3 (69.6%), IR09A130 (66.7), CR 2859-S-B-2-1-B-7-1 (60%) and NSIC 2016 RC 468 (57.9%) survived and 42 lines falls under 20-56 % survival, were recorded. The entries were selected on the basis of (i) selection based on survival % and vigor, (ii) selection based on productivity under submergence, (iii) selection based on the variables of morphological and agronomic characters. The entry IR103410-B-B-2-3 (87.5%) (4667 kg/ha),IR 97034-21-2-1-3 (69.6%)(4667 kg/ha),TTB 944-31-10-1-2(95.2%) (4000 kg/ha) and NSIC 2016 RC 468 (57.9%) (3333 kg/ha) also good for survival and yield. These lines are considered promising for tolerant to submergence as well as yield.

Introduction

Rice (*Oryza sativa* L.) is one of the most important crops of the world and provides food to more than 50% global population. More than 90% of the world's rice is grown and consumed in Asia, where 60% of the earth's people live. It was estimated that 35-60% of the calories consumed by 3 billion Asians comes from rice. Rice demand in

Farmers in flood prone areas mostly use only urea without any solid recommendations. Possibilities of recurrent flooding/submergence during the season are one of reasons for avoiding nutrient application, through it has a strong bearing on regeneration growth and yield of rice varieties after floods, hence suitable nutrient management strategies are essential to enhance the productivity. However, higher dose of N (60 Kg ha^{-1} as basal) showed positive response on plant growth during submergence but higher elongation caused plant mortality during post oxidative phase. Meanwhile, popular package and practices among flood prone farmers, addition of Zero Kg N before submergence to minimized risk was not justified. So far, higher N applied as basal showed negative effect on survival during post submergence. Plants grown without N fertilizer before submergence showed 12-23% plant mortality in both Sub-1 rice varieties during post oxidative phase even though submerged field was substituted with higher dose of N @60 kg ha^{-1} at 5^{th} days after desubmergence, mainly due to energy starvation during submergence. After de-submergence frequent addition of split doses of N might be helpful to meet out the demand of submerged plants for faster recovery.

Introduction

Rice is semi aquatic plants. Thus, traditionally grown rice cultivars in flooded soil have a reputation for growing well under flooded conditions. About 22 million ha of rice in South Asia is prone to flash flooding. In India, about 17.4 million ha of rainfed lowland rice are grown each year, of which 5.2 million ha are submergence-prone, out of the 2.65 million ha flash-flood prone areas, about 1.6 million ha rice are frequently inundated. Even during normal years, approximately 20% of the geographical area is affected by flooding, due to serious crisis most of the rice cultivars die within days of complete submergence, often resulting in total crop loss (Mackill *et al.*, 2012).

These losses heavily affect rice farmers where alternative livelihood and food security options are limited. Farmers of flood prone

Foliar spray of salicylic acid and oxalic acid ameolirates temperature (Heat) stress on wheat at anthesis stage

Anand Kumar Pandey, AK Singh, Alok Kumar Singh and RK Yadav

DOI: https://doi.org/10.22271/chemi.2020.v8.i2ah.9085

Abstract
This study endeavors to quantitatively cognize the impact of changes in physiological mechanism due to climate change on wheat at vegetative stage and reproductive stage of crop. This experiment was conducted and evaluated for wheat crop using two chemicals salicylic acid and oxalic acid and meteorological data from a field site at Students Instructional Farm of the Narendra Deva University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) during Rabiseasons of 2015-16 and 2016-17. This experiment was planned under FRBD (Factorial Randomized Block Design) with three replications and two date of sowing *viz*; 25th November and 25th December with two varieties NW-5054 and NW-2036.Results indicated that physiological traits were adversely affected by time of sowing due to onset of high temperature during crop growth and particularly grain filling. All the treatments reduced the detrimental effect of heat stress on both the varieties by improving physiological traits which ultimately helped in obtaining higher yield.

Keywords: Wheat, climate change, heat stress, salicylic acid, oxalic acid

Introduction
Wheat (*Triticum aestivum* L.) is the second most important staple food crop of the world. It accounts nearly 30% of global cereal production covering an area of 220 million hectare with an average productivity of 3.2 tonnes ha^{-1} (FAO, 2015) [6]. Wheat production in the year 2017-18 was recorded as 92.08 million tonnes covering an area of 26 million hectare in India (DES, 2014) [2]. The country further required 100 million tonnes of wheat by the year 2030 to fulfill the demands of the growing population which poses a major challenge in the background of prevailing changed climatic scenario. Crop performance and yield is the ultimate result of interaction of a crop genotype and its environment. Among various stresses, abiotic stresses such as heat, drought and salinity are considered as major threats to sustainable wheat production in India. According to world estimates, average yield losses in agricultural crops up to 50% is mainly due to different abiotic stresses as a result of these changing climatic conditions (Theilert *et al.*, 2006) [18]. The growth and yield of wheat crop is adversely affected by different environmental stresses like high temperature, soil moisture deficit, low light intensity etc. The cultivation of wheat is limited by temperature at both ends of the cropping season and high temperature stress has an adverse effect on wheat productivity. The terminal heat stress was at anthesis and grain filling stages accelerate maturity and significantly reduce grain size, weight and yield (Kamal *et al.*, 2013) [6]. High temperature is considered to be most important factor to reduce the wheat yield among the various stresses (Modarresi *et al.*, 2010) [13]. Heat stress reduces the leaf area, the duration of vegetative growth and leaf number in wheat. Heat stress is injurious to the photosynthetic apparatus during reproductive growth of wheat, diminish source activity and sink capacity, which results in reduced productivity and enhance leaf senescence causing reduction in green leaf area during reproductive stages. The rapid leaf senescence ultimately resulted in less productive tillers/plant, which is one of the major causes of yield loss of wheat. High temperature above 32 ^{0}C has been reported reducing grain yield and grain weight during grain filling, it's considered as a major determinant of wheat development and growth, decreasing yields by 3-5 % per 1 ^{0}C increase above 15 ^{0}C (Wollenweber *et al.*, 2003) [19].

Effect salinity on germination percentage (%) and seed vigour index of rice (*Oryza sativa* L.)

Ankit Singh, AK Singh, Anand Kumar Pandey, Alok Kumar Singh, Reeshu Singh, Anubhuti Singh and RK Yadav

DOI: https://doi.org/10.22271/phyto.2020.v9.i2s.11003

Abstract
Present investigation was conducted during *Kharif* 2017-18 in laboratory, at experimental study Department of Crop Physiology, Narendra Deva University of Agriculture and technology, Kumarganj Faizabad (U.P.). Soil salinity has become a severe threat to ensure food security. salinity-imposed limitations on plant growth. At the present, salinity level stimulates many of the metabolic processes involved in phases (2nd, 4th, 6th, 8th and 10th day) of germination, resulting in an improved performance of germination and higher. Experiment was laid out in complete randomized design (CRD) with three replication on six genotypes of rice crop *i.e.* tolerant- CSR-36, CSR-43, Usar Dhan-3 and Susceptible-Swarna Sub-1, IR-28, Pusa-44. Present investigation was carried to study the effect of salinity with 0, 50 and 100 mM concentration of NaCl on germination. The exposure of rice varieties to increasing concentration of NaCl had significantly increased germination (%), seed vigour index. It is evident from the result that concentration with NaCl significantly improved the germination and enzymatic activities of rice genotypes. The concentration are effective in increasing the germination percent. Seed vigour index, radicle length, plumule length, and enzymatic activities like α- amylase, catalase and carbohydrates biochemical parameters like proline accumulation, in all varieties under normal as well as under laboratory condition. The concentration with NaCl 0, 50 and 100 mM influences the germination and biochemical changes under normal as well as under anaerobic condition and might be useful in mitigating the adverse effect of laboratory condition or helpful in increasing the yield and yield attributes in all the varieties. Thus, it may be recommended that salinity level with concentration (0, 50 and 100 mM) of NaCl is the most desirable for mitigating the adverse effect of salinity.

Keywords: Rice, salinity, NaCl, Seed vigor, anaerobic condition

Introduction

Rice (*Oryza sativa* L., 2n= 24), belongs to the family Poaceae (Graminae). Rice is the most important food crop of the developing world and is the staple food of more than half of the world's population. It is especially important crop of Asia, where more than 90% of world rice is grown and consumed and where more than half of world's people live. Rice is the most important cereal food crop of India. It occupies about 23.3% of gross cropped area of the country and plays vital role in the national food grain supply. Rice is rich in nutrients and contains a number of vitamins and minerals. It is an excellent source of complex carbohydrates the best source of energy. It contains a reasonable amount of protein 6-10%, carbohydrate 70-80%, mineral 1.2-2.0% and vitamins (Riboflavin, Thiamine, Niacin and vitamin E). Rice contributes 43% of total food grain production and 46% of the total cereal production of the country. At least 114 countries grow rice and more than 50 have an annual production of 100,000 or more. Asian farmers produce about 90% of the total, with two countries, China and India more than the half. Among the rice growing countries in the world, India has the largest area under rice crop and ranks second in production next to China.

Salinity is a common environmental stress seriously affecting crop growth, food production and crop yield in many regions, particularly in arid and semi-arid regions. It is estimated that over 800 million hectares of land in the world are affected by both salinity and sodicity globally (Munns, 2005) [6]. Salt contaminated soils (ECe> 4 dS m^{-1} or 40 mM NaCl or osmotic potential < 0.117 MPa) are defined as saline land, which directly affects plant growth and development in vegetative growth prior to reproductive stage, especially crop species. Some of crop species are susceptible to salt stress (ECe 1.0-1.8 dS m^{-1}), which decline crop growth and productivity about 6-19% *i.e.* rice, corn, bean, eggplant, onion, potato, pepper, sugarcane and cabbage. In general, biochemical, physiological, anatomical and morphological characteristics

Abstract
A field experiment to induce dormancy in rice (*Oryza sativa* L.) was conducted during *Kharif* season, 2017-2018 at the experimental field of Department of Crop Physiology, ANDUA&T, Ayodhya to study the effect of foliar feeding with growth inhibitors by different concentration *viz*. Maleic Hydrazide (500ppm and 1000ppm) and Cycocel (500ppm and 1000ppm) along with untreated control. The experiment was laid out in randomized block design comprising nine treatments at two stages (*viz* flowering stage and anthesis stage) in three replications. Observations had been studied *in vivo* on germination percentage, viability test. Yield characters *i.e.*, number of tillers per plant, ear bearing tillers per plant and biomass per plant, number of seeds per panicle, grain yield per plant and harvest index. Among all the concentrations, maximum number of tillers per plant, ear bearing tillers per plant and number of seeds per panicle was recorded in MH@1000ppm, grain yield per plant and biomass per plant MH@500ppm, harvest index was found maximum in cycocel @500ppm followed by MH@1000ppm where as maximum inhibition of germination was observed with cycocel@1000ppm followed by MH @1000ppm and cycocel @500ppm but cycocel @ 500ppm was found most appropriate and was very much effective for safe induction of seed dormancy in rice because of its minimum viability loss. Loss in viability was may be due to some toxic effect caused by high concentration of MH and cycocel.

Seed quality has multiple concepts having several components such as genetic purity, Physical Purity, insect-pest, weeds, germination, moisture content, vigour and uniformity. The quality seed is the main and principle mean to secure crop yield in less favorable areas, and this is the main vehicle for rehabilitation in agriculture. The inability of newly harvested seeds to continue their development under favourable environmental conditions like moisture, temperature, oxygen supply is generally known as Dormancy. It is the natural phenomenon in the plant kingdom. It allows plant to survive under unfavorable environmental conditions. It is generally assumed that dormancy is mainly of two types *i.e.* Primary and Secondary types. The dormancy due to embryo factors or due to seed coat is called as Primary dormancy. The state of dormancy in seed may also be induced due to secondary factors like light, temperature etc. is called as secondary dormancy. Dormancy is a mechanism by which seeds maintain their viability in unfavorable conditions. The characteristics of dormancy may be considered as beneficial in short duration varieties because the crop attains the maturity stage in rainy season itself at that time the proper threshing may not be possible. On the other side it possess cereal problem in testing giving misleading result and require induction of dormancy. Post harvest sprouting is nowadays became a serious problem which adversely affect the quality of seeds and make farmers suffer from great loss. There are many chemicals and plant hormones by which dormancy can be induced.

Materials and Methods

The changes in the climate due to global warming and ever dwindling arable land due to the population pressure are increasing strain on available resources for sustainable food production. Therefore, it is an urgent need to have proper idea about the effect of drought stress on crop plants for getting stable production through research intervention. Water deficit due to drought stress influences a wide range of plant processes, from whole plant growth and development to the molecular regulation of essential transcriptional pathways, and thus significantly impacts both physiology and metabolism. The studies about the changes in behavior of crop plants under drought condition have progressed at a rapid pace and extensive results of such analysis have been made public through various research articles, which can now be easily accessed through the World Wide Web. This review describes some aspects of drought induced effect of drought stress on different important traits of crop plants.

Introduction

The response of plants to drought stress is one of the most complex biological processes, and it involves numerous changes at the physiological, cellular, and molecular levels. Drought is the most frequent yield-reducing factor in arid and semiarid regions, although water deficit may occur even in high rainfall areas. The ultimate detrimental effect of drought stress is reduction in yield, as reported in major crops like rice (Venuprasad *et al.*, 2007), wheat (Keshavarzi *et al.*, 2013), and maize (Kamara *et al.*, 2004) and some other important crops such as soybean (Kobraei *et al.*, 2011) and chickpea (Khodadadi, 2013). Water stress due to drought can lead to major physiological and biochemical changes such as reduced photosynthesis (Zlatev *et al.*, 2004; Tezara *et al.*, 1999) and reprogramming of gene expression (Neill and Burnett, 1999; Pattanagul and Madore, 1999). Physiological changes under drought stress are often reflected at the transcription level, where the levels of mRNA related to key processes such as photosynthesis are down-regulated (Bartels and Salamani, 2001) and mRNA related to

Biochemical Assimilates Accumulation and Remobilization at Reproduction Stage Drought Stress in Upland Rice (*Oryza sativa* L.)

Alok Kumar Singh, Ashutosh Kumar Mall

Received 22 September 2016 ; Accepted 24 October 2016 ; Published online 12 November 2016

Abstract A very week correlation obtained between leaf rolling score and yield, shoot soluble sugar and RWC, respectively. Leaf depth ; score in well correlated with leaf soluble sugar. Plant height is often considered as a factor in plant response to drought stress. Rice accumulates significant amount of carbohydrate before and wide variability exists among genotypes. Improved variety like NDR-97, Vandana and DH line have higher content of total soluble sugar at flowering than do low yielding traditional cultivar like Azucena and Saita correlation study revealed strong positive relationship between grain yield in stress and shoot soluble sugar. Assimilate accumulated prior to flowering are of paramount importance when plant experience drought at later stage. We hypothesized that grain yields of rice crops drought stressed at flowering, directly related to reserve food materials and the ability of the plant to translocate those assimilate. Translocated-CHO for grain growth is supported by apparent contribution rate (ACR) and value of ACR was higher in stressed plant. This result indicated that under several water deficits at flowering stage, grain growth depend of previously accumulated assimilates. Correlation study showed strong positive regression coefficient (R^2 = 0.54) with grain yield, justified the ability of the plant to translocated assimilate to minimized the sterility due to water deficit. Among the cultivar tested here IR-64, NDR-97, Vandana, Azucena, Moroborokan and DHLs had at par ATR value in irrigated control but generally had more CHO coupled with high ATR and ACR under drought. In present investigation genotypic variability's were observed regarding other stress adoptive plant traits. Higher Nitrate reductase was observed in all genotypes at the end of drought stress and higher correlation coefficient was obtained with grain yield. It seems that higher NR active at the end of drought delayed the leaf senescence, which helps to sustain photosynthesis during stress. Furthermore, linear increase in SOD (antioxidant) was observed after re-watering and stressed plants. The increased in antioxidant activity is believed to be associated with recovery growth.

Abstract The present investigation attempt has been made to combine different type of germplasm in order to identifying the physiological basis of genetic variation in drought tolerance. The High estimates of PCV and GCV were observed for sterile grains per panicle, root dry weight, root volume, root length and fertile grains per panicle under both the conditions. High estimates of heritability and genetic advance were recorded for water potential, fertile grains panicle^{-1}, sterile grains panicle^{-1}, straw yield, total biomass at flowering, total biomass at maturity, ACR, root length, root volume and grain yield under both the conditions. Thus, selection practiced for these characters in plant materials under study may be expected to be highly fruitful for isolating high yielding genotypes for irrigated/drought environments. The other traits would be unreliable indices for improvement through selection due to existence of low to moderate transmissibility along with low variability. None of the morpho-physiological traits appeared as strong associates of grain yield in irrigated control condition, whereas four traits, namely, straw yield, panicle length, total biomass at maturity and total biomass at flowering were found to be strong associates of grain yield in water stress condition. In over all consideration, soluble sugar upper root and starch at re-watering in control condition and starch in leaf, starch at re-watering and chlorophyll a in stress condition emerged as most important direct yield components owing to their high order positive direct effects at phenotypic as well as genotypic level.

Keywords Upland rice, drought, physiological traits, direct and indirect selection parameters

Introduction

Drought stress at either vegetative or reproductive stages of plant growth is the major constraint to rice production and yield stability in the rainfed upland regions [1]. Most of the farmers in India usually grow local varieties in upland rice under diverse agro climatic conditions. Even though these varieties are well adapted to the local conditions, they are poor yielders. Therefore, stable genotypes which perform better under stress as well as under favorable condition are desirable in target environment for sustainable rice production. Short duration varieties with tolerance to drought suit drought prone upland ecology.

The direct selection parameters help us in developing suitable selection strategy for enhancing the effectiveness and efficiency of selection in improving plant characters. The literature pertaining to assessment and comparison of direct and indirect selection parameters in rice drought condition is meager. Most of the earlier reports in respect of above aspects in rice are based on studies involving either irrigated or drought environments so such studies fail to provide finer understanding and comparison of genetic parameters in relation to water stress and stress free conditions. Moreover, the results of the earlier studies on such aspects are relevant only for materials and environments involved in particular study and cannot be generalized. The results of character association studies in rice by earlier workers have been found to be non-consistent varying with the materials and environment used [2 & 3]. Further probe in this respect in rice might prove useful due to non-consistent findings reported earlier. Therefore, studies on above aspects in rice involving genetic stocks and environments in question are essential for obtaining information required for planning and execution of a successful breeding programme aimed at development of superior varieties for irrigated and drought prone environments.

Materials and Methods

The present investigation was carried out in wet season at the Instructional Farm of Department of Crop Physiology, N. D. University of Agriculture & Technology, Kumarganj (Faizabad), U.P., India. The genotypes of upland rice from different geographical regions were screened for reproductive stage drought tolerance. The genotypes were seeded and seedling establishment was done in dry beds and transplanting was done 21 days after seeding. Each genotype was transplanted in Randomized Block Design with three replications in a 5 m length row. Row spacing was 20 x 15 cm and one seedling per hill was used. Recommended agronomic practices were followed. Pesticides and bird nets were used to protect the plants against pests. All other crop management practices were at the optimum level.

Management of water stress

The experiments were conducted with well defined protocol for water management under natural field conditions during wet season in both the years.

Irrigated (NS): The experimental field was left uncovered to receive natural rainfall. In addition to this, experimental plots were irrigated using well laid channels for supplying tube well water, as and when required, to maintain appropriate moisture levels as recommended for irrigated rice.

Abstract- The importance of additive gene effects for most of the nine traits in the three crosses under two transplanting conditions suggested substantial scope of improvement in yield status can still be achieved by using breeding procedures. GY/P, BY/P and PH possessed high heritability and genetic advance in both conditions and emerged as ideal traits for selection. G/P, T/P and DFF in E1 and HI in E2 appeared also as ideal traits for selection owing to their high estimates for both parameters in respective conditions. At both levels, positive correlation of GY/P was recorded with HI in both transplanting conditions. BY/P, PL in both transplanting conditions and T/P and G/P in E1 appeared as strong positive associates of GY/P at both levels. Path analysis identified BY/P and HI as most important direct components and PL and G/P as most important indirect components of GY/P in both conditions. These characters merit due to consideration in formulating effective selection strategy in rainfed lowland rice for developing high yielding varieties for normal and delayed transplanting.

Keywords- Rice, normal and delay transplanting, GCV, PCV, correlation, direct and indirect effects

Introduction

Rainfed lowland rice is a dominant rice culture in countries that form a belt from India to Cambodia. Barker et al. [1] found that research in rainfed lowland rice would produce higher rates of return than research on irrigated rice. At present, however, most research is directed to irrigate environments, even in countries where rainfed rice predominates. The research investment was lower in countries with a high proportion of rainfed rice compared to countries with predominantly irrigated rice [1].

Various agronomic and morphological characters, photoperiod sensitivity is another highly important and desirable feature of all rainfed lowland rice. According to Pushpavesa and Jackson [2], the photoperiod sensitivity provides adaptive advantages of tolerance to late transplanting and a dependable maturity date after the rainy season ends. Transplanting is the most widely used method by which rainfed lowland rice crops are established because it allows farmers to be flexible in dealing with water related stresses. In rainfed lowlands, drought or flooding often makes it impossible to transplant 3-4 week old seedlings which most agronomists consider as the optimum age for transplanting [3]. In fact, in more than 50 per cent of rainfed lowland rice area, transplanting is frequently delayed [4]. If drought occurs just after seeding due to delayed rains, the plants can be maintained in the seedbed until sufficient water in available for transplanting and subsequent growth. In medium deep area, farmers have to transplant older seedlings to escape or survive flood damage. The photoperiod sensitive cultivars are suitable for delayed transplanting because by virtue of having constant maturity date such cultivars are usually harvested before conditions become too dry. By contrast, photoperiod insensitive cultivars flower and ripen late on late transplanting which increases the chance that crop will fail due to drought. Thus, genetic studies in rainfed lowland rice and subsequent breeding efforts must be planned after taking into consideration photoperiod sensitivity and delayed transplanting aspects of this rice culture.

So far, rainfed lowland rice has got very little attention of rice breeders as compared to irrigated rice in India as well as abroad. The high yielding cultivars of irrigated rice often perform below satisfactory levels in adverse and diverse rainfed lowland conditions because different agronomic traits and plant type are needed for each type of rice cultures [5]. To understand of direct and indirect selection parameters also helps in effective application of selection in isolating superior genotypes for a particular environment or situation. However, very little literature is available in respect of gene effects and direct and indirect selection parameters in rainfed lowland rice, especially under delayed transplanting conditions. Keeping in view these facts, the present investigation was undertaken on rainfed lowland rice under normal and delayed transplanting conditions.

Materials and Methods

The investigation was conducted at Crop Research Station, Masodha, Faizabad (U.P.) during *Khanf* season. The site falls under sub tropical to semi arid region in Indo-Gangatic plains and lies between 26.47°N latitude, 82.12°E longitude and at an altitude of about 113 m above mean sea level.

Experimental Details

Abstract: Change in global climate is primarily due to rising concentrations of greenhouse gases in the atmosphere that is mostly caused by human activities. The important factors affecting the occurrence and spread of the plant diseases are temperature, moisture, light, and CO_2 concentration. These factors cause physiological changes in plants that result in increase in intensity of crop diseases. Climate change causes a significant impact on germination, reproduction, sporulation and spore dispersal of pathogens. Climate change affects all life stages of the pathogen as well as its host to cause impact on host-pathogen interaction which facilitates the emergence of new races of the pathogen ultimately breakdowns the host resistance. It also affects the microbial community in the soil which is beneficial to the plants in various aspects. The minor diseases become major ones due to alteration in climatic parameters thus posing a threat to the food security.

Key words: Climate change, greenhouse gases, temperature, elevated CO_2, pathogens, sporulation.

1. Introduction

Climate change is a long-term shift in the statistics of the weather. Worldwide climate change is a major concern of discussion within both scientific and political forums. According to World Meteorological Organization (WMO) the decade (2010-2020) is the warmest decade on record. Changes in climate are still going unstopped and temperature is projected to increase by 3.4 °C and CO_2 concentration to 1,250 ppm by 2095, along with much greater variability in climate and more extreme weather-related events [1] accompanied by more climatic variability and adverse weather events [2]. In India, it is likely to experience a temperature rise of 1-4 °C; rainfall will increase by 9%-16% by 2050. This change in the earth's atmospheric composition is mostly due to the unscrupulous activities of the human beings. The changes in the earth's climate are the result of changes in the cryosphere, biosphere, hydrosphere, and other interacting factors. Greenhouse gases like water vapor (H_2O), methane (CH_4), carbon dioxide (CO_2), nitrous oxide (N_2O), hydrofluorocarbons (HFCs) and ozone (O_3) present in the earth's atmosphere trap the reflected radiation; and in turn warm the earth surface [3]. Biological processes are strongly influenced by temperature and water availability. Climate change is affecting all the four pillars of food security: availability (yield and production), access (prices and ability to obtain food), utilization (nutrition and cooking), and stability (disruptions to availability) [4].

Many environmental factors affect plant disease development viz., temperature, light and water availability, soil fertility, wind speeds, and atmospheric ozone, methane and CO_2 concentrations. Among these, three factors viz., CO_2 concentration,

Abstract: Partial resistance to *Alternaria blight* (*Alternaria brassicae*) was assessed in 15 genotypes of Indian mustard under field conditions. four genotypes viz., NDRE-7, NDWR-05-1, NDRE-4 and NDRE-16 exhibited partial resistance and had lowest per cent blight cover, minimum number of spot/ 10 cm^2, size of spot (mm), sporulation (conidia/spot), disease severity (PDI), apparent infection rate, leaf defoliation, AUDPC and maximum yield, respectively. Numbers of spot were positively & significantly correlated with size of spot (0.949), disease index (0.905), leaf defoliation (0.954), AUDPC (0.917), infection rate (0.878), except sporulation and negatively correlated with yield kg/ha (-0.952).

Introduction

Oilseed crops play an important role in agricultural economy of India. Our country is the fourth largest oil economy in the world after the U.S., China and Brazil in terms of vegetable oils. Out of annual commercial cultivation of 7 edible oilseeds (groundnut, rapeseed-mustard, sesame, linseed, soybean, safflower and niger) in India, rapeseed-mustard (Brassica species.) contributes 28.6% in the total production of oilseeds. The edible oil industry is one of the most vibrant sectors of the Indian agriculture economy. The county ranks first in the world in the production of castor, safflower, sesame and niger; second in groundnut and rapeseed-mustard; third in linseed and fourth in soybean.

The cultivation of oilseed crops along with many other minor oilseed crops has been possible due to favorable agro ecological conditions. Rapeseed and mustard belongs to family Brassicaceae which is grown in Northern India comprising traditionally grown indigenous species namely Indian mustard (*Brassica juncea*), brown sarson(*Brassica campestris* var. brownsarson), yellow sarson (*Brassica campestris* var. yellow sarson) toria (*Brassica campestris* var. toria) and Taramira (*Eruca sativa*) along with nontraditional species like gobhisarson (*Brassica napus*), white mustard (*Brassica alba*) and Ethiopian mustard (*Brassica carinata*). It is the most important group of rabi oilseed crops and contributes a major share to the vegetable fat economy of the country.

Rapeseed-mustard oil is the cooking medium and dietary fat of a very large population in northern and eastern states in our country. Rapeseed-mustard oil is characterized by a low level of saturated fatty acids, a relatively high level of mono unsaturated fatty acids, moderate level of polyunsaturated fatty acids and an appreciable amount of the α-linolenic fatty acid. The content of saturated fatty acids, which are known to increase cholesterol levels (viz., Lauric, Myristic and Palmitic), is only 4%. Higher levels of monounsaturated and polyunsaturated fatty acids provide the advantage on lowering total cholesterol of plasma and low-density lipoproteins (LDL) cholesterol as well as protective against oxidation of LDL.

The fairly high level of phyto-sterols present in the oil are also reported to lower plasma cholesterol level of absorption of dietary cholesterol and the reabsorption of billary cholesterol. Oil and meal quality have an important place in rapeseed-mustard breeding programme. Quality of oil is important for good health of human being (nutrition point of view, keeping quality (shelf life of oil) and industrial uses. Oil quality and usage of oil, by and large, is determined by the proportion (percentage) of various fatty acids present in oil. Meal quality is determined by levels of anti-nutritional factors particularly by glucosinolate and proportional protein and fiber contents. Canola is a registered name given by Western Canadian Oilseed Crusher's Association for varieties having less than 2 per cent erucic acid in oil and less than 22 μ moles of glucosinolate/g in defatted seed meal. Indian cultivars have high erucic acid (40-50%) in oil and high glucosinolate (80-120 μ moles/g) in seed meal. So there is an urgent need to make concerted efforts for breeding varieties with improved quality of oil (< 2% erucic acid) and meal (≤ 22 μ moles/g glucosinolate) at par with international quality norms. Edible oils or fats are associated with an increased risk of heart diseases, so major emphasis should be given on quality of oil and fat, which are very high in polyunsaturated fatty acids (PUFA). PUFA causes Atherosclerosis' a disease in adults and uipidosis in children, which interferes in myocardial conductance and peripheral vascular system, thereby decreasing coagulation time and increases blood cholesterol. Concentrated scientific approach for the improvement of quality of oil is the need of the hour. Among oilseed crops, rapeseed-mustard occupies a prominent position in the country. Rapeseed-mustard are major rabi oilseed crops of the northern India. The oilseed crop is predominantly cultivated in Assam, Bihar, U.P, W.B, Rajasthan and North Eastern states particularly Meghalaya & Sikkim, (North & Central India) India occupies the second position in area after China and third position in production of rapeseed-mustard in the world after China and Canada. In India, it is the second most important edible oilseed crop after groundnut sharing 25-30.0% in the India's oilseed economy.

Varietal Screening and Molecular Analysis against Alternaria Blight in Indian Mustard Genotypes

SAMRIDDHI SINGH[1], NA KHAN[1], SUMANT PRATAP SINGH[1], HK SINGH[2] AND DK DWIVEDI[1]

ABSTRACT

Indian mustard [Brassica juncea (L.) Czern & Coss] is an important edible oilseed crop in India. There are 154 genotypes screened under natural condition against Alternaria blight. Disease appeared on leaves after 90 days were noted as, 9 genotypes found moderately susceptible (Rohini, PAB-14-14, PBZ-4, PRD-14-1, PAB-14-5, PRD-14-16, PAB- 14-17, PHR-2, Parvati), 29 were susceptible and 116 were highly susceptible. In case of biochemical analysis, only ten genotypes, maximum phenolic value in non-infected and infected leaves was in found same variety NDRS-2009-1 and peroxidase activity maximum values was found non-infected and infected leaves NDRE-1-11-1, Vaibhav. In catalase activity, a height value was found non-infected and infected leaves varieties NDRS-2007, NDRS-2009-1. Cluster analysis dendogram is divided in two group I and II, this similarity showing mean 0.45 and group I had only one variety namely NDRS-2009- 1. Group II had divided in to two sub groups A and B. Group A is in to two clusters A1 and A2 in this group similarly 0.60 and cluster A1 divided in to two sub cluster A1-1 and A1-2, sub cluster A1-1 had found three varieties NDRE-1-11-1, NDYR-2008 and Narendra Rai but NDRE-1-11-1 0.75 more similar both varieties NDYR-2008 and Narendra Rai. Sub cluster A1-2 had two varieties Vaibhav and Rohini both similar only 0.70. Cluster A2 had found three varieties NDRE -7, Vardan and PM-26 but both NDRE -7, Vardan dissimilar 0.81 then PM-26 and group B had found only one variety NDRS-2007.

INTRODUCTION

Indian mustard [*Brassica juncea* (L.) Czern & Coss.] is an important edible oilseed crop in India, it is commonly referred to as rapeseed mustard along with four other related cultivated oilseed species viz. *B. rapa, B. napus, B. carinata* and *Eruca sativa*. Oilseed brassica shares 23.5% area and 24.2% production of total oilseeds in the country. Indian mustard is belonging to Brssicacea family. In this three diploid species, namely, *Brassica rapa* (AA, 2n=20), *Brassica nigra* (BB, 2n=16), *Brassica oleracea* (CC, 2n=18), and their three natural amphidiploid species, namely, *Brassica napus* (AACC, 2n=38), *Brassica juncea* (AABB, 2n=36) and *Brassica carinata* (BBCC, 2n=34), constitute cultivated Brassicas. These are cultivated across the globe for use as vegetables, oilseed crops and condiments (Maheshwari and Kovalchuk, 2016).

The estimated area, production and yield of rapeseed-mustard in the world was 36.59 million hectare (mha), 72.37 million tonne and 1980 kg /ha, respectively, during 2018-19. Globally, India accounts for 19.8% and 9.8% of total acreage and productivity (USDA). During 2018-19 the production was 1980 kg/ha and production 72.42 mt (DRMR, 2018-19). In Uttar Pradesh, Rapeseed – mustard was grown on 1099 ha with a production of 8041 tonnes and 1054 kg/ha productivity during 2017-18 (Anonymous, 2018).

Disease resistance depends upon the induction of defenses following exposure to organisms. Several types of biochemical changes which include the level of phenolics was found to be important in the investigation of resistance mechanism (Arora and Wagle, 1985; Meena *et al.*, 2008). The aim of this research was to explore the possibility of biochemical changes for defense and symptom logical changes in the three genotypes of oilseeds *Brassica* infected by *A. brassicae* under natural conditions at different stages of Alternaria blight disease development. *Alternaria* infection causes considerable changes in the sugar and phenolic contents of the plant (Chopra and Jhooty, 1974; Nema, 1983; Chahal, 1986; Kumar and Singh, 1996; Saharan and Saharan, 2004; Joshi *et al.*, 2004; Kushwaha and Narain, 2005). The biochemical and physiological changes associated with induction of resistance and plants peroxidases have been implicated in varieties of defense-related processes, including the hypersensitive response, lignifications, cross-linking of phenolics and glycoprotein, suberization and phytoalexin production. (Rakow and Raney, 2003). Catalase is frequently used by cells to rapidly catalyze the decomposition of hydrogen peroxide into less reactive gaseous oxygen a water molecule thus avoiding cellular disintegration (Bolwell and Wojtaszek, 1997). Peroxidase convert H_2O_2 to water provide an efficient system to prevent oxidative damage. Induction and accumulation of POX correlated with onset of induced resistance suggest an active role for this enzyme in defense against pathogenic fungi and retard fungal growth (Jung *et al.*, 2004).

MATERIALS AND METHODS

The experiment was conducted at the Student's Instruction Farm, Acharya Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya (U.P.) during *Rabi* 2019-20. The planting of 154 Indian mustard genotypes were done

In vitro efficacy of fungicides against *Myrothecium roridum* causing leaf spot of Bael

Satya Prakash Vishwakarma, HK Singh, Manish Kumar Maurya, Vikash Kumar Yadav, Krishna Kumar, Shyam Babu Gautam and Rajendra Prashad

Abstract
Leaf blight caused by *Myrothecium roridum* is a devastating disease of Bael in nursery stage. The experiments were conducted to test the efficacy of fungicides against *Myrothecium roridum* causing leaf spot of bael in *in vitro* condition. The results showed that the complete (100%) mycelial growth inhibition was recorded with Tebuconazole (50%) + Trifloxystrobin (25%) 75 WP @ 0.05%, Carbendazim (12%) + Mancozeb (63%) @ 0.2%, Propiconazole (25%) EC @ 0.1%, Tebuconazole (25%) EC @ 0.2% and Carbendazim 50% WP @ 0.1%. The minimum mycelial growth (mm) and maximum growth inhibition at 24 day after inoculation was Hexaconazole (5%) EC @ 0.1% (39.66mm and 55.93%) followed by Mancozeb (75%) WP @ 0.2% (45.66mm and 49.26%) and Azoxystrobin (18.2%) + Difenconazole 11.4% SC @ 0.2% (50.33mm and 44.07%). Maximum mycelial growth was found in control (90.00).

Keywords: Bael, *Myrothecium roridum, in vitro*, efficacy, fungicides

1. Introduction
Bael (*Aegle marmelos* Correa) is an indigenous fruit of India belongs to family Rutaceae, chromosome number is 2n = 18(36) and it is commonly known as Bengal queen, Golden apple, Japanese bitter orange, Stone apple, Wood apple (John and Stevenson, 1979) [1]. Nevertheless, the Bael tree grows in almost all the states of India; however, it is widely distributed in U.P., Bihar, West Bengal, Orissa and Madhya Pradesh (Roy *et al.*, 1992) [6].
Bael plants are widely and abundantly grown in eastern Uttar Pradesh particularly in Mirzapur, Varanasi, Gorakhpur, Basti, Gonda, Ayodhya, Etawah districts and also Sewan district of Bihar (Teaotia *et al.*, 1963) [8]. The average height of tree, 8.5 meters. Flowers, greenish white, sweetly scented, 8 mm long; diameter of a fully open flower, Fruits, yellowish green, with small dots on the outer surface, The flowering was observed to the second fortnight of June to the first fortnight of July. The fruits take almost one year to mature. The peak fruiting season is during May and June. The average yield of a wild Bael tree was 62.5 kg. (Parmer and Kaushal, 1982) [4].
In the ancient medical Ayurvedic treatise `Charaka Samhita` every part of this tree, stem, bark, root, leaves and fruit at all stages of maturity have medicinal merits and have been used as remedy for a long time. It cleanses and strengthens the intestines. Its ripe fruits flesh used for syrups or can be eaten both fresh and dried. Bael tree is considered a sacred tree, commonly grown in temple gardens in the country. It is important indigenous fruit of India. The fruit is known to possess significant therapeutic and medicinal value and is widely used in Homeopathy and Ayurveda. Bael is the most effective herbal remedy for diarrhea and dysentery. Anti-diarrheatic activity of Bael root (Pitre and Srivastava, 1984).
Bael plant is affected by fungal diseases is very serious in nursery condition like Alternaria leaf spot disease caused by *Myrothecium roridum*. The symptoms were found on leaves as small, circular or irregular in shape, brown in colour and chlorosis around the lesions were observed but later on these spots enlarges and covered the more area. Disease symptoms recorded first in rainy season (July-August) as circular brown spots on the upper surface of the leaf. The older leaf spots (15-20 days after formation of new spots) frequently exhibited concentric rings along with sporodochia arranged in a somewhat concentric pattern. At advanced stage of disease development a characteristics shot hole in the leaves were seen due to shedding of necrotic tissues.

Yield Loss Assessment due to Alternaria Blight Disease in Rapeseed and Mustard

H K SINGH[1*], PRADIP KUMAR[1] AND S K SINGH[2]

ABSTRACT

An experiment was conducted to assess the yield losses due to Alternaria blight in different released cultivars of rapeseed-mustard during Rabi 2016-17 and 2017-18 planting 15 varieties of the rapeseed-mustard namely RH-749, Pusa gold, KBS-3, GSL-5, GSL-2, Pusa mustard-27, Jhumka, Anuradha, PT-30, T-27, PM-25, Pusa aditya, PT-303, Sheetal, TMLC-2 in six replications. The minimum disease severity on leaves and pods were recorded in protected and unprotected conditions in the variety GSL-5 (2.65% and 16.26%), (1.75% and 6.32%) followed by GSL-2 (3.20% and 19.72%), (1.89% and 6.75%) Pusa aditya (6.91% and 19.89%), (2.18% and 7.20%) and Sheetal (7.99% and 23.13%), (3.21% and 7.43%), respectively. On the basis of mean values the minimum infection rate on pods was recorded GSL-2 (0.083 and 0.042) followed by Pusa aditya (0.089 and 0.045), respectively. The minimum AUDPC on leaf under protected and unprotected was recorded on cultivar GSL-5 (76.40 and 496.20) followed by GSL-2 (88.80 and 596.85), Pusa aditya (205.35 and 588.25), Sheetal (241.70 and 717.30) and RH-749 (244.95 and 950.85), respectively. Whereas the minimum AUDPC on pod was recorded with variety GSL-5 (32.10) and Pusa aditya (200.25) followed by [GSL-2 (34.65) and Sheetal (206.65)], [Pusa aditya (39.35) and RH-749 (566.41)] and [Sheetal (60.95) and Pusa mustard-27 (741.75)], respectively. The maximum yield avoidable loss (%) was recorded T-27 (46.67%) followed by Jhumka (44.53%, Anuradha (40.00%), KBS-3 (38.77%) and Pusa gold (34.13%), respectively. Minimum avoidable loss (%) was recorded on cultivar GSL-5 (11.09%) followed by Anuradha (14.36%), GSL-2 (17.73%), RH-749 (17.90%) and Pusa aditya, respectively. In present investigation out of 15 genotypes examined for blight resistance, GSL-5, Pusa Aditya, Sheetal and GSL-2 exhibited good level of partial resistance i.e. moderately resistance. Other 11 varieties RH-749, Pusa gold, Pusa mustard-27, Jhumka, Anuradha, PT-30, PT-303, T-27, KBS-3, TMLC-2 and PM-25 were susceptible based on the mean basis severity (PDI), reduced apparent infection rate and lesser value of AUDPC.

INTRODUCTION

Rapeseed-mustard is one of the major oilseed crops cultivated in India and around the world. It is extensively grown traditionally as a pure crop as well as intercrop (mixed crop) in marginal and sub-marginal soils in the eastern, northern and north-western States of India (Singh *et al*, 2017). Rapeseed and mustard belong to family Brassicaceae, Indian mustard commonly known as *rai* is the most important member of Cruciferous oil seeds occupying nearly 70 per cent of the total area under rapeseed-mustard (Singh *et al*, 2014b). The leaves of young plants are used as green vegetable and whole plants as green fodder. The seeds are highly nutritive containing 38 to 57 per cent erucic acid, 4.7 to 13 per cent linoleic acid and 27 per cent oleic acid (Singh *et al*, 2011). The rapeseed and mustard group dominates among oilseed crops in area and production on global level. India is one of the largest rapeseed-mustard growing countries in the world, occupying the third position in area and production after China and Canada sharing 12 per cent of world's total production. At global level, rapeseed-mustard is cultivated on 5.96 million hectares with production of 8.32 million tonnes and productivity of 1397 kg/ha (Anonymous, 2018). Rapeseed-mustard is the second most important oilseed crop after groundnut and accounts for nearly 30.7 per cent of the total oilseed production in the country. There are several diseases known to affect the mustard crop but foliar diseases like Alternaria leaf spot, white rust (blister), downy and powdery mildews cause heavy yield losses to the crop. Alternaria blight caused by Alternaria brassicae (Berk.) Sacc and Alternaria brassicicola (Schw) Wiltshere is a worldwidely distributed and economically important disease on rapeseed (Brassica napus), mustard (Brassica campestris) and other brassicas (Singh *et al*, 2014a), Tewari and Conn (1993) , Kumar (1997), Meah *et al* (2002), Meena *et al* (2010). The characteristic symptom is the development of circular spots on leaves and pods with concentric ring. Later on spots coa-

First Report of Fusarium pallidoroseum (Cooke) Sacc. on Bael (Aegle marmelos Correa) causing Leaf Spot and Die Back Disease in Nursery

SANTOSH KUMAR, H K SINGH* AND SANJEEV KUMAR

ABSTRACT

Bael is a very popular indigenous fruit of India. Cultivation of bael is a lucrative venture because of its high pharmaceutical importance. The deciduous tree with trifoliate aromatic leaves offering of bael leaves is a compulsory ritual of the worship of lord shiva. In bael nursery, disease appeared during post rainy season (September) as irregular pustules, which was brown in colour, increases very fast and covers the most of the leaf area. After severe infection, affected leaves become dry and fall off. The disease progresses downward causing dieback symptoms but roots remain healthy and they produces new shoots after destroying the vegetative parts. This type of symptoms incited by Fusarium pallidoroseum (Cooke) Sacc. was identified as a causal organism. The pathogenicity test of the fungus was established. Fusarium pallidoroseum produce smooth and creamy white colony, grew rapidly on PDA medium at 25°C to 26°C and produced rose pink colored woolly to cottony, flat spreading colonies when mature. The mass of the mycelium was very compact in nature. The fungus produced both macro and micro conidia, which are hyaline, septate and ends are also hook shaped. Mycelia are thin and septate. Macro conidia were produced from phialides on unbranched or branched conidiophores. Macro conidia born in sporodochia were curved, possess a foot cell, 3-5 septate. Micro conidia are single celled, smooth, hyaline, ovoid to cylindrical.

INTRODUCTION

Bael (Aegle marmelos L. Correa) is one of the most utilitarian medicinal plants of India; it grows under adverse agro-climatic conditions. It is known by different names in different parts like Bengal quince, golden apple, stone apple, Bael and Sirphal maredu (Andhra Pradesh), bael (Bengal), bil (Gujarat), bil (Himachal Pradesh), bael (Hindi), bilpatra, kumbala, malura (Karnataka), vilwam (Kerala), bilwa (Sanskrit), kuvalum (Tamil Nadu). The deciduous tree with trifoliate aromatic leaves offering of bael leaves is a compulsory ritual of the worship of lord shiva. It has capacity to adapt successfully to a wide range of habitat from arid, semiarid to mesophytic conditions and a wide temperature tolerance (from -7°C to 48°C). The ripen bael fruits are popular among people because of the delicious fruit pulp, which is ideal for making jam, syrup and pudding. Bael possesses many medicinal values and theretore used as an ingredient in ayurvedic herbal medical preparations. The fruits, bark, leaves, seeds and roots of bael contain bioactive compounds such as coumarin, xanthotoxol, imperatorin, aegelineand marmeline. These compounds can provide anticancerous, antidiabetic, antimicrobial, antifertility, immunogenic and insecticidal activities. Bael is also essential as a species for reforestation, especially in the unfertile marginal lands. Bael seeds possess a unique fatty acid (12 hydroxyoctadeccis 9-enoic acid or ricinoleic acid) a convertible item into biodiesel (Pathirana *et al*, 2020). The importance of bael lies in its curative properties, make the tree one of the most useful medicinal plant of India. Disease causing agents have potential to imapare the quality of economic produces, and needs time and energy to for its effective management (Singh *et al*, 2013). Bael nursery plants suffer from a number of fungal foliar diseases namely root rot, collar rot and wilt caused by F. solani, leaf spot caused by Myrothecium roridum and Alternaria alternata (Anonymous, 2019).

MATERIALS AND METHODS

The field experiment was conducted at Main Experiment Station, Horticulture situated at main campus of Narendra Deva University of Agriculture and Technology, Kumargani, Faizabad (U.P.). This centre is situated between 26.47° N latitude to 82.12° E longitude and at an altitude of 113 m above mean sea level on Faizabad-Raibarelly road about 42 Km away from Faizabad city. The location falls under Indo-Gangatic plains of Eastern Utter Pradesh of North-India.

Isolation of pathogen

The diseased leaves were collected from the nursery of bael seedling showing distinct characteristics of symptoms, selected for the isolation of the pathogen. The leaves were washed with fresh sterilized water in order to remove the dust particles and surface contaminants. The washed leaves samples were cut into small bits with some healthy portions with

First report of *Myrothecium roridum* causing leaf spot on bael (*Aegle marmelos* Correa.) from India

Santosh Kumar and HK Singh

Abstract
Beal (*Aegle marmelos* L. Correa) is native across the Indian subcontinent and is found wild throughout the Indian Peninsula. Cultivation of bael is a lucrative venture because of its high pharmaceutical importance. The deciduous tree with trifoliate aromatic leaves offering of bael leaves is a compulsory ritual of the worship of lord Shiva. The importance of bael lies in its curative properties, make the tree one of the most useful medicinal plant of India. Bael plants suffer from a number of fungal foliar bacterial diseases namely root rot, collar rot, wilt, Alternaria leaf spot, bacterial shot hole, fruit canker, sooty mould and gummosis. In bael nursery/plant, disease appeared during post rainy season, disease symptoms recorded first during rainy season (July- August). Initial symptom were recorded on leaves as small, circular in shape which are brown in colour but later on these spots enlarges and cover the more area up to 40 mm in diameter and later become dark brown with grayish centre. Chlorosis around the lesions may be seen and concentric rings are produced on the middle of the spot on the leaves. Characteristic symptoms of this disease are formation of shot hole due to shedding of necrotic tissues of the leaves. In severe condition number and size of lesions increases, black sporodochia with white and marginal mycelia tuffs bearing black in colour spores masses were observed in the older lesions. This type of symptoms incited by *Myrothecium roridum* was identified as a causal organism. The pathogenicity test of the fungus was established. Fungus produces creamy white colonies on PDA which are 1.5 cm diameter after 5 days at 25+2 ^{0}C. Concentric pattern of sporodochia of *Myrothecium roridum* which are black in colour formed on PDA after 32 days of inoculation. Conidia were aseptate, hyaline, rod shaped and rounded to both ends.

To study the effect of different fungicides against Alternaria leaf spot of ber, fungus was isolated from the infected leaves of ber plant and cultural and morphological study was done through Poison Food Technique to find that the fungus was *Alternaria alternata* having branched and septate mycelium with light brown to blackish conidiophores in acropetal chain and the conidia having olive green to dark brown colour with transverse and longitudinal septa. The evaluation of the fungal growth was done with chemical fungicides. A total of nine fungicides were tested at 100, 250, 500, 1000, 1500, 2000 and 2500 ppm concentrations, out of which Hexaconazole 5% EC (97.95%) showed maximum mycelium growth inhibition followed by Tebuconazole 25% EC (96.57%) and Tebuconazole 25% + Trifloxystrobin 25% WG (95.27%) while minimum inhibition was by Propineb 70% WP (78.41%) followed by Carbendazim 50% WP (79.17%). The fungicides tested in present study have also shown potential in controlling *A. alternate* leaf spot disease of Ber.

Introduction

Indian jujube or ber (*Zizyphus mauritiana* Lamk.) is one of the most common fruit trees grown in tropical and sub-tropical regions, indigenous to an area stretching from India to South West China and Malaysia. It belongs to family *Rhamnaceae*. It is commonly called as Poor man's fruit. Ber is mostly grown in arid and semi-arid regions. The area occupied by Ber in India is over more than 50,000 ha of land with a production of 513,000 MT (Anonymous, 2018; Kaur *et al.*, 2020). It is grown for different purposes *viz*., fruits, green fodder, green manure. The production of ber in terms of fruits and fodder is limited mostly due to the *Alternaria* leaf spot disease caused by *Alternaria alternata*. The fruit are widely acknowledged as a rich and cheap source of minerals such as iron, calcium and

Abstract

Evaluation of different botanicals against alternaria leaf spot of ber (*Zizyphus mauritiana* Lamk.) was done under *in-vitro* at the NDUAT, Kumarganj main experiment station of Horticulture and Plant Pathology laboratory during 2018 to 2020. The fungus was isolated from the infected leaves of ber plant and cultural and morphological study was done through Poison Food Technique to confirm that the fungus was *Alternaria alternata* having branched and septate mycelium with light brown to blackish conidiophores in acropetal chain and the conidia having olive green to dark brown colour with transverse and longitudinal septa. The growth of the fungus was tested with botanicals. The nine different botanicals *ie. Azadirachta indica* (Neem), *Allium sativum* (Garlic), *Parthenium hysterophorus* (Parthenium), *Ocimum sanctum* (Tulsi), *Datura stramonium* (Dhatura), *Curcuma longa* (Turmeric), *Zingiber officinale* (Ginger), *Allium cepa* (Onion), *Eucalyptus oblique* (Eucalyptus) were tested against *A. alternata* infection in ber leaves. 100-gram leaves or cloves or rhizomes from each plant were collected and after washing extract was prepared in 100 ml distilled water. The extract was filtered through muslin cloth and then sterilized by passing them through a Millipore filter using a swimming filter adapter. All the botanicals were tested at 10%, 15% and 20% concentration, out of which garlic (74.88%) showed maximum mycelium growth inhibition followed by ginger (73.51%) and *neem* (69.25%), while minimum inhibition was found by Parthenium (34.64%) followed by Dhatura (53.37). It was concluded that the botanicals are also effective in controlling the alternaria leaf spot of ber.

Keywords: *Alternaria alternata*, ber, botanicals, leaf spot disease, phytochemical

1. Introduction

The Ber (*Zizyphus jujube* Lamk.) is mainly grown as a fruit tree in wide range of tropical and sub-tropical and Mediterranean region, is native of India and spread over more than 50,000 ha of land with a production of 513,000 MT (Pareek, 1983., Singh et al., 2016; NHB, 2018., Kaur et al., 2020). "Zizaif" is the Arabic name of the fruit which has been derived from the genus *Zizyphus*. It is commonly called as Poor man's fruit. In India, it is commercially cultivated in Haryana, Punjab, Maharashtra, Uttar Pradesh, Rajasthan, Madhya Pradesh, Bihar, Andhra Pradesh and Tamil Nadu. In U.P., Ber orchards are found in Varanasi, Faizabad, Agra, Raebareli districts. The fruit are widely acknowledged as a rich and cheap source of minerals and other nutrients such as iron, calcium and phosphorus, ascorbic acid, carbohydrates and essential minerals (Abbas et al., 1988; Pareek et al., 2002; Alam et al., 2017). The importance of ber is due to the fact that it is hardy fruit which can be grown in alkaline soils with pH as high as 9.2. However, deep sandy loam to loamy soils with neutral or slightly alkaline pH are considered optimum for growth. A principal limiting factor in profitable cultivation of Ber tree is the attack of several diseases mainly fungi which cause heavy crop loss at all the stages, right after initiation of leaves to fruiting and harvest stage. Some important fungal diseases are powdery mildew (*Oidium erysiphoides* f.sp. *ziziphi*), rust (*Phakospora zizyphus vulgaris*), leaf spot (*Alternaria alternata*, *Cercospora zizyphi*, *Cladosporium zizyphi*, *Phoma macrostoma*) and mouldy leaf spot (*Isariopsis indica* var. *zizyphi*). Ber black fruit spot disease caused by *Alternaria alternata* reduces the fruit quality and also yield of the ber (Bai., et al., 1915; Kumar et al., 2015; Manjot et al., 2019; Kaur et al., 2020; Wang et al., 2021: Ajayabhai et al., 2018). The leaf spot disease caused by *Alternaria alternata* is an important disease in the major crop growing areas of the country. The disease leads to formation of irregular brown spots on the upper surface of leaves followed by dark brown to black spots on the lower surface. Later on, the spots coalesce and leaves drop off. The disease occurs widely in crop grown in deep sandy loam to loamy soils. Alternaria leaf spot was a minor disease, but due to climatic changes, it emerged moderately to severe form nowadays.

Documentation variation for Alternaria blight resistance in varieties of Rapeseed mustard

Sumant Pratap Singh, NA Khan, Reeshu Singh, HK Singh, S Prasad and DK Dwivedi

DOI: https://doi.org/10.22271/chemi.2020.v8.i4m.9793

Abstract
The study was conducted with the objective to assess the resistance source against blight in rapeseed-mustard at Student's Instruction Farm, Acharya Narender Deva University of Agriculture and Technology Kumarganj Ayodhya (U.P.) during *Rabi* 2018-19. Screening of Indian mustard 47 genotypes, these screening was not found highly resistant, resistant and moderately resistance against Alternaria blight of rapeseed mustard six genotypes *viz*., Kiran, TMR-14-6, TMR-14-1, TMR-14-5, TMR-14-3, TMR-14-4 with disease severity of 5-10 per cent respectively were rated as moderately susceptible were found nine genotypes with disease severity 11-25 percent. 31genotypes were marked as susceptible in which disease severity was found to be 26 to 50%. The highly susceptible only one genotypes was found to be >50 present with disease severity respectively. It could be noticed that the vulnerability level was relatively quite high as compared to resistance status.

Keywords: Rapeseed- mustard, Alternaria blight, disease reaction, screening

Introduction
Brassica species are the largest oilseed crop in the world oilseed production followed by peanut (*Arachis hypogaea* L.) and sunflower (*Helianthus annus* L.). In India, rapeseed-mustard is grown over in diverse agroclimatic conditions ranging from north-eastern/north-western hills to down south. These crops require cool growing season and moderate temperature throughout, hence are sown in the month of 1 November to 15 November in northern India (Das *et al*., 2009) [4].

Brassica juncea (L.) Czern & Coss., also known by the name of Indian mustard, belongs to the plant family *Brassiceae* (*Cruciferae*) or the mustard family. It is commonly referred to as Rapeseed-mustard along with four other closely related cultivated oilseed species *viz*. *B. rapa*, *B. napus*, *B. carinata* and *Eruca sativa*. Indian mustard is largely self pollinated. Indian mustered (*B. juncea* L. czern and coss). popularly known as rai, raya or laha is one of the most important oil seed crop of the country. *Brassica juncea* (n = 18) is an amphidiploid species derived from interspecific crosses between *B. nigra* (n = 9) and *B. rapa* (n = 10).

Rapeseed mustard are the world's third most important sources of vegetable edible oil. It also contains adequate amounts of the two essential fatty acids, linoleic and linolenic, which are not present in many of the other edible oils. The oil is also used as hair oil and as lubricant. A peculiar use of mustard oil is to retard the fermentation process when making cider from apples. Vegetable oils and fats are valuable food ingredients in human diet. They contain saturated and unsaturated fatty acids. The Indian mustard have nutritional value *viz*., carbohydrates 4.51g, sugar 1.41g, dietary fiber 2g, fat 0.47g and protein 2.56g per 100 g (3.5 oz). It is a good source of protein (28-36%).

The tender leaves of these cultivars serve as vegetable, while the seeds as a source of lubricating and cooking oil. The residue left after oil extraction being rich in protein (Durrani and Khalil, 1990; Chattopadhyay *et al*., 2005) [6, 3] can be used as livestock feed. It produces 9 k cal energy from 1gm of oil per unit in comparison with other diets (carbohydrate and Protein). Mustard seeds have relatively high protein content (28-36%). Until now mustard seeds have been used mainly for condiment production. (Gadei *et al*., 2012) Mustard oil contains a high amount of selenium and magnesium, which gives it anti-inflammatory properties.

Rapeseed-mustard belongs to family Brassicaceae. It is the most important group of *rabi* oilseed crops and contribute a major share to the vegetable fat of the country. Effectiveness of the six fungicides *i.e.* Quintal (Iprodione 25% + Carbendazim 25%), Nativo (Tebuconazole 50% + Trifloxystrobin 25% 75GW), Tilt (Propiconazole 25 EC), Score (Difenoconazole 25 EC) and Propineb (Antracol 70 WP), Folicur (Tebuconazole 250 EC) were used at three concentrations of each @ 0.05, 0.1 and 0.2 per cent and one is no treatment (control) under *in vitro* against *Alternaria brassicae* by poison food technique. At 0.05% concentration of fungicides the minimum growth was recorded in Iprodione 25% + Carbendazim 25% (47.47mm) followed by Propineb 70 WP (52.56mm) had significantly reduced the mycelia growth of tested pathogen by food poison technique than the control (90.00mm). In case of 0.1% concentration of fungicides the minimum growth was recorded in Iprodione 25% + Carbendazim 25% (38.09mm) followed by Propineb 70 WP (43.00mm) had significantly reduced the mycelia growth of tested pathogen than the control (90.00mm). In case of 0.2% concentration of fungicides the minimum growth was recorded in Iprodione 25% + Carbendazim 25% (27.84mm) followed by Propineb 70 WP (30.84mm), had significantly reduced the mycelia growth of tested pathogen than the control (90.00mm). Four treatments namely Tebuconazole 250 EC + Trifloxystrobin WG 75; Propiconazole 25 EC; Difenoconazole 25 EC and Tebuconazole 250 EC were tested by poison food technique *in vitro* and result cent per cent restriction of radial growth of *Alternaria brassicae* in 0.05%, 0.1% and 0.2% concentration.

Introduction

Rapeseed-mustard belongs to family Brassicaceae, which is grown in northern India comprising traditionally grown indigenous species namely Indian mustard (*B. juncea*), brown *sarson* (*B. campestris* var. brown *sarson*), yellow *sarson* (*B. campestris* var. yellow *sarson*), toria *(B. campestris* var. toria), taramira (*Eruca sativa*), gobhi *sarson* (*B. napus*), white mustard *(B. alba)* and Ethiopian mustard (*B. carinata*). It is the most important group of *rabi* oilseed crops and contribute a major share to the vegetable fat of the country. Oil and fats comprise a vital component of human diet as these are good

A B S T R A C T

Ber (*Zizyphus mauritiana* Lamk) is one of the important fruit crops of arid and semi arid zones of the world. In India though it is a minor fruit but recently the ber become an important cash crop in some areas and its acreage and production are increased. Due to rapid spread of commercial cultivation, the crop is also affected by different biotic and abiotic factors including pathogens causing many serious diseases. Among the diseases, *Alternaria alternata* is one of the most important, widespread and easily recognized disease. The disease is characterized by the formation of small, irregular brown spots on upper surface of leaves. Corresponding lower side appears with dark brown to black spot 3 to 6 mm in diameter with a gray to tan centre and distinct brownish yellow margins. Under humid conditions, black patches comprising plenty of conidia can be seen and which severe as air borne inoculation. As in case of ber plants, under severe conditions many spots coalesce to form big patches and later such leaves defoliated from branches. In varietal screening, forty varieties/germplasm was screened against *Alternaria alternata* (Fr.) Keissler. It was recorded that none of the variety was found free from disease and only 3 germplasm, Narendra ber Selection-1 (3.50%) Seo (4.0%) and Narendra ber Selection-2 (4.60% area covered with the pathogen) were found resistant and 20 genotypes having disease intensity 5.01 to 20% area covered with the pathogen were moderately susceptible, 13 genotypes having disease intensity to 20.01 to 50% area covered with the pathogen were susceptible and 4 genotypes namely genotypes having disease intensity > 50% area covered with the pathogen were found highly susceptible.

Introduction

Indian jujube or ber (*Zizyphus mauritiana* Lamk.) is one of the most common fruit; indigenous to an area joined from India to China belongs to family Rhamnaceae. It is also known as Chinese date or Chinese fig or plum and commonly considered as poor man's fruit. It is popularly called the king of arid zone fruit (Yamadagni, 1985; Shoba and Bharathi, 2007; Mishra *et al.*, 2013). This fruit probably originated in India. It is reported to be grown in other countries like Iran, Syria, Australia, USA, France, and certain part of Italy, Spain, Africa, etc. Precisely, it is seen to grow under tropical and

ABSTRACT

Alternaria blight is a destructive disease of rapeseed-mustardcaused by *Alternaria brassicae* (Berk) Sacc. and *A. brassicicola* (Schw). The field experiments were conducted during 2013-14 and 2014-15, with 200 genotypes for evaluation of their resistance to Alternaria blight, as well as to develop effective management strategies for this disease. None of the genotypes were found disease-free or highly resistant, only 7 genotypes namely (DLSC-1, DRMR-261, DRMR-270, GSC-101, GSL-1, NPC-20, and PHR-2) were found resistant, 15 genotypes were rated as moderately resistant. Rest of the genotypes was either recorded susceptible or highly susceptible. For disease management, newly molecules of 6 fungicides were evaluated with 13 treatments combinations for their effectiveness. Propiconazole 25% EC @ 0.10% was found most effective in reducing the disease severity followed by the same fungicide @ 0.05%. It was followed by Hexaconazole 5% SC @ 0.010%. Maximum test weight and yield were also recorded with the sprays of Propiconazole 25% EC @ 0.10% followed by the same fungicide @ 0.05%. In comparison to other fungicides, the maximum B:C ratio was recorded with three sprays of Hexaconazole 5% SC @ 0.05% followed by Propiconazole 25% EC @ 0.05%.

INTRODUCTION

The oilseed crops, especially *Brassica* spp. play a pivotal role in the agricultural economy of India. Rapeseed-mustard, among these, are most important *rabi* crops. India is one of the leading countries with respect to production, consumption ,and import of vegetable oils (Singh *et al*.,2013). Alternaria blight caused by *Alternaria brassicae* (Berk) Sacc. and *A. brassicicola* (Schw) Wiltshire is one of the major limiting factor, causing yield losses from 17 to 45% in mustard (*Brassica juncea* L.) (Singh and Singh, 2005a, Singh and Singh, 2006, Kumar *et al*., 2009) and upto 70% in rapeseed of yellow *sarson* and brown *sarson* (*Brassica compestris*) (Kolte, 2002). The blight also reduces the seed size; seed colour and oil content. In the absence of resistant cultivars, the disease was managed through cultural practices and by using different fungicides up to certain levels (Singh and Singh, 2005b, Singh *et al*., 2008 and Singh *et al*., 2013).

Since the chemical compound is not safe for the human being, animals even also to the microbes (Ko and Farley, 1969). The ideal and most economical means of managing the Alternaria blight disease of rapeseed and mustard would be the use of resistant varieties. In the absence of resistant cultivars, chemical fungicides provide the most reliable means of disease control (Singh *et al*., 2014). Therefore, in the present study, efforts have been made to find out suitable genotypes, newly molecule of fungicides for the management of *Alternaria* blight of mustard.

MATERIALS AND METHODS

The investigations were carried out at Genetics and Plant Breeding Research Farm and in the laboratory of the Department of Plant Pathology, N.D. University of Agriculture &Technology, Kumarganj, Faizabad, Uttar Pradesh, India. This investigation consisted of two separate components *i.e.* varietal screening for host resistance and use of newly molecule fungicides in Indian mustard [*Brassica juncea* (L.) Czern & Coss.]for the management of the disease.

Varietal resistance:

Two Hundred (200) promising genotypes/cultivars supplied by Directorate of rapeseed-mustard research, Sewar, Bharatpur, Rajasthan were normals own in the first week of November during 2013-14 and 2014-15*rabi* season. All the entries were planted in paired rows and replicated twice. Plant to plant and row to row spacing was maintained as 30x10cm. The crop was fertilized with NPK in the ratio of 120:60:60 kg/ha to obtain a good crop. The disease severity was recorded following scale as per the recommendation of All India Coordinated Research Project on Rapeseed-Mustard, 2017 which is as under. [0=No lesion [Immune (I)]; 1= Non sporulating pinpoint size or small brown necrotic spots, less than 5% leaf area covered by the lesions [Highly resistant (HR)]; 3= small roundish slightly sporulating larger brown necrotic spot, about 1-2 mm in diameter with a distinct margin or yellow halo, 5-10% leaf area covered by lesions [Resistant (R)]; 5= moderate sporulation, non-coalescing larger brown spots, about 2-4mm in diameter with a distinct margin or yellow halo, 11-25% leaf area covered by the lesions

SHORT COMMUNICATION

Genetics and allelic relationship between genes conferring resistance to wilt in linseed

M. P. Chauhan[1] · H. K. Singh[2] · J. K. Yadav[2] · S. K. Singh[3]

Received: 15 November 2017 / Accepted: 29 January 2018 / Published online: 15 March 2018
© Indian Phytopathological Society 2018

Abstract
The inheritance of resistance against wilt caused by *Fusarium oxysporum* f. sp. *lini* in linseed was studied in F_1, BC_1, BC_2 and F_2 generations of three resistant varieties, Nagarkot, Shekhar and NDL 2004-05 crossed with two susceptible cultivars, Chambal and Shikha. On the basis of the segregating ratio obtained in F_2 and back cross generations of the two crosses, Nagarkot × Chambal and Nagarkot × Shikha, the disease resistance was controlled by two recessive alleles with complimentary gene action in the variety Nagarkot. On contrary, in the cross Shekhar × Chambal and Shekhar × Shikha two dominant genes with complimentary gene action confirming wilt resistance in Shekhar. In NDL 2004-05 × Chambal and NDL 2004-05 × Shikha, reaction of linseed plants to wilt in F_1, BC_1, BC_2 and F_2 generations suggested that resistance to disease is under monogenic control with one dominant gene responsible for resistance in NDL 2004-05. These resistant genotypes may be used as donor for transferring resistance in otherwise susceptible cultivars using breeding programme.

Keywords Genetics · Linseed · Resistance · Wilt

Linseed is one of the oldest oil seed crop cultivated by human being for food, fibre, industrial and value addition. Recent advances in neuro-biology have established that it is best herbal source of Omega-3 fatty acids which helps in regulating the nervous system. The lustrous fibre of linseed coupled with strength, durability, blending quality with natural and artificial fibres has made its fibre an essential raw material for high value linen fabrics and paper industry for use of printed bank notes and cigarettes. The unique and diverse properties of linseed are reviving interest in this crop and because of its adaptability and product diversity, it is being considered as a platform for the development of novel bio-products. India ranks second in area after Canada in the world, but is at fourth place in terms of production after Canada, China and USA. In terms of productivity India (435 kg/ha) is far below to Canada (1492 kg/ha), USA (1484 kg/ha), Egypt (1465 kg/ha), Russia (1292 kg/ha) and China (944 kg/ha) (Anonymous 2015). The linseed crop is affected by several diseases throughout the world. Wilt caused by *Fusarium oxysporum* Schl. f. sp. *lini* (Bolley) [Snyder and Hansen (Syn. f. sp. *lini* Bolley)] is the most serious disease of linseed (Kishore et al. 2011). The first record of this disease was by Luggar (1890) from Minnesota, USA. In India, the disease was first reported from Madhya Pradesh (Pearl 1924). The plants are susceptible at all growth stages and growth of the plant ceases when infected at seedling state. Leaves at ground level get constricted, gradually wither off and die out. In the grown up plants, ill-defined dark green or brownish spot develops on the leaves. Such leaves shrivel and dry off followed by drooping off and death of the plants. Kumar et al. (2015) reported loss up to 80% under conditions favourable for wilt development. However, extent of damage largely depends upon incidence of disease and time of attack during the crop season (Vasudeva 1962). In the severe form of the disease, the crop may be completely destroyed. Use of resistant cultivars are the best options available for the management of the wilt. Therefore, the breeder has to look the gene(s) for resistance in the genotypes. The information on inheritance

Alternaria blight caused by *Alternaria brassicae* (Berk) Sacc. and *A. brassicicola* (Schw) Wiltshire is one of the most common and destructive disease of rapeseed-mustard. The experiments were conducted under field condition to develop effective management strategies for this disease through evaluation of genotypes for resistance and application of fungicide, bio-agents and botanical. Out of 200 promising genotypes evaluated for resistance, none of the entry was found resistant, twenty two genotypes namely DLSC-1, DRMR-261, DRMR-270, GSC-101, GSL-1, NPC-20 and PHR-2, CNH-11-13, CNH-11-7, EC-552608, HNS-1001, PAB 04-10, PAB 05-16, PAB 05-19, PAB 09-05, PAB-2004-4, PAB-2005-16, PPBJ 5, PPBJ-2, PPBJ-3, PPBN 3 and PPBN-2 were moderately resistant and 63 genotypes moderately susceptible. Seed treatment with Apron @ 6g/Kg seed and spray of all fungicides, bio-agents and botanical extract, significantly reduced the blight severity in comparison to the untreated control (water spray). Of the fungicides, Nativo @ 0.05% was found most effective followed by Difenconazole @ 0.05%, Iprodione @ 0.2, Folicure @ 0.2, Difolatan@ 0.2, Mancozeb @ 0.2, Antracol @ 0.25, *Pseudomonas fluorescens* @ 1.0, *Trichoderma harzianum* @ 1.0 and Garlic bulb extract @ 1.0 which showed 8.70%, 14.62%, 16.27%, 16.41%, 18.54%, 20.51%, 21.42%, 24.27%, 25.42%, and 26.83% severity, respectively after third spray of each chemical, bio-agents and botanical extract. The disease severity of water spray control was 69.10%. Same tread was also recorded with per cent disease control. Maximum seed yield (kg/ha) and yield increase (%) of 1740.22, 37.90 was recorded with the treatment Nativo @ 0.05% followed by Difenconazole @ 0.05% (1629.61, 29.16), Iprodione @ 0.2 (1617.11, 28.17), Folicure @ 0.2 (1587.50, 25.85), *Trichoderma harzianum* @ 1.0 (1525.68, 20.93), Difolatan @ 0.2 (1516.98, 2024), *Pseudomonas fluorescens* @ 1.0 (1512.37, 1987), Antracol @ 0.25 (1511.45,19.80), Mancozeb @ 0.2 (1507.99, 19.52), respectively. The maximum benefit cost ratio 1:12.60 was obtained with Garlic bulb extract @1.0 followed by *Trichoderma harzianum* @ 1.0 (1:6.0), Nativo @ 0.05% (1:4.01), *Pseudomonas flurescence* @ 1.0 (1:3.79).

In case of fungicidal trails all the treatments reduced the disease severity in comparison to unsprayed plots. The severity of disease after eight spray of Mancozeb @ 0.2 % was found minimum disease severity (5.0 %) followed by seven spray (6.0 %) and six spray (10.33 %), respectively. Maximum seed yield of 2000kg/ha was recorded with eight spray of Mancozeb @ 0.2% followed by seven spray (1922.22 kg/ha), and six spray (1902.77 kg/ha), respectively. Similar trend was recorded in case of test weight also. All the treatments avoided test weight loss of 5.70 to 21.81 %. Maximum being with eight and seven spray of Mancozeb @ 0.2 % (21.81 %) followed by six spray (21.67 %) and five spray (20.81 %).Maximum yield loss of 48.61 per cent was also avoided with eight spray of Mancozeb @ 0.2 % followed by seven sprays (46.53 %) and five spray (45.94 %).The maximum benefit cost ratio of 1:7.94 and 1:7.18 were obtained with four and three spray of Mancozeb @ 0.2 % followed by five sprays (1:6.82) and two spray (1:6.11).

Introduction

Oilseed crops play an important role in agricultural economy of India. Oilseed brassicas often called rapeseed-mustard Kumar *et al.*, (2014) placed in *Brassicaceae* family which contains about 3500 species and 350 genera, is one of the 10 most economically important plant families. According to ancient scripture and literature, it has been cultivated as early as 5000 BC. There is evidence of its cultivation in Neolithic age. Seeds of mustard were found from the Channhudaro of Harrapan civilization ca. 2300-1750 BC. Among the oilseed brassicas, mustard (*Brassica juncea*), yellow sarson (*B. campestris* var. *yellow sarson*), brown sarson (*B. campestris* var. *brown sarson*), toria (*B. campestris* var. *toria*), oilseed rape (*B. napus*) and Karan rai (*B. carinata*) are grown for edible oil whereas black mustard (*B. nigra*) is used as a condiment for pickle making Kumar *et al.*, (2014).

Among rapeseed-mustard, Indian mustard [*Brassica juncea* (L.) Czern & Coss.] is one

ABSTRACT

Sixty six genotypes of linseed were analysed for the morphological traits to investigate the genetic diversity between and within the genotypes. The field data was initially subjected to analysis of variance. There were highly significant differences among the genotypes for all the traits indicating the presence of variability among the genotypes and the possibility to undertake cluster analysis. The phenotypic divergence and relative importance were estimated by multivariate analysis. The cluster analysis classified linseed genotypes in to nine major groups. The maximum intercluster diversity was observed between cluster VIII and V. Based on mean performance of the genotypes and intercluster distance the crosses between ICAR Sel-1 and L-9, NDC 2005-34, H660, LCK 87042, NDL2005-22, GS335 is recommended to get use full transgressive sergeants in linseed.

Key words: Crosses, Diversity, Genotypes, Intercluster, Linseed

INTRODUCTION

Linseed/flax is among the oldest crop plants cultivated in temperate climate for the purpose of oil and fibre (Pati and Mehta, 2015). Recent genetic diversity studies suggest that flax may have initially selected as an oil seed crop. Linseed a minor crop is grown in a wide range of countries (47), climates, cropping situations and for many products. At present it is widely cultivated in Asia, Europe, Americas and Africa for oil and fibre. In South west Asia including Turkistan, Afghanistan, India, Nepal and Canada it is primarily cultivated for oil whereas in Russia, Egypt and Near the North western Europe it is mainly cultivated for the production of high quality fibre for making linen fabrics and several other products (Anonymous, 2017).

Breeding programmes is currently focused on enhancing oil content and nutritional value to meet the demand of nutraceutical market. The lustrous fibre of linseed coupled with strength, durability, blending quality with natural and artificial fibres has made its fibre an essential raw material for high value linen fabrics and paper industry for use of printed bank notes and cigarettes. Studies on variation in the germplasm are very useful for developing high yielding disease and insect pest resistant cultivars. The available germplasm serves most valuable natural reservoir in providing donor, parents for in corporating or importing the characteristics by genetic reconstruction of plant for developing high yielding crop varieties.

The proper evaluation of germplasm is essential for understanding its potential value as a breeding material as the success of any breeding programmes depends upon nature and extent of variability present in the germplasm collection. In view of these facts, large numbers of germplasm lines (sixty six) were evaluated in the present investigation.

MATERIALS AND METHODS

A total number of sixty six genotypes of linseed were used in the present study. All the genotypes including three checks T 397, Mukta and Hira were raised at Genetics and Plant Breeding Farm of N.D. University of Agriculture and Technology, Kumarganj, Faizabad (U.P.) during rabi session 2015-16under irrigated conditions for recording the data. The experiment was laid out in augmented block design. The experimental field was divided into three blocks of twenty four plots. The checks were distributed randomly in each block. Each plot consisted of double row of 5 meter length spaced 30 cm apart with plants to plant distance of 10cm observations on the ten traits were recorded viz: days to 50 % flowering, plant height (cm), number of primary branches / plant, number of secondary branches /plant, number of capsules / plant, number of seeds / capsule, biological yield per plant (g), seed yield per plant (g), harvest index (%)and test weight (g).

Five randomly selected plant were tagged from each row for taking observation of all the traits except days to 50% flowering which was recorded on line basis. The data recorded for each genotype was subjected to statistical analysis. Harvest index in per cent was calculated by dividing the seed yield per plant in grams by the biological yield per plant in grams. The data were subjected to statistical analysis to work out mean range as per standard methods. The genetic divergence was studied by employing and non–hierarchical Euclidean cluster analysis (Beale, 1969; Spark, 1973).

ABSTRACT

Early blight caused by *Alternaria solani* is a severe constraint in potato production. The severity of this disease has been increasing day by day for last few years in India due to changes in weather. Disease severity and area under disease progress curve (AUDPC) was recorded in each treatment plot. The early blight disease had significant negative correlation with maximum relative humidity during 2012-13 and in year 2013-14 minimum temperature was significantly correlated. The severity of early blight showed significant positive correlation with maximum temperature and highly significant positive correlations with sun shine hours in year 2013-14 in all tested treatments. The study showed that minimum temperature and rainfall revealed negative but non-significant correlation in all treatments except untreated control in year 2012-13. The maximum tuber yield 223.70 and 222.00 q/ha in first and second years, respectively, were recorded with spray of Fenamidone @ 0.2% at disease initiation and 2nd spray of Mancozeb @ 0.25% followed by Mancozeb @ 0.25% at 15 days intervals in both respective years.

Key words: Early blight, *Alternaria solani*, Infection rate, Severity, Potato, Fungicides

INTRODUCTION

Potato (*Solanum tuberosum* L.) belongs to family Solanaceae and it is the most important crop among the all vegetables. Potato crop suffers from a number of fungal diseases and causes 20 to 64 per cent losses in yield when favourable condition prevailed. It is attacked by several pathogens, causing serious diseases. Among fungal diseases, early blight is a major one on potato. It is caused by fungus *Alternaria solani* (Ell. and Mart.) Jones and Grout is the most important disease attacking potato plants in different countries of the world. The disease in severe stage can lead to complete defoliation. It is most damaging on potato in regions with heavy dew, rainfall, high humidity, and fairly high temperature (24-29°C). *A. solani* has the capability to grow over a temperature of 4-36°C. Temperature is one of the most important uncontrollable factors affecting crop yield and heat stress is an agricultural problem in many areas in the world (Birch *et al.* 2012).

At global level annual production of potato during 2013 was 453.44 million tonnes covering an area of 19.92 million hectare with the productivity of 22.8 tonnes per hectare. Indian contribution to the world's production was 45.34 million tonnes from 1.99 million hectare area with average productivity of 22.8 tonnes per hectare (Anonymous, 2013). The management of potato crops against this pathogen is important to maximize the crops' yield. The disease occurs throughout the major potato production areas and it is difficult to produce both the crops during the main rainy season without chemical protection measures (Sahu *et al.* 2013a; Kumar and Shrivastava, 2013). Several components are available on their management. Basically, this disease is controlled with chemicals. Several chemicals, derivatives of chlorothalonil, are more effectiveness for potato late blight control and early blight also, compared to copper based products. A number of control measures for minimizing the disease losses have been recommended by different workers but the use of resistant cultivars remains the most reliable and economical one. Environmental factors play a key role in the development of the disease. The spores remain on the soil surface and on the leaves. Early blight develops more rapidly during periods when environmental conditions alternate between humidity and drought.

In recent years, many studies have been carried out to examine the presence and dispersion of pathogenic fungal spores in crops (Olga *et al.*, 2010). Many authors have developed epidemiological models, in order to predict when the disease will occur and to improve the use of control measures. The correlation between weather and disease severity has been recognized by many authors in different parts of the world (Devi and Chanu, 2012). Atmospheric *Alternaria* spores, temperature and humidity are the factors that most closely correlate with the occurrence of this disease. In the present study, investigation was carried out to elucidate relationship between weather variables and disease progression and evaluate the fungicides in different spray schedules for management of early blight disease. Keeping in view the need of management practices with meteorological factors, the "study on early blight development and infection rates under field conditions" is undertaken with objectives: To

ABSTRACT

Among the oilseed *Brassica* crops, Indian mustard [*Brassica juncea* (L.) Czern & Coss.] is an important source of oil from a nutritional point of view. The nutritional value of oil and cake quality is governed mainly by the composition of its fatty acids, iodine value, saponification, acid value, glucosinolates, crude fibre, protein and limiting amino acids, etc. Seventeen varieties/strains of Indian mustard were taken for saturated and unsaturated fatty acid analysis. The eicosenoic was absent in genotype (NUDBYJ-10) and erucic acid (NUDBYJ-10, LES-46 and Pusa mustard- 21). The fatty acid composition found a variable in different genotypes. Saturated fatty acid, Palmitic + Stearic ranged between 2.3 to 6.5%, Oleic 10.6 to 40.7%, Linoleic 16.1 to 37.7%, Linolenic 13.3 to 26.7%, Eicosenoic 0.00 to 10.30% and Erucic acid 0.00 to 47.50%, respectively. Alternaria blight severity also varied in different genotypes and ranged between 18.75 to 56.25%, maximum being in genotype Kranti and minimum in LES-47. No significant correlation was observed between the fatty acid composition and disease severity. The oil content range from 38.1 to 42.60% and protein content was found highest in variety RGN-73. The amino acid viz. methionine and tryptophan range between 0.41 to 1.81 g/16gN and 0.41 to 1.81 g/16g N, respectively.

Keywords: Indian mustard, Fatty acid, Alternaria blight, Methionine, Tryptophan

INTRODUCTION

Brassicas are members of the Brassicaceae family (Singh *et al.*, 2017a). They occupy a unique position in world agriculture as the source of vegetables, oilseed, forage and fodder, green manure and condiments. *Brassica* seed oil is used for the edible purpose, as industrial lubricants and as a base for polymer synthesis. Oilseed brassica cake is used as a source of protein in animal feeds (Singh *et al.*, 2017b). Among the oilseed *Brassica* crops, Indian mustard [*Brassica juncea* (L.) Czern and Coss.] is an important source of oil from a nutritional point of view (Singh *et al.*, 2014). The nutritional value of oil is governed mainly by the composition of its fatty acids *viz.* Palmitic acid, Stearic acid, Oleic acid, Linoleic acid, Linolenic acid, Eicosenoic acid, Erucic acid along with anti-nutritional factors (Singh *et al.*, 2017a).

Indian mustard has a higher amount of erucic acid and glucosinolates in its oil and meal, respectively (Kewat, 2002). The high amount of glucosinolates in the meal and erucic acid in oil may create health problems *viz.* lipidopsis in young animals, fibrosis in older animals, reduce food intake, causes goitre, stroma and cancer (Singh *et al.*, 2013). In *Brassica* breeding, considerable emphasis is being laid to develop the varieties with low glucosinolates and low erucic acid. The development of rapid and accurate methods for determination of glucosinolate levels in seed in early 1960's led to the identification of *B. napus* cultivar "Bronowski" from Poland. The first double low spring *B. napus* cultivar "Tower" was released in 1974 and afterwards, a number of double zero cultivars were identified in different countries of the world. In India till date, the main emphasis has been to improve the rapeseed-mustard seed yield and oil content. It is necessary that seed oil quality especially the fatty acid composition also be improved wherever possible. Keeping this in view there is a need to screen/develop Indian mustard varieties having low erucic acid (Singh *et al.*, 2013).

MATERIALS AND METHODS

Seeds of seventeen genotypes of Indian mustard were obtained from different coordinating centers of AICRP on Rapeseed-mustard and Department of Genetics and Plant Breeding of ND University of Agriculture and Technology, Kumarganj, Faizabad and were sown at GPB Farm of the University. Five plants of each genotype were bagged for self-pollination and seeds were collected for a further study of chemical composition. Incidence and severity of Alternaria blight disease on each genotype were also recorded. The collected seeds were sun-dried followed by oven drying and were used as the experimental materials in the present investigation for chemical composition analysis. The oil content was determined by Soxhlet Extraction Procedure using petroleum ether (boiling point range 40-60°C) by AOAC (1970).

Oil content

Seed sample was kept in the oven at 70°C for removal of moisture. After removal of moisture, the seed was ground in mortar and pestle for extraction of oil. The conventional

ABSTRACT

Effect of different doses of sulphur and zinc application was studied on Indian mustard [*Brassica juncea* (L.) Czern & Coss.] for protein, methionine, tryptophan, allyl-isothiocynate, mineral status content in oil/cake and Alternaria blight severity (%). The highest protein content was obtained in Varuna variety followed by strain NDR 8501. Application of 40 kg sulphur and 40 kg zinc resulted in highest protein percentage over control in seeds of mustard. Methionine content ranged from 0.743-1.561 g/16g N in Varuna variety whereas it varied from 0.899 to 1.503 g/16 g N in strain NDR 8501. Methionine contents were increased significantly due to the application of sulphur and zinc. Sulphur is an essential constituent of sulphur containing amino acids viz. methionine, cysteine and cystine. Variation in tryptophan content was recorded from 0.545 to 1.079 g/16 g N in Varuna variety whereas it varied from 0.501 to 1.545 g/16 g N strain NDR 8501. The highest rate of application of sulphur and zinc resulted in the highest content of minerals. The highest allyl-isothiocynate content in oil (0.342%) was recorded in variety NDR 8501 followed by Varuna (0.311%) variety. The minimum Alternaria blight severity was recorded in the dose of $S_{40}Zn_{40}$ (34.57, 32.04) in variety Varuna and NDR 8501, respectively.

Key words: Indian mustard, Nutritive value of cake and oil, Sulphur, Zinc, Alternaria blight

INTRODUCTION

Brassicas are members of the Brassicaceae family. They occupy a unique position in world agriculture as the source of vegetables, oilseed, forage and fodder, green manure and condiments (Singh *et al.*, 2017) *Brassica* seed oilis used for edible purpose, as industrial lubricants and as base for polymer synthesis. Oilseed brassica cake is used as a source of protein in animal feeds. Among the oilseed *Brassica* crops, Indian mustard [*Brassica juncea* (L.) Czern & Coss.] is an important source of oil from nutritional point of view (Singh *et al.*, 2013). The nutritional value of oil is governed mainly by the composition of its fatty acids *viz*. Palmitic acid, Stearic acid, Oleic acid, Linoleic acid, Linolenic acid, Eicosenoic acid, Erucic acid along with anti-nutritional factors.

Indian mustard has higher amount of erucic acid and glucosinolates in its oil and meal, respectively. The high amount of glucosinolates in meal and erucic acid in oil may create health problems *viz*. lipidopsis in young animals, fibrosis in older animals, reduce food intake, causes goiter, stroma and cancer. In *Brassica* breeding, considerable emphasis is being laid to develop the varieties with low glucosinolates and low erucic acid. The development of rapid and accurate methods for determination of glucosinolate levels in seed in early 1960's led to the identification of *B. napus* cultivar "Bronowski" from Poland.The first double low spring *B. napus* cultivar "Tower" was released in 1974 and afterwards a number of double zero cultivars were identified in different countries of the world. In India till date, the main emphasis has been to improve the rapeseed-mustard seed yield and oil content. It is necessary that seed oil quality especially the fatty acid composition also be improved wherever possible. Mustard is cultivated in mostly under temperate climates. Sulphur fertilizers have been reported to increase the seed yield and oil content of mustard (Singh *et al.*, 2013).

Sulphur has been reported to influence productivity of oilseed (Singh *et al.*, 1999). Similarly, Biswas *et al.* (1995) reported that application of S fertilizer increase the seed yield of mustard. Sulphur (S) is increasingly being recognized as the fourth major plant nutrient after nitrogen, phosphorous and Potassium. Sulphur and Zinc content and uptake were significantly higher with the application of $ZnCl_2$ as a source of Zinc in soyabean. Yasari (2012) studied the effect of applying Zn to compare the effects that incorporating them in the soil and spraying them on the soybean crop on seed oil and contents and percentages. Application of micro-nutrients like zinc, sulphur, magnesium and boron significantly increased yield. Alternaria blight is one of the major biotic limit factors for realizing quality mustard production (Singh *et al.*, 2013).

Keeping this in view there is a need to screen/develop Indian mustard varieties having low erucic acid and effect of different doses of Zinc (Zn) and Sulphur (S) on protein content, tryptophan, methionine, and allyl-isothiocynate content, mineral status of the cake and Alternaria blight severity in mustard.

Abstract

This review on Alternaria blight caused by *Alternaria brassicae, A. brassicicola and A. raphani* singly or by mixed infection is one of the most widespread and destructive disease of oilseed brassicas in all the continents. These pathogens are necrotrophs. The disease appears as black spot but later on enlarge and develops into prominent round spots with concentric rings. Many spots coalesce to form large patches showing blight and cause defoliation in severe cases. The spots on the mid-ribs of the leaves are linear and sunken. Circular to linear lesions also develop on stem and pods, which elongate at later stages. Infected pods produce small, discoloured and shrivelled seeds. This disease causes substantial yield losses as a result of several factors including reduced photosynthetic potential, early defoliation, flower bud abortion, premature ripening, siliquae dehiscence, seed shrivelling and reduced seed size, impairs seed colour and reduced oil content. This paper reviews the research on the development of Alternaria blight, describes the pathogens of Alternaria blight on rapeseed-mustard, which includes geographical distribution, economic importance, symptoms, habitat and host range, pathogen taxonomy, survival, pathogenicity and disease development, epidemiology, host resistance, breeding for disease resistance, genotypic stock, and management.

Introduction

Oilseed brassicas, also known as rapeseed-mustard *(Brassica spp.)*, is the second largest oilseed crop that contribute 32 per cent of the total oilseed production in India. Out of 75.55 m tones of rapeseed-mustard in the world from over 30.51 m ha area, India shares 7.80 m tones of rapeseed-mustard production from the area of 6.50 m ha with productivity of 1208 kgha^{-1}. (Anonymous, 2013). Among the oilseed brassicas, yellow *sarson (Brassica rapa* var. yellow *sarson)*, brown *sarson (B. campestris* var. brown *sarson)*, toria *(B. campestris* var. *toria)*, Indian mustard *(B. juncea)*, Karan rai *(B. carinata)* and oilseed rape *(B. napus)* are grown for edible oil, where as black mustard *(B. nigra)* is used as condiment and for pickle making, food preserving and spices to improve flavour, also as fodder for live-stocks. The leaves of young plants are used in the human diet as green vegetable. Mustard seed and oil has multiple uses in health care system. It improves the body complexion because of its antifungal property. It is used as a very good massage oil, which brings vitality and strength to the body and improves the circulatory system and cures bodyache. It also kills various microbes and thus, keeps skin infections away. Oral doses of oil help in strengthening the teeth and cure various mouth related diseases. It helps in healing wounds by stopping the pus formation and in curing various skin disorders by removing unwanted fluids from the body (Kumar and Chauhan, 2005). Erucic acid and glucosinolate are the two major deterrents of oil and seed meal in oilseed brassica, respectively (Singh *et al.*, 2013[3]). The oilseed brassicas usually contain 38-57% of erucic acid, 4.7-13% linolenic acid and 27% of oleic and linoleic acid, which are of high nutritive value required for human health (Singh *et al.*, 2011[4]; Singh *et al.*, 2012).

Huge volume of edible oil is still to be imported to meet the ever increasing domestic need, which can easily be met by bridging the wide gap existing between the crop potential and

ABSTRACT

Field experiments were conducted during *Rabi* 2013-14 to 2014-15 on various aspects related to the management of Alternaria blight of linseed (*Linum usitatissimum* L.), caused by *Alternaria lini* Dey and *A. linicola* (Groves and Skolko). In this endeavour total 95 genotypes including checks were screened to find out resistant sources against the disease and explore the possibilities for its economical management through newer molecules and 5 ready to use (RTU) fungicides having their different combinations. Out of 95 genotypes, none was found disease free (Immune). However, 15 genotypes (KL-31, KL-229, Polf-2, LCK-11, H-22, KL-168, KL-225, KL-221, KL-220, SJKO-17, H-12, H-15, H-43, H-5, Ayogi) showed resistant reaction having one rating in 0 to 5 scales. Likewise, 37 genotypes reacted as moderately susceptible (MS) with rating scale 3 and 13 genotypes showed susceptible reaction (Scale 4). Rest two genotypes were found highly susceptible reaction against Alternaria blight. Among the five RTU fungicides tested for their efficacy *(In-vivo)* against the disease maximum (79.45 %) disease control was worked out in the plots sprayed thrice with Mancozeb @ 0.25% on the basis pooled data of 2 years of experimentations. This treatment also resulted in maximum yield increase (196.58%) over check are water sprayed plot. However, on the basis of benefit-cost ratio maximum net return exhibited through three sprays of mancozeb @ 0.25 per cent followed Krizole (Hexaconazole 5% SC) @ 0.1 per cent.

Key words : *Linum usitatissimum, Alternaria lini and A. linicola, Alternaria blight, genotypic resistance and fungicides*

Linseed (*Linum usitatissimum* L.) is commonly known as Flax, and is a member of the genus *Linum* belonging to the family Linaceae is one of the oldest cultivated oilseed crop in the world. Among the oilseed crops raised during *Rabi* season, linseed is next in importance to rapeseed and mustard in area and production. In technical oil production India, ranks first. It is raised both for its seeds as well as fibre which is used for the manufacture of linen.

Almost every part of the linseed plant is utilized commercially, either directly or after processing. On a very small scale, the seed is directly used for edible purposes, about 20% of the total oil produced is used in farmer's homes and about 80% of the oil goes to industries in various forms, such as boiled oil, borate oil, eposidized oil, aluminated oil, urethane oil, etc. The oils is also utilized for manufacturing paints, varnishes, oilcloth, linoleum, pad ink, printers ink, soaps, patent leather and other products.

The stem yield fibre of good quality having high strength and durability. The fibre is weather resistant lustrous and blends very well with wool, silk, cotton etc. Strong twines, canvas, suiting's, shritings and various indispensable products for defense purposes are manufactured from it. Woody matter and short fibres are used as rough pulp for making paper of good quality comparable with that of currency notes. The rough, strong fibre can be effectively used for low-cost roofing tiles based on convertible polymers and for fibre-reinforced plastics based on unsaturated polyesters.

Its seed cantinas 33-47% Oil, 5.5% Linolenic acid, 20.3% Protein, 38% Fat, 29% Carbohydrate, 4.8% Fibre, 2.4% Ash in different varieties. Its oil cake is good in taste and feed for milch cattle and poultry and hence priced 50% higher than rapeseed and mustard cake.

The important linseed growing countries are India, Canada, China, USA and Ethiopia. Globally, its production was 19.23 lac tones from 22. 18 lac ha with an average yield of 867 kg/ha. While our national production was 1.47 lac tones from an area of 3.59 lac ha with poor productivity of 408 kg/ha). India rank 1st in area in the world, but is at fifth place in terms of production after Canada, China, USA and Ethiopia. In term of productivity, India (408 kg/ha) is for below to UK (1636 kg/ha), USA (1484 kg/ha), Argentina (1371 kg/ha), Canada (1197 kg/ha), Ethiopia (1065 kg/ha) and China (1029 kg/ha) (Anonymous 2012).

Amongst the various factors, behind low productivity, diseases are one of the major hurdles. The important diseases affecting the linseed crop are Alternaria blight, powdery mildew, rust and wilt. Alternaria blight, earlier designated as a minor disease has assumed greater importance in different parts of the country, especially mid eastern India. The disease caused 18-43.88% yield loss

ABSTRACT

Field experiments were conducted at SIF in Narendra Dev University of Agriculture and Technology Kumar Ganj, Faizabad, Uttar Pradesh to assess the economics of fungicides, botanicals and bio-agents for the management of Alternaria blight of Indian mustard during 2012-13 and 2013-14. Most economical (B: C ratio of 3.60 and 3.79) scheduled was recorded in the treatment T_{12} i.e. three spray of SAAF (Carbendazim 12% + Mancozeb 63% WP) @ 0.2% were done at at 40, 55 and 70 DAS with highest seed yield (1624.60 and 1646.67 kg/ha) fallowed by treatment T_{10} (Potash @ 50 Kg/ha as basal dose) 3.06 and 3.10 with seed yield (1408.30 and 1398.43kg/ha) and treatment T_7 (Spray of Garlic bulb extract @ 2%) 2.91 and 2.95 with seed yield (1438.00 and 1424.77 kg/ha) during both years respectively. Minimum B: C ratio (0.79 and 0.78) was recorded in treatments T_4 (Seed treatment and spray of *P. fluorescence* @1%) with seed yield (1379.63 and 1366.37 kg/ha) and treatment T_{11} (Sulphur 30 Kg/ha as basal dose) i.e. 0.86 and 0.87 with seed yield (1606.47 and 1598.23 kg/ha) during both the year respectively over treatment T_{13} (untreated check).

Key words *B: C ratio, Fungicides, Botanicals, Bio-agents, Yield, Economics*

Indian mustard (*Brassica juncea* (L.) Czern & Coss.) is one of the most important oilseed crops among rapeseed mustard which is grown during *rabi*. It belongs to the family *brassicaceae*. and is mostly cultivated in Rajasthan, Uttar Pradesh, Madhya Pradesh, Haryana, Gujarat, West Bengal and Assam in India. Mustard is the second largest produced oilseed in the world with an area of 37.0 m ha, with the production of 63.09 m t. and the productivity of 18.50 q/ha (Singh and Singh, 2015). India contributes 28.3% and 19.8% in world acreage and production (Anonymous, 2013). The seed and oil are used as condiments in pickles, for flavoring curries and vegetables. Oil is used for cooking and frying purposes. It is also used in preparation of hair oil and medicine. It has industrial importance in soap making and in mixtures with mineral oils for lubrication and grease of various machines. Oil cake serves as feed for cattle, fish and poultry and as manure. Tender leaves of young plants are used as green vegetables and are good source of sulphur and other minerals in diet. The seeds are highly nutritive containing 37.7-52.9 % euric acid, 8.5-19.0 % linoleic acid and 8.6-17.1 % oleic acid (Robbelen and Thies, 1980). Alternaria blight disease caused by *A. brassicae* (Berk.) Sacc. and *A. brassicicola* (Schw.) Wiltshire is one of the most important diseases of Indian mustard, causing 47% yield losses (Singh *et al.*, 2015). The fungus attacks both vegetative and reproductive parts of the plants; therefore it causes high yield loss (Chattopadhyay, 2008). The present study was undertaken to access the yield losses due to Alternaria blight in Indian mustard by using different treatments such as Bio-agents, Plant product and fungicides.

MATERIALS AND METHODS

The experiment was carried out on seed treatment, basal application and spray schedules of different fungicides for the management of Alternaria blight of mustard, cultivars *Varuna* was sown on dated 6th November, with three replications and thirteen treatments in RBD design along with recommended package and practices during 2012-13 and 2013-14 at Student's Instructional Farm of Narendra Deva University of Agriculture & Technology, Kumarganj, Faizabad. The different treatments *viz.* T_1-Seed treatment with *T. harzianum* 10 g/kg seed, T_2-Seed treatment with *P fluorescence* @ 10 g/kg seed, T_3-Seed treatment and spray of *T. harzianum* @1%, T_4-Seed treatment and spray of *P fluorescence* @1%, T_5-Spray of *E. globosus* leaf extract @ 5%, T_6-Spray of *D. stramonium* leaf extract @ 5% T_7- Spray of Garlic bulb extract @ 2%, T_8- Spray of $ZnSo_4$ @ 0.2 %, T_9- Spray of Borax @ 0.5%, T_{10}- Potash @ 50 Kg/ha as basal dose, T_{11}- Sulphur 30 Kg/ha as basal dose, T_{12}- Spray of SAAF (Carbendazim 12% + Mancozeb 63% WP) @ 0.2% were done at 15 days interval by using knapsack sprayer. The first spray was done immediately after appearance of the disease. Treatment T_{13}-(Check) serves as untreated. The observations on yield was recorded from individual plot in q/ha. Benefit cost ratio was point out to evaluate the most economical spray among all treatments applied as different spray schedule. The benefit – cost ratio (BC ratio) was calculated on the basis of seed yield of each treatment by using the following formula (Singh, *et al.* 2014).

$$\text{Benefit-Cost ratio (B : C)} = \frac{\text{Additional income generated by the treatment}}{\text{Total cost involved in protection}}$$

RESULT AND DISCUSSION

Economics of treatments for the management of Alternaria blight of mustard

The data showed in Table-1 and Table-2 indicated that highest B: C ratio of 3.60 and 3.79 was recorded in the treatment T_{12}- three spray of SAAF (Carbendazim 12% + Mancozeb 63% WP) @ 0.2% were done at at 40, 55 and 70 DAS fallowed by treatment T_{10} (Potash @ 50 Kg/ha as basal dose) 3.06 and 3.10 and treatment T_7 (Spray of Garlic

The present investigation entitled "Studies on changes during growth and development of ber (*Zizyphus mauritiana* Lamk.) fruit cv. (Narendra Ber Selection-1)" was carried out during the year 2016-2017. The studies comprised three experiments namely fruiting behaviour of ber. Ber flowering started from mid of September and completed at mid of November the peak period of flowering was mid of October. Whereas fruit setting took place between 3rd week of September to 1st week of December but peak setting period was last week of September to mid of October. Fruit drop and fruit retention percentage also changes during growth and development of ber fruit. Ber fruit was harvested in five pickings, and peak period of yield was first week of March.

Introduction

Ber (*Zizyphus mauritiana* Lamk.) is an ancient fruit tree of India and China. In fact it was one of the prominent fruits on which sages in ancient India lived during Vedic ages. There is a reference to ber in "Yajurved", written not later than 1000 B.C. Ber (*Ziziphus mauritiana* Lamk.) is also known as Chinese date, Chinee/Chinkee apple, jujube, Indian plum, Regi pandu, Indian jujube and masau, belongs to the family Rhamnaceae and genus *Zizyphus*. It is a tetraploid (2n=48) in nature. It is grown in countries like Iran, Syria, Australia, USA, France and certain parts of Italy, Spain and Africa. Precisely it is seen to be growing under tropical and sub-tropical as well as Mediterranean regions of the world. It grows even on the marginal soil and various kinds of waste land situation such as sodic saline soil, ravines, arid, semi-arid region including plated area of Bundelkhand and South India. Regarding its distribution it grows most widely in Punjab plains, U.P., Haryana, Rajasthan, M.P., Bihar, Maharashtra, Assam, A.P., Tamil Nadu and West Bengal. In U.P. ber orchards are found around Varanasi, Aligarh, Saharanpur, Faizabad, Agra and Raibareilly districts. However, scattered planting is common in plains. It is hardy and flourishes well under little care in wide range of soils and climatic conditions. The ripe ber fruits have high nutritive values and

Studies on changes in biochemical attributes during growth and development of ber (*Zizyphus mauritiana* Lamk.) fruit cv. (Narendra ber selection-2)

Vartika Singh and Bhagwan Deen

DOI: https://doi.org/10.22271/tpi.2021.v10.i4l.6055

Abstract
The Studies on changes in biochemical attributes during growth and development of ber (*Zizyphus mauritiana* Lamk.) fruit cv. (Narendra Ber Selection-2) was conducted during growing season of 2019-20. The fruits on tagged current season shoot were harvested at 21, 36, 51, 66, 81, 96, 111, 126, 141, 156, 171 and 186 days after fruit set. Samples were collected from Main Experiment Station, Horticulture and transported to the post graduate laboratory of Department of Fruit Science, College of Horticulture and Forestry, ANDUA&T, Kumarganj, Ayodhya, Uttar Pradesh. The objective was to probe the pattern of biochemical changes in developing ber fruits. The outcomes reveal that total soluble solids increased from 1.04% to 17.94% during 186 days of fruit growth and development whereas acidity content continuously decreased and recorded 0.39% on 21st day and 0.14% on 186th day of growth and development. Ascorbic acid content increased from 3.29 mg/100g to 90.26 mg /100g of fruit. Reducing, Non-reducing and total sugar content significantly increased from 0.22% to 4.76%, 0.11% to 5.77% and 0.35% to 10.87%, respectively. Moisture content showed decreasing trend and was maximum 71.12% on 21st day and minimum 65.79% on 186th day of observation. An abrupt decrease in chlorophyll content was recorded with growth and development of the fruit.

Keywords: Ber, Zizyphus mauritiana, NBS-2, fruit growth and development, arid fruit, dryland horticulture

Introduction
Ber (*Zizyphus mauritiana* Lamk.), the king of arid fruits, is a considerable minor hardy fruit crops symbolizing the production at a modicum cost. There are two major cultivated jujubes-Indian jujube (*Zizyphus mauritiana* Lamk., 2n=48) and Common or Chinese jujube (*Zizyphus jujube* Mill., 2n =24). Genus *Zizyphus* comprises almost fifty species, out of which 18 to 20 are local to India (Pareek, 2001) [20]. It is evergreen, small (up to 15m height), spiny tree with about 30 cm diameter trunk. Fruit is juicy drupe with 2.5cm (diameter) and 4.5cm (wide) and can be round, oval, ovate oblong or elliptical in shape. Ber is a perfect tree for arid as well as semi-arid culture and one of the most nutritious fruit crop having medicinal as well as processing potential. The ber fruit is excellent source of proteins, carbohydrates, fibers, fats, TSS, ascorbic acid, antioxidants, total phenolics, reducing, and non-reducing and total sugars (Kumara *et al*., 2015) [9]. It can be consumed as fresh or can be used in processed forms such as powder, candies, murrabbah, jams and beverages. It can tolerate salinity, alkalinity and pH as high as 9.2and even waterlogged condition upto certain extent. This crop requires less water compare to other fruits therefore, suitable fordry land farming. Successful cultivation of ber can be done even in the most marginal ecosystem of tropics and subtropics (Pareek, 2001) [20] and can tolerate extremely high temperature and are grown in region with maximum temperature of 39-42 °C. The area under cultivation of ber is extending because of its unique ability to flourish even on neglected land, specific demand, hardy nature, good return, and Indian Government policies under National Horticulture Mission.
The studies on changes in biochemical attributes during growth and development are essential requirement to determine the maturity and harvesting time in order to maintain high nutritional quality, reduced post-harvest losses as well as better marketability. Therefore, the present investigation has been undertaken to observe the changes in biochemical attributes during growth and development of recent ber variety Narendra Ber Selection-2 (NBS-2).

Gradual increase was observed in total soluble solids and ascorbic acid with the advancement of maturity in aonla under northern Indian conditions. Keeping in view above facts the present investigation entitled "Studies on chemical changes during growth and development of Aonla (*Emblica officinalis* Gaertn.) fruit cv. Narendra Aonla-10" is carried out with objectives to observe the chemical changes during growth & development of fruits and the maturity index for right stage of fruit harvesting during 2019-2020 at Main Experimental Station of Department of Horticulture, A.N.D. University of Agriculture and Technology, Kumarganj - Ayodhya (U.P.). Results showed that all chemical parameter of growth and development viz- Vitamin C and total sugar increased up to maturity.

Chemical, Fruit, Parameter, Acidity and TSS

Introduction

Aonla (*Emblica officinalis* Gaertn.) is one of the most important traditional and under utilized fruits of Indian origin, having immense potential for cultivation on marginal or wastelands. It belongs to family Euphorbiaceae and indigenous to tropical Asia. Among all the fruit crops, aonla is the richest source of ascorbic acid, except Barbados cherry. It is grown all over Asia for its nutritional, medicinal and commercial value. Wild aonla trees are also found in China, Sri Lanka, Pakistan, USA (Hawaii and Florida) and Puerto Rico. In recent years, the processing and value addition of aonla has increased many folds due to increase in its area and production. Aonla has acquired wide popularity all over the world f or its medicinal properties. Its fruits are used in traditional Indian system of medicines, like ayurvedic, due to its therapeutic values (Agarwal and Chopra, 2004).

The growing popularity for alternate medicines, health foods, and herbal products are enhancing the demand for aonla fruit. Its fruits are rich in vitamin C, protein, fat, crude fibre, starch, sugars, minerals and tannins. Because of its highly acidic and astringent nature, the consumers do not relish this fruit in fresh form (Goyal *et al.*, 2008).

Plasmodium falciparum Cysteine-Rich Protective Antigen (CyRPA) Elicits Detectable Levels of Invasion-Inhibitory Antibodies during Natural Infection in Humans

Syed Yusuf Mian,[a] Anjali Somanathan,[a] Kritika Chaddha,[a] Alok K. Pandey,[b#] Hina Singh,[b§] S Sri Krishna,[c] Neha Chaturvedi,[c] Seemalata Uchoi,[a] Man Mohan Shukla,[c] Praveen K. Bharti,[c] Neeru Singh,[c] Virander Singh Chauhan,[b] Deepak Gaur[a]†

[c]ICMR-National Institute of Research in Tribal Health (NIRTH), Jabalpur, Madhya Pradesh, India

ABSTRACT *Plasmodium falciparum* cysteine-rich protective antigen (CyRPA) is a conserved component of an essential erythrocyte invasion complex (RH5/Ripr/CyRPA) and a target of potent cross-strain parasite-neutralizing antibodies. While naturally acquired human RH5 antibodies have been functionally characterized, there are no similar reports on CyRPA. Thus, we analyzed the parasite-neutralizing activity of naturally acquired human CyRPA antibodies. In this regard, CyRPA human antibodies were measured and purified from malaria-infected plasma obtained from patients in central India and analyzed for their parasite neutralizing activity via *in vitro* growth inhibition assays (GIA). We report that, despite being susceptible to antibodies, CyRPA is a highly conserved antigen that does not appear to be under substantial immune selection pressure, as a very low acquisition rate for anti-CyRPA antibodies was reported in malaria-exposed Indians. We demonstrate for the first time that the small amounts of natural CyRPA antibodies exhibited functional parasite-neutralizing activity and that a CyRPA-based vaccine formulation induces highly potent antibodies in rabbits. Importantly, the vaccine-induced CyRPA antibodies exhibited a robust 50% inhibitory concentration (IC_{50}) of 21.96 μg/ml, which is comparable to the IC_{50} of antibodies against the leading blood-stage vaccine candidate, reticulocyte-binding-like homologous protein 5 (RH5). Our data support CyRPA as a unique vaccine target that is highly susceptible to immune attack but is highly conserved compared to other leading candidates such as MSP-1 and AMA-1, further substantiating its promise as a leading blood-stage vaccine candidate.

KEYWORDS *Plasmodium falciparum*, malaria vaccine, RH5, CyRPA, naturally acquired immunity, growth inhibition assay

Malaria remains a major global health challenge, accounting for 200 million cases and around 0.4 million deaths each year, primarily in children under 5 years of age (1). The disease severity and clinical manifestations are a result of the parasite's blood-stage life cycle (2, 3). Several merozoite antigens have been identified to play a critical role during erythrocyte invasion, of which *Plasmodium falciparum* reticulocyte-binding-like homologous protein 5 (RH5) has emerged as a key invasion determinant that plays an essential role during *P. falciparum* erythrocyte invasion (4, 5). Antibodies targeting RH5 or its erythrocyte receptor, basigin, exhibit potent parasite neutralization *in vitro* and *in vivo* (6–10). RH5-based vaccines were found to be safe and immunogenic in a phase 1a controlled human malaria infection-based clinical trial (10–12).

The molecular redundancy associated with the highly rapid *P. falciparum* erythrocyte invasion process presents a major hurdle to achieving high antibody titers for efficacious neutralization that is unlikely to be overcome by a vaccine based on a single antigen like

Physiological maturity in aonla is mainly determined on the basis of specific gravity, ground colour, fiber content and seed colour. Gradual increase was observed in average fruit weight, stone weight, pulp weight and pulp: stone ratio with the advancement of maturity in aonla under northern Indian conditions. Keeping in view above facts the present investigation entitled "Studies on physical changes during growth and development of Aonla (*Emblica officinalis* Gaertn.) fruit cv. Narendra Aonla-10" is carried out with objectives to observe the physical changes during growth & development of fruits and the maturity index for right stage of fruit harvesting during 2019-2020 at Main Experimental Station of Department of Horticulture, A.N.D. University of Agriculture and Technology, Kumarganj - Ayodhya (U.P.). Results showed that all physical parameter of growth and development viz- length, width, weight, pulp / fiber percentage showed significant change from 6th August to 6th December and then showed non-significant change till 6th January.

Introduction

Aonla (*Emblica officinalis* Gaertn.) belongs to family Euphorbiaceae. It is indigenous to Tropical South-East Asia, particularly in Central and Southern part of India (Morton, 1960). Naturally growing aonla has been reported from Cylon, Cuba, Puerto Rico, Hawaii, Florida, Iran, Iraq, Java, West-Indies, Trinidad, Pakistan, Malaya and China (Benthal, 1946). It is being cultivated since long back and occupies an important place among indigenous fruits of India. Aonla finds mention in "Vedas, Ramayana, CharakSamhita, SushrutSamhita" literatures describing its fruit highly valuable as food, medicine and hair dye (Anon, 1964). Aonla is the second richest source of vitamin-C (500 mg/100g pulp) among the fruits, after Barbados cherry.

Aonla is one of most nutritious fruits and it is fair source of minerals particularly iron, phosphorous, calcium, magnesium and rich source in pectin. Beside these, aonla fruit has adequate amount of sugars and acids. Fresh

Physiological maturity in aonla is mainly determined on the basis of specific gravity, ground colour, fiber content, seed colour and TSS/ acid ratio. Gradual increase was observed in average fruit weight, stone weight, pulp weight, pulp: stone ratio, total soluble solids and ascorbic acid with the advancement of maturity in aonla under northern Indian conditions. Harvesting of fruits at proper stage of maturity is desirable for maintaining the quality and consumer acceptability. Keeping in view above facts the present investigation entitled "To determine the maturity index for right stage of fruit harvesting during growth and development of Aonla (*Emblica officinalis* Gaertn.) fruit cv. Narendra Aonla-10." is carried out with objectives to observe the physical and chemical changes during growth & development of fruits and the maturity index for right stage of fruit harvesting during 2019-2020 at Main Experimental Station of Department of Horticulture, A.N.D. University of Agriculture and Technology, Kumarganj - Ayodhya (U.P.). Results showed that all physiochemical parameter of growth and development viz- length, width, weight, pulp / fiber percentage showed significant change from 6th August to 6th December and then showed non-significant change till 6th January. Pulp / seed ratio, Vitamin C and total sugar increased up to maturity. Therefore, fruit of aonla variety NA-10 indicated maturity between 6th December to 6th January and this stage showed right stage of harvesting.

Introduction

Indian gooseberry or aonla (*Emblica officinalis* Gaertn.) is an important indigenous fruit crop of India. Botanically, fruit is a berry and its mesocarp, an edible portion. It is acrid, astringent, cooling, refrigerant, diuretic and has laxative value. The fruit is rich source of vitamin-C, pectin and tannin(Pathak *et al.*, 2003). If, the fruits of aonla are not properly mature, tannic acid, vitamin-C and other constituents may not attain the optimum level and pose heavy post-harvest losses, including desiccation, browning of skin and prone to microbes, which resulted in poor shelf life with inferior quality.

Maturity is influenced mainly by cultivars, climate, soil, cultural practices, canopy

Abstract
Indian Farm workers are highly involved in various agricultural operations. They perform a sequential work through manual efforts. In the present investigation efforts have been made to assess the occupational risk related to various agriculture activities and to compare the physical strength of male and female farm workers, during manual method to perform agricultural operations. For the study, twenty female and twenty male subjects were selected. From this study, it has been recommended that there is dire need to create awareness among the farm workers about the low cost improved technologies related to flower cultivation which can significantly improve the livelihood security and working conditions of farm workers. It will also reduce the level of occupational risk and enhance the physical strength of the workers.

Keywords: Occupational risk, Physical strength, Agricultural Workers, Agricultural Activity

Introduction
In the context of occupational safety and health, the term 'agriculture' is generally used in a broad sense including all activities directly related to cultivating, growing, harvesting and primary processing of agricultural products, animal and livestock breeding including aquaculture, and agroforestry. Agricultural work is dangerous; workers in this industry have among the highest rates of fatalities (BLS, 2014 and Liabraa *et al.* 2013). Furthermore, Wang *et al.* (2013) also mentioned that work in agriculture involves exposures to a variety of hazards, including dust, noise, thermal stress, pesticides and other chemicals, and ergonomic risk factors. As a result, agricultural workers have elevated rates of injuries and illnesses. Das *et al.* (2011) also supported that agricultural works are associated with several occupational disorders among the farmers and agriculture farming involves several types of hazardous activities including prolonged and awkward postures. Agriculture workers perform many strenuous activities. These are: spading, carrying seeds, uprooting, transplanting saplings, harvesting or cutting crops, sheafing, carrying crops, threshing, sweeping and winnowing. Therefore, the main aim of this investigation was to know the level of occupational health hazards among agriculture workers and an attempt was made to compare the physical strength of male and female farm workers during the performance of work.

Materials and Method
Selection of subject and field
From Faizabad district of Uttar Pradesh state, India, twenty male and twenty female subjects with normal health, without any major illness or cardio-vascular problems were purposively selected because only without illness or cardio- vascular problems, agricultural workers can perform the activities more efficiently. This study was conducted in the month of February- August in the year of 2016. The age range of the selected subjects was 20-55 years. Care was taken to select the female farm workers who were not pregnant and who can perform the agricultural activities regularly. The agricultural operations were performed for 7:00 A.M to12:30 P.M. and 2:00 P.M. to 5:30 P.M. Agriculture workers performed the continuous agriculture operations for 50 minutes and taking 10 minutes break.

Calibration of subjects: The subjects were calibrated with the Body Mass Index to determine their physical fitness index. The body mass index of subjects was calculated by dividing square of height (m2) to weight (kg).

Quantification of safety and Health Hazards
Semi quantitative observational tool to characterize safety and health hazards developed by Neitzel *et al.* (2014) has been used to quantify the level of safety and health hazards among

Comparative study on weight loss and volume loss of tomato under Janta cool chamber and ambient condition

Nilam Mishra, Dr. Razia Parvez, Dr. Abha Singh and Dr. Diksha Gautam

Abstract
An evaporative cool chamber was designed and constructed by using soil & river bed sand and named Janta Cool Chamber. The maximum and minimum temperature of inside and outside of the chamber was recorded for 76 days. It was observed that the inside temperature was 3-4°C lower than outside temperature. A comparative study was made to determine weight loss and volume loss of tomato inside the Cool Chamber and in the ambient condition. The Janta Cool Chamber does not require any mechanical or electrical energy input and can be constructed with locally available materials and build by unskilled Labours. It proven economical as it can store the tomato for longer period with no significant loss in quality to tomato stored.

Keywords: Janta cool chamber, storage structures, weight loss, volume loss, tomato

Introduction
Tomato is one of the most important vegetables grown in India. Post-harvest storage of tomato is the major cause of seasonal fluctuation in availability, deterioration in quality and other socio-economic inadequacies. Deterioration of fresh tomato can result from physiological breakdown due to natural ripening processes, water loss, temperature injury, physical damage, or invasion by micro-organisms. All of these factors can interact and all are influenced by temperature. Fresh fruits, vegetables and flowers are highly perishable because they are alive. They breathe (just like humans) release heat from respiration and consequently, loose moisture, which may cause weight loss, volume loss and also nutritional quality.
Maintenance of air-conditioned structures /appliances in villages is not possible for farmers due to high energy consumption and erratic supply of electricity. The cold storage facilities, confined to rural areas only are not so popular among the farmers. Evaporative cooling method of storage has been found to be an efficient technique to increase the shelf life of stored foods by reducing weight loss and volume loss. Vakis (1981)[5] also developed a cheap cool store in Kenya, with the help of local grass for the storage of vegetables. He kept the roof and walls wet by dripping water from the top of the roof. Roy and Khanda (1986) [7] constructed an evaporative cooled structure for the storage of the fruits and vegetables with a double wall made of baked brikis chamber fulfils and all these requirements and is helpful to small and people at household level in rural areas.
Mukharjee *et.al* (2008) [6] studied on comparative study of fruits and vegetables in cool chamber and in ambient. In the study an evaporative cool chamber was constructed with the help of baked bricks and river bed sand, maximum and relative humidity were recorded inside and outside the chamber for one month. Weight loss and freshness were observed every day. It has been recorded that weight loss of fruits and vegetables kept inside the chamber was lower than those stored outside the chamber.
In the present study of Janta Cool Chamber was made to store the horticultural produce for a short period of time. The principle of working of this cool chamber is based on technique of evaporative cooling. This maintains low temperature and relative humidity in low temperature and relative humidity in the inner space compared to the ambient condition. This Janta Cool Chamber fulfils all these requirements and is helpful to small farmers and people at household level in rural areas.

Value addition techniques used for strengthening of bags

Swapnil Singh, Poonam Singh and Abha Singh

Abstract
Value addition techniques are used on bags of old clothes and plastic sheets. Colour combination has been used to enhance the beauty from ancient time. It is believed that strength of bags by lining jute cloth and synthetic sheets were developed earlier than the use of bags itself, used value added materials is the knowledge, selection and application of the basic knowledge of durability of cloth. The present study was conducted to stitch bags that were suitable for value addition materials. Thirty value added bags were identified for application in old cloth and thick plastic works. Created works got evaluated from 100 respondents including both experts and consumers. 5 top ranked value added techniques used on bags were selected from each category.

Keywords: value addition, bags, plastic, pollution

Introduction
Plastic pollution is a problem all over the world. Each year at least 8 million tons of plastic find their way into the ocean. The problem is equivalent of dumping the contents of one garbage truck into the ocean every minute. Plastic shopping bags, carrier bags or plastic grocery bags are a types of plastic bag used as shopping bags and made from various kinds of plastic in use by consumers worldwide since the 1960; these bags are sometimes called single use bags, referring to carrying items from a store to home. Shopping bags are medium - sized bags typically ground 10-20 liters (2.5-5 gallons) in volume (though much larger version exist, especially for non-grocery shopping); that are used by shoppers to carry home, their purchases. Some are intended as single - use disposable products though people may reuse them for storage or as bin liners etc. Others are designed as reusable shopping bags. Reusable shopping bags are a kind of carrier bag, which are available for sale in super markets and apparel shops. In a 2011 study of 4.5 retail chain (Funded by a Pro - business group that opposes plastic bag bans), 23% of reusable bags were found to have levels of lead that were higher than the 100-ppm standard considered safe for product packaging though did not present a risk of contaminating food. Plastic consumption has become an integral part of our daily life. The complication in the existing reusable bag for shopping for a particular item along with its methodology is broadly discussed providing an ideal solution.
BYOB basically stands for "Bring your own Bag." Thus, bringing one's own bags to the grocery store, and having those bags visible while shopping could motivate more "green" choices by activating a broad goal to gain social approval or a goal to help the environment.
This makes a switch in alternatives like cloth bags, jute bags or eco-friendly bags made out of natural starches and vegetable wastes instead of plastic bag, whenever you visit the Kirana shop or a vegetable market. Stash away reusable bags in your house, care for it, is come handy without having any extra load on the health of mother earth. A company in Indonesia has created a plastic bag so ecofriendly you can eat it. It's made out of Cassava, the vegetable root which is a staple in the diets of many in Africa, Latin America and Asia, but which can also be used in manufacturing. The company Avani eco based in Bali has created a bag that they say looks and feels like plastic but is completely bio- degradable and compostable it also dissolves in water, so if animals eat it, it won't cause any harm. They say it's so safe, in fact that humans could even swallow it. Bags are also a form of storing commodities and these complement the overall appearance of the storing capacity. The selection of above treatment mainly depends on functionality, color combination, designing attributes, embellishment technique, texture.

Research methods
Various value addition bags were stitched from different material. From the collected material,

ASSESSMENT OF MUSCULO-SKELETAL DISORDER IN FLOWER PLUCKING WOMEN IN FAIZABAD DISTRICT OF UTTAR PRADESH

MANEESHA MISHRA *

Dr. ABHA SINGH **

ABSTRACT

Women play a significant and crucial role in Agriculture development, livestock production and Floriculture as a manager decision maker and skilled farm worker. In this study attempt has been made to study the role performed by farm women engaged in floriculture and to find out the MSD (Musculoskeletal disorder) and OH (Occupational Hazard) among women. The study was conducted in Faizabad District in U.P. 100 samples were taken of women involved in flower management. It was found from the study that majority of respondents (40%) suffered from the Back pain while (20%) women suffered Knee pain. The analysis of the study shows that Poor postures and finger nodes. Stress full work, unawareness of new techniques in the use of equipment and unwariness for safety measures were the reason for musculoskeletal discomforts. 70% women used foot wears due to the awareness of the advantages of it. The preferred activities by women were grading of flower (42%) as first followed by Deeping of flowers (34%), plucking of flower (12%) and storage flower (11%) respectively. The study will be use full in policy making designing women friendly implements for flower plucking and right posture training.

Key words: MSD (Musculo-Skeletal Disorder), Occupational Hazard, Knee pain, Back pain, Musculoskeletal Disorder.

Impact of shopping bags on environment by users of plastic shopping bags

Swapnil Singh, Poonam Singh and Abha Singh

Abstract
Plastic bag users are at risk of numbers of health hazards. The study indicates with regards to awareness of hazards associated with the usage of plastic bags among people and their perception towards the conscious of the access of plastic bag. This study was conducted in Acharya Narendra Dev University of Agriculture and Technology Kumarganj, Ayodhya. Data was collected by interview and judgment based in each of the selected respondent using interview schedule and judgement schedule for judging the awareness schedule of health hazards by the respondents.

Keywords: health hazards, plastic bags, environment

Introduction
The world plastic comes from the Greek word plastikos, which means "able to be shaped or molded". Molding and shaping plastic by using heat is a basic part of its manufacturing process. Plastic bags have been introduced in 1970's and gained an increasing popularity amongst consumers and retailers. They are available in huge numbers and varieties across the world. Plastic industry is one among the rapidly growing industries in India. The production of plastic has reached 8.5 million tons in 2013 with a growth rate of 8% over the previous five years. The growth rate is expected to be 10% over the next five years. The reason for popularity for using the plastic bags are light weight, resistance to degradation (by chemicals, Sunlight and bacteria), durability and above all low cost.
Plastic bag packing for hot edible items causes migration of harmful chemicals to food. These include styrene which is carcinogenic, phthalates and bisphenol these chemicals cause diabetes and diseases of the heart and liver. Plastics are not only dangerous towards human health but also making survival impossible for other flora and fauna on planet earth.

Materials and Methods
This study was undertaken in 2020 in the A.N.D.U.A.&.T. Kumarganj, Ayodhya. The sample size for the study was aimed at 100 respondents including both experts & consumers. A written informed consent was taken from each participant. Socio demographic information viz age, educational status and occupational status were inquired from each participant. Questions regarding frequency of usage of plastic bags and what do they do or how do they dispose the bags after every usage were asked. They were also enquired about that they felt was the reason for popularity of plastic bags, whether they were habituated in demanding the bags more than the actual requirement from shop keepers or o whether the shop keepers, generously; offered them the bags without checking their actual requirements and whether they were habituated in refusing plastic bags by carrying their own bags for shopping visits. The questions on their awareness regarding hazards and types of hazards associated with plastic bag usage, awareness about recyclable plastic bags, awareness regarding eco- friendly alternative material for making bags and environment protection were inquired.

Statistical Analysis: The bags were coded from A_1 to A_{10}. The responses were marked in the interview schedule. The data was coded, tabulated and calculated in term of frequency and percentage.

Frequency: The no. of respondents marked in any particular parameter is its frequency.

Percentage: It is calculated by dividing obtained score by the total score and multiplying it by 100.

Impact of mass media on academic achievement of school going adolescent in Varanasi city

Dr. Alpana Singh and Sarita Srivastav

Abstract
Mass media is a type of communication means, which is used to reach large numbers of population via newspaper, radio, magazine and television. Academic achievement is a simple word that denotes status of achieving educational goals by students, decided by teacher through formal or informal tests. This study done with the objective, to find out the impact of mass media exposure and contribution of mass media on academic achievement of selected group. 200 boys and 200 girls of 15-19 years of age group from 8 schools of Varanasi city were selected for the study. Study reveals that there is significant impact of mass media exposure on academic achievement and significant contribution of mass media on achievement was found on male and Female intermediate students of Varanasi city.

Keywords: mass media, academic achievement, school going adolescent

Introduction
The term mass denotes great volume, range or extent of people or production, while communication refers to the giving and taking of message, the transmission and reception of message. The term mass media refers to the organized means for communicating openly and at a distance to many receivers within a short space of time. Mass media transfer knowledge more effectively to large number of receivers at multiple points irrespective of the distance between source and the receiver.

Mass media has prominent importance for developing country like India, such countries face number of problems. They have to find out their solutions and communicate it to the people, about four to five decades ago this was not possible, but with advent of mass media as an effective means of propagation and communication it has been achieved. Mass media have created a media audience which is now more conscious about learning and knowing.

The academic achievement is the end product of the instructions. It is a desirable learning that is observed in the learner. Any behavior that learned is achievement. It is learned amount of knowledge, understanding and acquisition of skills. Academic achievement is the task oriented behavior that allows the individuals performances to be evaluated according to some internally or externally imposed criterion that involved the individual in competing with others or that otherwise involves some standard of excellence. Academic achievement is level of attainment or performance in academic work measured by standard test or teachers or both. Good (1973) has defined academic achievement as the knowledge attained or skills developed in the school subjects, usually designated by test scores or by marks assigned by teachers or by both.

In school situation academic achievement generally means the quality and quantity of master the curriculum by students. In present study academic achievement was conceived in terms of percentage of marks obtained by the students in their previous class examination and teachers rating about the students.

Objectives of the study
Without good objective researcher cannot achieve their goal. The present investigation was designed with specific objectives:

1. To find out impact of mass-media exposure on male and female intermediate students on academic achievement.
2. To find out contribution of mass media exposure on academic achievement of male and female intermediate students.

STUDY OF THE ECONOMICS OF MUSTARD (*BRASSICA CAMPESTRIS*) UNDER DIFFERENT FARM SIZE GROUPS

Ajit Verma[1], Sarita Srivastava[2] and Anil Kumar Singh[3]

[1]Department of Farm Management, Krishi Gyan Kendra, Baribag, Ghazipur (U.P.), India.
[2]Department of Home Science, Krishi Gyan Kendra, Deoria (U.P.), India.
[3]Department of Agricultural Economics, College of Agriculture, Kotwa, Azamgarh (U.P.), India.

Abstract

The present study consisting the economics of mustard (*Brassica campestris*) in different farmers group during 2012-13 in Ghazipur district of U.P., Comparing with local check. It was found that yield was increasing more and more from smaller to large farmers on demonstrated field because they adopted advance package of practices thoroughly and properly, but the same farmer whenever of they fallow traditional practices their yield was goes down. There were a wide range of differences in Benefit Cost ration in demonstrated and local ones. There should be a chance to maximize the profit and minimize the cost in future to make a proper attention for this crop.

Key Words: Farmers, yield, increasing trends, groups

Introduction

Mustard yield the most important edible oil. The content of the seeds or different farms ranges from 32 to 50 percent. The oil obtain is the main cooking medium in our country, which cannot be easily replaced by any other edible oil. The seed and oil are used as condiment in the preparation of pickles and for flavouring curries and vegetables. The leaves of young plants are used as a green Vegetable. This crop requires relatively cool temperatures for satisfactory growth. Mustard are grown normally in the *Rabi* Season from September to October in our country which requires light to heavy loan soils. Higher yield Indian mustard of higher rate of isoproturon as a pre planting might be due to efficient weed control at initial crop growth stage, reducing crop-weed competition for inputs and creating better atmosphere for good plant growth oil seed crops more bio fertilizer, Sulphur and Nitrogen for their oil and protein synthesis causing increase in the yield and quality of oil seeds. Chauhan *et al*., 1994. More number of plants compensated the loss in seed yield due to less plant stand. The straw yield was significantly more under narrow spacing resulted large number of primary and secondary branches or plant under wider row spacing in brown Sarson (*Brassica campestrix*) affected the yield and quality Bali *et al*., 2000.

Materials and methods

The present study was conducted in randomly selected Village Govindpur of Mardah Block in Ghazipur district of Uttar Pradesh during 2012-13 with the help of farmers Scientist collaborations. Two farmers from each small, medium and large size groups has been randomly selected. Suggested Kranti variety of mustard along with seed rate 5-00 Kg./ha, N:P:K application was @ 120:40:40 Kg./ha. The crop was taken on the farmers during first fort night of October, also suggested for better yield and good response apply Sulphur @ 15 to 20 Kg./ha. Emphasis has been given an intercultural operation to avoid dense plant populations. Higher seed yield obtained when the planting distance are maintained properly. The age of seedling is an important factor better growth and vigour of the plants, Momoh *et al*., 2000. All information's has been collected through survey method and tabular analysis is being used. Family schedule has been used to collect the data regarding family size, area of the crop, expenditure and incomes etc. A comparative study has also been made through their local check along with their traditional

STUDY OF THE COST AND RETURN OF PIGEON PEA (*CAJANUS CAJAN* L.) UNDER DIFFERENT FARM LEVELS

Ajit Verma[1], Sarita Srivastava[2] and Anil Kumar Singh[3]

[1]Department of Farm Management, Krishi Gyan Kendra, Baribag, Ghazipur (U.P.), India.
[2]Department of Home Science, Krishi Gyan Kendra, Deoria (U.P.), India.
[3]Department of Agricultural Economics, College of Agriculture, Kotwa, Azamgarh (U.P.), India.

Abstract

The present study has been taken on cost and return of Arhar (*Cajanus cajan* L.) in different size of holdings during 2012-13 in Ghazipur district of Uttar Pradesh village and farmers has be en selected on random basis. It was found that when the farmer was adopt old practices they have got low yield and low returns. Whenever, the same farmers applied all the scientific package of practices their yield and net return was on higher side. It is therefore to say that in future if the farmers apply all the scientific practices properly and timely their yield and net return becomes much more and higher.

Key Words: Farmers, Yield, Demo, Local Check, Specific.

Introduction

This crop is extensively used as dal; its green pods may be used as vegetable. The green leaves and top of the plants are fed to animal. Dry stalks obtained after threshing are used for basket making etc. Being deep rooted, it is also planted as a soil renovator to break up the hard subsoil and as a hedge to check erosion. The heavy shedding of leaves adds considerable organic matter to the soil. The crop can grown best on well-drained, light to medium soils, most and deep enough to permit a free development of roots. The plants cannot with stand frost. Good drainage is an essential requirement, as the crop cannot stand lodging. Though perennial, this crop is invariably grown as an annual crop. The crop may be due to their tall growing nature dense population and standing in the field for a long while yield of Arhar (*Cajanus cajan* L.) Crop in inter cropping system will be reduced due to competition occurs by inter crop for nutrients etc. by Rajput *et al.*, 1989, Significant reduction in the yield in delayed sowings along with dense plant population giving a small loss in the grain yield, Shankar Lingappa *et al.*, 1989. For a better yield and quality timely sowing along with proper spacing is most important.

Materials and methods

The present study has been taken in the randomly selected village Naseerpur of Block Devkali in the Ghazipur district of Uttar Pradesh during 2012-13. Two farmers has been randomly selected from each small, medium and through large size of holdings. A proper farmers scientist attention was made in the visions. Narendra Arhar-1, variety was suggested for this programmes, along with allow to apply 15 Kg/ha of Seed with a dose of N:P:K:Sulphur @ 15:40:0:20 Kg/ha for better yield. The crop was taken on the field during second fort night of July, line sowing was suggested on ridges for higher yield with better quality. All advance packages of practices has been specify for timely application. For a comparative study same farmer has to advise that they were take in other field for this crops on their own traditional practices to see that what was the difference between scientific and traditional practices. Survey method has been used to collect the data and tabular analysis was being used. Family schedule has been used to collect the data from the selected farmers according to their size of holdings, family size, area of the production and income of the crop etc sharp decrease in the grain yield of Arhar (*Cajanus cajan* L.) during the raining is more and proper drainage system when

STUDY OF THE ECONOMICS OF CHILLI *(CAPSICUM ANNUUM)* ON DIFFERENT FARM CONDITIONS

Ajit Verma[1], Vinay Kumar Singh[2], Anil Kumar Singh[3], Ashok Kumar Singh[4] and Sarita Srivastava[5]

[1]Department of Farm Management, Krishi Gyan Kendra, Baribag, Ghazipur (U.P.), India.
[2]Department of Horticulture, Krishi Gyan Kendra, Baribag, Ghazipur (U.P.), India.
[3]Department of Agricultural Economics, College of Agriculture, Kotwa, Azamgarh (U.P.), India.
[4]Department of Agricultural Economics, College of Agriculture, Kotwa, Azamgarh (U.P.), India.
[5]Department of Home Science, Krishi Gyan Kendra, Deoria (U.P.), India.

Abstract

The main objective of the present study was to study the Economics of Chilli in the randomly selected farmers of villages in Ghazipur district of Uttar Pradesh, India. It was found that farmers has adopted all the advance package of practices and applied time to time during the cropping time resulted good yield and high net incomes. In future it will also be improved whenever they use better crop management practices with high profile business thinking.

Key Words: Village, Yield, Farmers, Specific, Trends, Exhibits.

Introduction

Chilli also called 'red pepper' is an important cash crop in India and is grown for its pungent fruits, which are used both green and ripe (the latter in the dried form) to import pungency to the food. As a condiment, it has becomes indispensable in every Indian home. It is also used medicinally, and in chantries and pickles. Capsicum plants are herbaceous or semi woody annuals or perennials very high rainfall during its growth is harmful. Under irrigation and good manuring, excellent crops can be raised in sandy and light alluvial loans as well as in red loamy soils. As a garden crop, it is sometimes allowed to grow as a stand-over crop for one or two seasons. The land is ploughed and harrowed 3 or 4 times to obtain a fine filth. Recommended dose of FYM is better for good yield and better qualities. The Chilli is generally transplanted, through direct sowing. Foliar spray of Zinc and Iron not increase the yield and quality of the crop Pillai and Vadivelu (1967). The combined spray of Zinc, boron and iron through soil or its foliar Spray is better for good yielding; Saryandrayra and Hariprasad (1985) reported that these micronutrients increased the green yield of Chillies. Hosmani and Hosmani (1993) give details about Chillies in their second edition. Seeds taken from healthy, well matured fruits selected for the purpose are mixed with ashes and shown evenly in well-manured nursery beads. The nursery treatment and other recommended practices had been taken at the time of their requirements.

Materials and Methods

The present study was conducted on the field in Ghazipur district of Uttar Pradesh, India in randomly selected two villages namely Bishunpura (Block-Karanda) and Secondly Gajpatpur (Block-Berno) through farmers-scientist collaborations ranging small, medium and large size farmers groups. Seven farmers from each groups has been selected randomly. Pusa Sadabahar Chilli Variety has been offered for the demonstrations. Allowed 1 Kg. seed for a hectare to maintain line to line distance about 50 Cm and plant to plant distance 45 Cm. The crop has been taken on the field on the field during August-September. All the package of practices has been introduced to the farmers for their better yield and qualities regarding time to time applications. All the information has been collected through survey method and tabular analysis was being used. Family schedule has been used to collect the data regarding family size, area of the crop, expenditure and net income. Emphasis has been given on cultural operation irrigation and other recommended practices for the upliftment of the crop.

Plant Archives Vol. 19 No. 2, 2019 pp. 3653-3654 e-ISSN:2581-6063 (online), ISSN:0972-5210

STUDY OF THE YIELD AND PROFIT OF LENTIL (*LENS CULINARIS* L.) UNDER NUMBER OF FARM LEVELS

Ajit Verma[1], Sarita Srivastava[2] and Anil Kumar Singh[3]

[1]Department of Farm Management, Krishi Gyan Kendra, Baribag, Ghazipur (U.P.), India.
[2]Department of Home Science, Krishi Gyan Kendra, Deoria (U.P.), India.
[3]Department of Agricultural Economics, College of Agriculture, Kotwa, Azamgarh (U.P.), India.

Abstract

The main aim of the present study to judge the yield and profit of Lentil in different Size of the farmers in Ghazipur (U.P.) during 2012-13. It was found that farmers of all size groups applied all the recommended package of practices and utilize its timely therefore their yield and net return better in comparison to precious years. Their yield and net return becomes more in future if they also alert to attained the fruit full advice and implement it time to time.

Key Words: Farmers, Yield, Small, Medium, Large Size groups.

Introduction

Lentil is grown as a cold weather unirrigated Crop. When sown rather late, apply, one irrigation. Sometimes, it is grown mixed with barley and mustard or with both. Unripe pods are used as a green Vegetable and dry leaves, stalks, husk and broken grain as cattle feed. The crop is like light loams and alluvial soils. It resembles grain a great deal in plant habit and cultivation requirements. The crop normally receives no manure, weeding or intercultural. The crop matures during 120 to 125 days. This pulse crop also responds to Rhizobial inoculation. The yield of lentil increases due to irrigation in the absence of winter rains, if the raining is in winter than the yield has been goes down reported by Saxena *et al*., 1973. Whenever phosphorus applied in legumes enhances the activity of Rhizobia resulted root development consequently rise. Nitrogen Fixation in the root nodules and improve the plant growth and if quality reported by Choudhary *et al*., 1974. The application of phosphorus significantly increased the grain and straw yield.

Materials and methods

The present study has been conducted in randomly selected village Dhamupur of Jakhaniya block with farmers scientist collaboration in Ghazipur district of Uttar Pradesh during 2012-13. Four farmers from each has been randomly selected through small, medium and large size groups. The Narendra Masur-1 (*Lens culinaris* L.) variety has been suggested, seed rate 60 Kg/ha along with N:P:K:S @ 20:60:40:20 Kg/ha for better responses. The crop was taken on the field during fist fort night of November Irrigation and Kaolin spray has been recommended at the time of their need, resulted for better grain yield and straw yield also better for their growth and developments Murari et.al. 1984. All the information has been collected through survey methods and tabular analysis was used. Family schedule has been used to collect the data for the size of holdings, size of family, area of the crop production and net returns etc. All other package of practices has been given to the farmer at the time of Crop needs.

Results and Discussion

The Table 1 shows that Grain yield Qt./ha. was 16 Qt., 18Qt., 20 Qt. and straw yield 24 Qt., 30 Qt. and 38 Qt. ranging from smaller to large size of farmers, exhibits increasing trends. It is clear that farmers has already being alert about to apply all the recommended package of practices time to time resulted better yield in all size group of the farmers. Application Kolin Spray and irrigations timely was helpful to increase the yield. The Table 2 show that the gross cost Rs./ha was Rs. 14,850, Rs. 16,200, Rs. 18,370, Gross return Rs. 48,200, Rs.49,150, Rs. 52,680 exhibits increasing trends while net return was

Short Communication

STUDY AND ANALYSIS OF INCOME AND EXPENDITURE LEVEL OF POTATO (*SOLANUM TUBEROSUM*) UNDER DIFFERENT SIZE OF HOLDINGS

Ajit Verma[1], Sarita Srivastava[2], Pradip Kumar[3] and Vinod Singh[4]

[1]Department of Farm Management, Krishi Gyan Kendra, Baribag, Ghazipur (U.P.), India
[2]Department of Home Science, Krishi Gyan Kendra, Deoria (U.P.), India.
[3]Department of Plant Pathology, Krishi Gyan Kendra, Baribag, Ghazipur (U.P.), India
[4]Department of Farm Management, Crop Research Station, Baribag, Ghazipur (U.P.), India.

Abstract

The main objective of the present study was to work out the income and expenditure level of potato by the use of bio fertilizer along with organic and inorganic fertilizer also in randomly selected villages of district Ghazipur, U.P. during 2011-12. It was found that yield and net return was increased from smaller to large farm ranges increasing trends under demo and local checks. Benefit cost ratio also ranges increasing from smaller to larger ones. The study concludes that yield and net return was increased only due to proper use of organic and bio fertilizer management. this study further concludes that in future more better use of organic and bio fertilizer management produces more yield and better net return in all size groups.

Key words: Yield, bio fertilizer, increasing trends.

Introduction

The potato crop has a special value as food. Potato belongs to the family Solanaceae. It occupies the largest area under any single vegetable in India. The consumption of potato per head in our country is not very much highered in comparison to others. This crop needs irrigation at frequent intervals. Five to six irrigations are sufficient. Potato tubers are planted either whole or cut into pieces sowing time is mid of September to the first week of January. Where crop has been sown in plains of the Northern area. Two successive crops can be raised on the same land. Organic manures as play very much important role in the production of yield and quality. This should be put into the soil 3 to 4 weeks before planting 80 Kg. of Nitrogen, full dose of phosphorus and full dose of potash will be incorporated into the soil as basal dressing, rest 40 Kg. of nitrogen should be apply as top dressing at the time of first earthing. Use of proper planting measures resulted to protect the crop from late blight and insect pest etc. Application of good quality of organic manure or FYM along with recommended doses of NPK provides significantly higher yield and better quality reported by Emin Caliskan *et al.* (2004). Organic manures not only been responsible for adding the natural sources of NPK but it play an important role to improve the physical and chemical properties of nutrient, deficiency in the Soil which improves higher tuber yield said by Rouat and Neyroud (2003). The tuber and their size has been increased when they have got sufficient amount of nitrogen because this is one of the very much most important food as well as Vegetable (crops in our country which is responsible for producing better calories and weight in comparison to others, Application of herbicides or hand weeding resulted higher tuber yield.

Materials and Methods

The present study was conducted along with farmers scientist collaboration in randomly selected village and block namely Sepah of Kasimabad Block. The study has been taken during the Season of 2011-12 in Ghazipur district of Uttar Pradesh. Three farmers have been selected on random basis under small, medium and large size of holdings. The main motto was to increase their production with better quality and also suggested them to compare the advance practices along with local ones.

Plant Archives Volume 20 No. 2, 2020 pp. 8463-8464 e-ISSN:2581-6063 (online), ISSN:0972-5210

STUDY OF THE ECONOMICS AND BENEFIT COST RATIO OF BRINJAL AT DIFFERENT FARM LEVELS

Ajit Verma[1], Sarita Srivastava[2], Vinay Kumar Singh[3], Ashok Kumar Singh[4] and Anil Kumar Singh[5]

[1]Department of Farm Management, KrishiGyan Kendra, Baribag, Ghazipur (U.P.), India.
[2]Department of Home Science, KrishiGyan Kendra, Deoria (U.P.), India.
[3]Department of Horticulture, KrishiGyan Kendra, Baribag, Ghazipur (U.P.), India.
[4]Department of Agricultural Economics, College of Agriculture, Kotwa, Azamgarh (U.P.), India.
[5]Department of Agricultural Economics, College of Agriculture, Kotwa, Azamgarh (U.P.), India.

Abstract

The main objective of the present study was to analysis the economics and benefit cost ratio of Brinjal in two villages of Ghazipur district of Uttar Pradesh, India. It was found that the farmers of all selected randomly groups has been taken the crop on their field through a good advance package of practices, therefore their yield and net return in all size groups increased respectively in time. The study concludes yield and net return should be increased in future if they go through a good farm plans along with better crop management systems.

Key Words: Village, Farmers, Yield, Income, Farm plans.

Introduction

Brinjal (*Solanum melongena* L.) is warm season crop its plant not with stand frost the main sowing season being during July-August for a good yield 20-25 tons of FYM per hectare incorporated into the soil at the time of field preparation. It is necessary to maintain an even moisture supply in the soil; over watering is as harmful as insufficient irrigation. In this crop, phomopsis wilt is the most important fungal disease and is seed borne. Hot water treatment of the Seed helps to reduce the incidence of the disease. Little leaf is caused by mycoplasma and can be partially controlled with antibiotics. Brinjal is prone to attack by many damages caused by insects, pests, fungus, bacteria and viruses Purohit ML and Khatri AK (1973). Brinjal productions area consistently and extensively damaged by brinjal fruit and shoot borer and other fruit borer insects reported by Kuppu Swamy and Balasubramanian (1980). To reduce pest linked damage in brinjal as well as to protect the environment from adverse effect of pesticides, as an insect resistance management strategy Ghosh *et al.*, (2003). In India brinjal is the major source of profitable income for farmers because of local demand and it is a perennial crop so that fruit can be harvested throughout the year. A large number of brinjal varieties and hybrids are grown by small, medium, large size of farmers throughout the year.

Materials and Methods

The present study was conducted in two randomly selected villages namely Jaitpur (Block-Sadar) and secondly Gaura (Block-Sadat) in Ghazipur district of Uttar Pradesh, India with farmers Scientist Collaborations in demonstrated groups small, medium and large size while selected randomly seven farmers from each groups Narendra hybrid Baigan-1 has been suggested seed rate 500-600 gram per hectare during field preparations 25 tons of FYM allowed to the soil planting distance line to line 60-75 cm and plant to plant are 45-60 cm, was proposed. Crop was taken on the field during July-August Season N:P:K @ 100:50:25 Kg/hectare for better quality and better yield advised. All the advance package of practices has been specify for timely whenever needed. Survey method has been used to collect the data and tabular analysis was being used. Family schedule has been used to collect the data from the selected farmers according to their size of holdings, family size, area of the productionand income of the crop etc. The economics has been calculated at their current price rates.

[3]Department of Home Science, Krishi Gyan Kendra, Deoria (U.P.), India.
[4]Department of Farm Management, Crop Research Station, Baribag, Ghazipur (U.P.), India.
[5]Ph.D., Narendra Deva University of Agril. & Tech., Kumarganj, Faizabad (U.P.), India.

Abstract

The objective of present study was to work out yield and economics of high yielding wheat in compare with local cheque at different farm levels in randomly selected village Chariyan Khas of Deoria District, Uttar Pradesh during 2011-12. It was found that on demonstrated track by applying advance package of practices yield and net return was increased but, it was not in local cheques due to lack of technical knowledge's, lack of awareness etc. Benefit Cost ratio in both shows no specific trends. Finally it will confine that there should be a more chance to increase their yield and net returns with low cost by making to apply a good frame of advance package of practices, go through a good farm plan timely.

Key Words: Farmers, time, yield, increasing trends, package of practices.

INTRODUCTION

The wheat crop requires a well-pulverized but compact seed bed for good and uniform germinations. There are four ploughings in the summer, repeated harrowing in the rainy season, followed by three or four cultivations and planking immediately before sowing produce a good, firm seed bed for the dry crop on alluvial soils. Timely Cultivation and conservation of moisture are essential. It is second important food crop being next to rice and contributes to the total food grain production to the extent of about 25 percent wheat straw is used for feeding the cattle. The Indo-Gangetic plains form the most important wheat area. The cool winters and the hot summers are very conducive to a good crop of wheat. Well drained loams and clayey loams are considered to be good for wheat. However, good crops of wheat are raised on sandy loams and the black soil also. Sowing with seed drills, whether tractor drawn or bullock drawn, will deposit the seed at a uniform depth, give a uniform stand and lead to the early emergence of vigorous seed lings. For better yield and quality it requires a balance dose of NPK 30 ton per hectare FYM needed at the time of preparation. In some soils, zinc is becoming deficient, resulting in poor yields. In moderately deficient soils, 25 kg. of zinc sulphate per hectare is sufficient. In a cropping system involving the rice wheat rotation, it is advocated that all the potash needed under this system should be given to the rice crop and all the phosphorus to the wheat crop and nitrogen to both the crops. By addition zinc significant improvement in grain and straw yield has been observed because zinc enhances the cation exchange capacity of roots where nitrogen is responsible for higher protein content of wheat Said by Malakouti *et al* (1998). Thus, application recommended doses of NPK along with zn to wheat resulted letter flowering and fruiting also obtaining higher productivity along with significant increase in net returns reported Sharma, P.K. *et al* (2000). The seed used for sowing should have a good germination capacity and it should be healthy and freeform seed borne diseases and seed of wheats.

Materials and Methods

This study has been conducted in randomly selected village Chanyonkhas of Gauri Bazar Block in Deoria district of Uttar Pradesh during the year 2011-12. Eight farmers has been selected randomly in small, medium and large size categories [illegible]

STUDY OF THE INCOME FROM SORGHUM (JOWAR) UNDER DIFFERENT FARM SIZE GROUPS

Ajit Verma[1], Sarita Srivastava[2], Pradip Kumar[3] and Vinod Singh[4]

[1]Department of Farm Management, Krishi Gyan Kendra, Baribag, Ghazipur (U.P.), India.
[2]Department of Home Science, Krishi Gyan Kendra, Deoria (U.P.), India.
[3]Department of Plant Pathology, Krishi Gyan Kendra, Baribag, Ghazipur (U.P.), India.
[4]Department of Farm Management, Crop Research Station, Baribag, Ghazipur (U.P.), India.

Abstract

To judge the income level of the sorghum was the main objective of the present study which has been taken on the farmer's field during 2011-2012 in Ghazipur district of Uttar Pradesh at different from levels in comparison with local checks. It was formed the yield and net income was higher in demo. groups in Comparison to local checks, because all the advance package of practices has been applied properly and timely while local checks are only based on traditional practices, by virtue of lacking the knowledge local checks are suffered. The study has fi rely been concluded that there should be a wide range in future so increase their productivity and income by applying more and more advance technologies of cultivating the crop.

Key words: Farmers, yield, increasing trends, size groups.

Introduction

Sorghum, popularly known as Jowar. It grain is primarily as human food in various farms, such as Roti or is cooked like rice. Sorghums are also malted, popped and several local preparations are made. Green and dried fodder is the most important roughage for feeding cattle throughout the country. The utilization of grain sorghum as a cattle not very significant, although considerable scope exists. *Rabi* sorghums are wholly confined to black cotton soils, the *Kharif* Sorghums are grown on light soils also on a limited scale. Medium and deep black soils are predominantly suitable for this crop.

Sorghums are grown during in *Kharif* last week of June to July. The differed spread of high yielding varieties tends to enhance the attack of shoot fly on in this verities and the increased midge incidence on the locals, particularly during the *Kharif* Season. Wheat crop yield formed significantly higher after *Kharif* Sorghum, cowpea grain etc. Yield of wheat will be go down only after sorghum by using not a proper dose of organic fertilizer and cost of other sources of factors of production on higher side Sinsinwar (1994). Cultivatins of cereal forages along with legumes makes an increased quantity and nutritson's fodder resulted a greater improvement in soil quality. Green forage and dry matter yields formed significantly higher where maize and cow pea has been taken in consequent lines. The increase in the yield of green and dry matters in the intercropping system might be owing to the nutrient sparing effect of leguminous fodder, Tripathy *et al.* (1997). Nutrients requirement of the crop increasing day by day due intensive cropping system etc.

Materials and Methods

The present study has been taken on the field through farmers-scientist collaborations during the year 2011-12 in randomly selected village Nasirpur, Block Devkali of Ghazipur District of Uttar Pradesh Two farmers from each-groups ranging small, medium and large sizes has been randomly selected. The sorghum (Jowar) has been taken on the farmers field during last week of June to first week of July. Suggested the variety C.S.B.-15, Seed rate 15 Kg./ha. along with for better yield NPK application was put into the soil @ 40:20:20 Kg. per hectare. All the recommended package of practices has been applied to the crop during at the time of their needs for better yield and income. A comparative study has also been made through local check from same groups

STUDY THE PRODUCTIVITY AND BENEFIT COST RATIO OF ARHAR (REDGRAM) IN VARIOUS FARM SIZE GROUPS

Ajit Verma[1], S.P. Singh[2], Sarita Srivastava[3], Vinod Singh[4] and Avinash Kumar[5]

[1]Department of Farm Management, Krishi Gyan Kendra, Baribag, Ghazipur (U.P.), India.
[2]Director Extension, Narendra Deva University of Agril. & Tech., Kumarganj, Faizabad (U.P.), India.
[3]Department of Home Science, Krishi Gyan Kendra, Deorja (U.P.), India.
[4]Department of Farm Management, Crop Research Station, Baribag, Ghazipur (U.P.), India.
[5]Ph.D. Narendra Deva University of Agril. & Tech., Kumarganj, Faizabad (U.P.), India.

Abstract

The main aim of the present study was to find out the productivity and benefit cost ratio of Arhar Variety Narendra Arhar-2 in randomly selected various farms size groups in randomly selected village Laharanpur of Bemo Block in Ghazipur district of Uttar Pradesh during 2011-12. It was found that yield and net return was increased in each size group, percentage of yield increases in comparison to local cheque also. The result of productivity clearly shows that the norms of advance package of practices not properly followed. It shows that result will all be better in future when the cultivation process of red gram has done post form planting manner along with the application of better fertilizer irrigation, interculture and insect pest management results better yield and more net returns.

Key Words : Crop yield, groups, increasing trends

Introduction

The crop can be grown on almost all types of soils, ranging from alluvial soil, well drained light to medium soils, moist and deep enough to permit a free development of roots. The crop can be grown both in dry and moist hot climate. Bright sunny weather is needed during flowering, and the ripening of pods. The plants cannot with stand frost; the crop is sometimes irrigated late in December or early in January to protect it against frost. Extra-early and early types, maturing in 4-5 months, however, can be harvested before frost normally occurs good drainage is an essential requirement, as the crop cannot stand water lodging. Where subsurface drainage is poor, ridge planting is effective. In the case of mixed crops, the preparatory tillage for the major crop in the mixture is considered adequate for redgram. The mixed crop receives the interculture usual for the principal crops. The plants make slow growth until the cereal are other major crop is harvested. There after the plants of the Arhar put on fresh growth and flower profusely. Sowing of the crop in rows is better for growth and yield. Inter-row [illegible] optimum space resulted maximum branches and pods. Sowing times and inter row spacing caused significant difference in branches, plant and pod, delayed sowings, giving lowest grain yield Ahuja, K.N. (1984). Late sowing affects seed germination due to higher existing soil moisture resulting decrease in pod numbers, grain yield goes down due to lower temperature with higher attack of pest at flowering times, quality of crop will be decreases Sukhadia, M.M. *et al.* (1990). The heavy shedding of leaves adds considerable organic matter to the soil. It is also often grown as a cover crop in plantations. The yield of redgram in intercropping system was generally reduced depending on nature of inter crops. Inter cropping cereals, pulses and oil seeds reduced the yield of red gram in many demonstrations might be seem to 30% to 40% respectively. In intercropping system groundnut proved to be most compatible inter crop with redgram probably because groundnut utilizes early season resources efficiently Roy sharma, R.P. *et al.* (1981). The maximum net return can be found from intercropping of groundnut with redgram in upland area.

STUDY OF THE PRODUCTIVITY AND ECONOMICS OF MUSTARD (*BRASSICA COMPESTRIS*) UNDER DIFFERENT FARM SIZE LEVELS

Ajit Verma[1], Sarita Srivastava[2], Pradip Kumar[3] and Vinod Singh[4]

[1]Department of Farm Management, Krishi Gyan Kendra, Baribag, Ghazipur (U.P.), India
[2]Department of Home Science, Krishi Gyan Kendra, Deoria (U.P.), India.
[3]Department of Plant Pathology, Krishi Gyan Kendra, Baribag, Ghazipur (U.P.), India.
[4]Department of Farm Management, Crop Research Station, Baribag, Ghazipur (U.P.), India.

Abstract

The main motto behind this study was to judge the productivity and economics of mustard at different farm's level among the randomly selected farmers in Ghazipur district of Uttar Pradesh during the year 2011 – 2012. The productivity of net return was varies in demo. farmers in comparison to local check groups between small, medium and large size groups. It was only due to proper application of Sulphur, FYM and organic fertilizers timely. Irrigation and inter cultural operation management was better in demo groups. Crop was taken on the field in time was main key factor. The study concluded that in future organic and inorganic fertilizer management with weed management and proper irrigation facilities application productivity and income will be increase more and more.

Key words: Mustard, Yield, FYM, increase

Introduction

India, is one of the independence centers of origin of brown Sarson. Yellow Sarson is commonly grown in eastern parts of the country. Mustard yields the most important edible oil. The oil obtain is the main cooking medium in northern areas of the country. The seed and oil are used as condiment in the preparation of pickles and for flavouring curries and Vegetables. The oil cake is mostly used as a cattle feed where leaves of young plants are used as a green Vegetable. In our country it is grown in *Rabi* season. The seed from healthy and desirable plants, grown in isolation in the case of self-sterile form should be used. Whenever moisture in the field is inadequate, the seed is mixed with moist soil and kept overnight. For distributing evenly, the seed is usually mixed with sand before sowing. Whenever recommended doses of nitrogen along with farm yard manure put into the soil at the time of Rice and mustered cultivation resulted highest yield, if it application is goes down then the productivity will be affected. Therefore proper application of nitrogen and farm yard manure in Indian mustard cropping system for better productivity reported by Singh *et al.* (2001). Use of high yielding varieties is also an important factor, resulting for higher yield within optimum sowing time.

Materials and Methods

The present study was carried out on the field during 2011-12 in randomly selected village and block namely Belsari of Mardah Block, of Ghazipur district (U.P.) Six farmers has been selected from each farm size groups ranging small, medium and large on random basis with farmers scientist collaborations. Suggested variety Krishna, seed rate 5 Kg/ha., N.P.K. @ 120:40:40 Kg./ha. along with Sulphur 15 to 20 kg./ha. preferred 5 to 10 tones per hectare FYM for better yield and quality. The amount of Sulpher put into the soil not only for increasing the yield but oil yield also be increased with increasing level of Sulphur 10 to 15 Kg. per hectare more oil yield increased significantly by the use of Sulphur and proper irrigation needed Panda *et al.* (2000). Emphasis has been given more and more on thinning along with other inter cultural operations has been taken on the field time to time. Proper irrigation will be managed at the time of crop requirements. All information has been collected

Abstract

The main aim of present study was to find out the productivity and income levels of Potato (Kufri Sindari) on randomly selected in different farm size groups in randomly selected village Govindpur and Kusmahi Khurd of Ghazipur district of U.P., India. It was found that yield and net income was increased in all size groups in both villages, but village Kusmahi Khurd farmers perform well. The result shows that all the package of practices was properly used. For the better yield and good quality of crop in future farmers of the both villages have aware about their application of all the Agro-Economical package of practices and crop management.

Key words: Yield, Income, Package of practices, Specific trends.

Introduction

Potato is one of the most valuable and cash crop in the world as well as in our country Indian. It is capable of producing more weight and calories for human beings in comparison to other crops. For this crop some time manual weeding is tedious which causes root injury resulting yield and qualities are affected under such circumstances chemical weeding is economical and preferable. Gran manuring, recycling crop residues and animal manures, and the inclusion of legumes in rotation, is important. Integrated nutrient supply is essential for production and qualities. Nitrogen plays an important role in improving the growth and its yield. Evidence is growing of favorable effect of phosphate solubilizing bacteria in providing plant nutrients to several crops and in supplements the expensive inorganic fertilizers. Sing and Sharma (1994) and Daka and Datta (1997) reported significant response of potato to Nitrogen level in acidic soils. Combine inoculation of Azotobacter and Phospho-inoculant culture is good for tuber yield and qualities. Use of Azotobactor and phospho-inoculant indicates that the bio-fertilizer increased the efficiency of applied nitrogen. Use of organic sources of nutrients, good quality of compost is better for tuber yield with better qualities Potato tubers are planted either whole or cut into pieces. This crop needs irrigation of frequent intervals depend upon the soil and climatic conditions. Usually, six irrigation are sufficient.

Materials and Methods

The present study was conducted in the selected randomly Village Govindpur of (Block-Mardah) and Kusmahi Khurd (Block-Devakali) in Ghazipur district of Uttar Pradesh, India through collaborations of farmers-scientist on the basis of small, medium and large size of farms. Randomly selected seven farmers from each groups Kufri-Sinduri Variety of potato suggested for the above demonstrated groups. For better yield suggested 25 tons of FYM along with 120:80:100 Kg/hect of NPK. The crop has been taken on the field during second fort night of November on ridges. All advance packages of practices has been specify for timed application or whenever it needed. Survey method has been used to collect the data and tabular analysis was being made, family schedule has been used to collect the data from the selected farmers according to their size of holdings family size, area of the production and income of the

Abstract
The development of simulation model is a powerful tool for prediction of performance and can help designers to optimize the dryer geometry at various operating conditions. Commercialization of any drying technology for agro processing or industrial use needs thorough performance prediction and evaluation of system in techno-economic perspectives.
Estimation of solar radiation at Hisar with the help of ASHRAE model has been in close agreement with the observed values taking 5% as level of significance. Thus the model can safely be used to predict isolation at Hisar. The calculated efficiency of the flat plate solar collector using the data at different point in the solar dryer during testing has been consistent.

Introduction

Drying is one of the essential unit operation performed to increase the shelf life of agricultural / horticultural produce and it is one of the most practical methods of preserving food and the quality of horticultural produce. Use of proper drying techniques can significantly reduce the post-harvest losses of fruits and vegetables (Arikan and Alam, 2018). There exist many technical problems associated with open sun drying namely cloudiness and rain, insect infestation, high level of dirt and atmospheric pollution and intrusions from animals and men. In addition to this there is no control on the drying process (VijayaVenkata Raman et al., 2012). Hence, developing countries, receiving significant amount of solar radiation must realise the importance of controlled drying using solar energy. Traditional method for fruits and vegetables drying in rural areas in India is to spread the products on the ground with exposure to the sun in the open air. Sun-drying method may be efficient and cheap process but has disadvantages such as contamination by dirt, insects and bacteria and loss due to wetting by rain squirrels (Esper and Muhlbauer, 1998). These are usually accepted as an inherent part of the method of processing. In order to protect the products from above mentioned disadvantages and also to accelerate the time for drying the products, control the final moisture and reduce wastage through bacterial action. Solar energy is fast becoming an alternative source of energy because of the high rate of depletion of the conventional energy sources. It has many advantages over other alternative source of energy such as wind because of its abundant, inexhaustible, renewable and non-polluting nature. Equally, it can be tapped at a relatively low cost. The associated danger of fire or other hazards are less (Ekechukwu and Norton, 1999).

Whereas, controlled solar drying system leads to faster rate of drying and exposure of products against rain, dust, storm, birds, rodents, insects and pests are avoided. This ensures better quality of dried products which would fetch higher prices (Hossain and Bala, 2007). In solar drying method, faster drying takes place which result a significant reduction in drying time. Product dried in solar dryer are superior in quality (colour and flavour). Though the same superior quality product can be obtained by using electricity or electric power, but the electric operations are expensive and are not within the reach of our rural and tribal population. There is also inadequate supply of electricity in rural areas. In such conditions solar-energy crop dryers appear increasingly to be attractive as commercial propositions (Das and Kumar, 1989).

The development of simulation model is a powerful tool for prediction of performance and can help designers to optimize the dryer geometry

Abstract

This research investigation was undertaken in ANDUAT, Kumarganj, Ayodhya, Uttar Pradesh, India to study the numerical optimization of natural convection heat suppression in a solar flat plate collector with straight fins. Optimal characteristics of an array of thin fins attached on the absorber plat were obtained by Particle Swarm Optimization algorithm (PSOA). Free convection considered dominant in the cavity. Governing equations contained continuity; momentum and energy are discretized by finite volume method. The medium is considered incompressible, whose free convection is dominant and Boussinesq approximation is applied. A simplified model of real systems is applied with free convection. Free convection problem is solved by SIMPLER algorithm. Two confined cavities with aspect ratios 30 and 60 are considered as flat plate solar collectors. The results indicate that significant reduction on the free convection heat loss can be obtained from solar flat plate collector by using plate fins, and an optimal plate fins configuration exit for minimal natural convection heat loss for a given range of Rayleigh number. Reduction of up to a maximum of 25% at 0 inclination angle was observed in aspect ratio 30. Results showed PSOA is able to obtain characteristics of attached adiabatic fins on the absorber plate also it can obtain optimal inclination angle of cavity to decrease heat losses from solar collectors. The results obtained provide a novel approach for improving design of flat plate solar collectors for optimal performance.

Keywords: Particle swarm optimization algorithm, solar collectors, natural convection

1. Introduction

Flat plate solar collectors are technique to utilizing solar energy. The flat plate absorbs incoming solar radiation and converts it in to heat and also transfers this heat to a fluid flow. Glazing cover plate prevents from heat loss by force convection but when temperature difference between flat plate and glazing cover plate exceeds to a critical value, natural convection will exist between absorber and cover plate. In present work of heat loss from absorber plate is reduced by investigating optimal characteristics of an array of thin fins are considered. Grossman et al. (1977) expanded a model for heat transfer in a flat plate solar collector with a rectangular channel for water or air fluid flow. The analysis was performed for temperature and heat flow distributions in both dimensions of the collector to investigate the thermal boundary layer development. Overall efficiencies are calculated for uniform solar

[3]*Department of Farm Machinery and Power Engineering, Acharya Narendra Deva University of Agriculture and Technology, Kumarganj, Ayodhya, India*
[4]*Council of Scientific and Industrial Research, Central Scientific Instruments Organisation, Chandigarh, India*

A prototype of an electrostatic nozzle was developed for spraying cotton crops in a project titled 'Design and development of an electrostatic nozzle for agricultural applications'. The study was carried out to evaluate the locally-developed electrostatic nozzle and compare its performance with an imported electrostatic nozzle and solid cone nozzle (conventional knapsack sprayer) in the cotton crop at the departmental research farm of Punjab Agricultural University, Ludhiana, India. Different spray performance parameters, *i.e.* number median diameter (NMD), volume median diameter (VMD), uniformity coefficient, droplet density, the volume of spray deposition, and area covered with droplets were determined with the help of water-sensitive paper (WSP) method of deposition collection. There was comparatively less variation in uniformity coefficient with the imported and locally-developed electrostatic nozzles than the solid cone nozzle at a 5 % level of significance. The average droplet density obtained with both the imported and locally-developed electrostatic nozzles was significantly more compared to the solid cone nozzle. The area covered by the droplets of the locally-developed prototype of the electrostatic nozzle was more than the solid cone nozzle. The volume of spray deposition differed significantly for all three treatments at a 5 % level of significance. Overall, there was no significant difference in the performance of both electrostatic sprayers, but they were found to be more effective than the solid cone nozzle.

Key words: electrostatic nozzle, uniformity coefficient, droplet density, volume of spray deposition.

INTRODUCTION

Cotton is one of the most important textile fibres in the world, accounting for about 35 % of the total worldwide fibre usage. It is the single most cash crop that is cultivated extensively throughout the world. India, China and the United States of America are the major cotton-producing countries and together account for approximately two-thirds of total world cotton production (Anon 2015a). India is the largest cotton-producing country in terms of total production with an average of 6.10 Mt per year on a total sown area of 11.8 Mha. However, it has the 33rd ranking in the world in terms of yield per hectare because of a low average yield of about 517 kg/ha as compared to the world's average of about 566.27 kg/ha (Anon. 2015b).

Although cotton production and yield increased by introducing new crop varieties and production practices, still significant yield loss was observed as 4.1, 6.5, and 8.8 % in the cotton crop in three districts of India, namely Firozpur, Mansa, and Bathinda, respectively (Dhawan *et al.* 2008). Crop loss due to different insects has been reported to run to 18.0 to 50.0 % (Dhaliwal *et al.* 2010). In an another study the range of yield loss due to cotton leaf curl virus disease was reported to be from 81.4 to 88.4 % in all northern cotton-growing states of India (Monga 2014, as cited in Kumar Sain *et al.* 2019)

There are several spraying methods to protect crops from pests and diseases. Based on the volume application rate, there are three types of sprayers: high volume sprayer, low volume sprayer, and ultra-low volume sprayer. The high volume sprayer leads to loss of spray due to the larger size of droplets and more liquid application

■ **ABSTRACT :** Mahua stamen remover was evaluated for its performance. It was tested at four moisture levels (11.9, 13.17, 15.64 and 17.66 % d.b.) and three feed rates (15, 21, 27 kg/h). The stamen removal efficiency and whole flower recovery were determined to optimize feed rate and moisture content of mahua flower for better performance of the machine.The present study revealed that the optimum flower moisture content and feed rate were found to be 13.17 per cent and 15 kg/h, respectively with stamen removal efficiency of 88.23 per cent and whole flower recovery of 81.2 per cent.

■ **KEY WORDS :** Mahua stamen remover, Stamen removing efficiency, Whole flower recovery ans desceder

Mahua *(Madhuca indica)* of Sapotaceae family is a large tree found inthe deciduous forest of India. Every part of the mahua tree is used by the tribals for their livelihood. Its flower is used as foods and can be fermented to alcoholic drinks due to its high sugar content. It is a multipurpose tree providing food, fuel, timber, green manure, oil, oil cake, liquor and raw materials for several products and is one of the most important trees of Indian forest. It also has a religious and a high bio-asthetic value in the tribal culture. It is one of those multipurpose forest tree species that provide an answer for the three major Fs *i.e.*, food, fodder and fuel (Banerji and Mitra, 1996). It is very important from the point of view that it can help inpromoting nutritional and economic security in backward areas.

The estimated annual production of mahua flower is around 2 lakh tonnes (*www. jhamfcofed.com*) in Jharkhand. Mahua tree produces edible flowers and fruits. The ripe flowers, which fall from the tree, are collected. The yield per tree ranges from 100-200 kg. Mahua is also famous for its seed oil.

Mahua flower can be utilized in a variety of ways in home, as animal feed and also as raw material for industrial products. They can be used as a sweetener inpreparation of many local dishes like *Halwa, Kheer, Puri* and *Burfi* (Patel and Naik, 2008). It is also used for preparation of bakery and confectionary goods. Tribal people also use it for brewing alcohol. It contains tannin as tannins are excellent antioxidant that helps in giving the structure, texture and flavour to wine. Mahua flowers are also considered good for cooling and are used as a tonic and demulcent. However, an estimated 90 per cent of the production goes into brewing beverages. Mahua has various types of medicinal uses due to its tannin content. It is used as anti-diabetic, antiulcer, hepato protective, anti-pyretic, anti-fertility, analgesic, anti-oxidant, swelling, inflammation, piles, emetic, dermatological, laxative, tonic, anti-burn, anti-earth worm, wound healing headache and many more problems (Patel *et al.*, 2012). On account of various advantages of mahua

Sugarcane is multipurpose crop that serves as source of sugar, juices, jaggery and various products for man and raw materials for industry. But prior to the process of machining process, some processing is required to remove the solid particles, spots and sludge on the cane. The processing of sugarcane strip for industrial or human use involves different operations of which peeling is a major one and cannot be neglected. Of all the unit operations involved in cane processing, several processes have been mechanized successfully. This study presents the features, prospects, performance evaluations and limitations of some sugarcane peeling machines in world like the fixed outer drum peeler, automated cane peeler, knife-edge type self-fed peeler, etc. Their peculiar advantages and operational parameters such as machine speed, output capacity, peeling efficiency and cane losses were evaluated. Aside from the manual ones, the ranges of the peeling efficiency and cane loss were recoded in range of 59.9 – 91.4 % and 2–4% respectively. As machine speed increased, the output capacity and cane loss increased while peeling efficiency decreased. Mechanization of this peeling process has the potential of encouraging growth in cultivation, cane utilization and improving the product quality of value-added products. The product quality, processing efficiency, minimum loss of cane and increased processing rate will be affected by improved sugarcane peeling process.

Introduction

The sugar cane family is made up of over 30 sugar cane varieties. Sugar cane is a perennial grass that thrives in hot, humid locations like Brazil and India. The sugar derived from sugar cane is used in syrups, juices, and molasses, but the rest of the plant can also be used in the production of environmentally friendly paper products.

The juice from the sugar cane's stalk is highly prized and is the source of 70% of the world's sugar. It also has the highest number of calories per unit area of any plant. Fresh sugarcane juice is a popular beverage in many countries particularly in Asian region such as China, India, Malaysia and Thailand due to its taste and cheap price. Flavonoids that can be found in sugarcane juice have the abilities to protect cells from degenerative processes and to reduce the development of health problems

Abstract: The experiment conducted at Mahamaya College of Agricultural Engineering & Technology, Ambedkar Nagar (U.P.). The pump tested for analysis performance is ELGIMACE model no. LLO3022 single acting reciprocating pump equipped with 2 HP three phase induction electric motor with 1440 rpm. A hose measuring of water source of 4.12x3.25x1.23. G.I.20 mm size, suction pipe was used. The delivery pipe was high density pliable reinforced rubber pipe to withstand abundant pressure (up to 25 kg/cm^2). Stop watch was measuring discharge of 1/100 sec. of leastcount. For three different speeds of 242 rpm, 285 rpm and 344 rpm with five dissimilar pressures are 1.5 kg/ cm^2, 5.7 kg/cm^2, 10.3 kg/cm^2, 15 kg/cm^2 and 24 kg/cm, pump was tested. Track record of all pipe pressure used for this testing was measured by a pressure gauge having adequacy 0-35 kg/cm. In motor shaft a V(twin) belt the electric connection was energized and a pulley with minimum diameter 6.25 cm was fitted. The outcomes based on the exploratory observation showed that the efficiency rises when pressure is rises. At speed of 344 rpm the efficiency is detected 90% and at dupe speed the volumetric efficiency is 77% for least pressure 1.5 kg/cm and volumetric efficiency is 95% for maximum pressure 24 kg/cm^2. The discharge increases as pressure goes up and it is showed by the average discharge and pressure, which is almost linear. The relationship sequence is mostly same for all above circumstances; this stated that discharge is mutual to the pressure for a reciprocating pump.

Index Terms: Discharge, Efficiency, Volumetric efficiency, Pressure, rpm, Static head, Reciprocal and Pressure head.

I. INTRODUCTION

Reciprocating pump is a pneumatic machine which gets converted in hydraulic energy from mechanical energy. A cylinder containing a reciprocating piston absorbs liquid which expend a thrust (impel) force on the liquid and hike its hydraulic energy (pressure energy of liquid). It's a kind of positive displacement pump which comprises of piston or plunger. It is used at a place where relatively small amount of water is to be delivered at high pressure. Water in cylinder is displaced by the movement of piston for the functioning of reciprocating pump. Valves control the flow. A piston or plunger is cylindrical piece which moves backward and forward inside hollow cylinder. Reciprocating pump's capacity depend on the sizes of cylinder chamber, piston length and piston stroke. Electric motor engine operate a pump which have to come into prominence in a large lift irrigation schemes, high output levels can be quickly attained and managed by this process. Reciprocating pump generates high head, but their capacity is smaller compared to other types of pump. Reciprocating pump works on single acting independent suction and discharge strokes works on double acting suction and they discharge in both the direction. Although, recommendation of specific purpose pumps is very tough due to the inaccurate figures about scientific information such as efficiency discharge, head relation and other characteristics. Understanding all this circumstances, under laboratory conditions a study was approached for evaluation of volumetric efficiency, pressure discharge relationship and speed-power-discharge.

Precision attributes based index for the selection of efficient agricultural machinery

Manjeet Singh[1], Karun Sharma[2*], Pramod Mishra[1], Bharat Patel[1] and S K Singh[1]

[1]Department of Farm Machinery and Power Engineering, Punjab Agricultural University, Ludhiana, India.
[2]Krishi Vigyan Kendra, Samrala, Punjab Agricultural University, Ludhiana, India.

Received 5 May, 2016; Accepted 25 January, 2017

Development and introduction of high capacity, precise, reliable and energy efficient machinery/equipment is the need for judicious use of inputs. Manufacturing of agricultural machinery in India is varied in nature and starts from village artisans, tiny units, cottage to small scale industries, organized tractor and agricultural machinery manufacturers including energy and processing machinery industry. Precision in application rates for higher input-use efficiency can be achieved only by improving the designs of the existing machinery/equipment. Precision index (PI) of machine/equipment is based on its capability to perform a given task in an accurate manner. It is a worthwhile attribute to compare the performance of different equipment and operations to enhance the productivity of a given farm. The purpose of study was to propose an index, that is, PI to select efficient and precise machine/equipment for the farmers. PI values were calculated for three types of machinery namely zero seed cum fertilizer drills, planters and spraying machines. It was concluded that drill Make 2, tested in the year 2004, was having the highest PI value, that is, 0.87 or 87% followed by drill Make 1 having PI value 0.86 or 86% tested in the same year. Drill Make 6 tested in the year 2013 was having minimum PI value, that is, 0.80 or 80%. PI value for happy seeder machine was 0.88 or 88%. During the testing of multi-crop planter in year 2014, the variability of doubling attribute was more, that is, 28% followed by missing having 20% value and produced influence on PI which was observed to be 0.83 or 83%. PI of semi-automatic and automatic potato planter was found to be 0.70 and 0.80, respectively. The value was not much satisfactory and could be ranked under average category. PI of electrostatic sprayer mounted with single as well as twin nozzle was observed to be the highest, that is, 0.89 followed by PI of air assisted sprayer with single and double nozzle, that is, 0.83 and 0.84, respectively.

Key words: Precision index, zero till seed cum fertilizer drill, happy seeder, spraying machines, planting machines.

INTRODUCTION

Mechanization imparts capacity to the farmers to carry out farm operations, with ease and lesser drudgery. It helps the farmers to achieve timeliness, precisely meter and apply costly input with better efficacy and efficiency. Efficient machinery helps in increasing productivity by about 30% (Kulkarni, 2012) besides enabling the farmers

Abstract: The study was made in order to establish correlation between rainfall and ground water fluctuation of Ambedkar Nagar District in Uttar Pradesh through regression analysis. To study the trend in ground water level in eastern U.P. Ambedkar Nagar a model was fitted known as regression model with data for every year from 2008-2017 .The developed model equation is $Y' = -3.59 \times 10^{-3}X + 13.7678810$ .The coefficient of correlation between water table and rainfall was observed as − 0.5735. The result of study had been evaluated through r^2, RMSE and EC were found to be -0.574, 1.23 & 96.6% respectively. The above empirical equation may be useful in prediction of water table depth from rainfall for base line for boring of tube well for timely irrigation of crop.

Index Terms: Rainfall, Regression Analysis, Correlation, Groundwater, Fluctuation.

I. INTRODUCTION

In 1959-60 the area underground water irrigation which is less than six million hectare but went up to 18 million hectare in 1980-81 to 33 million hectares in 1999-2000. More than half of the total irrigation is based on ground water, the share of ground water in area increasing from 30% in 1960-61 to 58.77% in 1999-2000. The area underground water is increasing progressively because it the most reliable and cost effective source of irrigation (Joshi, 2002).

The rainfall contributes to the annual increment in the ground water reserve which in turn is reflected in the rise of water table during the post monsoon period. Estimation of water table is needed for planning and developing the resources. With increasing demand for water for both agricultural and industrial use, the need to develop ground water resources to maximun possible extent has gained importance. The main component of recharge of ground water is precipitation. The ground level is an indicator of ground water availability. Ground water is an important resource of irrigation of India. It contributes to enhance agricultural production was better realize during green revolution and miss management has result in several problem likes fluctuation in water table and increasing in depth of well. In last 10 year out of total monitoring wells 60% showed depletion in water table depth during per monsoon dry session. This leads to associated problem off lowering tube well depth and drying of open dug wells in the areas. Few areas with associated problem of lowering tube well depth and drying of open dug wells has becomes the major issues. This also indicates the decreasing trend of ground water table depth over a period of time. The fluctuation of water table is mainly depending upon the precipitation received in the area. Being insufficient annual rainfall and which is not sufficient to crop production, it is become essential to have the use of ground water. For irrigation purpose the ground water is utilized through tube well, pumping etc. For installation of the tube well is necessary to know the base the depth of table.

The present investigation entitled to "develop the model for the prediction and relationship between rainfall and ground water fluctuation of Ambedkar Nagar District" was carried out with objective to establish correlation between rainfall and ground water fluctuation.

ENERGY INPUT FOR FODDER CROP PRODUCTIONS UNDER DIFFERENT TYPES OF FARMING SYSTEMS

Pramod Kumar Mishra*, Sunny Sharma, Himanshu Tripathi and Dharmendra Pandey

Lovely Professional University, Phagwara, Punjab, India

Abstract

The pattern of energy utilize in cultivation of fodder crop was studied under traditional and partially mechanized farming system. It was observed that the total operational energy was found to be 6883.83 MJ/ha and 7298.73 MJ/ha in traditional and partially mechanized farming system respectively. Out of which 48.52 and 56.21 percent was utilized by direct source of energy in different farming systems, whereas 51.48 and 43.79 percent was utilized by indirect sources of energy. The total energy cost in traditional farming system was Rs 86450 /ha. Similarly, the cost of energy in partially mechanized system was Rs 93201 /ha. This difference clearly indicates that traditional farming system can be replaced by partially mechanized farming system with more return.

Key word: Partially mechanized farming system Energy ratio, energy productivity etc.

Introduction

Energy is integral part to national development process and to provide major vital services that improve human requirements; fuel for cooking, light for living, motive power for transport, and electricity for modern communication. In agricultural sector, its use is in every form of inputs, seed, fertilizer, agro-chemical for plant protection, machinery use for various operation, housing, transport, and processing. Apart from solar energy, production agriculture uses basic additional energy inputs, soil, water, tractive power, chemicals for growth of plants. The amount of energy invested through these inputs and quantity actually used by the plant govern the crop growth and yield during their life cycle.

Singh *et al.* 202 has estimated that total energy input Indian agriculture increased by 3.6 times. In modern agriculture, commercial energy sources (fuel, machinery and chemicals) contribute bulk of the energy supplies to the production system. Commercial energy use in agriculture has been increasing since revolution with increasing use of diesel and electricity in farm operations. The share of agriculture in electricity consumption has increased from 3.9% of the total consumption in 1950-51 to 29.6% in 1993-94. Total commercial energy use in agriculture increased nearly fivefold with growth rate of 11.8% between 1980-81 to 1994-95. The share of agriculture in total consumption in the country increasing marginally from 3.2 to 5.2% during the same period. Increase in land productivity and efficient diversification of agriculture for better economic return to the producers will call for significantly higher level of input to agriculture (Mahapatra, 1991).

India is presently under heavy stress on account of a large-scale exploitation for fuel wood, timber and fodder, mismanagement of forest resources and frequent fires. There is acute shortage of fodder especially green nutritious fodder, which is major cause of low productivity of livestock, especially in hilly area (Deb Roy *et al.*, 1989). The main reasons for low productivity is insufficient and low quality fodder and feed including grazing facilities (Deb Roy, 1993). Therefore, India has been the home of major draught, milch and dual-purpose breeds of cattle. Indian dairy production system is complex and generally based on traditional and socioeconomic considerations. However, there has been a rapid change in way of agriculture (*i.e.* cropping system, water resources, diversification of crops, intensification of agriculture), increasing use of mechanical power, transformation from

Impact of mass media on academic achievement of school going adolescent in Varanasi city

Dr. Alpana Singh and Sarita Srivastav

Abstract
Mass media is a type of communication means, which is used to reach large numbers of population via newspaper, radio, magazine and television. Academic achievement is a simple word that denotes status of achieving educational goals by students, decided by teacher through formal or informal tests. This study done with the objective, to find out the impact of mass media exposure and contribution of mass media on academic achievement of selected group. 200 boys and 200 girls of 15-19 years of age group from 8 schools of Varanasi city were selected for the study. Study reveals that there is significant impact of mass media exposure on academic achievement and significant contribution of mass media on achievement was found on male and female intermediate students of Varanasi city.

Keywords: mass media, academic achievement, school going adolescent

Introduction
The term mass denotes great volume, range or extent of people or production, while communication refers to the giving and taking of message, the transmission and reception of message. The term mass media refers to the organized means for communicating openly and at a distance to many receivers within a short space of time. Mass media transfer knowledge more effectively to large number of receivers at multiple points irrespective of the distance between source and the receiver.

Mass media has prominent importance for developing country like India, such countries face number of problems. They have to find out their solutions and communicate it to the people, about four to five decades ago this was not possible, but with advent of mass media as an effective means of propagation and communication it has been achieved. Mass media have created a media audience which is now more conscious about learning and knowing.

The academic achievement is the end product of the instructions. It is a desirable learning that is observed in the learner. Any behavior that learned is achievement. It is learned amount of knowledge, understanding and acquisition of skills. Academic achievement is the task oriented behavior that allows the individuals performances to be evaluated according to some internally or externally imposed criterion that involved the individual in competing with others or that otherwise involves some standard of excellence. Academic achievement is level of attainment or performance in academic work measured by standard test or teachers or both. Good (1973) has defined academic achievement as the knowledge attained or skills developed in the school subjects, usually designated by test scores or by marks assigned by teachers or by both.

In school situation academic achievement generally means the quality and quantity of master the curriculum by students. In present study academic achievement was conceived in terms of percentage of marks obtained by the students in their previous class examination and teachers rating about the students.

Objectives of the study
Without good objective researcher cannot achieve their goal. The present investigation was designed with specific objectives:

1. To find out impact of mass-media exposure on male and female intermediate students on academic achievement.
2. To find out contribution of mass media exposure on academic achievement of male and female intermediate students.

doi: 10.48165/aru.2022.2.2.2

ABSTRACT

Livestock plays a significant role in rural economy and livelihood by providing milk, meat, skin, drought power, etc. India's livestock sector is one of the largest in the world with a holding of 11.6% of the world's livestock population. But due to economic reasons, dairy farmers have a strong preference for female calves for milk production and hence there is a very limited demand for male calves. Furthermore, excessive focus on crossbreeding in the past few decades, increased mechanisation and the national policy to ban on cow slaughter have further added to the problem. In the common parlance, stray cattle include low-yield cows, bulls or calves that are abandoned and free to roam during dawn to dark because they are unproductive and creating a traffic nuisance in cities, they also attack crops in villages. Therefore, techniques for gender selection and skewing of sex ratio towards female are demanded of the hour. Flow cytometric sorting of spermatozoa is one of the best approaches to select the sexed semen for desire sex of calf, but its cost and patented technology is a definite disadvantage of this technology. In the present review, we will discuss in detail about the techniques available for skewing of sex ratio to address the stay animal population.

Introduction

India houses largest livestock population in the world (535.78 million) as per the 20th livestock census with a recorded increase of 4.6% over the previous livestock census of 2012. The total cattle inventory in the country is 305.5 million, which is the largest in the world followed by Brazil and China. Due to economic reasons, dairy farmers have a strong preference for female calves for milk production and hence there is a very limited demand for male calves. Rearing of male calf is an economic burden on dairy farmers. Hence a large number of male calves and unproductive animals are abandoned and are left as stray animals. India has over five million stray cattle, as per the 20th Livestock Census, which is a matter of concern for the country's livestock economy. All the major states with large livestock population, including Uttar Pradesh (17.34%), Madhya Pradesh (95.01%) and Punjab (38.69%)

Influence of Fortifying Graded Levels of *Moringa oleifera* Leaf Powder on Growth Performance and Haemato-biochemical Indices of Broiler Chickens

Ajeet K. Verma[1]*, Partha S. Pramanik[1], Manoj K. Verma[2], Sachin Gautam[3], Rajesh Kumar[4], Saurabh[4]

Abstract

The study was conducted to evaluate the influence of *Moringa oleifera* leaf powder (MOLP) on the growth and haemato-biochemical indices of broiler chickens. A total of 250-day-old broiler chicks (Vencobb-430) were randomly distributed into five groups with 5 replicates of 10 birds in each. Different dietary treatments were: basal diet with no supplement (NC- negative control) and a basal diet supplemented with antibiotics (PC-positive control), 1% MOLP (MOLP1), 1.5% MOLP (MOLP1.5), and 2% MOLP (MOLP2). Bodyweight gain (BWG), feed intake (FI), feed conversion ratio (FCR), haemato-biochemical parameters, and economics were assessed in 35 days of the experiment. The results showed that BWG of birds was significantly ($p < 0.05$) higher in all Moringa supplement groups than NC group, but similar to PC group birds. Feed intake and FCR of Moringa supplemented and PC groups were significantly ($p < 0.05$) lower than the NC group, except MOLP2, which showed no difference in FI compared with the NC group. MOLP1.5 group birds recorded the best value of FCR among different groups. The highest profit per broiler was recorded in MOLP1.5 followed by MOLP1 and MOLP2 than NC, similar to the PC group. Hb and PCV values of the MOLP1.5 group were significantly ($p < 0.05$) higher than the NC group but comparable to the PC group. Platelet and WBC count were significantly ($p < 0.05$) lower in Moringa supplemented groups than NC and PC groups. A significant ($p < 0.05$) reduction was observed in blood glucose, SGPT, SGOT, cholesterol, and triglyceride levels of Moringa supplemented groups as compared to broilers of PC and NC groups. From the results, it was concluded that supplementation of 1.5% *Moringa oleifera* leaf powder improved the performance of birds without any detrimental effect on their health.

Keywords: Broilers, Growth performance, Haemato-biochemical profile, Leaf powder supplement, *Moringa oleifera*.

Introduction

A very strong demand for animal protein for human beings has expanded, consolidated, and globalized in countries of all income levels. The poultry industry in India is one of the fastest-growing livestock sectors, with a growth rate of 8.51 and 7.52 % in egg and broiler production, respectively (BAHS, 2019). Antibiotic feed additives in food-producing animals have been used to meet the increasing demand for animal protein, including improved feed utilization, promotion in growth, and prevention from pathological micro-organisms. However, usage of antibiotic feed additives as growth promoters leads to harmfuleffects on consumer's health due to augmentation of microbial resistance and residual effect. Considering microbial resistance builds-up forces to reduce antibiotic feed additives in livestock and poultry production (Cheng *et al.*, 2019). Investigating safe and natural antibiotics alternatives is a tremendous challenge for animal scientists and veterinarians to meet the increased demand for providing wholesome meat at a low cost. Dietary inclusion of herbal plants and their extracts have been used as an alternative to antibiotic growth-promoter in poultry production (Movahhedkhah *et al.*, 2019).

Abstract

The present study was conducted to investigate the effect of different litter materials on growth performance of Kadaknath chicks. A total 300 Kadaknath chicks were raised on three litter treatments viz. Sand, rice hulls and rice hulls plus chopped paddy straw (1:1) comprising of two replicates in each treatment. The result showed that chicks reared on paddy straw + rice hulls litter had significantly higher body weight, lower feed intake and better FCR(P<0.05). The body weight of chicks raised under sand and rice hull liter did not differ significantly, however the average daily feed intake of chicks under rice hulls was significantly higher than that of under sand litter. The performance index of the earlier study period was significantly higher in paddy straw+ rice hulls followed by sand and rice hulls respectively.

Key words: *Kadaknath, feed, body weight, sand, rice hulls, litter materials*

Introduction

Desi fowls are cheaply reared as scavenging flocks by feeding household left over and their meat and egg taste are preferred over those of exotic chickens (Dessie and Ogle, 2001) .Wood shaving has been standard choice for poultry litter for many years. Rice hulls appear to be a favourable alternative to wood shavings (Grimes *et al*., 2007).Various types of litter materials like sand (shields *et al*., 2005), gypsum (Grimes *et al*., 2007), rice and wheat straw (Snehari Sharma 2010), ground corn cob and soyabean straw(De Avila *et al*., 2008) have been utilised as bedding materials for rearing of poultry birds. Sand has shown good potential as an alternate litter for more reuse usability and very less caking.

Pine shavings and saw dust are the most desirable and most widely used litter materials for broiler production in the United States. About 80% of farmers used saw dust as litter materials, 16.7% used wood shaving, 20% used both wood shaving and saw dust while 3.3% of farmers do not use bedding materials. The types of litter used by farmer depend on locality and availability (Kala S. 2015) . Paddy husk is most commonly used litter material in northern India.Sigroha et al., (2017) used saw dust, wheat straw, rice husk, river bed sand and sandy soil as litter materials and found higher weight of birds at +2 days of age in wheat straw followed by sandy soil, saw dust, river Bed sand and rice husk. As far as seen in literature there is no concert conclusion for litter type and thickness for various regions and climates. In view of above a study was undertaken with following objectives-

To investigate the effect of litter material on the growth performance of kadaknath fowls

To study the feed conversion efficiency of kadaknath fowls under various bedding materials

Materials and Methods:

The present investigation was carried out to study the effect of different litter materials on growth performance, feed gain ratio of Kadaknath fowl. The study was carried out at the poultry unit of Teaching Livestock and Poultry farm of the College of Veterinary science and Animal Husbandry, N.D.U.A.T. Kumarganj, Faizabad U.P., situated at a distance of 42 km away from Faizabad city and 38 km away from Jagdishpur Industrial area at an altitude of 113 m above sea level and latitude of 26° 47 North and longitude of 82° 12' East and it falls in Eastern Main Zone of Middle Gangetic Plain region of India.

Experimental period and climatic conditions

The experiment was conducted in the months of November to February which comprised winter season of this region. During this period, the climatic parameters have been shown in table 3.1. The average minimum temperature recorded during study period was 12.54°C, while the average maximum temperature was 24.86°C. There were a few showers of rain, ranging from 62 to 123 cm and average was 92.5 cm during this period. The topography of land is almost even and most of the farm area remains dry round the year. Parasitic infestation was moderate.

Climatological parameters recorded during experiment period

S.No	Climatological Parameters	Average Value	Average Max	Average Min
1.	Environmental temperature(°C)	18.7	24.86	12.54
2.	Relative humidity (%)	70.35	77.68	57.86

Experimental animals

To carry out present investigation, 300 straight run day old Kadaknath Chicks, from college hatchery were got issued. These 300 Kadaknath chicks were divided into two batches; each batch consisted of 150 Kadaknath Chicks. Each batch was subdivided in three equal groups of 50 chicks viz. Group1 (sand), Group2(rice hulls), Group3(paddy straw + rice hulls) randomly distributed among three pens. Each pen was equipped with fresh litter, feeder and waterer. All the birds were raised on pukka floor with sand, rice hulls and paddy straw + rice hulls (50:50) as litter materials. Chicks were reared under standard uniform managemental practices up to the age of 42 days and observations for different parameters were recorded simultaneously. Thereafter, a replication was made with the next batch of chicks.

Brooding and rearing of chick

Brooder house

The cold room brooding method was applied for brooding and rearing of Kadaknath Chicks in the brooder house. Brooding was done on pukka floor using deep litter system. Each group of Kadaknath chicks placed in separate pens which were visually isolated from each other along with provision of adequate ventilation and artificial light in the brooder house.

Preparation of brooder house to receive Kadaknath chicks

Brooder house was properly scrubbed and cleaned at least a week before the trail began. After the house, equipments were properly cleaned. The house was allowed to dry out thoroughly. The house and equipments were fumigated using 1% formalin. Three inches depth of litter were made on the floor. Few days before the chicks arrived, equipments were arranged in brooder house and the electric bulbs were started to adjust temperature and light. The temperature under the brooder house was slightly above 35°C. The corners of brooding space were made rounded off with cardboard and metal chick guards to prevent chicks from piling up in the corner. All these preparations

Eggs, Fertility, Hatchability, Kadaknath and Aseel

ABSTRACT

The present study was conducted to compare the fertility and hatchability of Kadaknath and Aseel fowls. For this purpose 50 birds from each breeds comprising of 45 females and 5 males were selected and kept in two different pens at poultry unit of Teaching Livestock and Poultry Farm of the College of Veterinary Science and Animal Husbandry, N.D.U.A.T. Kumarganj Faizabad (U.P.). Fertility was found higher in Kadaknath (86.18) than Aseel (81) with significant difference among them. Both hatchability on set egg and hatchability on fertile eggs were significantly differed among two breeds being higher in Kadanath. Average chick weight was found higher in Aseel than Kadaknath. Normal chick % was found highest in Kadaknath followed by Aseel. This result indicates that Kadanath are superior to Aseel in relation to fertility, hatchability and related traits.

Introduction

Indian poultry industry has made a tremendous and remarkable progress evolving from small scale backyard venture to the status of commercial, full-fledged, self sufficient and most progressive agro based industry. Poultry accounts for more than 30% of all animal protein consumption worldwide (Permin and Pedersen, 2000).Fertility and hatchability are the main factor which affects the profitability in the hatchery enterprise (Peters *et al.*, 2008).These parameters appears to be very important as for as parent stocks are kept to produce final hybrids. Hatchability is a major complex age dependent traits. Egg production and hatchability of broiler eggs can be influenced considerably by age of flock (Elibol *et al.*, 2002). Kadaknath (KN) is an important Indian reared poultry breed which is well known for poor egg production, slow growth rate, smaller body size as well as late sexual maturity. Aseel is noted for its Pugnacity, high stigma, and majestic gait and dogged fighting qualities.

The present experiment was designed –

1. To find the fertility, hatchability and associated traits in Kadaknath and Aseel.
2. To find out the correlation among hatchability traits in Kadaknath and Aseel.

EFFECT OF DIFFERENT LITTER MATERIALS ON BEHAVIOR OF KADAKNATH FOWLS

Abstract

The present study was conducted to investigate theeffect of different litter materials on behavior of Kadaknath chicks. A total 300 Kadaknath chicks were raised on three litter treatments viz. Sand, rice hulls and rice hulls plus chopped paddy straw (1:1) comprising of two replicates in each treatment. The results indicate that Kadaknath chicks reared on sand and rice hull litter had significantly higher proportion of time in activities like drinking, dust-bathing and perching than paddy straw+rice hulls. The behavioral activities like drinking, dust bathing, stretching, standing and perching in sand litter, dust-bathing, peaking, stretching, walking, lying and perching in rice hulls and peaking, stretching and standing in straw+rice hulls were seemed to be significantly differed in morning, noon and evening hour interval.

Key words: Kadaknath, feed, behavior, sand, rice hulls, litter materials

Introduction

Desi fowls are cheaply reared as scavenging flocks by feeding household left over and their meat and egg taste are preferred over those of exotic chickens (Dessie and Ogle, 2001). Wood shaving has been standard choice for poultry litter for many years. Rice hulls appear to be a favourable alternative to wood shavings (Grimes *et al*., 2007). Various types of litter materials like sand (shields *et al*., 2005), gypsum (Grimes *et al*., 2007), rice and wheat straw (Sreehari Sharma 2010), ground corn cob and soyabean straw (De Avila *et al*., 2008) have been utilised as bedding materials for rearing of poultry birds. Sand has shown good potential as an alternate litter for more resale quality and very less caking.

Pine shavings and saw dust are the most desirabe and most widely used litter materials for broiler production in the United States. About 50% of farmers used saw dust as litter materials. 16.7% used wood shaving, 20% used both wood shaving and saw dust while 3.3% of farmers do not use bedding materials. The types of litter used by farmer depend on locality and availability (Kalu E. 2015) . Paddy husk is most commonly used litter material in northern India.Sigroha et al., (2017) used saw dust, wheat straw, rice husk, riverbed sand and sandy soil as litter materials and found higher weight of birds at 42 days of age in wheat straw followed by sandy soil, saw dust, river bed sand and rice husk. As far as seen in literature there is no concert conclusion for litter type and thickness for various regions and climates. In view of above a study was undertaken with following objectives-

- To investigate the effect of litter material on the behavior of kadaknath fowls

Materials and Methods

The present investigation was carried out to study the effect of different litter materials on growth performance feed gain ratio of Kadaknath fowl. The study was carried out at the poultry unit of Teaching Livestock and Poultry farm of the College of Veterinary science and Animal Husbandry, N.D.U.A.T. Kumarganj, Faizabad U.P., situated at a distance of 42 km away from Faizabad city and 38 km away from Jagdishpur Industrial area at an altitude of 113 m above sea level and latitude of 26° 47 North and longitude of 82° 12 East and it falls in Eastern plain Zone of Middle Gangetic Plain region of India.

Experimental period and climatic conditions

The experiment was conducted in the months of November to February which comprised winter season of this region. The average minimum temperature recorded during study period was 12.54°C, while the average maximum temperature was 24.86°C. There were a few showers of rain, ranging from 62 to 123 cm and average was 92.5 cm during this period. The topography of land is almost even and most of the farm area remains dry round the year. Parasitic infestation was moderate.

Experimental animals

To carry out present investigation, 300 straight run day old Kadaknath Chicks, from college hatchery were got issued. These 300 kadaknath chicks were divided into two batches; each batch consisted of 150 Kadaknath Chicks. Each batch was subdivided in three equal groups of 50 chicks viz. Group1 (sand), Group 2(rice hulls), Group3 (paddy straw + rice hulls) randomly distributed among three pens. Each pen was equipped with fresh litter, feeder and waterer. All the birds were raised on pukka floor with sand, rice hulls and paddy straw + rice hulls (50:50) as litter materials. Chicks were reared under standard uniform managemental practices up to the age of 42 days and observations for different parameters were recorded simultaneously. Thereafter, a replication was made with the next batch of chicks.

Brooding and rearing of chick

Brooder house

The cold room brooding method was applied for brooding and rearing of Kadaknath Chicks in the brooder house. Brooding was done on pukka floor using deep litter system. Each group of Kadaknath chicks placed in separate pens which were visually isolated from each other along with provision of adequate ventilation and artificial light in the brooder house.

Preparation of brooder house to receive Kadaknath chicks

Brooder house was properly scrubbed and cleaned at least a week before the trail began. After the house, equipments were properly cleaned. The house was allowed to dry out thoroughly. The house and equipments were fumigated using 1% formalin. Three inches depth of litter were made on the floor. Few days before the chicks arrived, equipments were arranged in brooder house and the electric bulbs were started to adjust temperature and light. The temperature under the brooder house was slightly above 35°C. The corners of brooding space were made rounded off with cardboard and metal chick guards to prevent chicks from piling up in the corner. All these preparations were completed for Kadaknath chicks before they were procured to brooder house. A chick guard of about 15 cm height was used at a distance of 30 to 40 cm away from the brooder and was moved away for the every day. It was completely removed after two weeks.

Litter materials

For the present experiment three litter materials namely sand, rice hulls and paddy straw + rice hulls (50:50) were used for rearing the Kadaknath chicks. Rice hulls were procured from the nearby rice mill, paddy straw taken from village shivrathpur and sand was taken from kumarganj market. These litters were clean, dry and free from fungal growth. The thickness of litter was 3.0 cm. After spreading this litter on the floor with proper thickness was covered with newspaper up to 4 days of brooding.

Parameters recorded

Behaviour

The behaviours in the Kadaknath recorded in this study were chosen from preliminary observations and defined as a list of 12 states which have given here.

1. Eating
2. Drinking

Effect of various storage media and storage period on bare root transplanting of aonla (*Emblica officinalis* Gaertn.) budlings

HK Singh, CS Pandey, Ashish Singh, Bhanu Pratap and Anil Kumar

Abstract
The experiment was carried out at experimental orchard of Department of Horticulture, NDUAT, Ayodhya (U.P). Based on the finding from present experimentation it was concluded that aonla bare rooted budling can be transported to distant places with good success. Among the storage media moist gunny bag and sphagnum moss followed by polythene sheet + sphagnum moss proveel equally effective for a period of more than 48 hours in keeping bare rooted budlings fresh for transplanting success.

Keywords: Budling, gunny bag, moss grass, polythene sheet

Introduction
Aonla or Indian gooseberry is an important fruit Indigenous to India. It can be successfully cultivated in marginal soils and various kinds of wastland. The poor establishment of budlings after transplanting is a major problem. On other hand transplanting budlings with earth ball cost heavy loss of fertile nursery soil and increases cost of transport budlings to distance places (Pareek and Vashishthag), bare rooted transplanting with growth regulators (Singh *et al*., 1982; Singh and Pandey, 2003) [6] and other treatment has been done with varying success (Sandhu *et al*., 1983a) [5]. Storage of budling often required because of labour problem, unfavorable weather condition, delay in field prepration transplanting loss and transplanting success owing to excessive loss from budlings. To overcome these problems transplanting of bare rooted aonla budling success need to find a suitable storage and period of storage.
Media for storage of budling for longer period for better transplanting success.

Materials and Methods
The experiment was carried out at experimental orchard of Department of Horticulture, NDUAT, Ayodhya (U.P). For the study single stem defoliated uniform in age and vigour budlings were selected for different storage medium and period of storage. There were four storage media, V12 moist, gunny bag, sphagnum moss, polythene sheet and polythene sheet + sphagnum moss, similarly four storage period V12, control (zero day) 48, 96 and 144 hours. Ten budlings were transplanted in field at each date at 30x30 cm apart, replicated thrice. The observations were recovered on transplanting success and plant growth of budling were recoverd after 150 day of transplanting. The data was analyzed as per method given by Panse and Sukhatme (1989) [4].

Results and Discussion
Storage medium and period played vital role in esbalishment of anola budling (Table -1). Bare rooted budlings stored in moist gunny bag showed highest success (75.0%) closdy followed by sphagnum moss (74.17%) and polythene sheet + sphagnum moss (71.67%). Budlings establishment decreased during storage but budlings establishment was not affected up to 48 hrs storage. Data presented in Table 2 indicated quicker sprouting (25.75 days) in polythene sheet + sphagnum moss stored budlings. Budlings stored in moist gunny bag (28.42 days) was statistically at par with sphagnum moss stored budlings. The time taken was significantly less in case of 48 hrs storage (24.50 days as compared with other storage period. It is evident from table 3 & 4 that budling hight and diameter were influed by various storage media and period of storage. The plant hight was highest (109.25 cm) in moist gunny bag an minimum in polythene sheet stored budlings to were, the values did not differed significantly in other store medium except, polythene sheet storage. Bundling diameter ranged between 1.13 cm in polythene sheet to 1.21 cm in moist gunny bag storage media and differed significantly. Budling diameter decresed with increase in storage period being (1.25 cm) in immediate

Bird Diversity in Riverscapes of Ayodhya District, Uttar Pradesh

Yashmita-Ulman

Department of Silviculture & Agroforestry, College of Horticulture & Forestry
ANDUAT, Kumarganj, Ayodhya-224 229, India
E-mail: yashmita2018@gmail.com

Abstract: The bird diversity using line transect method along the 45 km stretch of Saryu river between Aharauli and Pitapur in eastern Uttar Pradesh was assessed. A total of sixty eight bird species, belonging to 56 genera, 35 families and 12 orders were recorded from the study area. Passeriformes (24) had the maximum number of bird species. The maximum encounter rate was for Indian Silverbill (2.685) and the minimum for Blue-tailed Bee-eater (0.054). Out of 68 bird species recorded, 56 bird species (82%) were resident, 11 bird species (16%) were winter visitors and only 1 bird species (1%) was summer visitor. A large number of Carnivores (29 species, 43%) were recorded in the area. Of the recorded species, nine were in the threatened category of IUCN Red List and eighteen species (26%) of birds had a declining population trend globally highlighting the conservation value of riverscapes of Saryu river. This study has helped in generating a baseline information on the bird diversity of the Saryu river and emphasis on carrying out long-term monitoring of birds in such threatened ecosystem.

Keywords: Avian, Freshwater ecosystems, Feeding guild, Ayodhya, Saryu river

Freshwater is a natural resource which is important in terms of economy, culture, science and education (Dudgeon et al 2006). Freshwater habitats including rivers, streams, lakes, oxbows, wetlands and estuaries etc. and their adjacent areas called riparian zones alone support around 6% of world known species (Hawksworth and Kalin-Arroyo 1995). Birds are an important constituent of the riverscape. A riverscape is a landscape constituting of the streams, floodplains and riparian zones along a river channel (Wiens 2002). The riverscapes provide essential dispersal pathways, shelter, breeding and nesting sites for the birds, thus supporting high bird species diversity (Sinha et al 2019). But as these riverscapes are exposed to anthropogenic pressure due to its productivity and developmental activities, these areas are the most threatened ecosystems of the world (Revenga et al 2005). Thus, leading to loss of the ecosystem and their associated bird diversity. These riverscapes are meagerly managed from conservation point of view. In addition, the existing knowledge on bird diversity in these ecosystems is incomplete and insufficient to assess the impacts of anthropogenic pressures on bird diversity loss.

The river Ganga is one of the largest rivers with many tributaries flowing through 2510 km from north to east India (Adel 2001). This river supports 8% of the world's population living in its catchment (Newby 1998). Understanding the bird diversity, abundance and habitat preferences are necessary baseline parameters for planning conservation activities, but such information is meagre from certain tributaries of Ganga. Studies have been conducted on the faunal diversity of some segments along the stretch of Ganga (Behera 1995, Bashir et al 2012). Ghaghra river is one of the principal tributaries of river Ganga. The Ghaghra joins its sub-tributary, the Sharda river and flows through the district of Ayodhya where it is locally known as Saryu river (Dhar and Nandargi 2002, Singh et al 2016). There have been no bird diversity studies done on the Saryu river flowing through Ayodhya district, Uttar Pradesh. Therefore, in this study, an attempt was made to document the bird diversity in the catchment area of river Saryu.

MATERIAL AND METHODS

The study was conducted in a 45 km stretch of Saryu river flowing between Aharauli 26.858°N and 81.814°E and Pitapur 26.782°N and 82.256°E in Ayodhya district, Uttar Pradesh (Fig. 1). The banks of this river are sandy or muddy; the floodplains are mosaic of agriculture, orchards, forests, grasslands etc. The climate of the district is tropical monsoon. The average temperature varies from 32°C in summers to 16°C in winters and the average annual rainfall is 1067 mm (Anonymous 2021). There are three distinct seasons – summer (March to June), rainy (July to October) and winter (November to February). Hundreds of pilgrims visit the river banks of Saryu during Hindu festivals to perform religious ceremonies.

The entire 45 km stretch of the Saryu river in Ayodhya district was divided into nine segments of 5 km each. Bird survey was done using line transect method (Gregory et al 2004) in five segments (selected based on their accessibility and feasibility of sampling), so in all covering a stretch of 25 km. Five transects (5 km each) were laid parallel to the river

Received 27 January 2020; revised 01 June 2021

Agroforestry is an age-old practice in Assam, the Northeastern state of India. But the documentation of such traditional practices is very meagre. Assam has six agro-ecological zones. This paper attempts to present the different types of traditional agroforestry systems practiced in North bank plains of agro-ecological zone of Assam. The documentation was done through direct observations. A questionnaire survey was done of 500 households in 250 villages distributed across four districts (Dhemaji, Lakhimpur, Sonitpur and Darrang) of Assam. Altogether 11 types of traditional agroforestry systems are recorded. Homegarden is the most common agroforestry system in all the four districts followed by aquaforestry and commercial crops trailed on support trees. The least common agroforestry system is *Machilus*-based agroforestry system and this system is not recorded from Darrang and Sonitpur districts of Assam. The choice of species and their planting pattern are influenced by their tradition, usage pattern and need of the agroforestry system's owner. These traditional agroforestry systems are a part of their traditional knowledge which is intervened with their traditions and culture. It is a blend of time-tested knowledge of indigenous species, their compatibility and species planting pattern such that the yield is maximized. So, the documentation of these environment-friendly traditional practices is essential to advocate climate-smart and sustainable approach in agriculture.

Keywords: Assam, Aquaforestry, *Areca*-based cropping, Live fence, *Machilus*-based agroforestry

IPC Code: Int. Cl.[22]: A01D 9/00, A01G 23/00

The traditional agroforestry is a human-managed land-use system in which woody perennials are intentionally grown in association with agricultural crops, pastures as well as livestock. Most of these traditional farming practices are rainfed and for household consumption purposes. The crops planted, the crop combination and the sequence of cropping in these traditional practices depend upon the edaphic, climatic, topographic conditions of the area and socio-economic status of the people. These practices are passed on from generation to generation but are not documented. In the recent years, these traditional ways of farming and cultivation are gaining importance as these practices are sustainable and environment-friendly. Therefore, emphasis is being given on documentation of these fast-depleting traditional methods of cultivation.

The traditional agroforestry systems and its practices have been documented in many countries such as Africa[1], China[2], Turkey[3] and Bangladesh[4]. In India, though agroforestry is being practiced from ancient times, only a few authors have documented these practices. A thorough literature review highlighted an inventory of the existing agroforestry systems in different states of India such as Kerala[5], Uttar Pradesh[6], Meghlaya[7], Arunachal Pradesh[8], Chattisgarh[9] and Nagaland[10]. Four agroforestry systems namely rainfed agrihorticultural system (*Cocos nucifera, Areca catechu, Citrus* sp., *Zingiber officinale, Curcuma longa*), silvipastoral systems (*Artocarpus* sp., Napier grass, Guinea grass), silvihortipastoral systems (*Bombax ceiba*, Thatch) and irrigated silviagrosystem (*Azadirachta indica, Oryza sativa* and oilseeds) are reported from Assam[11].

It is quite evident from the above that traditional agroforestry systems are present in Northeast India, and there is only a single case of inventory of the systems practiced in Assam. This shows that many agroforestry systems and practices still remain to be documented from this region. Therefore, there is a need to capture the local and traditional plant management practices before these are lost forever. Also, with the increasing

Abstract: Traditional agroforestry systems are designed to provide maximum and diverse yield (ranging from agricultural crops, forest trees, livestock and fish) to people. They also act as sources of food and shelter to wild animals leading to crop destruction, livestock depredation and injuries to people giving rise to negative human-wildlife interactions. The present study was carried out in three different agroforestry systems namely tea gardens, homegardens, and agrisilvicultural systems in Assam to document the attitude of people towards wild animals which damage the crops and livestock, through questionnaire surveys. In agroforestry systems, 13 animals were reported as destructive; rodents at 13% followed by Indian Hare at 12%. The least destructive were birds and bats with 4% each. In tea gardens majority of the people killed animals for meat (95%) and the most common method for killing was the use of catapults (77%). In homegardens and agrisilvicultural systems, owners chased the animals away (82%) by using catapults (68%). Hunting of animals and intolerance of people towards crop destruction and livestock depredation done by wild animals were the two main reasons causing negative human-wildlife interactions in agroforestry systems. The present study concludes that wildlife species found in the agroforestry system in Assam were threatened by local inhabitants and thus, a suitable conservation awareness and policy action plan should be developed in consultation with the owners of agroforestry systems by considering the ecological significance of the wildlife species found therein.

Keywords: Agrisilvicultural systems, agroforestry systems, crop destruction, destructive wildlife species, homegardens, tea gardens.

ABSTRACT

This study conducted from January to June 2018, attempts to determine the density, habitat preferences and attitudes of people towards *Gekko gecko* and its impact on the conservation of this species in human-dominated landscapes in Sonitpur district, Assam. Eight villages at different distances from Nameri Tiger Reserve were chosen for the study. The line transects analyzed using DISTANCE software estimated a density of 7.99 individuals ha^{-1} in fringe villages of Nameri Tiger Reserve which also had higher number of host tree species diversity with higher basal area and density as compared to that of villages distant from Nameri Tiger Reserve. *Gekko gecko* was sighted on a total of 30 trees (6 species, 2 families), the highest being *Ficus rumphii* (40%). Maximum sightings of *Gekko gecko* was done on trees (67%). The occurrence of *Gekko gecko* was highly influenced by distance from forest (12%), followed by source of income (11%) and gender (4%). The majority of the respondents (53.54%) revealed that *Gekko gecko* occurred naturally in the homegardens implying that homegardens provided the habitat that can support the populations of *Gekko gecko*. But 46.45% of the respondents reported that they were adopted (62.16% in villages distant from Nameri Tiger Reserve), which raises serious concerns about the conservation of *Gekko gecko* in homegardens. Though, majority of the people knew that it is illegal to trade *Gekko gecko*, the financial benefits of its trade is very alluring. To make homegardens more favourable for the survival of *Gekko gecko* there should be strict law enforcement, upgradation of the species in the IUCN Red List and options for alternative livelihood.

1. Introduction

Biodiversity conservation is a challenge for the conservationists, as the tropical forests are getting depleted, fragmented and isolated into human-modified landscapes [31,33]. Moreover, the protected areas set aside to protect the species and its habitat [5] are under constant human pressure [27]. Many studies have suggested that the natural habitats outside protected areas also have the ability to conserve species diversity [23]. So, the need of the hour is to conserve biodiversity in these rapidly increasing human-dominated landscapes which are outside the protected areas. But the anthropogenic pressure in these landscapes alters the ecosystems processes [45]. The existence of native fauna in such areas depends upon their ability to traverse through the modified habitats, patches and to adjust with the constant changes in their habitat [13]. Reptiles are conspicuous and abundant in nature making them good candidates for studies on understanding the impact of habitat change [20]. As reptiles are found in diverse habitats and niches, they are very sensitive to landscape level changes and deforestation [22,59]. They are also vulnerable to the micro-habitat level changes due to their ectothermic nature [42]. Yet studies have shown a high persistence of reptiles in altered habitats [54,60].

Northeastern India is known to harbor a good reptile diversity (121 species) with a high percentage of endemic and threatened species [44]. But as conversion of tropical forests into tea plantations, agricultural lands, human habitations etc. is very rapid in the northeastern states of India, it leads to fragmentation, deforestation [10–12] and thus habitat loss and decline in reptilian species [57]. The Sonitpur district of Assam alone has reported conversion of well stocked forests into human-dominated landscapes leading to an overall loss of 232.19 km^2 of forest between 1994 and 2001 [55]. The human-dominated systems like homegardens, agricultural lands, cacao and coffee plantations interspersed with secondary forest patches and remnant vegetation are known to harbor rich reptilian diversity comparable to the adjacent forests [50,60,61]. But in such human-dominated areas, the attitudes of the local communities plays an important role in the conservation of species as such areas are known for their negative interactions with faunal species [66,67]. Due to the dearth of information on the population density

Bird composition, diversity and foraging guilds in agricultural landscapes: a case study from eastern Uttar Pradesh, India

Yashmita-Ulman [1] & Manoj Singh [2]

[1] Department of Silviculture & Agroforestry, College of Horticulture & Forestry, Acharya Narendra Deva University of Agriculture and Technology, Ayodhya, Uttar Pradesh 224229, India.

Abstract: Birds have a significant role in maintaining the ecological balance of agro-ecosystems. But yet there is no documentation related to bird diversity in the agricultural landscapes of eastern Uttar Pradesh. This study was conducted from March 2019 to February 2020 using fixed radius point count method in Ayodhya district of eastern Uttar Pradesh. A total of 139 bird species belonging to 107 genera, 49 families and 15 orders were recorded from the study area. Passeriformes was the most dominant order with 28 families and 76 species. Accipitridae and Muscicapidae were the most diverse families with 11 species each and RDi value of 7.91. Among the recorded bird species, 105 species (76%) were resident, 29 species (21%) were winter visitors and only 5 species (4%) were summer visitors. According to the feeding guilds, omnivores (46 species, 33%) were highly represented, followed by insectivores (31%), carnivores (25%), granivores (6%), frugivores (4%) and nectarivores (1%). The Sohawal tehsil was found to have the highest species richness and a Shannon-Weiner diversity index (133, 4.30). *Aquila nipalensis* and *Neophron percnopterus* were the two 'Endangered' species, *Antigone antigone* and *Clanga hastata* were the two 'Vulnerable' species and *Ciconia episcopus, Gyps himalayensis, Mycteria leucocephala* and *Psittacula eupatria* were the four 'Near Threatened' species found in this region. In addition to this, the region also supported 31 species (22%) whose global population trend is decreasing. This study provides a baseline data on the bird diversity present in agricultural landscapes of this region. Based on which further studies should be designed to understand the factors influencing the diversity of birds in these agricultural landscapes which are continuously subjected to anthropogenic pressures.

Conservation of Plant Diversity in Agroforestry Systems in a Biodiversity Hotspot Region of Northeast India

Yashmita-Ulman[1] · Manoj Singh[2] · Awadhesh Kumar[3] · Madhubala Sharma[3]

Received: 18 January 2020 / Accepted: 15 October 2020

Abstract In Assam, a north-eastern state of India, most of the traditional agroforestry systems are still practised. The plant species composition of three agroforestry systems namely homegardens tea gardens and agrisilvicultural systems, were assessed using quadrat method. A total of 516 plant species belonging to 241 genera under 91 families were recorded, which consisted of 134 trees, 143 shrubs (67 shrub species and 76 species of saplings) and 239 herbs (93 herb species, 33 climber species and 113 species of seedlings). Homegardens had the highest species richness (475 plant species) belonging to 234 genera under 90 families. This was followed by agrisilvicultural systems (101 spp., 43 genera, 29 families), and the least was in tea gardens (79 spp., 41 genera, 25 families). The highest average number of plant species per system was recorded in homegarden (108.96 ± 5.96, range 23–207 spp.). A negative correlation was found between the agroforestry system plot size and plant species richness. Sorenson's similarity index showed a very low degree of similarity in the plant species recorded among the three selected systems. Out of 516 plant species recorded across the different agroforestry systems, 1.0% species (n = 3) were vulnerable (*Aquilaria malaccensis, Saraca asoca* and *Santalum album*), 8.9% species (n = 46) were least concerned, 1.6% species (n = 8) were data deficient and 88.6% species (n = 457) were not assessed. Only homegarden recorded all the three plant species under the vulnerable category of IUCN Red List. It can be concluded that the agroforestry systems, specially the homegardens harbour rich plant diversity and act as miniature versions of natural forests by conserving rare, threatened and data-deficient plant species. The results suggest that the agroforestry systems with some management interventions need to be promoted as conservation models in areas with high pressure on tropical forests.

Keywords Assam · Agroforestry system · Homegardens · Tea gardens · Plant species richness

Introduction

Traditionally, the farmers have been known to retain tree cover in agricultural landscapes, around home spaces and in cash crop plantations as shade trees. Apart from these traditional practices, the increasing rate of tropical deforestation has led to an increase in number of forest or secondary forest growth fragments intermingled with human-managed landscapes consisting of agriculture and plantations. These current forms of land-uses usually known as agroforests have now become the prominent landscapes which have a potential of conserving the natural and native vegetation [25]. These agroforestry systems not only provide food, fruits, vegetables, medicines and fuel but also

Conservation of Wildlife Diversity in Agroforestry Systems in Eastern Himalayan Biodiversity Hotspot

Yashmita-Ulman[1] · Manoj Singh[2] · Awadhesh Kumar[3] · Madhubala Sharma[3]

Received: 14 January 2020 / Revised: 22 February 2021 / Accepted: 1 March 2021

Abstract The highly diverse tropical forests are fast being depleted and converted into isolated fragments which endangers the existence of wild animals. These fragments are interconnected by human-dominated agroforestry systems. To conserve the wild animals it is important that such agroforestry systems have the potential habitat to support the survival of the enormous regional biota. The present study was carried out in agroforestry systems (agrisilviculture systems, home gardens and tea gardens) in Assam to understand their role in conservation of different biological groups (mammals, birds, butterflies, reptiles and frogs). Total visual count method was deployed in home gardens and agrisilviculture system and line transects were laid in tea gardens for recording the faunal diversity. Altogether, 364 animal species (consisting of 14 mammal species, 185 bird species, 133 butterfly species, 18 reptilian species and 14 amphibian species) were recorded from the selected study sites of agroforestry systems. The highest animal diversity was found in home garden (311 spp.), followed by tea garden (275 spp.) and agrisilviculture system (187 spp.). Out of the 364 species recorded, only 1.09% were threatened (endangered and vulnerable) species and 1.37% were near threatened species according to the IUCN Red List. Wild animal species richness was significantly and negatively associated with distance from forest and positively associated with fruiting and flowering vegetation. Thus, the agroforestry systems with their flowering and fruiting vegetation, though cannot substitute the forest habitat but can be useful in providing shelter to the generalist species and their populations.

Keywords Home gardens · Tea gardens · Agrisilviculture systems · Mammals · Birds · Butterflies

Introduction

Highly diverse ecosystems like the tropical forests, are being converted or deforested for agricultural expansion, developmental projects and land-use intensification (Pastur et al. 2012). It has resulted in habitat loss, degradation, fragmentation (Harris and Silva-Lopez 1992) leading to biodiversity loss (Flynn et al. 2009). One possible and effective solution to conserve biodiversity may be to manage the remaining contagious forest areas as protected areas and manage the human-dominated agricultural landscapes (Schroth et al. 2004) by adopting age-old methods of agroforestry. Agroforestry is the intentional growing of woody perennials along with annual crops and/or animals in the same unit of land (Nair 1993). Assam, a part of Northeast India region falls under the east Himalayan biodiversity hotspot. This state has abundant forms of agroforestry systems in place since ancient times. Ahmed and Hazarika (2007) broadly classified the agroforestry systems present in Assam into five types namely, Agri-horticultural system (*Ricinus communis*/*Sesamum indicum*/

Agroforestry Systems: A Boon or Bane for Mammal Conservation in Northeastern India?

Yashmita-Ulman[1] · Manoj Singh[2] · Awadhesh Kumar[3] · Madhubala Sharma[3]

Received: 28 December 2019 / Revised: 15 June 2020 / Accepted: 24 June 2020

Abstract The degradation, fragmentation and isolation of tropical forests have led to the formation of small patches of human dominated landscapes interspersed with forest fragments. This affects the wildlife habitat and its population negatively. These human landscapes have been observed to have agroforestry systems as a dominant cropping practice in Assam, India. The present study was carried out in agroforestry systems (agri-silviculture systems, home gardens and tea gardens) to understand their role in the conservation of mammal species. Line transects and camera traps were used for recording mammal diversity. Altogether, 17 species of mammals belonging to 16 genera and 14 families were recorded in the selected agroforestry systems. The highest species richness was found in the home gardens (14) and the lowest was found in the agri-silviculture system (10). Home garden had the highest mammal encounter rate and relative abundance. Only five species of mammals were recorded through camera trapping. According to the IUCN Red List, 6% of mammal species recorded in the selected agroforestry systems were endangered or near threatened and 18% were vulnerable. The highest hunting trap encounter rate was found in tea garden (139 traps, 0.181 traps km^{-1}, 24 captures). Distance from forest was inversely proportional whereas hunting threat was directly proportional to mammal species richness. The only and strongest predictor of mammal species richness was hunting threat which accounted for 53.5% of variation in mammal species richness in the study area, implying that the agroforestry systems are capable of conserving species if hunting pressure is reduced. Therefore, promotion of alternative livelihood and formation of community conservation groups are needed to increase and protect the mammalian diversity in these agroforestry systems. Thus, agroforestry systems can act as a suitable habitat next to forests for the dwindling wildlife population.

Introduction

Agroforestry systems (practice of combining trees with agricultural crops) are known to contribute in wildlife conservation owing to their structure and vegetation composition. Schroth et al. (2004) identified three roles of agroforestry in biodiversity conservation namely, provision of alternative habitats for generalist species, reduction of primary forest conversion rates and conservation of wildlife populations by connecting isolated habitat remnants. The various types of agroforestry systems like live fences, riparian forests and shade-grown crops etc. have been known to provide habitats for animal species such as moths (Ricketts 2001), birds (Greenberg et al. 2000; Klein et al. 2003; Bos et al. 2007; Schroth and Harvey 2007), terrestrial mammals (Estrada et al. 1994) and bats (Estrada et al. 1993; Faria and Baumgarten 2007). Gallina et al. (1996) has studied the mammalian diversity in coffee agroforestry

Summary
This study examines the purple sunbirds' (*Cinnyris asiaticus*) vocalizations in different habitats to assess the vocal adjustments made by the bird to avoid masking of its acoustic signals in noisy conditions. Sampling of acoustic signals of purple sunbird at different sites was done at sites with varying background noise levels by simultaneously recording the audio samples as .wav files, and the corresponding sound pressure levels. We identified twelve different types of vocal signals in purple sunbird based on their morphological appearance in the spectrogram. Correlation analysis between background noise levels and spectral parameters of most of these signals showed weak and statistically non significant association between them. However, a statistically significant positive association was found between song amplitude and background noise levels. While our results support the presence of Lombard effect in purple sunbird vocalizations in noisy conditions, they do not seem to suggest any associated changes in spectral content in such conditions.

PACS no. 43.80.-n

1. Introduction

Globally expanding urban perimeters and fast developing transportation network have been associated with increasing anthropogenic noise [1]. It is now well known that increased noise levels in urban habitats may mask acoustic communication in many bird species, and can cause changes in their acoustic behavior [2, 3, 4, 5, 6]. Birds rely on acoustic communication for a variety of functions such as mate attraction, territory marking, predator alarm, begging for food, contact with neighbours, availability of food and for many other functions [7, 8, 9, 10]. Hence, their survival and reproductive success are adversely influenced by increase in the background noise which tends to mask bird vocalizations [11, 12, 13, 14].

Birds adjust their vocal behavior in different ways to overcome the negative effects of noise on signal communication. This includes shifting the vocalization temporally to quieter periods [15], increasing signal repetition [16], raising the amplitude i.e. Lombard effect [17, 18, 19, 20, 21] and altering the spectral content [22] of vocalization. Among these, the latter two strategies i.e. raising the amplitude and altering the spectral content have drawn considerable attention of researchers across the world.

Slabbekoorn and Peet (2003) reported frequency adjustment in great tits (*Parus major*) in the city of Leiden (The Netherlands) where individuals in territories with higher noise levels were found to sing songs at raised minimum frequencies [22]. Since then, this strategy of song frequency adjustment has been reported repeatedly in many other studies. For instance, similar frequency shift was also reported in other populations of great tits (*Parus major*) [5, 23, 24, 25], song sparrows (*Melospiza melodia*) [26], house finches (*Carpodacus mexicanus*) [27, 28], chiffchaffs (*Phylloscopus collybita*) [29], black-capped chickadees (*Poecile atricapillus*) [30]. Interestingly, many of these studies report that it is the minimum song frequency that is shifted upwards, presumably as a response to avoid signal masking by the low-frequency traffic noise.

However, Brumm and Zollinger (2011) argued that these studies did not measure the song amplitude and that such frequency changes may occur in association with Lombard effect as a byproduct [31]. They suggested that increase in the vocal frequency occurs involuntarily when the bird makes effort to be heard in noisy conditions by raising its amplitude. Such an increase in the vocal frequency coupled with the Lombard effect was reported in budgerigars [32], tinamous [33] and mallards [34], which are non-songbirds. However, other studies [35, 36, 37] reported the absence of such association between Lombard effect and frequency shift in songbirds. Dorado-Correa *et al.* (2018) suggest that songbirds might have developed the capacity to decouple the amplitude and frequency during the Lombard effect [34].

FEED ANALYSIS LABORATORY: REDUCING COSTS, BOOSTING PROFITABILITY AND STRENGTHENING AGRIPRENEURSHIP

V.K. Singh, R.K. Joshi, D. Tewari and S. Gautam
College of Veterinary Science & Animal Husbandry
Acharya Narendra Deva University of Agriculture & Technology
Kumarganj, Ayodhya-224229 (U.P.)

Livestock sector forms an important livelihood activity through supporting agriculture and supplementing incomes of the farmers. In India, livestock production and agriculture are intrinsically interlinked, and crucial for overall food security of people. It forms an important livelihood activity for most of farmers, supporting agriculture in the form of critical inputs, contributing to health and nutrition of household, supplementing incomes, offering employment opportunities, and finally being a dependable "bank on hooves" during adverse conditions.

A shift from agriculture to agribusiness is an essential pathway to revitalize Indian agriculture and to make more attractive and profitable venture. Agripreneurship have the potential to contribute to a range of social and economic development such as employment generation, income generation, poverty reduction and improvements in nutrition, health and overall food security in the national economy. Skill development of producers, laboratory technician and resource persons for sampling and chemical testing of feed ingredients and prepared products should be trained for quality control are actually the nerve centre of a reliable product. Agripreneurship has potential to generate growth, diversifying income, providing widespread employment and entrepreneurial opportunities in rural areas. Animal Nutrition is the science of feed preparation and feeding i.e. how feeds should be prepared and fed to animals to produce adequate and safe food and non-food materials such as wool or manure. Animal feed influences all livestock sub-sectors across production systems from animal reproduction, health and welfare – to farm economic viability, environment, animal product safety, quality, human nutrition, poverty, food prices and global economy.

Feed has a fundamental influence on productivity, health and welfare of the animal. Animal feeding impacts on many areas of agriculture: productivity, environmental emissions, water pollution, land use, animal health, product safety, product quality and animal welfare. Every sector of the livestock industry is influenced by animal feeding. Proper animal feeding is the supply of a diet balanced in all nutrients and free from deleterious components, at a level that meets the production objective, considering the animal's physiological state, and generates animal products that are safe for human consumption.

A sustainable animal diet framework translation into action would be beneficial for the animal, the environment and the society, and is likely to generate socio-economic benefits (FAO, 2014). Sustainable animal diets are balanced in all nutrients, free from deleterious components, meet production objective, generate animal products that are safe for human consumption and integrates the *Three-P* dimensions of sustainability (*Planet, People and*

ABSTRACT

The present study was conducted to discern the influence of dietary incorporation of polyherbal mixture (turmeric, mangrail, ashwgandha and punarnava) as feed additive on feed intake, haemato-biochemical parameters and carcass traits in "Vencobb 400Y" strain for 42 days. Day old broilers chicks(n=210) were procured and randomly divided into seven groups with six replicates of five chicks each.T_1 and T_2 were control (basal diet) and negative control (basal diet + antibiotics), respectively.T_2, T_3, T_4, T_5, T_6 and T_7 were the treatment groups, supplemented with 0.25, 0.5, 1.0, 1.5 and 2 percent polyherbal mixture along with basal diet, respectively. Body weight, feed intake, haemato-biochemical parameters and carcass traits were observed. At the end of the six weeks the body weight gain was significantly highest in 2% polyherbal mixture supplemented group (T_7). The feed intake of all the groups was significantly lower than control group, however it was significantly lowest in antibiotic supplemented group. Gain to feed ratio was significantly ($P<0.05$) higher in polyherbal supplemented groups than control, and was similar to negative control group broilers. The hemoglobin level and PCV % in T_6 and T_7 was significantly ($P<0.05$) higher than all groups except, control group and was highest in T_7 group birds. The mean WBC count was significantly higher in all the groups than T_1. The H: L ratio was lower in all the groups in comparison to control group and was lowest in T_7 among the polyherbal groups. The total serum cholesterol level was significantly ($P<0.05$) lower in T_6 and T_7 group than all other groups. The carcass parameters viz; dressed, eviscerated, giblet, drawn, liver, heart gizzard and drumstick yields were similar among the treatments. Therefore, incorporation of 2% polyherbal mixture in broiler chicken diet improved feed intake and performance. Lower values of biochemical parameters and increased carcass parameters with incorporation of 2% polyherbal mixture indicated the better health condition of the broilers.

Introduction

The basic objective of modern broiler faming is faster growth, high feed conversion efficiency and livability. Commercial poultry is being genetically selected for even increasing growth performance and efficiency. This selection for increased growth rate has resulted to changes in the gastrointestinal development

ABSTRACT

A study was conducted to assess the effect of polyherbal mixture as a replacement antibiotic in broilers. Day-old commercial broiler chicks (n=250) were distributed equally into five groups of 50 chicks each, which were further replicate to five groups of ten chicks each over a period of 6 weeks. The chicks were placed on one of the five dietary treatments- NCON (basal diet),PCON (basal diet + antibiotics), NGP-1.0 (basal diet + 1% polyherbal mixture), NGP-1.5 (basal diet + 1.5% polyherbal mixture)andNGP-2.0 (basal diet + 2% polyherbal mixture).Body weight and feed intake were recorded weeklyand accordingly feed conversion ratio were calculated. At the end of 6th week 5 birds per treatment were sacrificed to determine the carcass characteristics and sensory quality of meat. The heart weight and gizzard weight exhibited some differences between groups but herbal supplemented birds had significantly (P<0.05) higher spleen weight in comparison to NCON and PCON group birds. Weights of pancreas showed differences between herbal treated groups but did not observed any variation with NCON and PCON group birds. Herbal supplemented bird's viscera weight was similar to NCON but lower to PCON group birds. Drumstick weight of NGP-1.0 group birds was significantly (P<0.05) higher to NCON birds. Breast portion of the broilers in herbal supplemented birds were similar and significantly (P<0.05) higher than NCON and PCON birds breast. Wing portion of NGP-1.5 group had lower wing weight than PCON birds. Although statistically similar but mean sensory scores for appearance and flavour were slightly better in NGP-2.0 group than the NCON and PCON groups. Data showed that broiler's meat consistency was significantly (P<0.05) better in herbal groups in comparison to NCON group.The overall acceptability of NGP-2.0 group broiler's meat is significantly higher than NCON bird's meat No differences existed in the proximate principles of thigh and breast meat in different group birds. It was concluded that polyherbal mixture at level of 2% supplemented in the diet of birds showed potential to improve body weight, feed conversion ratio and sensory quality of broiler's meat and may prove a good alternate to AGP's for commercial broiler production.

INTRODUCTION

The history of herbs is as long as the story of mankind, for people has used these plants since earliest times. Wars have been fought and lands conquered for the sake of plants, and even today we continue to depend on exotic species for many of our newest medicines and chemicals [25]. Recently, many countries tended to minimize or prohibit the chemical components for their deleterious side effects on both animals and human. So, it is important to use natural promoters.

The emphasis here is on those herbs that, when used to supplement feeds, are helpful in achieving the objectives of improving growth performance, improving immunity response, improving intestinal microflora and controlling particular diseases; in other words the focus is on multifunctional herbs. Some important herbs are turmeric, mangrail, garlic, methi, aloe vera, ashwagandha, bhuiamla, punarnava, neem and tulsi.

Turmeric *(Curcuma longa)* have antifungal, immunomodulatory, antioxidative, antibacterial and nematocidal activities [17]. It is demonstrated that black cumin *(Nigella sativa)* seeds have considerable antioxidant, antibacterial, digestive and appetite stimulant, hepatoprotective and immunomodulative

ABSTRACT

The aim of this work was to compare the efficacy of a phytogenic feed additive (PFA) on the economic efficiency and cost of production of broiler chickens. Two hundred fifty Vencobb 400Y day old chicks were distributed equally into five groups of 50 chicks each, which were further divided into five replicate of ten chicks each. The chicks were placed on one of five dietary treatments i.e. basal diet without any supplement (NCON) or with antibiotic (PCON) and NARGROPHYT at 1.0% (NGP-1.0), 1.5% (NGP-1.5) and 2.0% (NGP-2.0). The effect of these supplements on economic efficiency and cost of production was assessed in a six week study. Feed productivity were significantly ($P<0.05$) higher in NGP-1.5, NGP-2.0 and PCON than NCON group. The cost productivity of phytogenic treated birds similar to NCON group, however significantly ($P<0.05$) lower than PCON group birds. The feed price ratio and feed productivity of NGP-1.5 and NGP-2.0 had significantly ($P<0.05$) higher value than NCON but similar to PCON group. Benefit: cost ratio of herbal treated groups was similar to NCON, however significantly ($P<0.05$) lower than PCON group birds. The feed cost per kg body weight gain was significantly ($P<0.05$) higher in NCON followed by NGP-1.0, NGP-1.5 and NGP-2.0. Feed cost per kg body weight gain of NGP-2.0 was similar to PCON group. Economic efficiency index (EEI) was highest in PCON which was similar to NGP-2.0. NGP-1.0 and NGP-1.5 posses significantly ($P<0.05$) higher EEI than NCON. Cost index (CI) in NGP-2.0 and PCON was also similar. The return on feed was similar in NGP-1.5 NGP-2.0 and PCON group and significantly ($P<0.05$) higher in comparison to NCON. Gross return of herbal treated groups was similar to PCON; but significantly ($P<0.05$) higher than NCON group. Return on investment of herbal treated groups were similar to NCON but significantly ($P<0.05$) lower than PCON group. Profitability, profitability index (PI) and return on investment of PFAs supplemented groups was similar to NCON, however significantly ($P<0.05$) lower than PCON group. The break even output values of Phytogenic mixture supplemented groups were similar to NCON, however significantly ($P<0.05$) higher than PCON group. The EE, REE-NC and REE-PC of herbal supplemented groups were similar to NCON group. However, the values were significantly ($P<0.05$) lower than PCON group. So it can be concluded that 2.0% phytogenic feed additives in broilers feed can be an effective alternative of antibiotic growth promoters.

LEAD PAPER

NUTRITIONAL APPROACHES TO MITIGATE GREEN HOUSE EMISSION THROUGH ANIMAL HUSBANDRY PRACTICES

Nidhi Verma, Dharmesh Tiwari, Sachin Gautam and Jadhav Akshay Waghamber
Nutrition, Acharya Narendra Deva University of Agriculture and Technology,

society is closely associated with the climatic conditions. An eco-friendly climatic condition influences the productivity of living beings. Modernization and advanced lifestyle are creating serious threats to the However, animal husbandry practices are also hidden contributors to the environmental safety. Current Gases (GHGS) are witnessed and future catastrophic scenario of such life threatening GHGs cannot be livestock population of our country is significant contributor of GHGs through anaerobic microbial and ultimately remarkable loses of costly feeding inputs. Thus, under mentioned useful nutritional or dietary supplementations to influence the eco-friendly animal husbandry practices are compiled to productivity and environmental hygiene.

safety. Dietary supplementations, Green house gases (GHGs), Nutritional approaches.

environmental condition influences the life expectancy and reproducibility of livestock and the food chain and disease free status of society might be possible due to the pollution free environmental the ancient time period, people were closely associated with the nature, and the natural conditions sustainability. However, currently environmental conditions are getting deteriorated owing to the and scientific interventions in all the aspects of livestock and human society. Green House Gases carbon dioxide, CFCs, methane, nitrous oxide and ozone traps infrared radiation in the atmosphere which leads to global warming, *i.e.* "greenhouse effect". Approximately 1/5th of the greenhouse increasing atmospheric methane concentrations. Methane is a potent GHG because of its higher (21 CO_2) potency and longer half life (persist for 12 years in environment). Next to CO_2, methane is the anthropogenic greenhouse gas (IPCC, 2007). Apart from vehicles, factories and machineries etc, animal practices and agricultural sector are also huge methane emitters through flooded paddy fields, enteric ruminants. Global quantitative analysis of methanogenesis through livestock sector, *viz.*, cattle, sheep contribute 86 million metric tonnes (Tg) of methane emissions per year. Furthermore, approximately is from dairy sector, 55.9 Tg emission from beef cattle and 9.5 Tg from sheep and goats (Mc Michael Global yearly methane contribution through buffalo is around 6.2-8.1 Tg and 0.9-1.1 Tg from camels. methane production within the hindgut of pigs and horses is approximately 0.9-1.0 Tg and 1.7 Tg, Johnson, 1996). On an average, domestic ruminant contributes 22% of the anthropogenic methane 15% of total global methane emissions. Thus, methanogenesis varies species-wise owing to different microbial mass and microbial fermentation (Johnson *et al.*, 1994).

dietary energy losses in the form of methane in dairy cattle, range-cattle and feedlot cattle varies from 7.5% and 3.5-6.5%, respectively. In buffalo and camel, a loss of diet energy in the form of methane 7.5-9.0% and 7.0-9.0%, respectively. Estimates of methane losses from ruminants also varies with feed quality, feed intake, feed composition and the processing of the feed (Johnson *et al.*, 1996). trations of carbon dioxide (65%), methane (26-27%), nitrogen (7%), traces of oxygen (0.5%) and a little %) are emitted through rumen fermentation (Hungate *et al.*, 1970). The primary gaseous end product of tation is carbon dioxide and its significant concentration is further reduced to methane. Methane is he rumen and hindgut of animals by a group of *methanogenic archaea*, which belong to the phylum Such archeal population utilizes carbon dioxide and hydrogen produced during carbohydrate

Performance of Broiler Chicken Fed Diets Supplemented with a Phytogenic Mixture

V.V. Singh, V.K. Singh*, D. Tewari, S. Gautam, V.B. Singh and P. Singh
Department of Animal Nutrition, College of Veterinary Science & Animal Husbandry,
Narendra Dev University of Agriculture & Technology, Kumarganj-224229, Ayodhya, Uttar Pradesh, India

ABSTRACT

Two hundred fifty (Vencobb-400Y strain), day old broiler chicks were randomly divided into 5 groups of 50 birds each. Each group was further divided in to 5 replicates of 10 birds each. These were kept either on basal diet without any supplement (NCON), basal diet with antibiotic (PCON), basal diet with 1% phytogenic mixture (LPH), basal diet with 2% phytogenic mixture (MPH) and basal diet with 3% phytogenic mixture (HPH) for 35 days in order to evaluate the effect of a phytogenic mixture on the performance of broiler chicken. The phytogenic mixture supplemented group's birds had higher body weight than the control group birds and the mean body weight of LPH, MPH and HPH was higher (P<0.05) than NCON group. After 35 days of experimental period, it was found that the total feed intake of phytogenic supplemented birds was similar to NCON group but higher than that of PCON birds. Among the phytogenic mixture supplemented birds, lowest feed intake was observed in MPH group. Among the herbal supplemented groups, lowest FCR was found in MPH group and it was similar to PCON group. The energy efficiency ratio (EER) of herbs supplemented groups was higher (P<0.05) than NCON group but lower than that of PCON group. The protein efficiency ratio (PER) of phytogenic mixture supplemented birds was better (P<0.05) than NCON group and lower than that of PCON group. Among herbal groups, the highest PER was found in MPH group. The performance index of phytogenic mixture supplemented birds was higher (P<0.05) in comparison to NCON birds. Rearing of broilers supplemented with phytogenic mixture was more economical than NCON group but less economical than the birds reared on conventional system of rearing *i.e.* on AGP. Therefore, 2% phytogenic mixture was economical and has potential to use as an alternative to AGP in broiler rearing.

Key words: Broiler, Chicken, Economics, Growth Performance, Phytogenic mixture

INTRODUCTION

Broiler chicken grow very fast and it is ready for marketing within 35-42 days. The rapid growth rate in broilers imposes severe stress on birds which leads to poor performance, immuno-suppression and high mortality (Xie and Song, 2005). To reduce stress in birds, antibiotics are added in feed. But the European Union in January, 2006 banned the majority of commercial antibiotic growth promoters used in poultry feed in order to protect consumer health. This has led to the interest in finding alternatives to antibiotics for poultry production (Hassan *et al.*, 2011).

Herbs can serve as safer alternatives as growth promoters due to their suitability and preferences, reduced mortality, reduced risk of diseases, minimum health hazards and environment friendliness. Our country abounds in herbal plants having pharmacological properties which needs exploitation by the modern methods. Tulsi (*Ocimum sanctum*) is an analgesic and antistress agent and has antimicrobial, anti-inflammatory, immuno-stimulant and anti-oxidative property (Singh *et al.*, 2014). Neem (*Azadirachta indica*) leaves have different medicinal properties like immunostimulant, antiviral, antibacterial, antifungal, hepatoprotective and antiprotozoal, and has no side effects (Ong *et al.*, 2014). Sahijan (*Moringa oleifera*) leaves are good sources of fats, proteins, minerals and have antimicrobial effects (Olugbemi *et al.*, 2010). Eucalyptus is a well known medicinal plant because of its biological and pharmacological properties. It has antibacterial activities against *Salmonella, Klebsiella, Streptococcus, Proteus, Staphylococcus and Escherichia* coli (Hassan *et al.*, 2011). Giloy *(Tinospora cardiofolia)* also known as guduchi has immune-potentiating, antibacterial, antidiabetic, analgesic and antioxidant properties. It has hepatoprotective effect

STUDY THE PHYSIO-HEMATOLOGICAL RESPONSE BEFORE AND AFTER DISBUDDING IN CALVES

Shiv Swarup[1], P.S. Pramanik[1], K.D. Singh[1], A.K. Verma[1], Vishuddha Nand[1] and A.K. Srivastav[2]
[1]Department of Livestock Production Management, College of Veterinary Science and Animal Husbandry NDUAT, Kumarganj, Faizabad- 224229, Uttar Pradesh, India [2]Department of Livestock Farm Complex, College of Veterinary Science and Animal Husbandry NDUAT, Kumarganj, Faizabad- 224229, Uttar Pradesh, India

Abstract

The aim of the present investigation was to examine the effect on Physio-haematological profile before and after disbudding in calves. The study was carried out at Livestock Farm Complex, College of Veterinary Science and Animal Husbandry, NDUAT, Kumarganj, Faizabad and nearby villages. Twenty four cattle calves were utilised to study Physio-haematological parameters that are Respiration Rate (RR), Pulse Rate (PR), Rectal Temperature (RT), Haemoglobin (Hb (gm/dl). Neutrophil (%), Basophil (%), PCV (%), Lymphocyte (%), Monocyte (%), TLC (10^3/ µl), Eosinophil (%) and N:L ratio) before and after disbudding in to four groups viz. control (T_0), lignocaine (T_L), tramadol (T_T) and lignocaine + tramadol (T_{L-T}). After medication calves were disbudded by hot iron method. The physiological parameters recorded just before (0h) and after disbudding on 1h, 6h and 24h. The blood samples were collected for haematological parameters just before (0h) and after disbudding on 6h, 24h and 72h. The results showed that, at 0h, 1h, 6h and 24h RR were significantly different among treatment groups. Only at 0h, PR was significantly different among different treatment groups and during rest of the period up to 24h there is no significant different among groups. There was significant difference for RT only at 24h among different treatment groups. At 24h, T_0 group showed significantly lowest Hb (10.66±0.49%) which was statistically similar to T_T and T_{L-T} groups. At 0h, 6h and 72h means of PCV% were significantly different among treatment groups during the whole period of study. The lowest lymphocytes (64.00±1.00) was observed in T_T group at 6h. The T_0 group showed significantly lowest basophil (0.00±0.00) which was statistically similar to T_T and T_{L-T} groups but significantly different from T_L group at 6h. At the same interval, T_0 group showed significantly lowest monocytes (4.66±0.61) which was significantly different with T_L, T_T and T_{L-T} groups. At 6h, T_0 group showed significantly lowest N/ L ratio (0.13±0.01) which was statistically similar to T_T and T_{L-T} groups but significantly different from T_L group. It may be concluded that generally physiological responses like RR, PR and RT were higher in control groups than treatment groups before and after disbudding. No significant difference was observed in eosinophil%, TLC, neutrophil% and monocyte% counts between control and treatment groups. However Hb%, basophil%, PCV% and lymphocyte% were significantly different between control and treatment groups. N/L ratio was significant only at 6h. Most of the cases T_{L-T} group showed comparatively better performance.

Introduction

Disbudding is painful yet common husbandry practice in the cattle industry, especially on dairy farms, because hornless cattle are safer (ALCASDE, 2009) and injuries to cattle and other animals are reduced (Prayaga, 2007). Dehorned cattle are safer to handle and cause fewer injuries to workers, other cattle, and farm animals (Stafford and Mellor, 2005). Cattle are also dehorned to reduce bruising and hide damage and to meet transport requirements (Goosewardene and Hand, 1991; Faulkner and Weary, 2000; Prayaga, 2007). Several disbudding methods exist, including cautery, the use of caustic paste, and hot iron. All of these methods involve tissue damage and have been described as painful (Stafford and Mellor, 2005; 2011). The *Model Code of Practice for the Welfare of Animals: Cattle*, however, strongly advises against caustic disbudding (PISC, 2004).

Despite this knowledge, dehorning is commonly performed without pain relief because of the costs and impracticalities associated with researched methods (Petherick, 2005). The breeding of polled cattle eliminates the need for dehorning and because horns are inherited as an autosomal recessive with polledness being dominant (Long and Gregory, 1978). The legislation pertaining to dehorning and disbudding differ between countries like in Sweden, disbudding without local anaesthesia and sedation was banned in the 1992 Animal Rights Act (Bengtsson *et al.* 1996), but calves may be dehorned in Denmark without local anaesthesia until they are 4 weeks of age (Grondahl-Nielsen *et al.* 1999). The Council of Europe recommends the use of anesthesia for the dehorning of calves over 4 wk of age (Oliver, 2009). Pain control is also required for all calves under the *Canadian Code of Practice for the Care and Handling of Dairy* Cattle (NFACC, 2009). Furthermore, the Australian *Model Code of Practice for the Welfare of Animals: Cattle* recommends the use of local analgesics for dehorning calves over 6 month of age (PISC, 2004). Thus, the need to meet industry standards and the availability of suitable dehorning pain relief regimens for commercial production remain a challenge. Very little work has been done on the disbudding distress in Indian dairy animals particularly in indigenous animals.

Materials and Methods

The aim of the present investigation was to examine the Physio-hematological response before and after disbudding in calves. Study was carried out at the Instructional Livestock Farm Complex of the college of Veterinary Science and Animal Husbandry, NDUAT, Kumarganj, Faizabad and around the campus. Twenty four (24) farm born cattle calves of 2 to 3 weeks were randomly divided into four groups within each comprising of 3 males and 3 females, Control (T_0), Lignocaine hydrochloride (2%) @ 1 ml/ bud (T_L) (Tramadol @ 0.25 mg/ kg body weight I/M) (T_T) and Lignocaine + Tramadol at above dose rate (T_{L-T}). Medication was done 5-10 minutes before disbudding. Two doses of ligocaine per bud were injected for cornual nerve block in calves.

(a) Physiological responses

Physiological responses recorded before and after disbudding were as follows-

Respiration rate (no./ minutes)	Pulse rate (no./ minutes)	Body temperature (^{0}F)

(b) Haematological parameters

Haematological responses recorded before and after disbudding were as follows

a) Hb (gm/dl)	d) Neutrophil (%)	g) Basophil (%)
b) PCV (%)	e) Lymphocyte (%)	h) Monocyte (%)

Abstract

To assess the ... score at calving (BCSC), BCS during lactation (BCSL), production performance and udder health status of ... at 2nd parity were selected randomly. The animals after random distribution into 3 groups i.e. group I (BCS<... 3.5, moderate), group III (BCS>3.5, fat) kept in observation for 120 days. The BCS of group-III cows were significantly ... higher than group I. The FCM, fat and SNF was positively correlated with BCSC and negative with BCSL. The somatic cell score ... was correlated negatively with BCSC and positively with BCSL.

Key words- BCS, Milk, Milk composition, Udder health, SCS

Introduction

...Milk quality is as significant as the milk quantity in dairy animals. ...High yielding dairy cows had higher incidence of mastitis that can be ...determined by ... of milk (Kehrenkedeen and ...Bryce, 2007). ... cow is important for ...attaining ... higher body reserves ...may pose ... higher SCC in milk ...respectively ... dairy cows exhibit ...negative ... may influence both ...immune ... that predispose the ...animals to ... a favourable correlation ...with SCC, but it was not strong (Berry *et al* Loc. cit.). Dang et al., (2010) reported non-significant relationship between BCS and SCC. ...ence, it is postulated that there are no consistent results regarding the relationship between body condition score and somatic cell counts of the dairy animals. Therefore, the present study was carried out to investigate the association among body condition score, production performance and udder health status of dairy cows.

Materials and Methods

This study was carried out in the area under subtropical zone of Indo-Gangetic plane. Fifty lactating dairy cows (HF cross) of second parity available at the Teaching Livestock Farm in the College of Veterinary Science and Animal Husbandry, N.D.U.A.T., Kumarganj, Faizabad (U. P.) and in the small dairy farms of the surrounding villages were selected. Observations were recorded for 4 months. The animals in farm and field conditions were maintained under loose housing system and the stanchion system, respectively. The data collected at fortnightly intervals were, the Body Condition Score (BCS), Production performances and Somatic cell count (SCC). Milk yield of selected animals in the farm and the field were recorded on the observation days both morning and evening. Milk samples were collected directly from the animal during milking to assess the milk composition such as fat, SNF (solid not fat), CLR (corrected lactometer reading) by EKO milk ultra, milk analyser (Milkana KAM98-2A). The milk yield was further corrected on 4% fat basis (Fat corrected milk, FCM) according to the formula given by Gaines (1928) as under-

FCM = 0.4 × milk yield (l) + 15 × milk fat (kg).

Body condition score of animals after calving were assessed in the morning milking by the chart formulated by Prasad (1994) having 1-6 scale with 1 indicating under body condition and 6 representing over body condition of the dairy cows. 1 to 6 scales were further splitted in to half or quarter point increment (e.g., 2.5 or 3.25). For the better interpretation of BCS effect on the milk yield, milk composition and udder health status, the animals were divided in to three groups on the basis of BCS at calving i.e. group-I (BCS <3.0, thin), group-II (3.0≤BCS≥3.5, moderate) and group-III (BCS > 3.5, fat). The udder health status was determined by somatic cell count (SCC) of milk immediately after collection as per methodology of IDF (1984). The SCC was log-transformed into the fortnightly test day observation SCS (Somatic cell score) as SCS=$\log_{10}$SCC (Mrode and Swonson, 1996).

The collected data were analyzed by SPSS (version 11.5). The means of various measurements were compared by Duncan's Multiple Range test (Duncan, 1955). The Pearson's correlation coefficient was estimated to find relationships among observations.

Results and Discussion

Out of 50 animals, 13 cows were classified as thin (group–I), 20 as moderate (group–II) and 17 as fat (group–III) at parturition. BCS of cows at calving was 2.83±0.06, 3.38±0.03 and 4.22±0.11, in group I, II and III, respectively (Table-1). BCSC differ significantly ($P<0.05$) among the three groups of cows. The BCS during calving to 15 days were significantly ($P<0.05$) higher than rest period of lactation. The declining BCS might be due to mobilization of body fat reserves to cover milk production during early lactation (Buckley *et al*., 2000, Friggens *et al*.,

engaged in agriculture and rearing of livestock in our country.

The effectiveness of sire evaluation is the backbone of any breed improvement programme. This investigation was planned to evaluate Sahiwal sires as its performance is remarkable in hot climate and has been recognized worldwide as one of the best milch breed (Ilatsia et al., 2011). Various sire evaluation methods viz. daughter's average, least-squares analysis and best linear unbiased prediction (B.L.U.P.) were used to evaluate the sires and their effectiveness were compared for Sahiwal cattle. The information on the production of first lactation is mainly required for getting genetic improvement through selection, since it serves as an index of life time production in dairy cows. Therefore, it is very much essential for the sire evaluation to correlate the first lactation milk yield with life time milk production.

Materials and Methods

The data for the present investigation were collected over a period of 71 years (1944-2014) from pedigree sheet of 1367 Sahiwal cows born to 112 sires maintained at Government Livestock Farm, Chakganjaria, Lucknow (U.P.). Only the sires having the records on at least three or more daughters were included in the present study. The total duration of the present study was divided into 8 periods.

Out of 8 periods 7 are of 9 years each and 8th period of 8 years only. Each year was divided into three seasons namely winter (November-February), Summer (March- June) and Rainy (July- October). In order to classify the data for different periods and seasons year and season of calving was considered for all the traits.

Statistical Analysis

Rank correlation

After estimation of breeding value of sires, the sires were given rank as per their genetic merit. The Spearman's rank correlation between breeding values of sires derived by various methods was used to judge the effectiveness of different methods. The rank correlation was estimated as per methods developed by Steel and Torrie (1960).

$$r_s = 1 - \frac{6\sum d_i^2}{n(n^2-1)}$$

Where,

r = Rank correlation coefficient

n = Number of sires under evaluation

d_i = Difference of rank between paired items under two methods

The significance of rank correlation was tested by t-test as given below

$$t = r\sqrt{\frac{(n-2)}{(1-r^2)}}$$

It was compared with t-table value with (n-2) degree of freedom.

Simple product moment correlations

The simple correlations (r) between the estimated breeding values of bulls by different sire evaluation methods were also calculated by the following formula:

$$r_{(XY)} = \frac{\text{Cov}(XY)}{\sqrt{[\text{Var}(x)\ \text{Var}(Y)]}}$$

Where,

$$\text{Cov}(XY) = \sum XY - \frac{(\sum X)(\sum Y)}{n}$$

$$\text{Var}(X) = \sum X^2 - \frac{(\sum X)^2}{n}$$

$$\text{Cov}(Y) = \sum Y^2 - \frac{(\sum Y)^2}{n}$$

Where,

X, Y= The breeding value of sires estimated by two different methods

n= Number of pairs of breeding value

Rank correlation

The rank correlations of most efficient method (LSM) of sire evaluation for LTMY was statistically highly significant ($P<0.01$) with their values 1.00 ($\bar{D}$ and LSM), 0.71 ($\bar{D}$ and BLUP) and 0.71 (LSM and BLUP). For LTLL, the rank correlation between the different methods were 1.00 ($\bar{D}$ and LSM), 0.79 ($\bar{D}$ and BLUP) and 0.79 (LSM and BLUP). The rank correlation of estimated breeding values of LTMY between daughter's average and least squares method was very high (100%) (Table-1).

It revealed that ranking of sires for the estimated breeding value by daughter's average and least-squares method was similar while ranking of sires from BLUP was different. Similarly, for the LTLL, the rank correlation of estimated breeding values between ($\bar{D}$) and LSM was very high (100%). It revealed that ranking of sires for the estimated breeding value by $\bar{D}$ and LSM was similar while ranking of sires by BLUP was different.

Agriculture & Engineering

Heritability estimate of post-partum oestrus interval was estimated to be 0.021±0.175. The magnitude of the effect of sires was non-significant and the variation in PPO accounted for due to sires was very small (8.7%) in total variation. The findings were indicative of zero heritability for this trait in these animals. Similar observations were reported by Prasad (1958) for Tharparkar cattle and Singh et al., (1964) for Hariana cattle.

Conclusion

Any selection programme based on post-partum oestrus interval will not prove beneficial in these cattle because the genetic variability for this character in these animals does not seem to exist. In view of the above observations, improvement in managemental practices may lead improvement in this trait.

Abstract

The present study was conducted to investigate the effect of different litter materials on behavior of Kadaknath chicks. A total 300 Kadaknath chicks were raised on three litter treatments viz. Sand, rice hulls and rice hulls plus chopped paddy straw (1:1) comprising of two replicates in each treatment. The results indicate that Kadaknath chicks reared on sand and rice hull litter had significantly higher proportion of time in activities like drinking, dust-bathing and perching than paddy straw+rice hulls. The behavioral activities like drinking, dust bathing, stretching, standing and perching in sand litter, dust-bathing, peaking, stretching, walking, lying and perching in rice hulls and peaking, stretching and standing in straw+rice hulls were assumed to be significantly differed in morning, noon and evening hour interval.

Keywords: Kadaknath, feed behavior, sand, rice hulls, litter materials

Introduction

Desi fowls are usually reared in scavenging flocks by feeding household left over and field grain and egg laste are performed over the of exotic chickens (Dinesh and Ajith, 2002). Wood shaving has been standard choice for poultry litter for many years. Rice hulls appear to be a favourable alternative to wood shavings (Grimes *et al.*, 2007). Various types of litter materials like sand (shields *et al.*, 2005), Rice hulls (Grimes et al., 2007), rice and wheat straw (Sreehari Sharma 2010), ground corn cob and soyabean straw (De Avila *et al.*, 2008) have been utilised as bedding materials for rearing of poultry birds. Sand has shown good potential as an alternate litter for more reuse quality and very less caking.

Pine shavings and saw dust are the most desirable and most widely used litter materials for broiler production in the United States. About 60% of farmers used saw dust as litter materials, 16.7% used wood shaving, 20% used both wood shaving and saw dust while 3.3% of farmers do not use bedding materials. The types of litter used by farmer depend on locality and availability (Kalu E. 2015) . Paddy husk is most commonly used litter material in northern India.Sigroha et al., (2017) used saw dust, wheat straw, rice husk, river bed sand and sandy soil as litter materials and found higher weight of birds at 42 days of age in wheat straw followed by sandy soil, saw dust, river bed sand and rice husk. As far as seen in literature there is no concert conclusion for litter type and thickness for various regions and climates. In view of above a study was undertaken with following objectives-

- To investigate the effect of litter material on the behavior of Kadaknath fowls

Materials and Methods

The present investigation was carried out to study the effect of different litter materials on growth performance, feed gain ratio of Kadaknath fowl. The study was carried out at the poultry unit of Teaching Livestock and Poultry farm of the College of Veterinary science and Animal Husbandry, N.D.U.A.T. Kumarganj, Faizabad U.P., situated at a distance of 42 km away from Faizabad city and 38 km away from Jagdishpur Industrial area at an altitude of 113 m above sea level and latitude of 26° 47' North and longitude of 82° 12' East and it falls in Eastern plain Zone of Middle Gangetic Plain region of India.

Experimental period and climatic conditions

The experiment was conducted in the months of November to February which comprised winter season of this region. The average minimum temperature recorded during study period was 12.54°C, and the average maximum temperature was 24.86°C. There were a few showers of rain, ranging from 62 to 123 cm and average was 92.5 during this period. The topography of land is almost even and most of the farm area remains dry round the year. Parasitic infestation was moderate.

Experimental animals

To carry out present investigation, 300 straight run day old Kadaknath chicks, from college hatchery were got issued. These 300 kadaknath chicks were divided into two batches; each batch consisted of 150 Kadaknath Chicks. Each batch was subdivided in three equal groups of 50 chicks viz. Group1 (sand), Group 2(rice hulls), Group3 (paddy straw + rice hulls) randomly distributed among three pens. Each pen was equipped with fresh litter, feeder and waterer. All the birds were raised on pukka floor with sand, rice hulls and paddy straw + rice hulls (50:50) as litter materials. Chicks were reared under standard uniform managemental practices up to the age of 42 days and observations for different parameters were recorded simultaneously. Thereafter, a replication was made with the next batch of chicks.

Brooding and rearing of chick

Brooder house

The cold room brooding method was applied for brooding and rearing of Kadaknath Chicks in the brooder house. Brooding was done on pukka floor using deep litter system. Each group of Kadaknath chicks placed in separate pens which were visually isolated from each other along with provision of adequate ventilation and artificial light in the brooder house.

Preparation of brooder house to receive Kadaknath chicks
